Nitriding is a type of coating that provides hardness to the desired depth in the material and does not impair the flexibility of the material. It provides high dimensional stability as well as high surface hardness and wear resistance. When determining the material structure, the correct process must be defined, otherwise it may increase the fragility of the part. While applying the process, attention should be paid to the amount of change in brittleness and surface hardness depending on the waiting times at temperatures. [9]

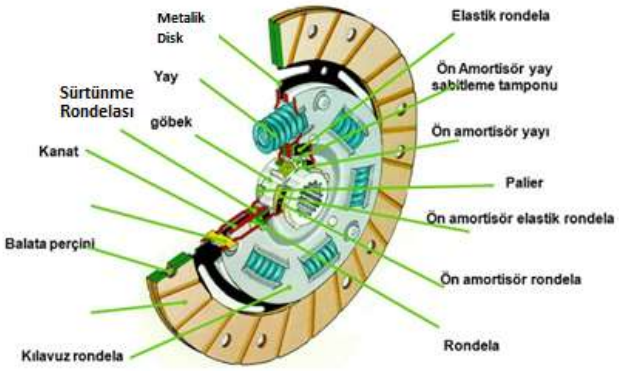

Figure 1. Clutch disc general component components

The function engine operation of during filtering the vibrations caused by this provided by the hysteresis feature of the clutch disc. Hysteresis transfer of the rotational movement from the crankshaft to the gearbox shaft occurs during the interaction of the inner components with each other. This formation is defined as the difference in friction torque that occurs during the angular rotation of the clutch disc, i.e. hysteresis. The hysteresis value to be defined is different for each motor and is determined by calculations, NVH and long-distance tests.

Clutch disc basically consists of facings, metallic disc, drive plate, hub, retainer plates, hysteresis elements, damper spring and rivets (Figure 1).

Hysteresis elements are the parts that determine the friction characteristics in the disc assembly and affect the ride comfort and vary according to the vehicle characteristics. Figure 2 and Figure 3 show the most important of these, the elastic washer, metal and plastic friction washers.

Figure 2. Finger type elastic washer

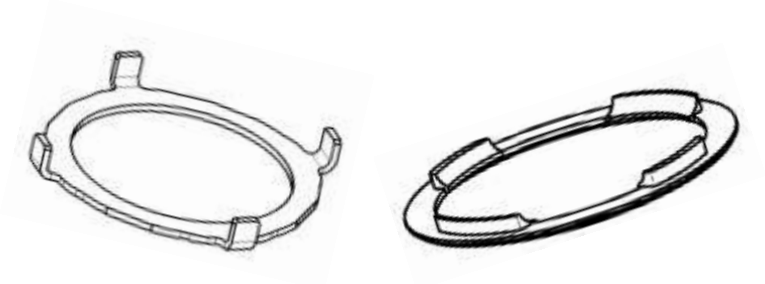

Figure 3. Metal and plastic friction washers

It has been observed that the examined material, geometry, part and product-based functions constitute a significant part of the hysteresis variability:

- Elastic washer load changes more than acceptable by over time,
- Metallic and plastic washers friction characteristics change

Although there are many parameters and variables affecting the hysteresis, the load change of the elastic washer which has the highest effect and the coating properties of the metal friction washers have been investigated. The data obtained at the end of the study can be used in the preparation of special production parts, especially for NVH vehicle tests. Time and cost savings can be achieved with the method used.

2. MAIN BODY

In this section, prototypes are produced with load-measured elastic washers and metal washers supplied according to the specified coating types. The theoretical load curve of the elastic washer is expected to be in the region where the load variation is the least throughout the product working life, as in Figure 4. As the working area starts to slide towards the left side of the curve, if the amount of compression decreases, changes in hysteresis value increase.

In the clutch disc used elastic washers have been produced using pre-thermal processless spring steel material such as C67 due to costs, wear life and easy procurement. Elastic washer thickness is preferred in the range of approximately 0.4-0.8 mm for clutch discs used in passenger vehicles. This thickness value can be up to 1.5mm thickness in heavy vehicles.

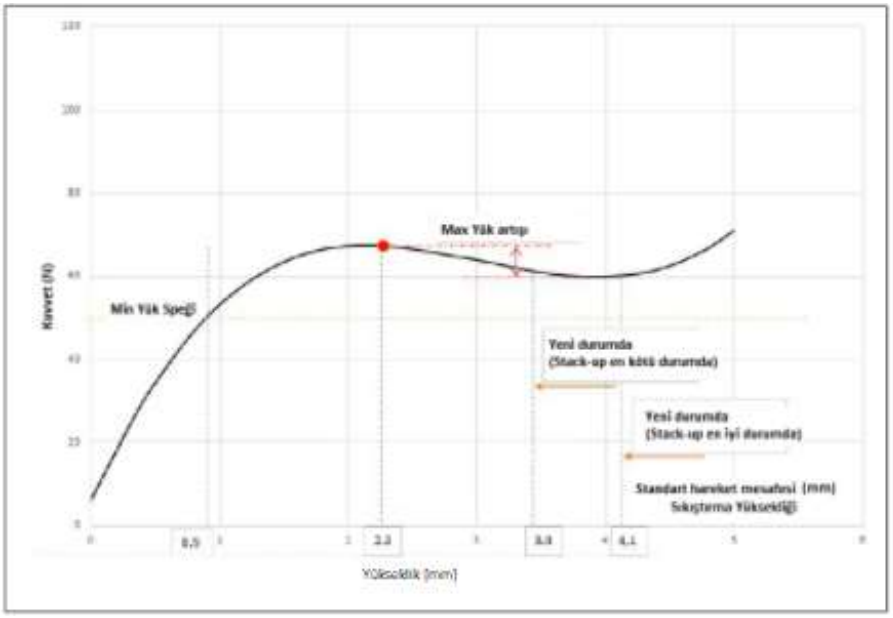

Figure 4. Toothed elastic washer load measurement curve

In general, plastic or metal friction washers can be used depending on the desired hysteresis value. The study was carried out with metal-metal friction hysteresis washers as it was desired to obtain high hysteresis values. The fact that metal surfaces have an unstable structure at the beginning causes the hysteresis values to behave similarly for a certain period of time. Since the parts are metal, the system takes longer to stabilize than metal-plastic surface friction. Although this is a disadvantage, after the metal-metal friction becomes stable, it provides longer stability due to the low amount of wear.

The hysteresis value created by the system;

$$\{H\} = 2\,[P]\,\{\mu\}\,[Rm] \quad (1)$$

H: Hysteresis (Nm)

2 -> Reason for both surface friction (Friction surface number)

P: Load force applied by elastic washer (N)

μ: Friction coefficient

Rm: Friction area effective radius

If we accept that the friction coefficient is affected by tribological factors, hysteresis is one of the most important parameters and affects the variables "μ" friction coefficient. If we change the friction coefficient or we can minimize its change, we can obtain the hysteresis value in the intervals we want. In general application, phosphate based coating methods are applied due to cost. In the study, the parts produced with the following coating methods will be used and their hysteresis effects will be examined.

- Alkali Zinc Phosphate
- Nickel Coating
- Titanium Nitride
- Nitriding (Nitride Coating)

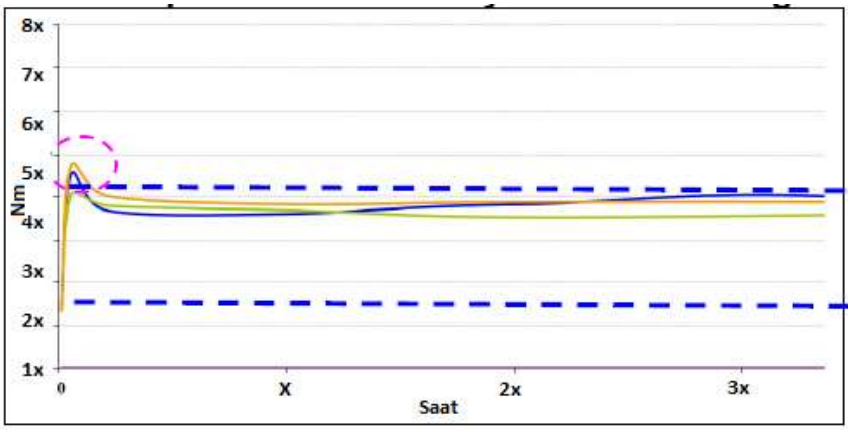

Figure 5. The Theoretical time dependent hysteresis change for the metal-metal friction clutch disc

The reason for the high hysteresis value at the initial stage is the fact that the friction surface properties are not yet stable and the load changes of the elastic washer are still to continue. After component analysis, geometric measurements and load measurements of elastic washers, data were analyzed and prototype clutch disc was collected.

While the disc assemblies used in the study were produced, the press, mold, process parameters and variables were recorded and certain angular bedding disassembled and reassembled after cycles.

A total of 12 prototypes were produced, 3 of each type of coating. All disc assembly hysteresis values were measured before starting angular fatigue tests of, and hysteresis measurements were repeated after 100, 200, 500, 1K, 2K, 5K ----, 100K cycles and the variations were recorded. Load measurements of elastic washers were measured by disassembling the products after 50K and 100K cycles, and the test was continued by completing the reassembly.

After each angular fatigue process of the clutch discs, functional (torsional and hysteresis) measurements were made and recorded as in Figure 6.

Figure 6. The Graph of torque / hysteresis due to angular motion

In this section, the angular fatigue processes of the products produced as prototypes were made, the angular fatigue cycle numbers were measured, and the hysteresis changes due to time were analyzed. In Figure 7 and Figure 8, height changes were measured before production, after 50k and 100k angular fatigue. For H1 elastic washers, the load change was stable between 50k cycles and 100k cycles. With the H2 elastic washer, the situation is slightly different and the load tends to decrease. This indicates that the variability of H2 hysteresis value may continue.

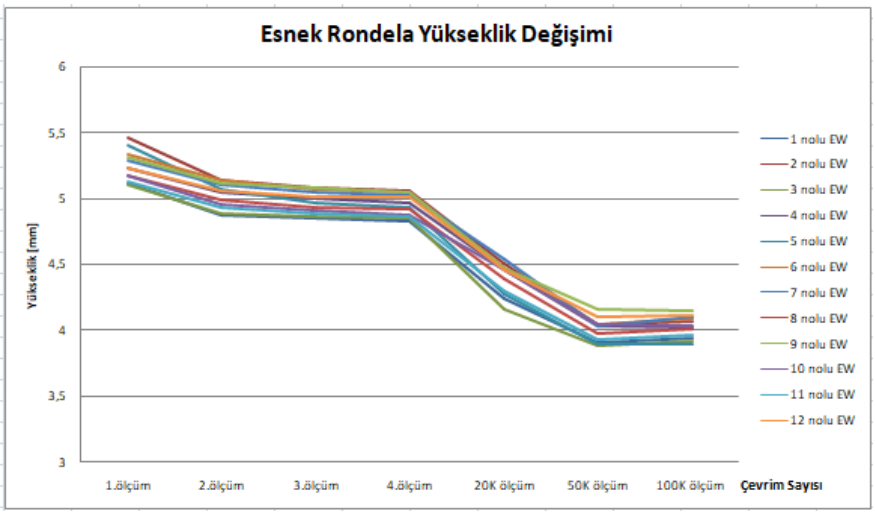

Figure 7. H1 elastic washer height change

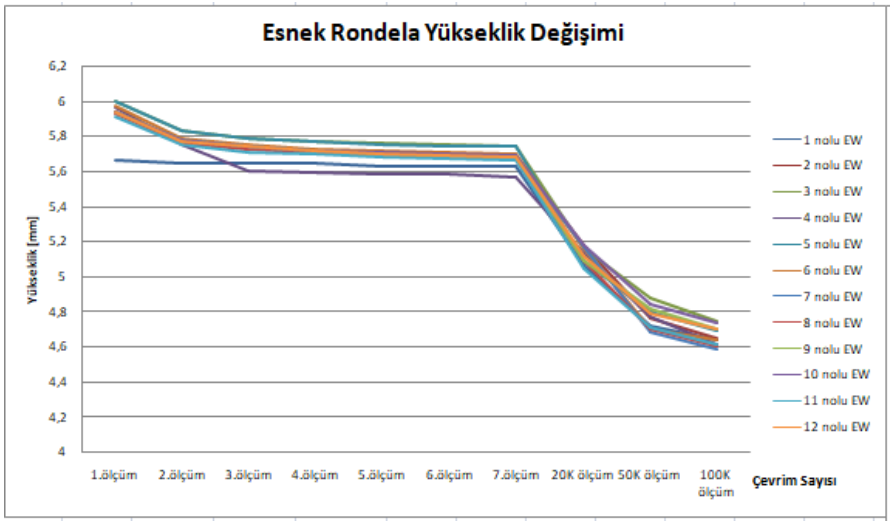

Figure 8. H2 Elastic washer height change

Although the elastic washers are like this, the change in hysteresis did not show the same behavior. The H1 and H2 hysteresis changes of depending on the angular cycle numbers were as in Figure 9 and Figure 10.

If the situation in Figure 9 is summarized, all the hysteresis values are within the limit at the initial stage and all of them went out of the lower limit between 100 and 1000 cycles and entered the limit again at 30K cycle levels and showed a variable characteristic according to the coating group.

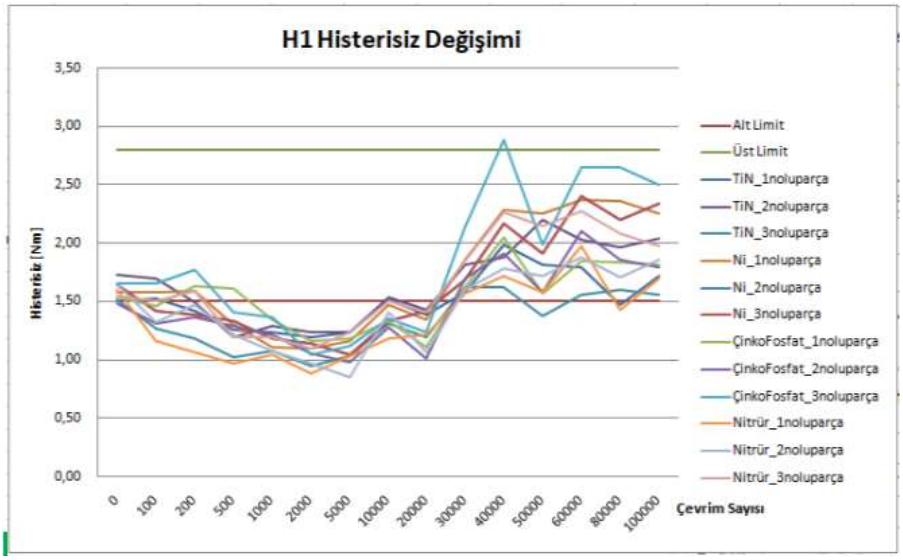

Figure 9. Change in H1 Hysteresis

Figure 10, all hysteresis values are out of the initial level and the lower limit distances differ according to the coating group. The cycle values of the elastic washer, regardless of the height and load drops, differ and each group exhibits a different behavior during the test period. This situation showed that the coating effect of the metal washer is more effective on the H2 hysteresis value and we can achieve different outputs if we change the coating.

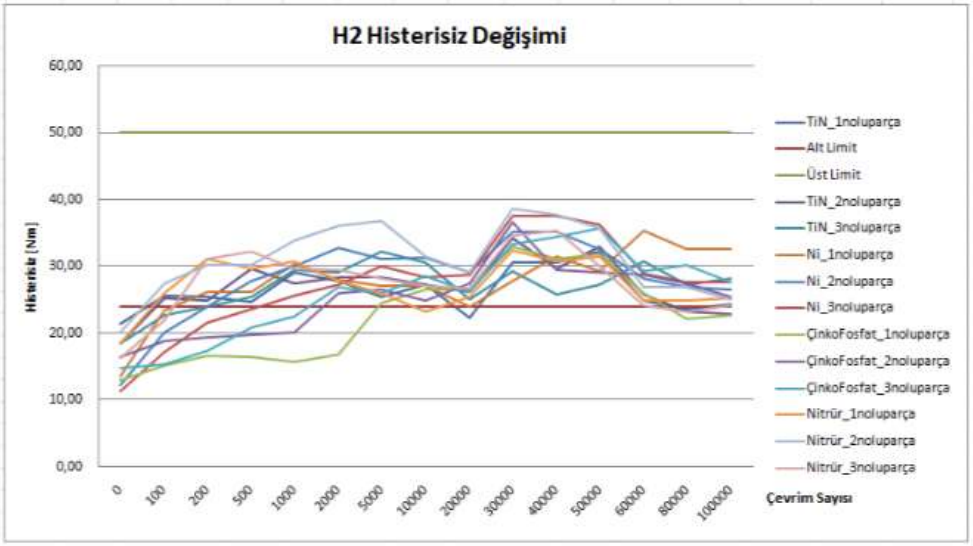

Figure 10. Change in H2 Hysteresis

4. CONCLUSIONS

In this study, it was observed that the coating properties of metal friction washers and elastic washers are effective in the change of hysteresis of load and height losses. During a certain working life, the effect of the elastic washer is at the forefront, and after the compatibility of its components with each other increased, metal-metal friction and effects caused by coating came to the fore.

The elastic washers load loss is above the target value of 10%. If exceptional circumstances are not taken into consideration, the load reduction rates and durations have the same behavior. When the hysteresis measurement graphs are examined using an elastic washer, the effect of the load and height loss on the hysteresis decrease is seen. However, it has been observed that this effect takes place for a certain period of time, and then metal-metal friction is more effective. In the first study of the product, it was observed that there were irregularities in hysteresis values due to the non-uniform surface friction, but irregularities and hysteresis changes decreased with time.

It has been observed that different coating properties show different friction behaviors and these properties disappear over time. This is a continuous behavior shown in the hysteresis variation. This is effective proof that the friction radius is constantly changing and variation continues throughout the product life. Considering the effects of the cost and the mechanical properties of the materials, the proof that not each coating method is suitable for mass production. In special works such as NVH, the prototype production process can be accelerated and parts with the desired properties can be produced in a shorter time.

DESIGN VERIFICATION OF THE VEHICLE DEVELOPED FOR THE AMERICAN MARKET ACCORDING TO FMVSS-305 REGULATION WITH VIRTUAL ANALYSIS

Ayberk Gökçe, Ümit Dardeh

Karsan Automotive, R&D Department, Bursa, Turkey
Correponding Author: Ayberk Gökçe, ayberk.gokce@karsan.com.tr

ABSTRACT

A rolling chassis that has been developed for the North America market was investigated in order to meet the requirements of FMVSS-305 with a frontal impact of 30 mph (48 km/h) velocity to the rigid wall and FMVSS-214 with a side impact of 20 mph (32 km/h) velocity to the rigid poll by using the results, design developments were conducted together with the developed finite element model. Design iterations were carried out together with the created virtual analysis model. Acceleration effect on the battery compartment during the crash and vehicle's structural and mechanical integrity was determined by using LS-DYNA explicit solver. Iterative design development studies were carried out to observe the non-continuous crash energy flow on the main carrier chassis rails (longitidunal member) during the crash with the front rigid wall. Also they were made to make the energy flow continuous and determine the insufficient structural strength of the vehicle during the intrusion with the side rigid poll and the entrances to the battery area and structural development studies.

Keywords: FMVSS-305, FMVSS-214, vehicle safety, crashworthiness, electrolyte spillage, crash test.

1. INTRODUCTION

Environmental pollution, which is negatively affected by the emission nowadays, and the increasing need for energy and have created a trend towards the preference of electric vehicles. Although electric vehicles have the potential to achieve high energy efficiency and zero emissions, and have significant problems to overcome, their development and improvement continues around the world, especially in terms of driver and battery safety. Since frontal impact is the most common crash scenario and the battery is often expensive and heavy, both passenger safety and battery protection should be considered in electric vehicles. Battery safety has three interrelated aspects: electrical integrity, thermal integrity, and mechanical integrity. Mechanical integrity is the least thought of as safety, but the most vital aspect for electric vehicles. (Wierzbicki, 2010)

In a vehicle development project, before vehicle production, virtual verification software and methods are among the indispensable tools used by research and development companies within the scope of mechanical integrity and strength. Thanks to the virtual verification activities performed on the virtual vehicle, both the product development cycle can be rotated faster and the physical prototype and test costs are reduced. Due to this positive effect on the time and cost parameters, which are very important for the automotive industry, the weight of virtual studies in product development studies is increasing day by day.

In vehicle projects, crash safety and driver-passenger safety parameters may vary according to the countries / regions where the vehicle will be used. Each country has some evaluation criterias specific to the region. These conditions, generally known as "regulation", are expected to be met in the relevant vehicle.

In this study, a vehicle developed for the American market was designed to meet the conditions of "front crash test on a rigid wall" according to FMVSS-305 and "crash test with side poll" according to FMVSS-214. It is based on improving passenger safety parameters with virtual verification. The issue of crash safety for electric vehicles was mentioned and the scenarios specific to battery safety were examined within the scope of compliance with the FMVSS-305 regulation. In the section related to crash safety, the preparation of the crash model and the solution made in LS-Dyna explicit solver, the examination of the results are emphasized and the design improvement studies of the crash model with the acceleration-time data taken from the crash model are explained.

2. SCOPE OF IMPACT TESTS

FMVSS-305 regulation examines the safety of passengers in case of frontal impact, side impact and rear impact for electric vehicles, and the prevention of electrolyte spillage from the batteries entering the driver and passenger compartments during the crash, so that they do not harm the driver and passenger.

In this part of the study, within the scope of the efforts to improve the front and side crash performance of a rolling chassis, “frontal impact on rigid wall at 48 km / h speed” specified in FMVSS 305 regulation and “side impact on rigid pole” at 32 km / h speed were carried out. Within the scope of FMVSS-214 regulation, there is a condition of “side impact to deformable barrier” at 56 km / h for side impact. However, since the vehicle is a rolling chassis, the condition of locally hitting a rigid pole at 32 km / h will cause locally higher deformation on the vehicle and the amount of interference to the battery will be at higher levels, and this condition has been preferred.

The rolling chassis model, in which development studies are carried out, includes the profile construction space frame structure Body-In-White, battery, electric motor, electronic components and chassis components. Other components of the vehicle (trim parts, driver's cabin, cargo cabin, etc.) are modeled by defining the mass from the connection points. There are a total of 2,381,779 2D-shell elements in the model (Figure 1, Figure 3).

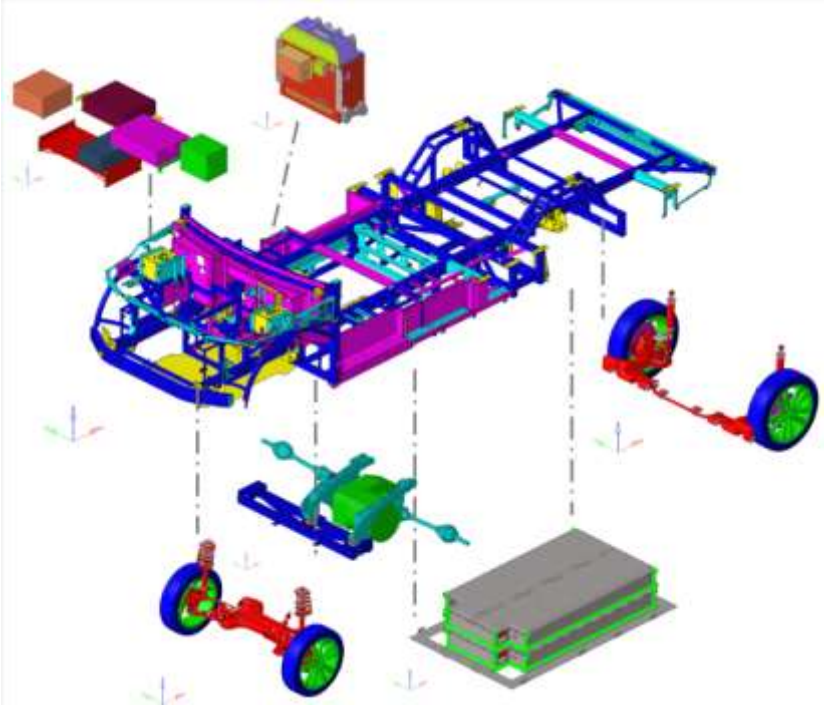

Figure 1. Components of Rolling Chassis

While evaluating the results of the structural analysis, it was based on the electrolyte spillage or deterioration of the batteries and electric motor functionality after the crash and the prevention of battery electrolyte spillage attempts to the driver and passenger area with the deformation that will occur in the battery cells after the crash. In addition, with the LS-Dyna software, in order to evaluate the crash situation, the acceleration in the driver's area in case of a frontal impact on the rigid wall at 48 km/h (Figure 2) and the side hitting the rigid poll at 32 km / h were obtained. During the crash, the structural condition of the vehicle and the maximum level of energy absorption and minimum acceleration to the driver and / or passenger were designed, and the thickness and shape optimization study was carried out on energy absorbing controlled folding zones with an iterative approach.

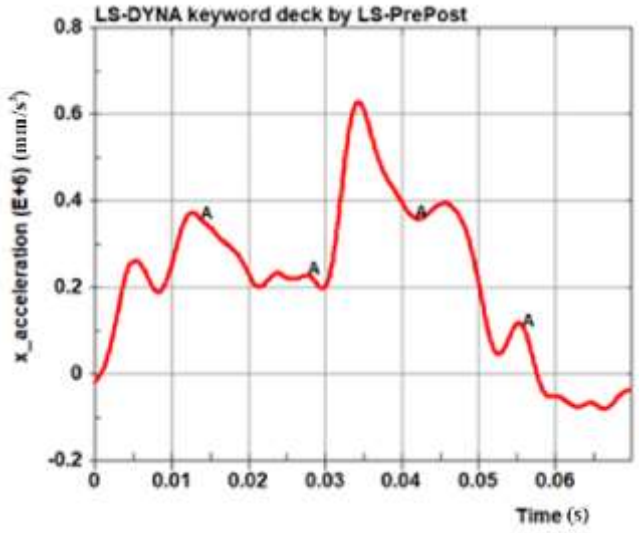

Figure 2. Acceleration/Time Graph of Frontal Impact

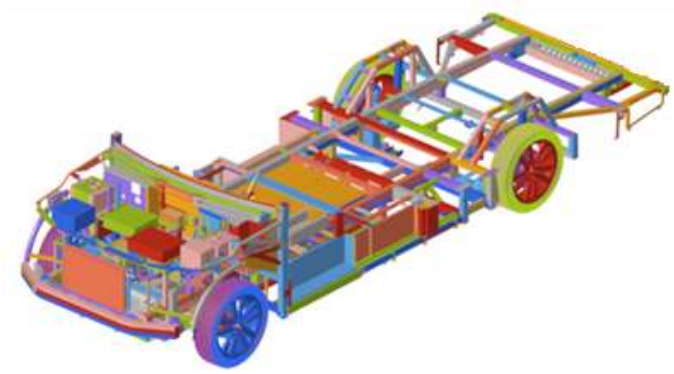

Figure 3. Rolling Chassis Vehicle Systems

3. IMPACT SIMULATION ON THE ROLLING CHASSIS VEHICLE

In this section, the G force values that will be reflected on the vehicle, driver and / or passenger in the vehicle model developed within the scope of frontal crash and side crash tests are calculated. Later, these G force values were again used with LS-Dyna to obtain "pass / fail" results for FMVSS 305. The graph of the acceleration-time values obtained from the iterations created with the current vehicle model and the changes applied subsequently and the energy conversions during the intrusion are included.

The main purpose is to ensure that the 2 batteries in the vehicle do not interfere or are at minimum level and that the battery connections within the scope of SAE J2464 can meet the loads generated during the crash.

3.1 FMVSS-305 Frontal Impact Simulation

In this section, according to FMVSS-305, the current state of the vehicle and the acceleration-time graphs of the improvements made by iterations under the conditions of "frontal impact test on a rigid wall" at a speed of 48 km / h are included.

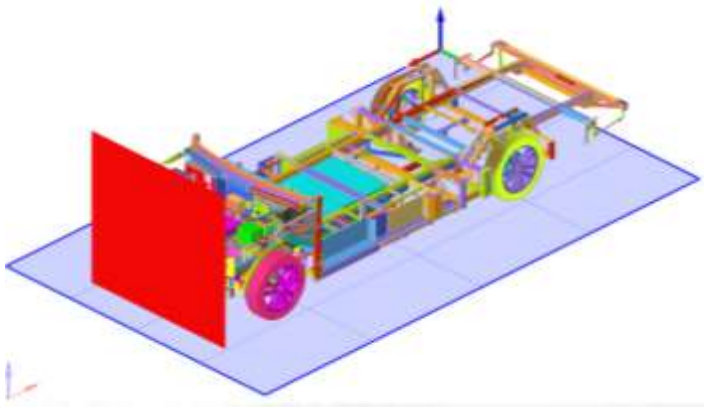

Figure 4. Scenario of Frontal Impact Test on a Rigid Wall

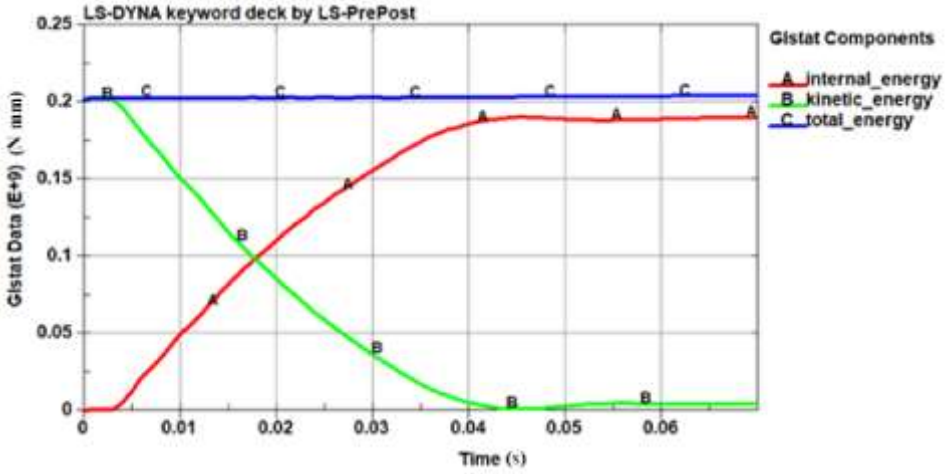

Figure 5. Energy Change Graph

With the current vehicle structure, the transformation of the total energy of the vehicle into internal energy in the event of a frontal crash at a speed of 48 km / h is shown in Graphic-5. This graphic indicates that approximately 90% of the kinetic energy of the vehicle is transformed into internal energy. Ideally, all of the kinetic energy of the vehicle is expected to be absorbed by the crash elements. (Witteman, 1999) The impact elements of the rolling chassis vehicle are respectively formed as crash bars, crash dampers(cross member), and longitudinal members.

The acceleration starts depending on the time when the vehicle first comes into contact with a rigid wall and the intrusion begins. SEA (Specific Energy Absorption) formula represents the specific energy that can be absorbed after beginning of intrusion. The E_{abs} is the mean crash load and is independent of the crash displacement, where ρ is the material density, A is the integration of cross-sectional areas;

$$SEA = \frac{E_{abs}}{\rho \int_0^{\delta} A(h)\, dh} \tag{1}$$

The deformation of the crash-absorbing system of the vehicle starts and is completed in the 1st zone indicated in Figure 6. In the 2. zone, the deformation of the area just behind the crash-damping system begins and is completed. Subsequently, the deformation of the longitidunal members extending along the length of the vehicle begins. In the current design, since the electric motor of the vehicle is mounted on the left longitidunal carrier member, the desired level of deformation was not achieved on this member. Due to the fact that the left longitidunal carrier member cannot be deformed, all the stress on the structure is transferred to the horizontal chassis profile to which it is attached. (Figure 7.) While this crash pulse value is expected to be in the range of 40-45 G in passenger vehicles as a reference point, since the crash pulse value generated in the current vehicle reaches the range of 50-60 G, it was needed to be developed by an iterative study.

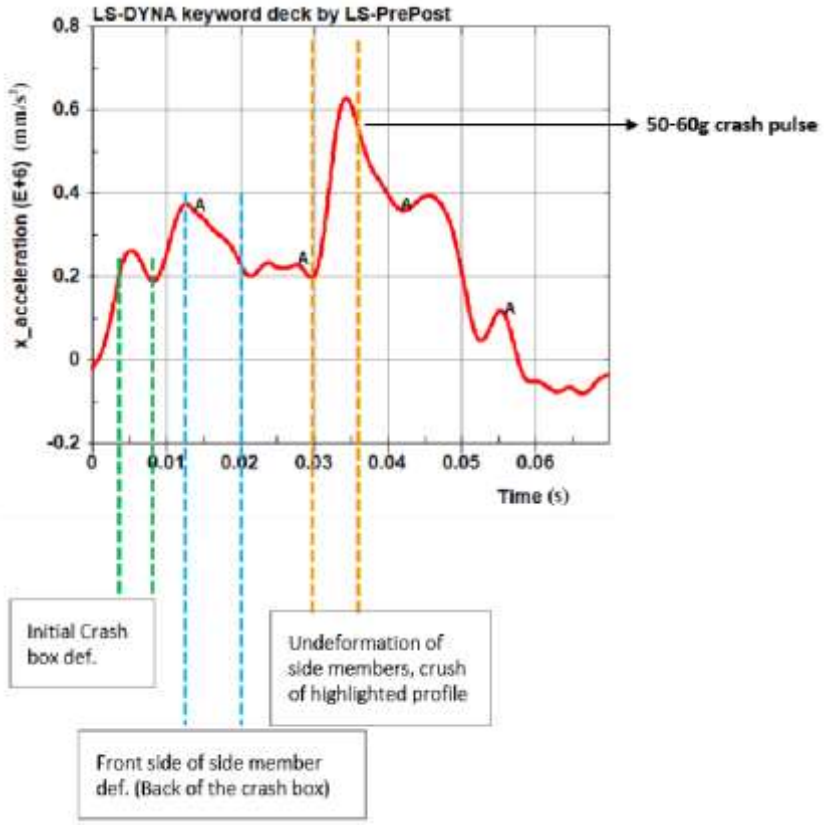

Figure 6. Acceleration/Time Graph of Base Model

Figure 7. Base model Non-deformable Region

3.1.1 Development of FMVSS-305 Frontal Impact Simulation

In this section, there are iteration studies carried out in order to reduce the G force values that occur in the front crash scenario of the vehicle.

Development studies on the crash management system will be examined in three main sections: crash bar, crash damper(cross member), and longitudinal carrier member.

Since it will first come into contact with the rigid wall during the frontal impact, the stiffness level of the crash bar was primarily intended to be reduced. The profile section thickness of the structure used in the current design was reduced to 2 mm, as it was seen that the 3 mm sectioned structure was almost not deformed. (Figure 8)

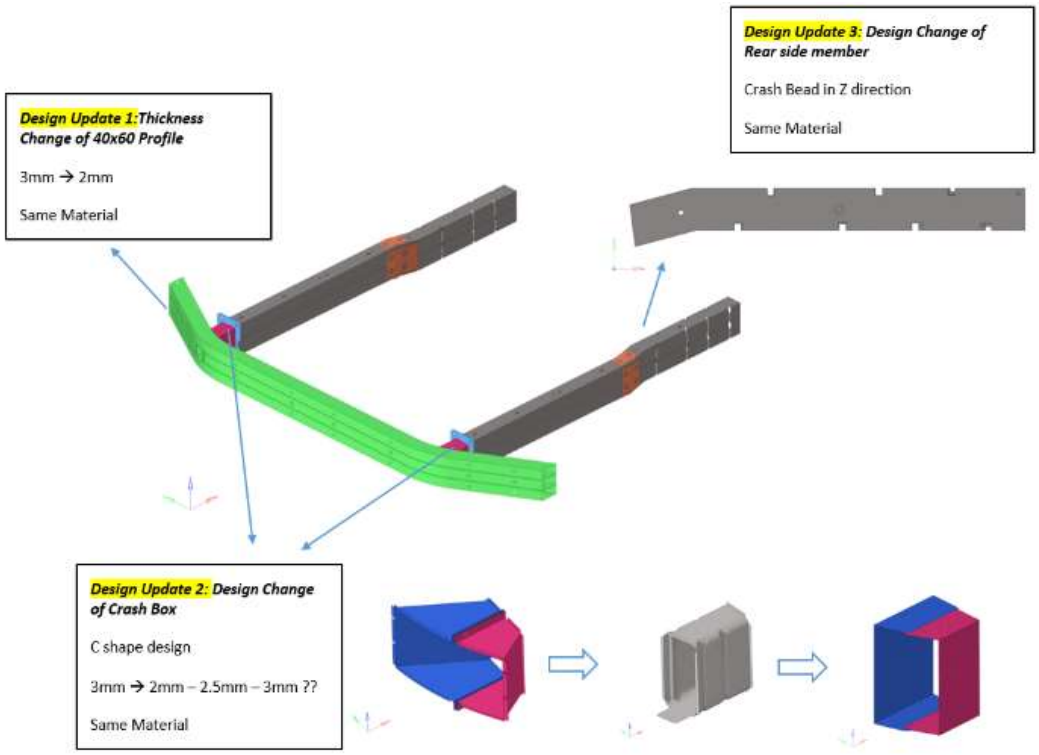

Figure 8. Frontal impact improvement suggestions

The structure of the shock absorber system located behind the crash bar is currently in V shape form. It was seen in the first analysis that this design form was not deformed sufficiently on the vehicle. (Figure 9).

The crossection of the sidemembers determines the geometry of the back of the crash-box. This is to ensure a reliable framework with sidemember support for the crash-box. Small geometrical variations are most common in the structure's corners. (Back 2010) To prevent bending collapse and create a damper effect on the longitudinal member in case of an angular impact its stiffness has to be developed to achieve a high bending resistance. For the cross-section of the profile, the bending resistance W in the undeformed state was calculated by the following;

$$W = (H^4 - h^4)/6H \ [mm^3] \tag{2}$$

The energy absorption E, profile thickness t and column width H in the formula are based on the Wierzbicki theory, and iteration studies were carried out in the light of the following relationship while designing.

$$E \sim t^{5/3} \cdot H^{1/3} \tag{3}$$

Preferred to switch to the form of the longitudinal members in order to ensure the continuity of the cross-section form of the longitudinal members and to capture the deformation at the desired level, which was formed by combining two profiles of 60x60x2 mm section thickness one on another by method welding process. (Figure 8).

In order to deform the impact-absorbing parts uniformly, there should be indentations or protruding structures called crash beads on the part. Uniform profile collapse flow that most important point of crashworthiness can be obtained by experiencing the accordion effect of the shock absorber system thanks to these indentations or protruding structures. The number and geometry of indentations or protrusions can be determined depending on the structure and dimensions of the part. (Witteman 1999)

The recesses or protrusions that should be present on the mentioned impact absorbing system can only be obtained from the molded production process. There are many restrictive factors in the production conditions of the profile structured

vehicle. In the absence of high vehicle production numbers in mass production conditions, the methodologies used in the production of parts are also limited.

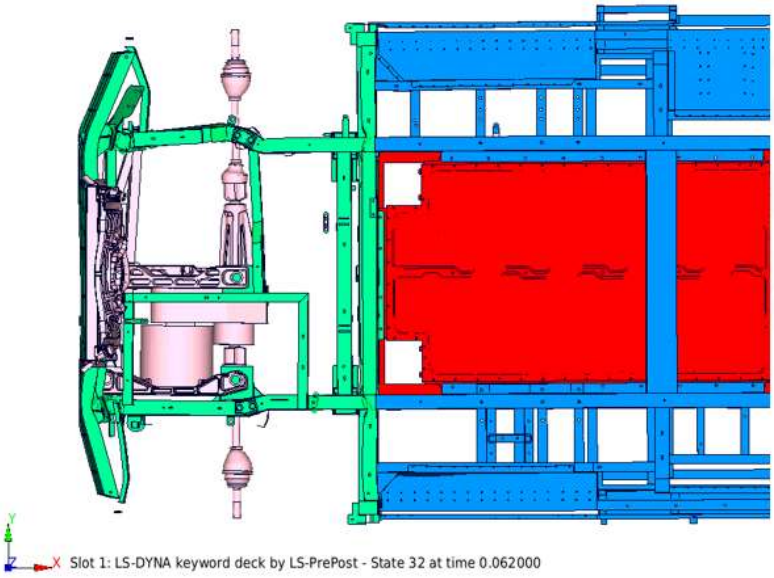

Figure 9. Base model in Crash Moment

In this case, in order to ensure the continuity of the cross-sectional form of the longitudinal carrier member and to capture deformation, the structure to be obtained by joining two interlocking C-section sheets by welding process was preferred. Thickness optimization study of this structure has been carried out. (Figure 10).

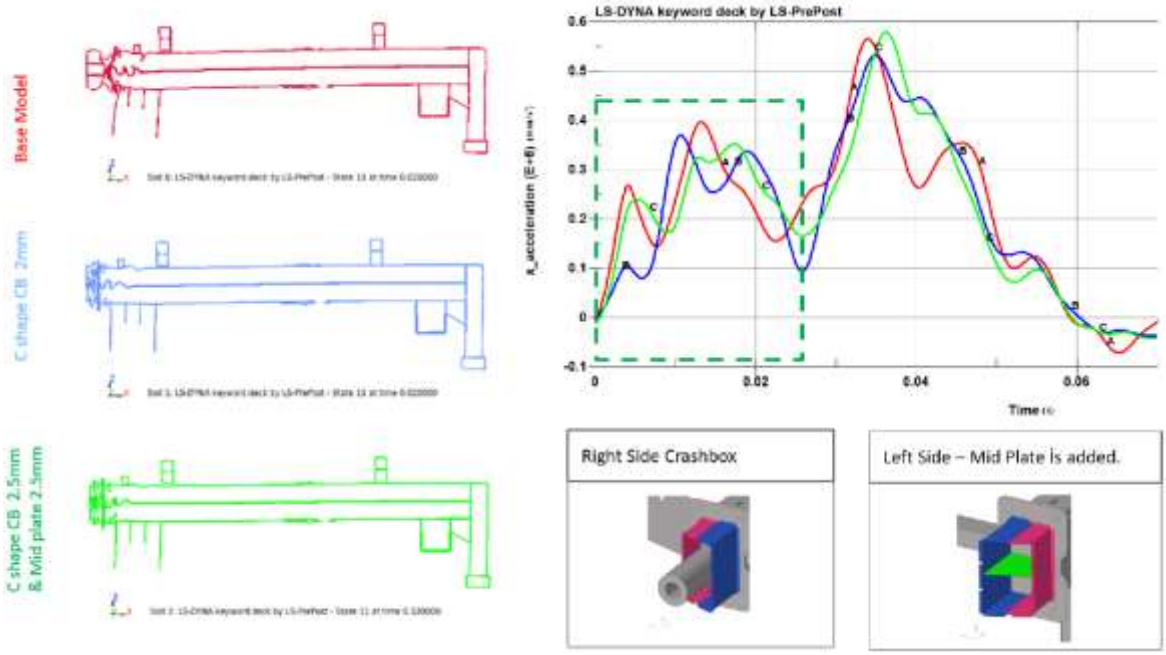

Figure 10. Crash Management System Thickness Optimization

The base model has been advanced by choosing 2.5 mm thickness in which there are no instantaneous peak structures and uniform flow is ensured, as can be seen in the acceleration time graph that occurs when the C-section sheets are 2 mm and 2.5 mm. However, it was observed that the more rigid left side of the right side was deformed before at the time of the intrusion due to the need to have a drawbar structure on the right side of the vehicle and on the crash bar. In

this case, a 2.5 mm thick sheet plate was added to the C-section shock absorber structure on the left side in order to deform both sides simultaneously and in a similar amount.

After the structures that need to be deformed before the longitudinal members are deformed, the longitudinal members will need to be deformed in a way that does not disturb the uniform flow. Since there are electric motor connections on the left longitudinal members, the right and left longitudinal members cannot be deformed at the same time and with similar amounts and cannot absorb a similar amount of impact. In order to improve this situation, first of all, deformation was created by opening channels in the left longitudinal member structures. As in the shock absorber system, channels are opened on the existing longitudinal members, considering the laser cutting process, as the profile structure vehicle production conditions are required. The number, width and depth of the channels opened were again determined by iteration studies. (Figure 11).

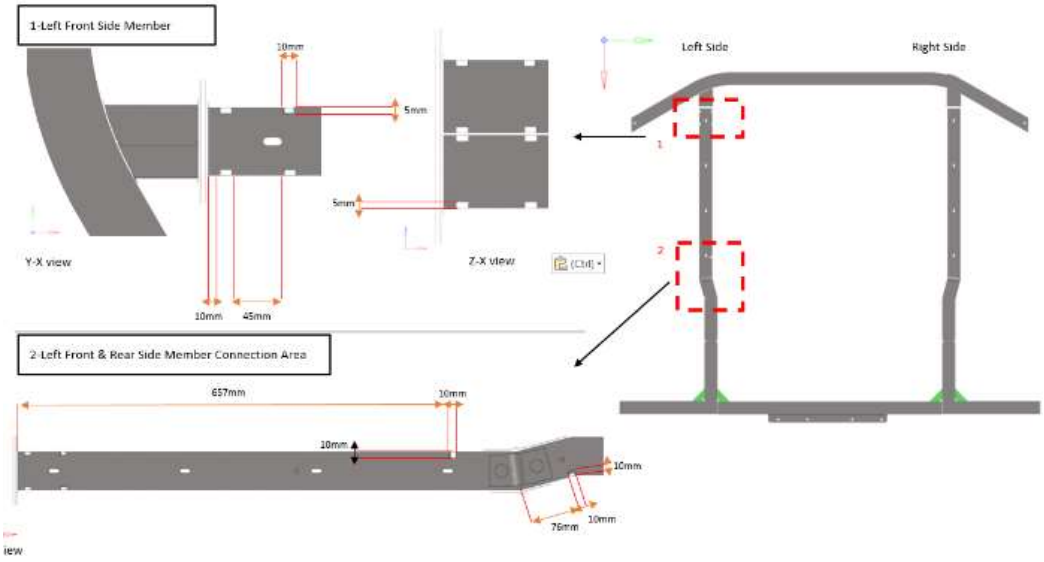

Figure 11. Longitudinal Member Crash Bead Optimization

Parameters such as the type of welding process to be applied on the longitudinal members and the length of the weld length significantly determine the effect that will occur during the crash. In the current analysis structure, intermittent welding application was preferred in a crosswise manner as in Figure 12. The selection of the welding method is also important due to the high heat input that will occur during the welding process. The purpose of this application is to make the heat dissipation homogeneous.

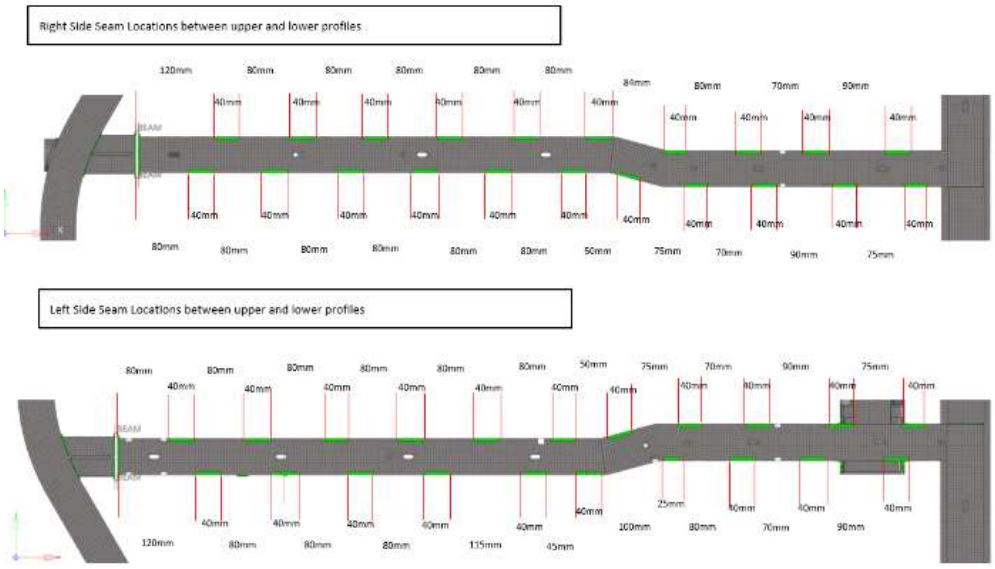

Figure 12. Welding Optimization of Longitudinal Member

As the last improvement study, in the welding application of the connection bracket of the electric motor mounted on the left longitudinal carrier member, as seen in Figure 13, the welding application on one side was canceled and it was aimed to provide vertical (Z-axis) movement in that area.

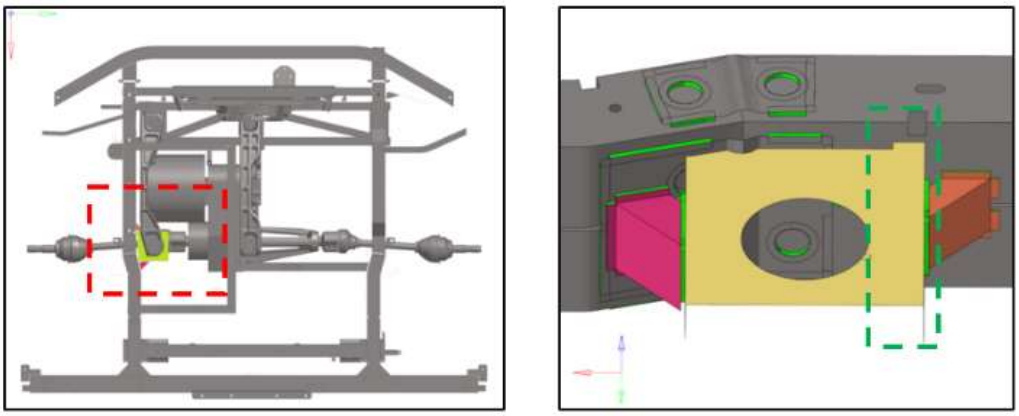

Figure 13. E-Drive Body Connection Structural Optimization

3.1.2 FMVSS-305 Frontal Impact Simulation Results

In this section, the results of the design improvements and improvements in the G force value as a result of the completion of all iteration studies and the analysis of the scenario of "frontal impact on the rigid wall" at 48 km / h are presented.

Figure 14 shows the displacement-time graphs of the left and right longitudinal carrier member before and after the iteration. The curve in red indicates the current base model, while the green curve indicates the developed model.

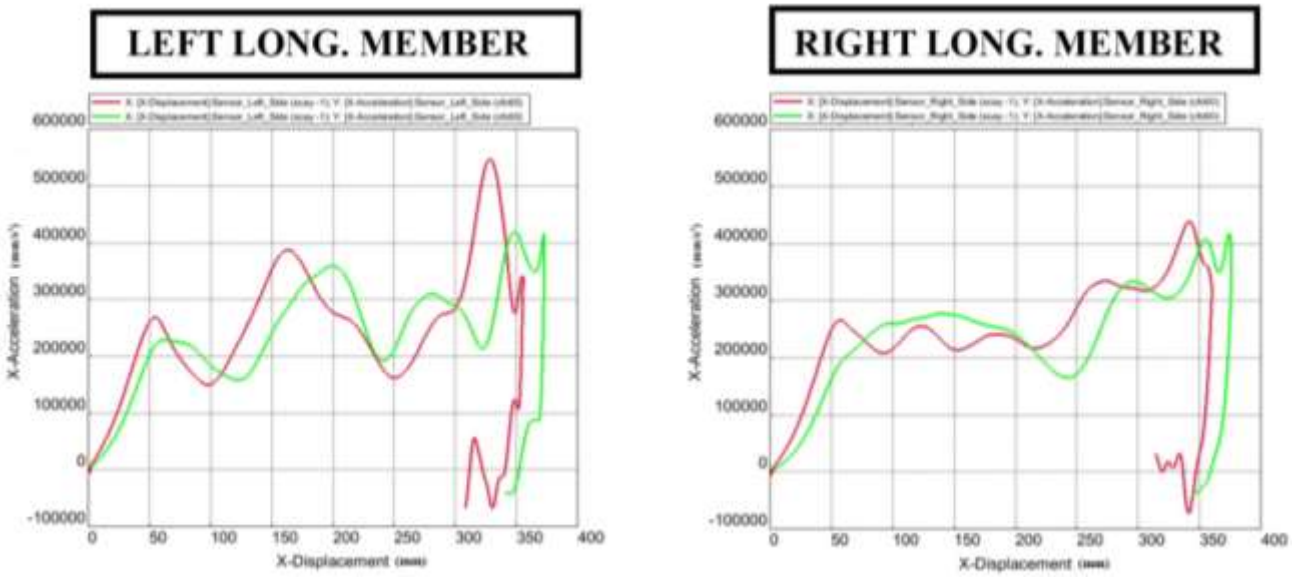

Figure 14. Pulse on the right and left Longitudinal Members

Before the improvement studies were carried out, the maximum acceleration value on the left longitudinal carrier member was 56 G, but after the improvement it decreased to 44 G. Again, before the improvement work was done, the maximum acceleration value on the right longitudinal carrier member was 43 G, while it was seen as 42 G after the improvement. In the last case, the desired result is seen as close to G force values on the right and left longitudinal carrier member.

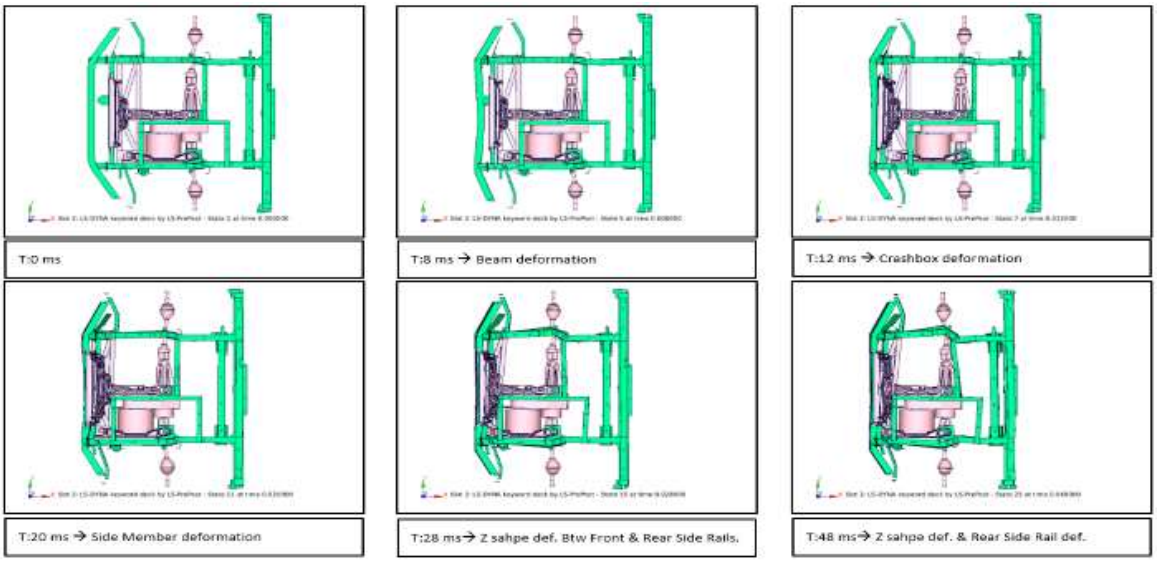

Figure 15. Body Structural Deformation Optimization Steps

The illustration of the G force values varying depending on the time on the vehicle can be seen in Figure 15. The deformation of the crash bar starts at 8 ms, the deformation of the impact-absorbing structure at 12 ms and the deformation of the longitudinal members after 20 ms and the energy is absorbed by the vertical (Z-axis) movement also can be seen formally.

After all these improvements, no deformation occurs in the batteries and battery connections in the vehicle in the frontal crash scenario. (Figure 16)

Figure 16. Stresses in the battery after front impact analysis

3.2 FMVSS-214 Side Impact Simulation

In this section, the tests that must be done according to the FMVSS-214, which is the condition for side impact, referred to in FMVSS-305, are mentioned.

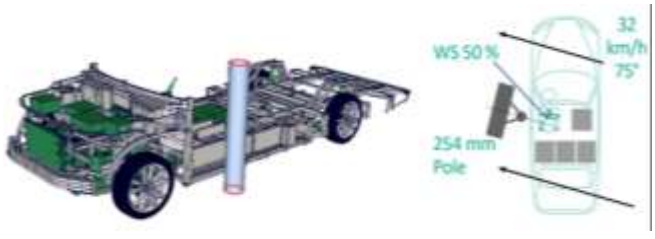

Figure 17. Crash Scenario with Side Rigid Wall

FMVSS 305 regulation for the side impact condition includes the case of crash with the moving deformable barrier (MDB) at 54 km / h. However, since the vehicle under development is a movable chassis, the A pillar ends at the steering level and there is no B pillar. In this case, "side poll with a rigid pole" conditions were preferred at a speed of 32 km / h, as it would cause a higher level of damage locally and would be more challenging. Between the A and B pillars, there are acceleration-time graphs of the current state of the vehicle and the improvements made by iterations in the axis of the driver's head at an angle of 75 degrees. (Figure 17).

The most challenging crash condition will be the side crash scenario, due to the fact that the batteries are in the center front of the vehicle and its current geometric structure. The structural projection of the left side of the vehicle where the driver zone step is located is given in Figure 18. As can be seen in the projection before and after the crash started, the batteries have a displacement of approximately 135 mm. (Figure 19)

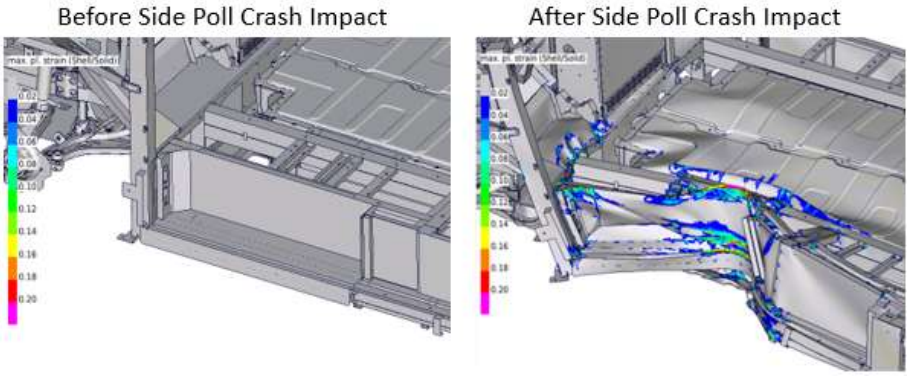

Figure 18. Before/After Side Poll Impact Situation

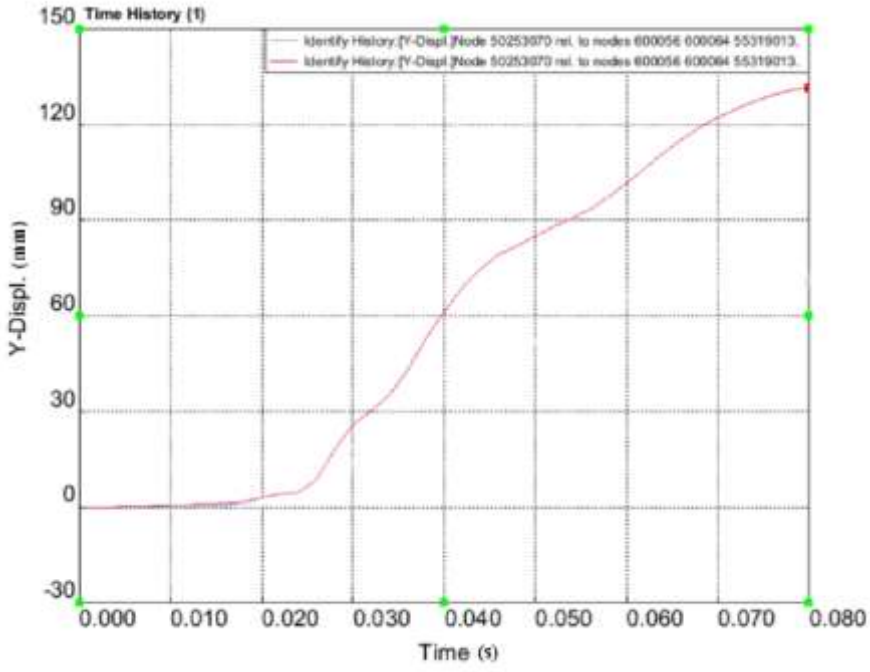

Figure 19. Subjected Deformation on Battery

In this case, the amount of deformation in the batteries also will be high. For this reason, development work should be done in the side impact scenario.

3.2.1 FMVSS-214 Side Impact Simulation Improvements and Results

In this section, the iteration studies carried out in order to reduce the high deformation force values that occur in the side crash scenario of the vehicle are included. It will be necessary to make iterations so that the left side area required for

the protection of the battery located between the middle longitudinal carrier member can absorb the energy at the maximum level.

Bending stress occurs in the middle longitudinal carrier member with the effect of the interference force created by the energy present during the crash in the step region. Driver seat mounting bracket is also located on this middle longitudinal carrier member. Due to this tension, interference occurs between the middle longitudinal member and seat connection body structure and the batteries. (Figure 20)

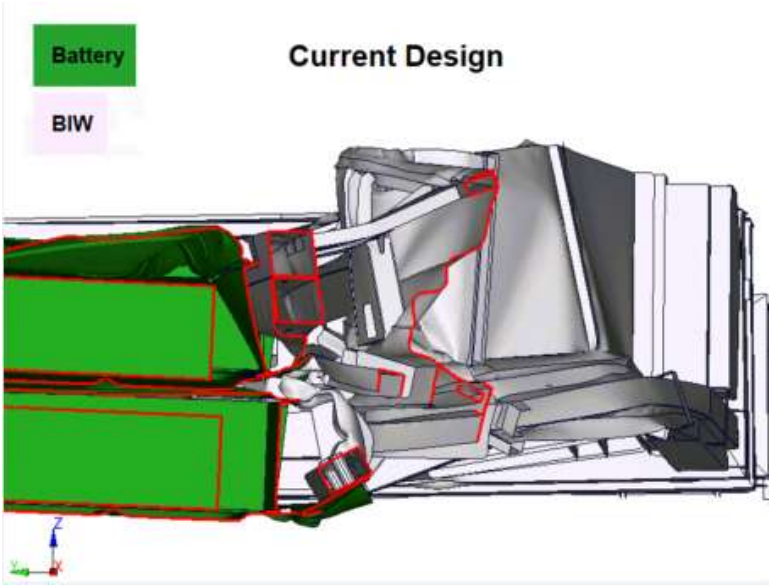

Figure 20. Section view of current design post-collision

In order to prevent the rigid poll used during the intrusion from interfering to the longitudinal members, energy absorbing structures must be created. Additional structures have been added with the increase in thickness and cross-section of the existing body structural elements. (Figure 21)

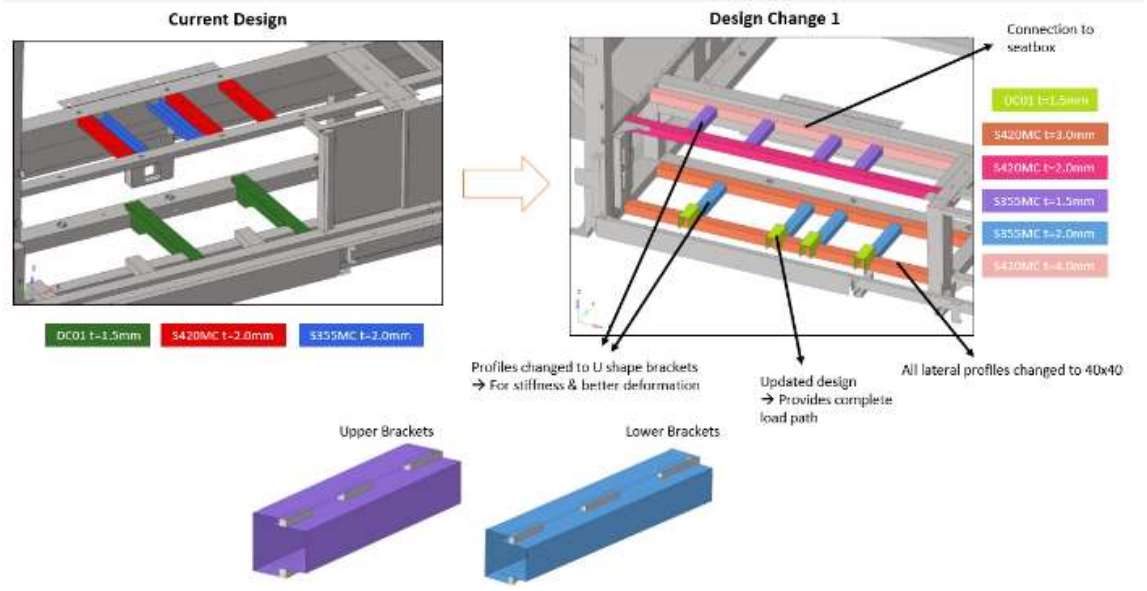

Figure 21. Side impact improvement work-1

The displacement amount of 135 mm in the current vehicle was retreated to approximately 60 mm after the first few iterations. (Figure 22). However, since this amount of displacement is not sufficient, iteration studies should continue.

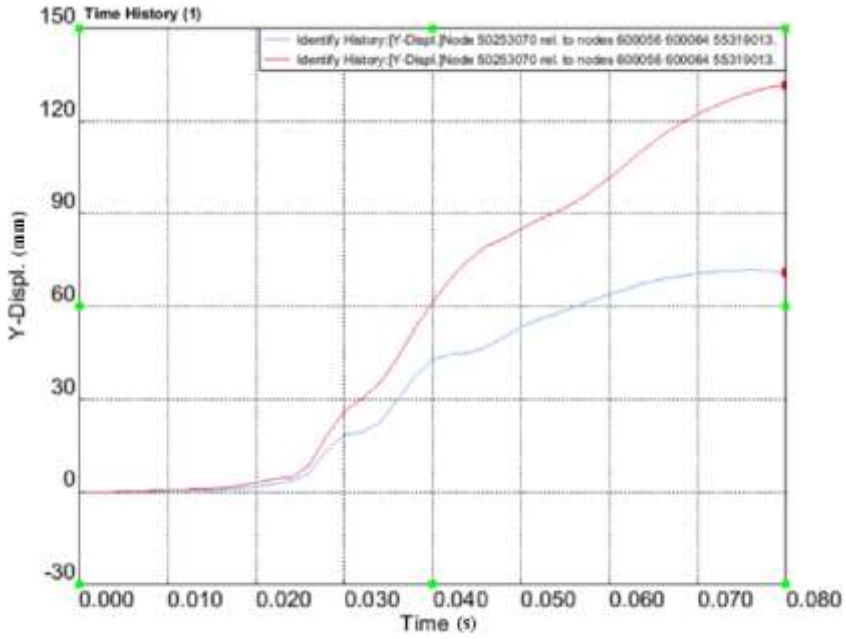

Figure 22. Deformation Ratio of Battery

In order to reduce the amount of displacement on the middle longitudinal carrier member, new development of structures have been defined between the lower and upper main rails. (Figure 23).

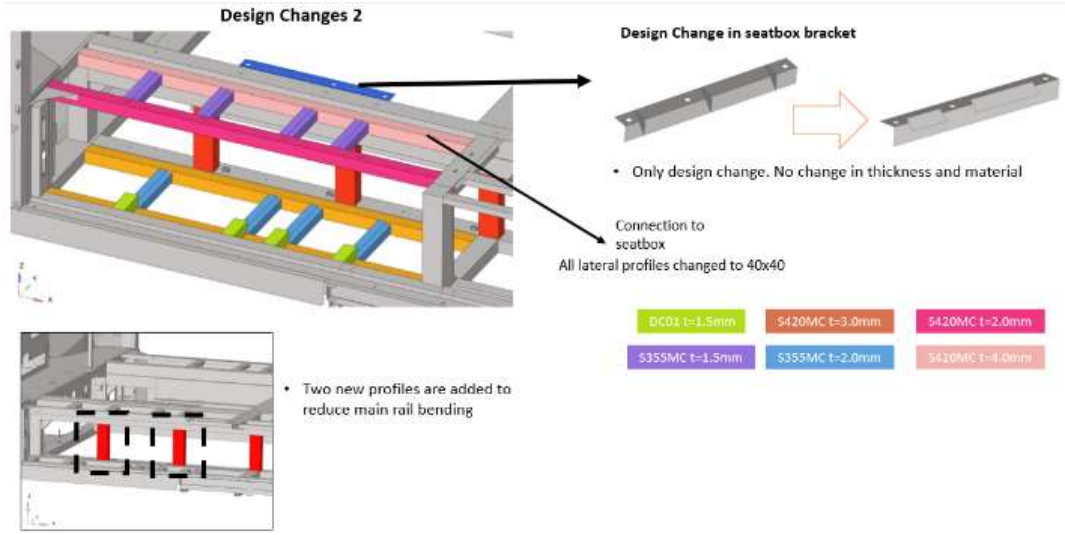

Figure 23. Side impact improvement work-2

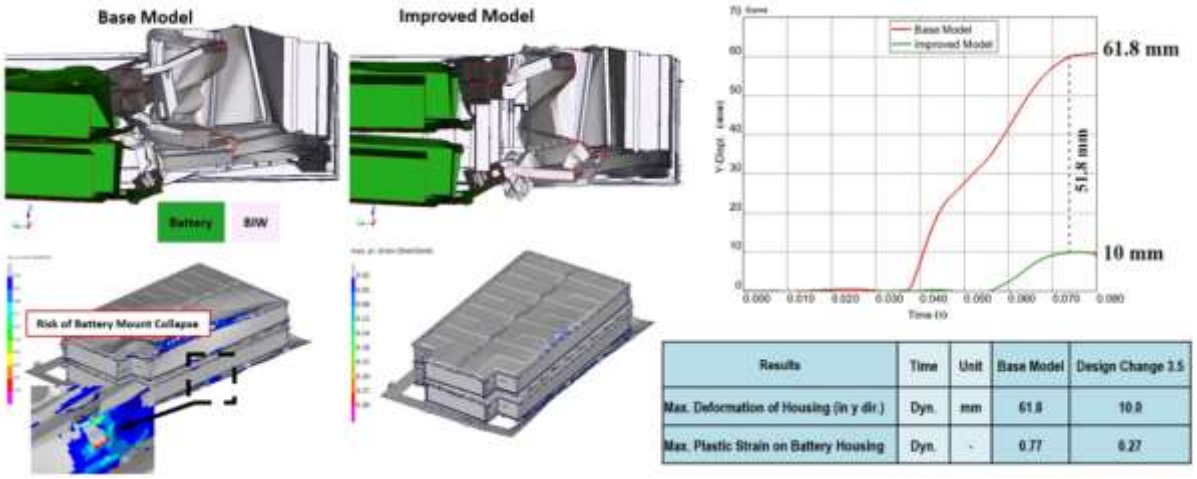
By this way, two important structures are connected with each other and they work together during the intrusion. In particular, it is aimed to reduce the bending stress on the upper longitudinal carrier member. As a result of the latest improvement work, the amount of displacement has been reduced from about 60 mm to 10 mm. (Figure 24).



Results	Time	Unit	Base Model	Design Change 3.5
Max. Deformation of Housing (in y dir.)	Dyn.	mm	61.8	10.0
Max. Plastic Strain on Battery Housing	Dyn.	-	0.77	0.27

Figure 24. Final Design and Deformation Ratio

After all of these improvements, there is no interference in the lower battery of the two batteries in the vehicle in the side crash - side poll scenario. In the upper battery, the amount of plastic deformation of 0.77 that occurred with the interference in the current situation was reduced to 0.27 as a result of iterations.

It is thought that FMVSS-214 test conditions can be met with the strain amount of 10 mm formed locally and at the top due to the geometric structure of the top battery. However, the present results were performed on the simulation-CAE without prototype crash test correlation. Therefore, the results show relative improvements in sidebar crash. However, according to FMVSS standards, a final decision such as test pass / fail cannot be made.

4. RESULTS AND RECOMMENDATION

As a result of the results in sections 3.1 and 3.2, the summary situation is as in Table 1. With the implementation of the improvement studies carried out, according to FMVSS-305 regulation, the absence of any intrusion in the batteries and the absence of any deterioration in the battery connections in the frontal crash scenario shows that the simulation results is positive. Within the scope of FMVSS-214 regulation, the amount of intrusion of 10 mm in the upper battery will be appropriate in the side impact scenario. However, the present results were performed on simulation (CAE) without prototype crash test correlation. Therefore, the results show relative improvements in sidebar crash. According to the FMVSS-214 reference in FMVSS-305, the side impact test is expected to be performed with a moving deformable barrier (MDB) at a speed of 54 km / h. For these reasons, the test is considered successful, but a final decision can be made in the real environment by applying MDB.

In order to be 100% sure of the accuracy of the analysis performed in frontal crash and side crash scenarios, crash tests can be performed in at least one vehicle in real environment, and their data can be taken and compared. In addition, since the vehicle is a movable chassis, it will be useful to see the results with a simple analysis over the final study where the iterations are applied after the driver's cabin and cargo area are also designed. As the amount of deformation will increase with the weight increase, an improvement in frontal crash is expected.

Table 1. FMVSS-305 Test Results

ABSTRACT

In this paper, a path planning method is described to perform an autonomous parallel parking of a four-wheel steered vehicle. This method is based on kinematic model of the vehicle and geometrical equations. Described method of obtaining the path works by first retrieving the vehicle from its final position. The interval the algorithm can function is found by performing simulations on Matlab with different lateral starting positions. Advantages of the four-wheel steering over front axle steering are proven by simulations and three newly derived equations. The first equation gives the maximum lateral position of the left front edge of the ego vehicle. The second equation is used to calculate the maximum approach of right front edge of the ego vehicle to parked vehicle. The last equation shows the longitudinal difference between the rear bumpers of parked vehicle and ego vehicle at the start of the reversing maneuvers. With the help of these equations, feasibility of the maneuver can be evaluated by considering kinematics of the vehicle and environmental telemetry. Since required longitudinal position at the start of reversing maneuvers is calculated according to lateral position, unnecessary longitudinal maneuvers can be avoided.

Keywords: Autonomous parallel parking, four-wheel steered vehicles, path planning, driver assistance systems

1. INTRODUCTION

Parallel parking is a difficult task for drivers as described in literature (Gupta continued, 2010). Especially in Europe, double side parking on road can be widely seen due to number of cars and narrow streets, as can be seen Fig. 2. Drivers have to be careful about the left side approach of their vehicles. Autonomous maneuvers in similar environments are investigated in TrustVehicle which is a H2020 Project. For instance, narrow street passage maneuver in a double-sided parked road is mentioned in literature (Hatipoğlu continued, 2020) with the scope of TrustVehicle Project.

One of the early works in the literature, (Reeds and Shepp, 1990) mentioned that optimal paths for a vehicle that can go forwards and backwards can be constituted with circles of minimal radius.

A path planning study related to parallel parking is described in literature (Gupta continued, 2010). The path is based on a straight line and two circular arcs. Ackerman model is used to model the motion of the vehicle due to low speed of the maneuver. Parking space is long enough to park in one trial. Front wheel steered vehicles are considered.

Another path planning study for parallel parking is proposed by (Choi continued, 2011). Parking path is obtained by first retrieving the vehicle from the final position. Described method is based on connecting two circular arcs. Minimum parking space length is calculated geometrically. Ackerman steering model is used for front wheel steered vehicles. Longitudinal starting positions of the maneuver according to lateral positions are given as a figure. The method can work independent of lateral position on condition that the vehicle is parallel to the parked cars within limits.

Design of an electric vehicle with rear wheel steering is mentioned by (Krčmář continued, 2019). An experimented vehicle is manufactured. Ackerman steering geometry is used. Maximum steering angle of rear wheel is stated as 5 degrees. A sinus function is used to calculate optimum steering of rear wheels. Maximum steering angle with respect to velocity is shown with a graph. Architecture of the vehicle is mentioned as a block diagram.

A four-wheel independent-steering and four-wheel driving vehicle with an autonomous and manual driving system is proposed by (Tzuu continued, 2016). The autonomous driving system have lane following, reverse and parallel parking features. The system is based on fuzzy control and machine vision theory. To verify the feasibility of the vehicle, an indoor experiment is conducted.

A study related to maneuverability of motor vehicles with two steering axis is proposed by (Pilisiewicz and Kaczyński). Parallel and perpendicular parking are analyzed to calculate the optimal steering angles and examine the kinematics.

Vehicle is parked in the middle of parking space in simulations. It is assumed that vehicle moves without slipping. Some values are given to mention four-wheel steered vehicles have better maneuverability in parking scenarios. There are no parametric equations to calculate maximum approach left side, longitudinal position at the start of reversing maneuvers. Also, different maximum steering angle limits of rear wheels are not considered in the referenced study.

In this study, autonomous parallel parking of a four-wheel steering vehicle is described. Advantages of the four-wheel steering in terms of autonomous parallel parking are demonstrated by equations, and Matlab simulations. Environment model is based on a common parking scenario where vehicles are parked either two side of street. For various maximum steering angle limits of rear wheels, advantages of four-wheel steered vehicle are presented and compared to front wheel steered vehicle under various kinematic constraints. New parametric formulas are derived to calculate these constraints and to show related parameters.

2. KINEMATICS AND PATH PLANNING

In this work, vehicle motion is modeled kinematically. Proposed path planning method is based on Ackerman steering. Ackerman steering is used due to low speed of the maneuver and Ackerman angle errors are neglected. The path consists of three steps, straight forward, left backward and right backward maneuvers, respectively.

2.1. Vehicle Model

Vehicle is modelled as a rectangular box that bounds the extremities of the vehicle for sake of simplicity. Vehicle is assumed to be a light commercial vehicle and the vehicle model is given in Fig. 1. Each wheel is represented as a line to obtain direction. These directions are used to check that all wheels have correct directions according to Ackerman steering. Parameters are given in Table 1.

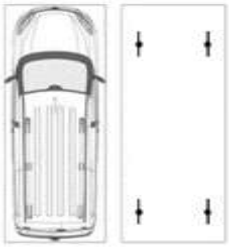

Figure 1. Vehicle model

Table 1. Required parameters & variables

Parameters & Variables	Notation	Value
Wheelbase	l	3105 mm
Front Overhang	l_1	911 mm
Rear Overhang	l_2	740 mm
Part of the wheelbase according to ratio	l_3	Variable
Part of the wheelbase according to ratio	l_4	Variable
Trackwidth	d	1530 mm
Width of the vehicle (side mirrors included)	d_0	2180 mm
Distance between side mirror and center of the wheel	d_{star}	325 mm
Steering angle (representative, in degrees)	δ	[-35° 35°]
Safety distance	fos	$(l + l_1 + l_2)/10$
Lateral distance between the ego vehicle and the stationary vehicle	$lateral$	Variable
Instantaneous center of rotation	ICR	Variable
Turning radius	R	Variable
Center coordinates of right backward maneuver circle	(X_{RRM},Y_{RRM})	Variable
Ratio between inner front and inner rear wheel steering angle	$ratio$	Variable
Left rear edge coordinate of the	(X_3,Y_3)	Constant

parked vehicle which is placed in front of the parking space		
Length of the parking space	$length_{parking\ space}$	Constant
Change in orientation angle of the vehicle during reversing maneuvers	$orientation_{angle}$	Variable

2.2. Four Wheel Ackerman Steering

Maximum value of the inner front wheel steering angle is assumed to be 35 degrees to consider the mechanical limitations of the vehicle. Inner rear wheel steering angle changes proportionally with inner front wheel steering angle as mentioned with Eq.1. Ratio between inner front and inner rear wheel steering angle are selected to be 3.5, 5 and 7, respectively. X-axis represents the lateral distance and Y-axis represents the longitudinal distance. Equations of required parameters are given in Eq 2-6.

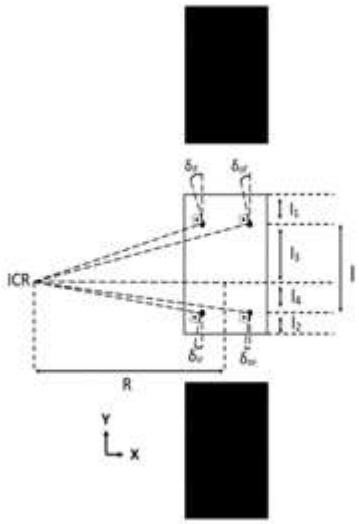

Figure 2. Ackerman steering

$$\delta_{ir} = \frac{\delta_{if}}{ratio} \tag{1}$$

$$R = \frac{l}{tan(\delta_{if}) + tan(\delta_{ir})} + \frac{d}{2} \tag{2}$$

$$l_3 = tan(\delta_{if}) * (R - \frac{d}{2}) \tag{3}$$

$$l_4 = l - l_3 \tag{4}$$

After calculating l3 and l4, steering angle of outer wheels can be calculated as follows.

$$\delta_{of} = \tan^{-1}(\frac{l_3}{\left(R + \frac{d}{2}\right)}) \tag{5}$$

$$\delta_{or} = \tan^{-1}(\frac{l_4}{\left(R + \frac{d}{2}\right)}) \tag{6}$$

2.3. Path Planning

Environment model consists of an ego vehicle, five stationary vehicles, a parking space and two road borders to simulate an environment that is given in Fig.3. All of the stationary cars are perfectly parallel to the road borders and aligned among themselves. Dimensions of the stationary vehicles and the ego vehicle are assumed to be the same. Parking space length is 1.6 times length of the ego vehicle. Ego vehicle starts the maneuver in parallel to stationary cars. Environment model is given in Fig.4.

Figure 3. Real world environment

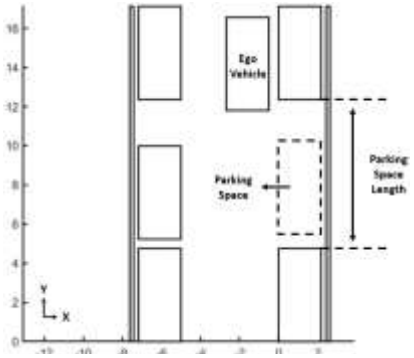

Figure 4. Simulation environment

Each wheel follows a trajectory which consists of a straight line and two circular arcs as described by (Gupta continued, 2010). The vehicle starts the reverse maneuver at perfect longitudinal position. Steering angles of the wheels change only when the vehicle velocity is equal to zero to be able to use Ackerman steering equations. Circles are generated according to turning radius (R) and vehicle geometry. These circles are given in Fig. 5.

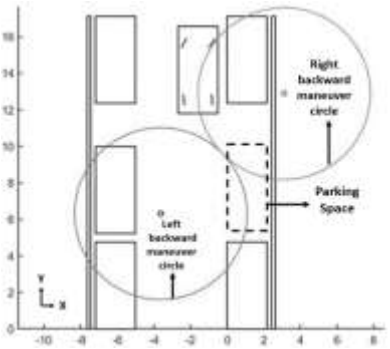

Figure 5. Maneuver circles

The proposed algorithm aims to calculate the parking path by connecting the final and initial position of the vehicle by using a straight line and two circulars arcs. In other words, the algorithm at first retrieves the vehicle from the parking space and uses the same path for parking as mentioned by (Choi continued, 2011). Vehicle positions at different stages of the maneuver are shown in Fig. 6.

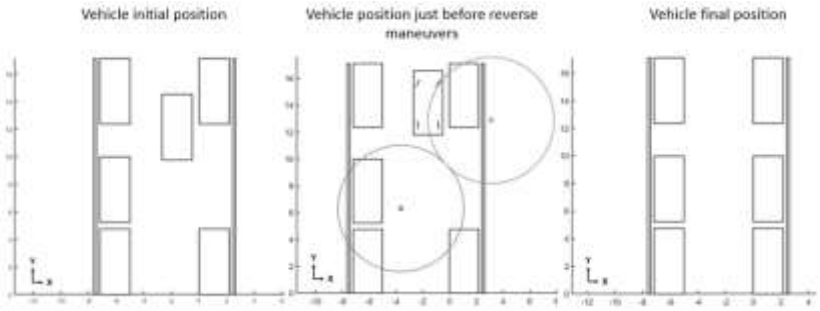

Figure 6. Positions of the ego vehicle

At first, left backward maneuver circle must be obtained since the circle's center coordinates are functions of parking space coordinates and vehicle kinematics. Related equations are given as Eq.7 and Eq. 8.

$$X_{LRM} = X_3 + d_{star} - \left(R - \frac{d}{2}\right) \tag{7}$$

$$Y_{LRM} = Y_3 + fos + l_2 + l_4 \tag{8}$$

Then, right backward maneuver circle is generated according to initial lateral position of the ego vehicle, left backward maneuver circle center and vehicle kinematics. Related equations are given as Eq.9 and Eq. 10.

$$X_{RRM} = X_3 - d_0 + d_{star} + \left(R + \frac{d}{2}\right) - lateral \tag{9}$$

$$Y_{RRM} = Y_{ICC} + \sqrt{(4 * R^2 - (X_{RRM} - X_{LRM})^2)} \tag{10}$$

Orientation angle change of the vehicle can be calculated by using circles' centers. Related equation is given as Eq. 11.

$$orientation_{angle} = \tan^{-1}\left(\frac{Y_{LRM} - Y_{LRM}}{X_{LRM} - X_{LRM}}\right) \tag{11}$$

3. SCENARIO AND SIMULATIONS

The ego vehicle is in parallel to the stationary cars at the start of the maneuver. Then, it goes straight forward until reaches to a coordinate which is a function of lateral distance and vehicle kinematics. After that, the vehicle stops and sets the steering angle and performs backward maneuver until the orientation angle reaches the pre-calculated value. Then, the vehicle stops and sets the steering angle to perform left backward maneuver. At the end of these maneuvers, the vehicle is placed perfectly in parallel to the road border. Parking maneuvers with three different ratios are proposed in Fig.7, Fig.8 and Fig.9. Parking maneuvers of front-wheel steered vehicle are given in Fig.10.

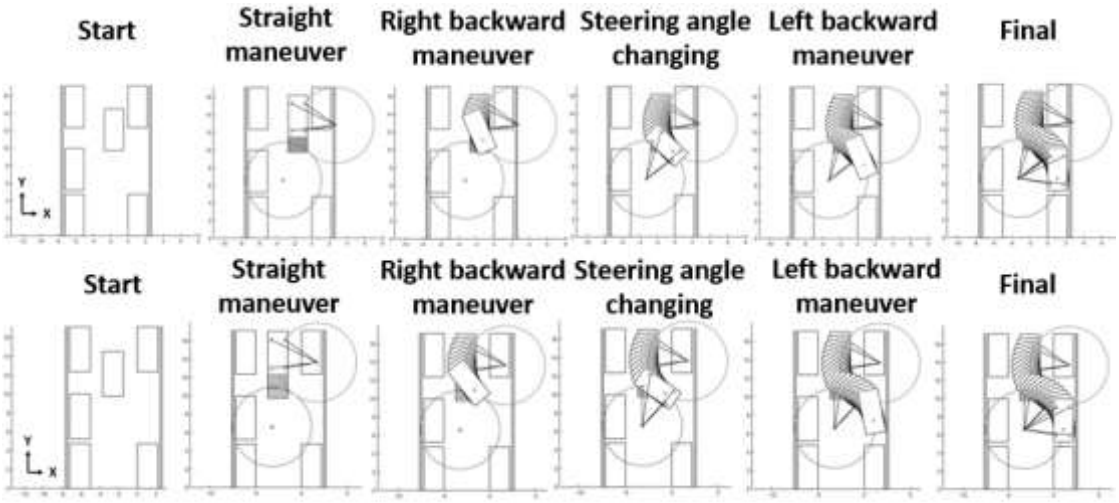

Figure 7. Parking maneuvers with lateral distances 0.5 meters & 1.5 meters; the ratio is 3.5 (Cases 1-2)

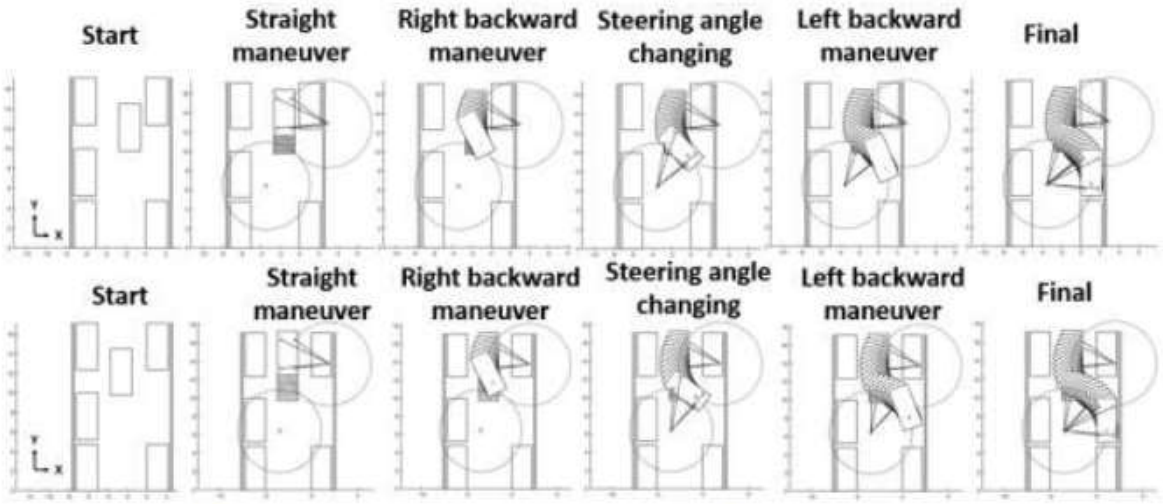

Figure 8. Parking maneuvers with lateral distances 0.5 meters & 1.5 meters, ratio is 5 (Cases 3-4)

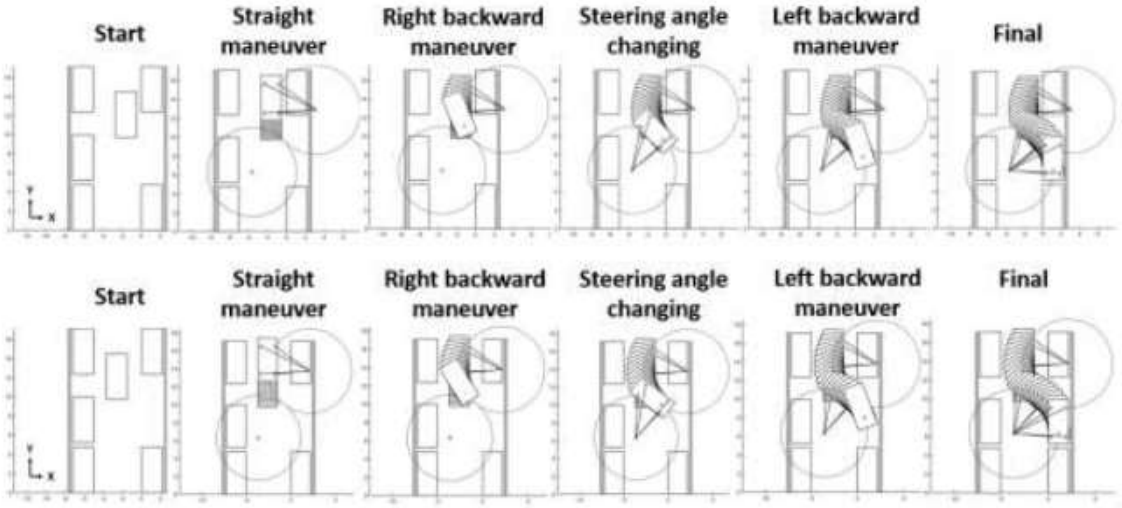

Figure 9. Parking maneuvers with lateral distances 0.5 meters & 1.5 meters, the ratio is 7 (Case 5-6)

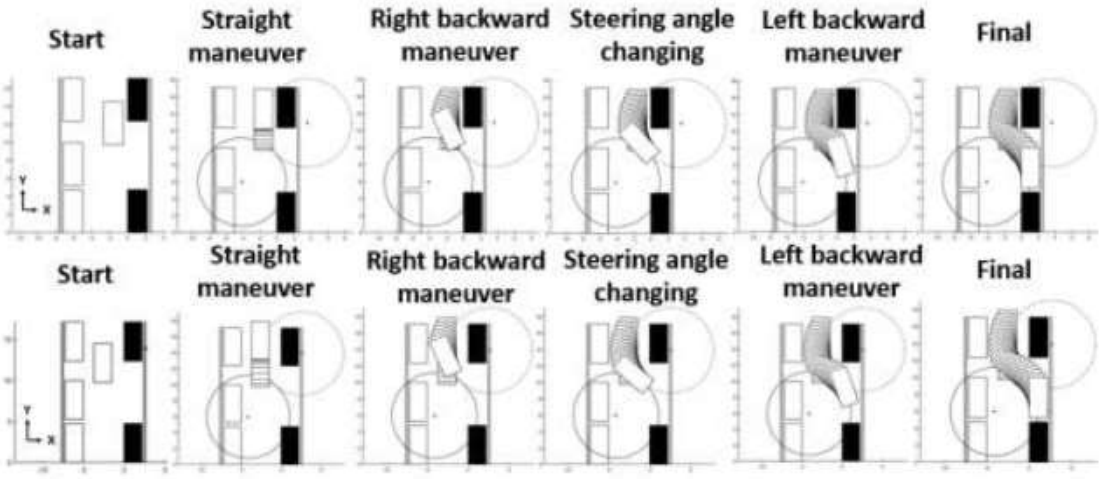

Figure 10. Parking maneuvers with lateral distances are 0.5 meters & 1.5 meters, front-wheel steered vehicle (Cases 7-8)

4. NEWLY DERIVED EQUATIONS

Longitudinal distance difference, maximum approach to left side and maximum approach to right side are presented with parametric equations in this section.

4.1. Longitudinal Distance Difference (LDD)

A new formula is derived to show related parameters of the distance between rear bumper of the ego vehicle and rear bumper of the parked vehicle that is in front of the parking space at the end of straight forward maneuver. This distance is also represented as ΔX in Choi and Boussard (2011) in a figure. The formula is given as Eq. 12.

$$LDD = fos + \sqrt{\left(4 * \left(\frac{1}{\tan(\delta_{if})+\tan(\delta_{ir})} + \frac{d}{2}\right) * (d_0 + lateral) - (d_0 + lateral)^2\right)} - length_{parking\ space} \quad (12)$$

As can be seen from Eq. 12, the distance is a function of steering angle, ratio between inner front and inner rear wheel steering angle, lateral, width of the ego vehicle, length of the parking space and fos.

4.2. Maximum Approach to Left Side

When parking in a narrow street, maximum approach to left side is an important indicator to evaluate feasibility of the parking maneuver. Within this scope, a formula is derived to mention related parameters. The formula is given Eq. 13.

$$left_{max} = X_3 - lateral - d_0 + d_{star} + \frac{d}{2} + R - \sqrt{(R + \frac{d_0}{2})\text{^}2 + (l_1 + l_3)^2} \quad (13)$$

This formula shows that maximum approach to left side is functions of steering angle, ratio between inner front and inner rear wheel steering angle, lateral distance, vehicle dimensions and environmental telemetry.

The formula comes from the circle which shows the trajectory of left front edge of the ego vehicle. Related geometry is given as Fig. 11.

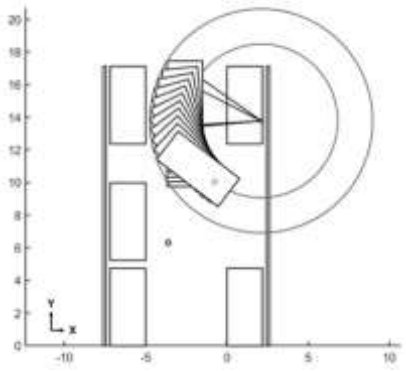

Figure 11. Trajectory circle of the left front edge

4.3. Maximum Approach to Right Side

During the left backward maneuver, right front edge of the ego vehicle approaches to left rear edge of the parked vehicle that is placed in front of the parking space. The derived formula shows the longitudinal difference of the right front edge of the ego vehicle when these edges are on the same lateral position. Related formula is given as Eq. 14.

$$right_{max} = length_{parking\ space} - (fos + l_2 + l_4 + \sqrt{\left(R + \frac{d_0}{2}\right)^2 + (l_1 + l_3)^2 - \left(R - \frac{d}{2} - d_{star}\right)^2})) \quad (14)$$

These formula shows that, this distance is effected by steering angle, ratio between inner front and inner rear wheel steering angle, dimensions of the ego vehicle, safety distance and environmental telemetry.

The formula is based on the circle which shows the trajectory of right front edge of the ego vehicle. Related geometry is given in Fig. 12.

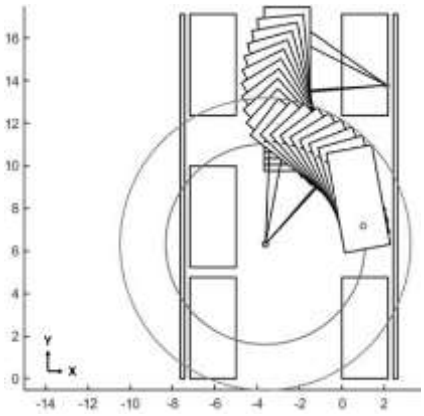

Figure 12. Trajectory circle of the right front edge

Table 2. Cases and results

Case	Steering Angle (in degrees)	Ratio	Lateral (in meters)	$right_{max}$ (in meters)	$left_{max}$ (Coordinate)	LDD (in meters)
1	35	3.5	0.5	0.2665	-3.6570	-0.8896
2	35	3.5	1.5	0.2665	-4.6570	-0.0727
3	35	5	0.5	0.2380	-3.7076	-0.6948
4	35	5	1.5	0.2380	-4.7076	0.1636
5	35	7	0.5	0.2182	-3.7447	-0.5556
6	35	7	1.5	0.2182	-4.7447	0.3321
7	35	-	0.5	0.1652	-3.8528	-0.1658
8	35	-	1.5	0.1652	-4.8528	0.8028

As can be seen from the Table 2, four-wheel steered vehicle approach less to stationary car during the left backward maneuver. As the ratio decreases, the difference between them increases. Only front wheel steered vehicle performs the maneuver with the biggest approach. In brief, four-wheel steered vehicle has a clear advantage compared to front wheel steered vehicle in terms of approach.

Table 3. Left side approach

Case	Initial Left Front Edge Coordinate	$left_{max}$ (Coordinate)	Difference (in meters)
1	-2.68	-3.6570	0.977
2	-3.68	-4.6570	0.977
3	-2.68	-3.7076	1.0276
4	-3.68	-4.7076	1.0276
5	-2.68	-3.7447	1.0647
6	-3.68	-4.7447	1.0647
7	-2.68	-3.8528	1.1728
8	-3.68	-4.8528	1.1728

As the ratio between inner front and inner rear wheel steering angle decreases means that the inner rear wheel turns more. As can be seen from the Table 3, as the ratio decreases, the difference is increases. Also, this table shows that front wheel steered vehicle has the biggest difference means that these types of vehicles need to wider streets to perform a collision free parallel parking maneuver.

5. CONCLUSION

An autonomous parallel parking algorithm that depends on only geometric equations of four wheel steered vehicles is described in this paper. This algorithm is independent of the lateral position of the ego vehicle within limits on condition that the ego vehicle is in parallel to parked vehicles. Parameters that effect longitudinal position at the start of reversing maneuvers, $left_{max}$ and $right_{max}$ are mentioned with derived equations . In brief, these parameters belong to dimensions and kinematics of the vehicle and measured environmental telemetry. As the ratio decreases, the maximum approach to left side decreases means that the vehicle can park narrower streets. In addition, vehicle can start the reverse

maneuvers with less longitudinal displacement. Also, the approach between edges during left backward maneuver decrases. Since equations are parametric, these distance s can be calculated for various vehicles that have different steering angles, ratios between inner front and inner rear wheel steering angle and initial lateral positions under existing assumptions. The ego vehicle steers at zero velocity means that maximum lateral displacement are taken with minimum longitudinal displacement so results of these calculations can be used for obtaining membership functions limits of fuzzy controllers. As a future work, multiple maneuver parallel parking of a four wheel steered vehicle can be investigated.

ABSTRACT

Bolted joints are widely used joining type in the automotive industry. It is common to use conical (belleville) washers to prevent the self-loosening phenomenon that can occur in time for bolted joints. Despite the extensive use of conical washers, there is no study regarding their loosening resistance under vibration conditions depending on some joint parameter changes. In this study, loosening behavior under transversal vibration of the conical washer usage in bolted joints investigated experimentally according to clamping length and clamping force.

Within the scope of the loosening tests, to observe clamp length effect, tests were performed with two levels which are 25 mm and 75 mm. In order to examine the effect of clamp force, which is great importance in terms of loosening, the tests were conducted to correspond to 50% and 75% of the "proof load" value according to the ISO 898-1 standard. M8x1.25x8.8 quality bolts were used during the tests.

Testing set was created as 2^3 full factorials with 6 replicates in the Minitab program and the effect of each parameter was examined with regression curves. The findings show that the clamping length and clamping force directly affect the performance of the conical washer.

ÖZET

Cıvatalı bağlantılar otomotiv sanayinde sıklıkla kullanılan bir birleştirme çeşitidir. Bağlantılarda zamanla oluşabilen gevşeme fenomenini önlemek için konik(belleville) rondela kullanımı yaygındır. Konik cıvataların yaygın kullanımına ragmen, titreşim altında göstermiş oldukları gevşeme dirençlerinin parametrelere bağlı olarak değişimini içeren bir çalışma bulunmamaktadır. Bu çalışma ile cıvatalı bağlantılarda konik rondela kullanımının, yatay titreşim altında gösterdiği gevşeme davranışları bağlantı kilitleme boyu ve kilitleme yüküne bağlı olarak deneysel olarak incelenmiştir.

Gevşeme testleri kapsamında kilitleme boyunun etkisini görebilmek adına testler 25 ve 75 mm kilitleme boyu değerlerinde gerçekleştirilir iken, gevşeme açısından büyük öneme sahip kilitleme yükünün etkisinin de incelenebilmesi adına testler ISO 898-1 standardında mevcut olan “proof load” değerlerinin %50 ve %75’ ine tekabül edecek şekilde seçilmiştir. Testler esnasında M8x1.25x8.8 kalite cıvatalar kullanılmıştır.

Deney seti, 2^3 tam faktöriyel 6 tekrarlı olarak oluşturulmuş, test sonuçları Minitab programında analiz edilerek, regresyon eğrileri ile her bir parametrenin etkisi incelenmiştir Elde edilen bulgular kilitleme boyunun ve kilitleme yükünün konik rondelanın performansına doğrudan etki ettiğini göstermektedir.

Anahtar kelimeler: Bağlantı elemanı, konik rondela, kilitleme boyu, gevşeme, regresyon

1. INTRODUCTION

Bolted joints are commonly used one of the joining methods in the automotive industry. The reason of that joints which are created with bolts and nuts, are relatively low cost compared to their durable, ductile benefits with respect to other joining methods, and at the same time, maintenance costs are low because they can be easily assembled and

disassembled. Bolted joints are exposed to high external loads such as fatigue or misuse loads which that can be triggered to the self-loosening phenomenon. To prevent this self-loosening phenomenon, bolts must be fastened required clamp load considering external loads and other boundary conditions. According to DIN 25201-2 standard, clamping length – bolt diameter ratio shall be 3..5 are recommended to provide more flexibility to the joint. In the literature, there are some experimental studies about clamping length – bolt diameter ratio. By determining the clamping length - bolt diameter ratio as 1 to 4, the resistance of the joints against sliding was investigated by applying a fixed shear force in the transversal direction under 2 different torques and clamping lengths. It was observed that the clamping length - bolt diameter ratio and clamping length did not have a significant effect on loosening. (Denkert continued, 2019)

Junker (1969), showed that transversal loads acting on bolted joints play a more critical role in self-loosening than axial loads which performed in Junker vibration test device. (Sanclemente and Hess, 2007) conducted a study to examine the loosening mechanism parametrically and the effects of clamp load and pitch on loosening resistance. The study shows that clamp load and pitch has a direct impact on loosening behaviors of fasteners. In another study, Nishimura et. al. (2007) directly focused on loosening prediction. Findings revealed that loosening was caused by the formation of micro slips in the thread area due to the lateral force. (Dravid continued, 2014) investigated that the vibration behavior of the usage of plain and spring washers under 3 different torque values in the experimental setup which they created themselves. As a result of experimental tests, it has been shown that the spring washer behaves worse performance than the plain washer, and the resistance of the joint to loosening increases when the applied torque increases. (Yokohama continued, 2008) created a virtual M10 dimensioned 3D joint model and performed virtual tests on the model to show conical washer effect on loosening. The clamping force adjusted as 10 kN and 20 kN for both 3D models and were subjected to vibration with transversal load and the loosening angle of the nut and the preload loss on the bolt were investigated. These two levels of clamping load application simulate the situation in which the washer is fully flattened and not. The conical washer used model under 10 kN clamping force behaves worse condition than without washer usage. It has been found that the use of conical washers under 20 kN clamping load has no advantage over usage of non-washer. (Izumi continued, 2009) showed that the loosening performance of the usage of double nuts and spring washers in bolted joints under vibration was examined on the 3D virtual analysis model, and it was revealed that the application of double nuts is an effective method of preventing vibration, but the spring washer does not have a positive effect on preventing vibration. (Bhattacharya continued, 2008) compared the vibration resistance of various locking fasteners. It was also used 4 different types of washers in these tests. These were plain washers, spring washers, bottom and top knurled washers. The vibration resistance of chemically locked solutions is better than all types of washers, the nylok nut comes after chemical locking fasteners.

2. MATERIAL AND METHOD

2.1. Test Sample Dimensions

Within the scope of the experimental tests carried out, M8x1.25x80 size 8.8 quality bolts according to ISO 15071 standard and M8x1.25 8 quality to comply with DIN 934 standard nuts were used in. The drawing of the bolts and nuts used during the tests is given in Figure 1. The drawing of the conical washers which is the main scope of the study, to comply with DIN 6796 is given in Figure 2. All bolts, nuts and washers used within the scope of the tests are coated with Delta Protect KL100 VH301 GZ coating and the friction coefficient range determined between 0.10-0.16.

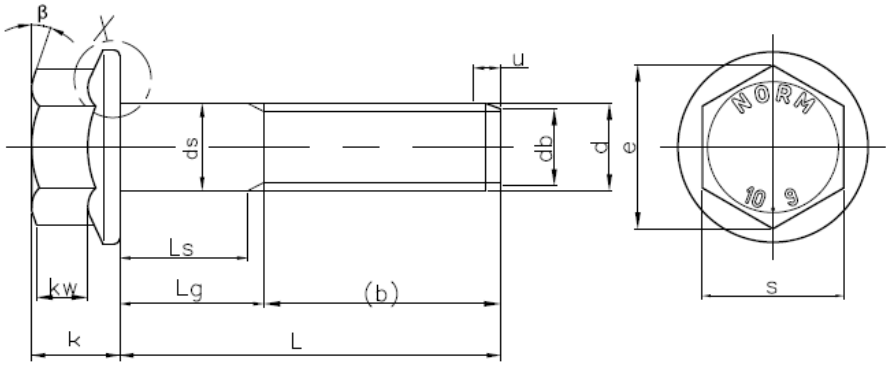

Figure 1. Drawings of ISO 15071 bolt used in the junker vibration tests.

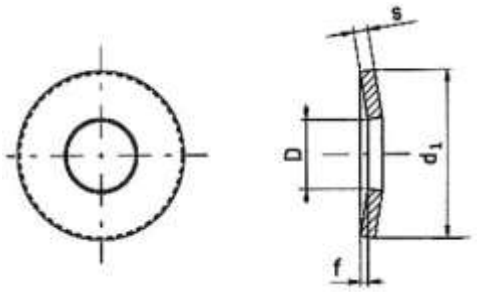

Figure 2. Drawings of the conical washer used in vibration tests

According to the DIN 6796 standard, the dimensions of the conical washer is shown in Table 1.

Table 1. Showing DIN 6796 Dimensions for Conical Washer

Size	D	s	d1	f
M8	8.4	1.5	22	0.65

2.2. Experimental Set-Up

The experiment set was prepared in order to observe the effect of the conical washer performance on clamping length and clamping force parameters which are given in Table 1. 8 different experimental sets were determined with 6 replicates. A total of 48 Junker vibration tests were carried out. The tests were conducted in the Junker test device under 0.9 mm horizontal displacement, which is shown schematically in Figure 3. Each fastener was used only once, so tests were carried out directly in the range of the friction coefficient value of the coating.

Table 2. 2^3 Full factorial experiment set-up

Experimental Setting	Clamping Force Level	Clamping Length (mm)	Conical Washer Usage
Set1	Proof load*0,75: 16 kN	75	No
Set2	Proof load*0,75: 16 kN	75	Yes
Set3	Proof load*0,75: 16 kN	25	No
Set4	Proof load*0,75: 16 kN	25	Yes
Set5	Proof load*0,50: 11 kN	75	No
Set6	Proof load*0,50: 11 kN	75	Yes

Set8	Proof load*0,50: 11 kN	25	Yes

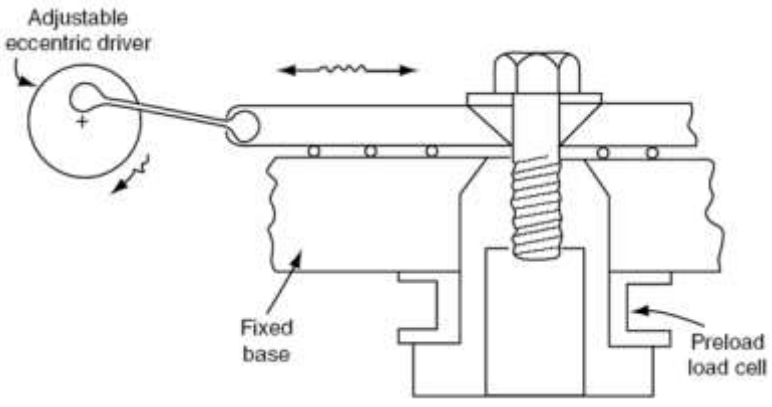

Figure 3. The Junker vibration test device (Bickford, 2008)

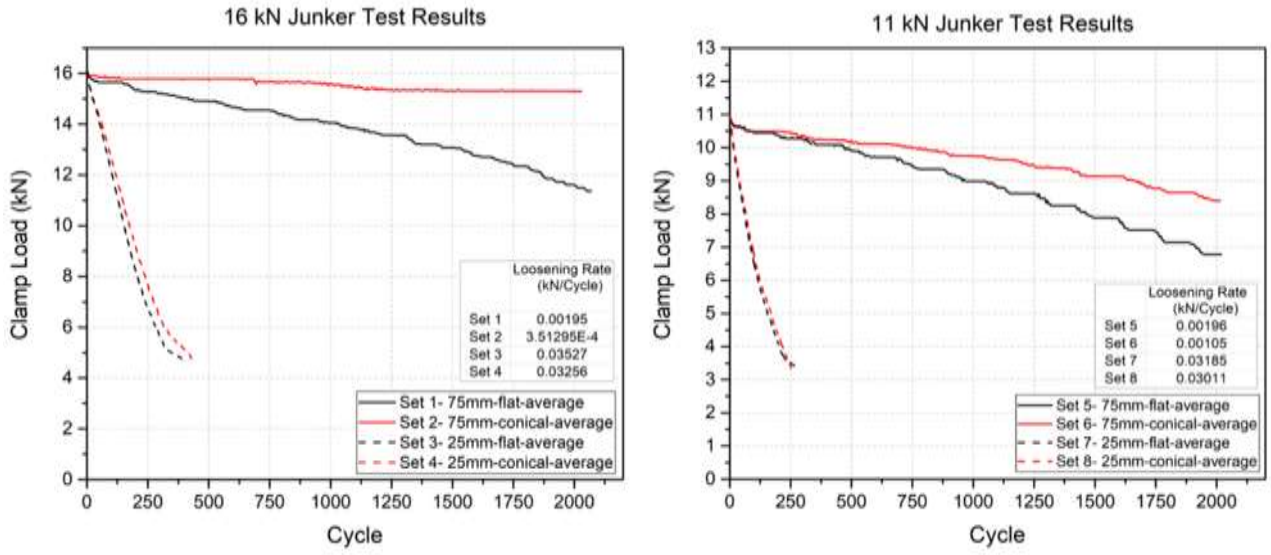
3. EXPERIMENTAL TEST RESULTS

Experimental studies were performed with reference to the DIN 65151 standard created by Junker's work. As a result of the Junker tests, clamping force – cycle graphics were created with the average values of 6 experiments performed for

each set of experiments. Clamping force – cycle graphics which obtained as a result of the experiments are given in Figure 4. The loosening rates were found from the clamp load - cycle graphics by the linear curve fitting method. Clamping length is one of the most important factors affecting bolted joint loosening. According to the findings obtained, as a result of the vibration tests performed with a clamping length of 75 mm, the loosening behavior of the joint was found to be more resistant as expected compared to the tests performed with a clamping length of 25 mm. Within the tests which performed at 75 mm clamping length, similar results were obtained for both clamping force values. Accordingly, the effect of the conical washer was clearly seen in the tests with a clamping length of 75 mm. Similarly, in the tests performed with bolts with a clamping length of 25 mm, it was observed that the conical washer had no positive effect with both clamping force levels.



(a) (b)

Figure 4. Junker vibration test results of 16 kN (a) and 11 kN (b).

4. REGRESSION ANALYSIS

A full factorial DOE was created using the Minitab program in order to examine the suitability of the loosening rate data obtained from the vibration tests and the effects of the parameters on the output relaxation rate were compared with regression analysis. The data used in the regression analysis includes 48 loosening rate values obtained as a result of physical tests and the average values are shared in Table 3.

Table 3. DOE experimental set

Experimental Setting	Clamping Force Level(N)	Clamping Lenght(mm)	Conical Washer Usage	Loosening Rate Average (kN/cycle)
Set1	16000	75	No	0,00195
Set2	16000	75	Yes	0,000351
Set3	16000	25	No	0,03527
Set4	16000	25	Yes	0,03256
Set5	11000	75	No	0,00196
Set6	11000	75	Yes	0,00105
Set7	11000	25	No	0,03185
Set8	11000	25	Yes	0,03011

The aim of the regression analysis is to create a multivariate equation that will express the loosening rate, which is the output, for the input parameters which are determined as the clamping length, clamping force and the usage of conical washer in this study. The regression formula resulting from this analysis is shared with Equation 1.

Loosening Rate = 0,04413 - 0,000626 Clamp Length + 0,000012 Clamp Force - 0,000785 Conical Washer Usage (1)

As a result of the regression analysis, the adjusted R-sq value was found to be 96.31%, this value means that the input parameters explain the output parameter at the rate of 96.31%. Adjusted R-squared is more important than R-squared. Meaningless independent variables eliminated and when we add a new variable, if the value increases, it is decided to add that variable to the equation. The model which is established as a result of the analysis is meaningful, there is 1 outlier in number of 48 experiments. Outlier value has no effect on the results, as a result of the analysis of conformity to normal distribution, the P-value value was found less than 0.005.

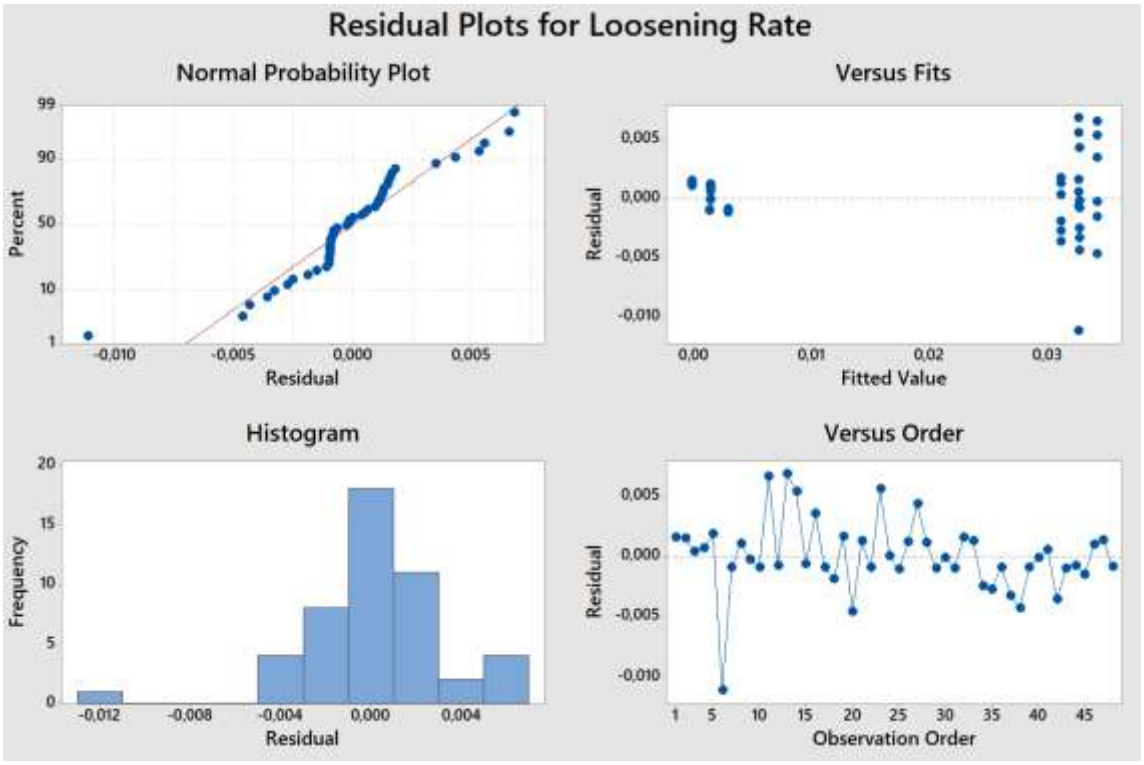


Figure 5. Residual analysis of loosening rate

According to the pareto graphic which is shown in Figure 6, the effect of the clamping length on loosening in the joints is much higher than the clamping force and the usage of a conical washer. Although the effect of clamping load and conical washer is close to each other, its effect on loosening has not been observed exactly due to the dominant effect of clamping length.

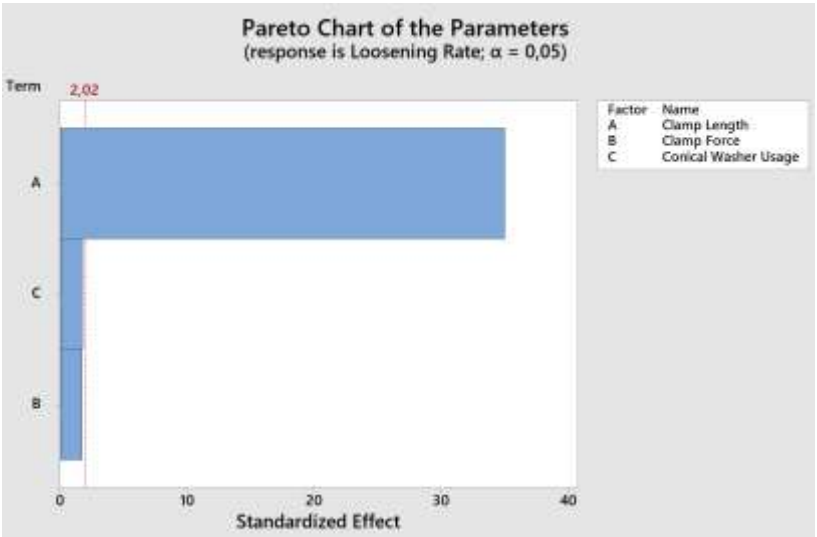

Figure 6. Pareto chart of parameter effects

With the created regression equation, the loosening rate can be calculated with different input parameters, or it can be predicted under which conditions this loosening rate will be seen by targeting the loosening rate. If we explain with an example, when the relaxation rate is taken 0.02 kN / cycle as the target, this value is formed for a clamping length of 47.6993 mm, under 16000 N clamping force and no usage of washers. As shown in Figure 7, the fact that the value of "d" which means desirability, comes out to 1 shows that the estimate is quite valid.

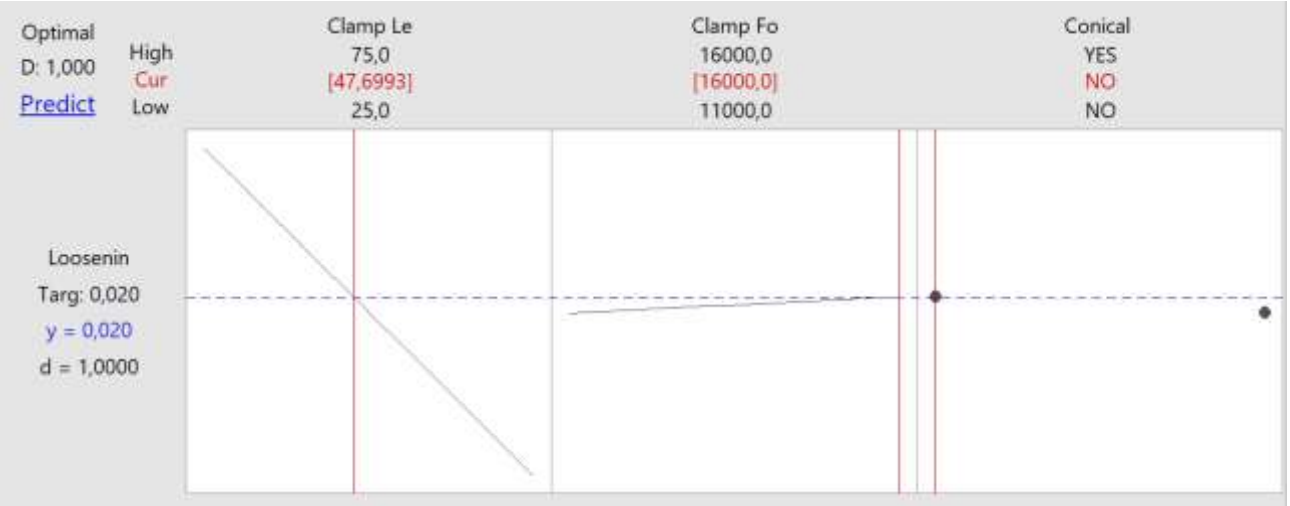

Figure 7. Prediction of 0,02 kN/cycle loosening rate conditions

5. CONCLUSIONS

Based on the vibration test results, conclusions which are listed below can be drawn from the experimental data in this study:

1. Clamping length has a major effect on the loosening of bolted joints. Due to this superiority, the influence of the other parameters which are the conical washer usage and the clamping length can not be fully observed.

2. In low loosening rate conditions, the conical washer positive effect on loosening can be seen more clearly. However, in high loosening rate which is heavily triggered by the shorter clamping length relatively no positive effect has observed in respect to non-usage of the conical washer.

3. More research is required to develop a deeper understanding of the relationships between conical washer effect and bolted joint loosening phenomenon. Experimental tests are needed to be increased with lower transvertial amplitude and clamping length must be taken as a constant.

ÖZET

Otomotiv endüstrisindeki ürün geliştirme süreçlerinde geliştirilen her ürüne sınırsız özellik eklenerek ürün pazara sunulabilir. Fakat ürün üzerindeki özelliklerin müşteri üzerinde oluşturduğu katma değerin tanımlanması gereklidir. Müşterinin kullanımına yönelik gereksiz özellikler yalınlaştırılarak, müşteriye değerli hissettirecek özellikler, kısıtlı kaynaklar ile en gerekli ürünün geliştirme faaliyetleri ile daha karlı olmak ve rekabette farklılaşmak için kullanılabilir. Otomotivde dış dikiz aynaları teknolojik özellikler kazandıkça kompleks bir yapı haline gelmiştir. Temel olarak mekanik ve elektrikli aynalar ve bunlara ek olarak otomatik katlanır aynalar bulunmaktadır. Bu makalede aynalar için otomatik katlanır ayna fonksiyonlarının müşteri üzerindeki etkileri kano metodu ile incelenmiş ve yorumlanmıştır. Otomatik katlanma fonksiyonunun çalışma şekli, katlanma açısı ve katlandığındaki açık kalma mesafeleri müşterilere sorularak müşterilerin üzerindeki değer etkileri belirlenmiştir. Çalışmanın sonucunda otomatik katlanır aynaların araçlarda bulunması kapı kilitleme butonu ile aktif olması müşteriler tarafından heyecan verici özellik olarak belirlenmiş ve ayna araç gövdesine ne kadar çok yaklaşırsa yani ne kadar çok katlanırsa müşterinin bu derecede memnun olacağı sonucuna varılmıştır. Bu makalede, detaylı olarak otomatik katlanır ayna için belirlenen özellikler müşterilere görseller ile gösterilmiş ve müşteri üzerindeki değer tanımlamaları nicel veriler ile gösterilmektedir.

Anahtar Kelimeler: Kano, otomotiv, otomatik katlanır, dış dikiz ayna, müşteri deneyimi

1. GİRİŞ

Müşteri memnuniyeti, dünya çapında büyümekte olan çok sayıda şirketi etkilemektedir. Günümüzde firma sayısının gittikçe artması, firmaları daha çok pazar payı elde etmek yerine, o pazarlarda kalıcı olmaya ve müşteri bağlılığını artırmaya yöneltmektedir. Pazarda kalıcı olmak ve müşteri bağlılığı oluşturmak ancak müşteri memnuniyeti ile sağlanabilir. Müşteri memnuniyeti, müşteriye sunulan ürün veya hizmetlerin, müşterinin beklenti düzeyini karşılaması ya da bunu aşması anlamına gelir.[4] Müşteri memnuniyetinin sürdürülebilir olması, müşterilerin işletmelere bağlılığıyla doğrudan ilişkilidir. Bu nedenle işletmeler, müşterilerin kendilerine olan bağlılıklarını artırmalıdır [6].

Müşteri memnuniyeti ve bağlılığı oluşturmak amacıyla günümüzde işletmeler artık, müşterilerini tanımak ve onların isteklerine göre üretimini yönlendirebilmek için müşteri bilgilerini sürekli olarak takip edip bu bilgileri değerlendirmeye başlamışlardır. Müşteri memnuniyeti ve bağlılığının sağlanmasında müşteri gereksinimlerinin karşılanması ve bu gereksinimlerin memnuniyet düzeyini nasıl etkilediği önemli bir husustur. İşte bu noktada, müşteri gereksinimlerini en iyi şekilde analiz edebilen Kano Modelinden yararlanılmaktadır. Prof. Dr. Noritaki Kano tarafından geliştirilen model, firmaların müşteri gereksinimlerini karşılayabilme derecesi ile müşteri memnuniyeti arasındaki ilişkiyi anlatan bir modeldir. [6]

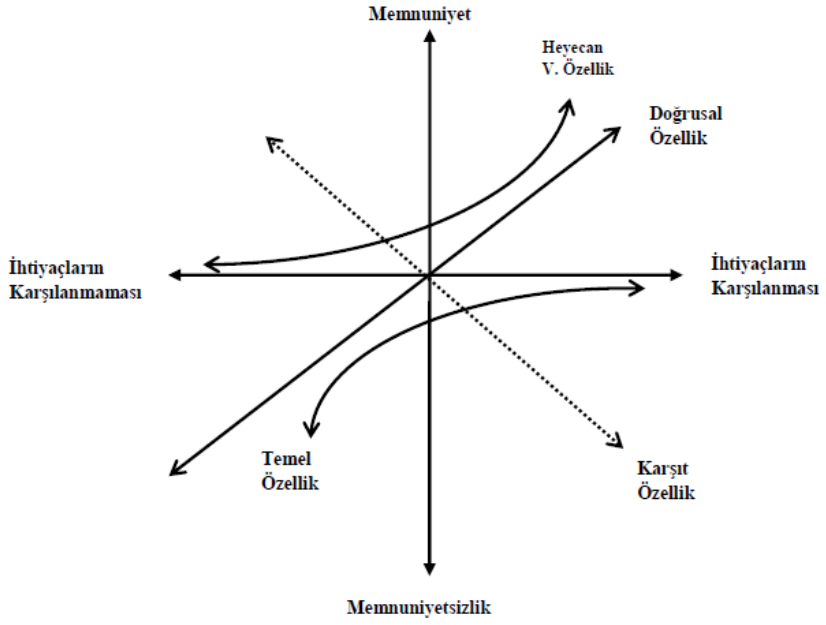
Bu çalışmanın amacı, otomatik katlanır ayna ile ilgili müşteri ihtiyaçlarını Kano modeli ile değerlendirmektir. Bu amaçla öncelikle Kano modeli ile ilgili literatürde yapılan çalışmalara yer verilmiş, daha sonra konu teorik açıdan ayrıntılarıyla incelenmiştir. İstanbul ve Bursa'da yetkili servislerde direk kullanılarak temas edilerek, uygulamalar yapılmıştır. İncelenen özellikler Kano modeli değerlendirme tablosunda frekansları incelenmiş ve müşteri üzerinde değer oluşturan özellikler belirlenmiştir.

2. KANO MODELİ

Müşteri isteklerinin tatmini konusunun araştırılması için Tokyo Üniversitesi'nden Prof. Dr. Noritaki Kano müşteri ihtiyaçlarını karşılayacak olan ürün/ hizmet özelliklerini sınıflandıran bir model geliştirmiştir. Tanımlanan bütün müşteri gereksinimlerinin veya müşteri gereksinimlerine karşılık gelen ürün özelliklerinin memnuniyet üzerindeki etkisi aynı değildir [1]. Bazı müşteri gereksinimleri memnuniyet üzerinde oldukça önemli bir etkiye sahipken, bazılarında bu oran daha düşüktür. İşte Kano modeli, müşteri gereksinimlerinin müşteri memnuniyetini ne düzeyde etkilediğini ortaya çıkararak bir sınıflandırma yapmaktadır ve müşteri gereksinimleri ve memnuniyeti konusunu bir bütün olarak ele

almaktadır. Mükemmellik esasına dayanan Kano modeli, müşterinin satın almakta olduğu ürün ya da hizmetten elde ettiği fayda seviyesini maksimuma, maliyet ya da zararını minimuma indirmeyi amaçlamaktadır. [6] Bir anlamda, beklenti ile bu beklentilerin karşılanması arasında oluşan ilişkinin rakamsal ifadesi olarak değerlendirilen bu yöntem üç temel özellik üzerine odaklanmaktadır [2]. Ürün ya da hizmette olması gereken temel özellikler, beklenen özellikler, beklenenin ötesinde olan ve heyecan verici nitelikte olan özellikler. Bu üç kalite türünün yanı sıra nötr ve karşıt olmak üzere iki tür daha belirlenmiştir.

1. Temel (Olması Gereken) Özellikler (T): Temel özellikler, bir üründe müşterinin açıkça belirtmediği ancak mutlaka olması gereken temel ihtiyaçlarıdır. Şekil 1'de de görüldüğü gibi, bu ihtiyaçların karşılanması müşteri memnuniyetini artırmazken, karşılanmaması yüksek düzeyde memnuniyetsizliğe neden olacaktır. Örneğin, lüks otomobiller için "hava yastığı" temel gereksinim olarak kabul edilir [3]. Otomobilde hava yastığının olması müşteri memnuniyetini etkilemeyecek, ancak hava yastığının olmaması durumunda, müşteri otomobili satın almayacaktır.



Şekil 1: Kano Modelinin Temel Gösterimi

2. Doğrusal Özellikler (D): Müşterilerin açık bir şekilde dile getirdiği, karşılanmasını istediği ihtiyaçlardır. Grafikten de anlaşılacağı üzere, müşterinin üründe olmasını istediği, açıkça söylediği özelliklerin karşılanması ile memnuniyet düzeyi arasındaki ilişki doğrusaldır. Arabanın benzin tüketimi bu özelliklere örnek verilebilir. Arabanın benzin tüketiminin az olması memnuniyete, fazla olması ise memnuniyetsizliğe neden olacaktır. Müşteriler araba satın alırken özellikle arabanın benzin tüketiminin az olmasına dikkat ederler ve bu özelliği açıkça dile getirirler. [3]

3. Heyecan Verici Özellikler (H): Müşterilerin dile getirmediği, karşılanması için bir beklenti içinde olmadığı ürün özellikleridir. Müşteri, söz konusu özellikleri üründe bulduğunda memnuniyeti çok fazla artacaktır, ancak bu özelliklerin olmaması müşteriyi memnuniyetsizliğe sevk etmeyecektir. Bu özellikler, genellikle rekabet avantajı sağlayabilen müşterilerin o anda farkında olmadığı gizli, gerçek ihtiyaçlarını karşılamaktadır. Örneğin, bir restoranda akşam yemeği sonunda hediye verilmesi müşterileri son derece memnun ederken, hediye sunulmaması memnuniyetsizliğe neden olmayacaktır [3].

4. Nötr özellikler (N): Müşteri için önemli olmayan ürün özellikleridir. Bu özelliklerin üründe bulunması ve bulunmaması memnuniyeti etkilemez [3].

5. Karşıt Özellikler (K): Bu özelliklerin performansı yüksekse müşteride memnuniyetsizlik olur. Memnuniyet ile sonuçlanan ürünün performans derecesi düşüktür [3].

Müşteri ihtiyaçları tanımlandıktan sonra bu ihtiyaçları analiz ederek sınıflandırmak amacıyla Kano anketi hazırlanır. Bu ankette, üründe bulunan ve bulunmayan özelliklerle ilgili (ayrı ayrı her bir özellikle ilgili) müşterilere bir çift soru sorulur. Soruların ilki, özelliğin üründe bulunması halinde müşterilerin ne hissedeceği; diğeri ise, özelliğin aynı üründe bulunmaması halinde müşterilerin ne hissedeceği yönündedir.

Her bir sorunun cevabı için 1- Çok hoşuma gider, 2- Öyle olmasını beklerim, 3-Fark etmez, 4- Hoşlanmam ama katlanabilirim 5- Hiç hoşuma gitmez şeklinde beş farklı şık sunulur, tablo 1.

Tablo 1. Kano Modeli İçin Değerlendirme Tablosu

Müşteri İstekleri		Olumsuz Soruya Verilen Cevaplar				
		Hoşlanırım	Öyle Olmalı	Fark Etmez	Katlanabilirim	Hoşlanmam
Olumlu Soruya Verilen Cevaplar	Hoşlanırım	Q	A	A	A	O
	Öyle Olmalı	R	I	I	I	M
	Fark Etmez	R	I	I	I	M
	Katlanabilirim	R	I	I	I	M
	Hoşlanmam	R	R	R	R	Q

M:Temel İhtiyaçlar **O:** Beklenen ihtiyaçlar **A:** Heyecan verici **Q:** Şüpheli İhtiyaçlar **R**: Zıt İhtiyaçlar

2. ARAŞTIRMA

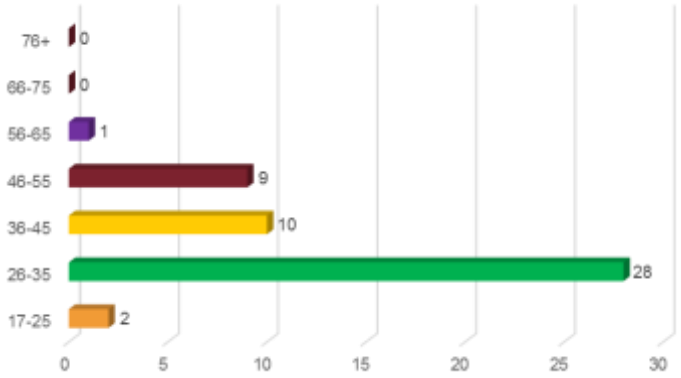
2.1. Araştırma

Araştırma otomotiv sektöründe öncelikle dış dikiz aynaların otomatik olması durumunun müşterinin gözünde etkileri incelenmektedir. Otomatik katlanır aynayı seçen müşterilerde otomatik katlanır aynalar için müşterilerin ihtiyaçlarını anlamak ve hangi fonksiyonların eklenmesi, geliştirilmesi, optimize edilmesi ve çalışma prensiplerinin nasıl iyileştirebileceğine karar vermek amaçlanmaktadır. Araştırmaya başlamadan önce 12 farklı rakip araç üzerinde benchmarking (kıyaslama) çalışması yapılmıştır. Yapılan benchmarking sonucunda kano çalışmasında sorulacak sorulara karar verilmiştir.

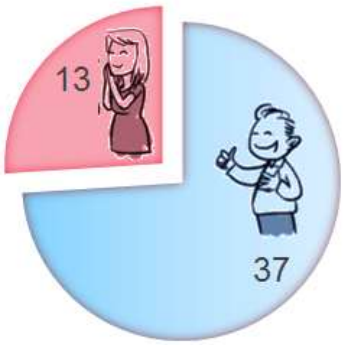
2.2. Araştırmanın Demografik Yapısı

Araştırma 2 farklı ilde ve 3 farklı lokasyonda gerçekleştirilmiştir, şekil 2. Araştırmaya katılan toplam 50 kişi bulunmaktadır. Katılan 50 kişiden 13 kişi farkındalığa sahip konu uzmanları tarafından değerlendirilmiştir, şekil 3. Katılan kişilerin cinsiyet, yaş, meslek bilgileri alınarak hazırlanan sorular yöneltilmiş ve hazırlanan prototipler ile deneme fırsatı sunulmuştur, şekil 4.

Şekil 2. Araştırmaya katılan katılımcı lokasyonları



Şekil 3. Araştırmaya katılanların yaş aralıkları



Şekil 4. Araştırmaya katılanların cinsiyetleri

2.3. Araştırmada Kullanılan Kano Soruları

S.n.	Soru
1	Aynada otomatik katlanabilir özelliği olsa ne düşünürsünüz?
2	Aynada otomatik katlanabilir özelliği olmazsa ne düşünürsünüz?
3	Otomatik katlanır aynalarınız, anahtardan kapılar kilitleniyor iken otomatik katlansa ne düşünürsünüz?
4	Otomatik katlanır aynalarınız, anahtardan kapılar kilitleniyor iken otomatik katlanmaması durumunda ne düşünürsünüz?
5	Otomatik katlanır aynalarınız, anahtar üzerindeki kilit tuşuna basılı tutulduğunda otomatik katlansa ne düşünürsünüz?
6	Otomatik katlanır aynalarınız, anahtar ile kilit tuşuna iki kez bastığınızda otomatik katlansa ne düşünürsünüz?
7	Otomatik katlanır aynalarınız, anahtardan kapı kilidi açıldığın otomatik açılsa ne düşünürsünüz?
8	Otomatik katlanır aynalarınız, anahtardan kapı kilidi açıldığın otomatik açılmasa ne düşünürsünüz?
9	Otomatik katlanır aynalarınız, kapalı olsa dahi, motoru çalıştırdığınızda otomatik açılsa ne düşünürsünüz?
10	Otomatik katlanır aynalarınız kapalı olsa dahi, motoru çalıştırdığınızda otomatik açılmasa ne düşünürsünüz?
11	Aynalarınız tam katlandığında ne düşünürsünüz ?
12	Aynalarınız az katlandığında ne düşünürsünüz ?
13	Aynalarınız düz katlandığında nasıl hissederdiniz?
14	Aynalarınız yukarı doğru katlandığında nasıl hissederdiniz?
15	Otomatik katlanma özelliği buton ile aktif edilse nasıl hissederdiniz?
16	Otomatik katlanma özelliği yol bilgisayarı ile aktif edilse nasıl hissederdiniz?

3. SONUÇLAR

Bu çalışmada toplam 50 kişi 3 farklı lokasyondaki katılımcılara otomatik katlanır ayna ile ilgili sorular yönetilmiş ve kano metodu aracılığıyla analiz edilmiştir. Gereksinimlerin karşılanmasının veya karşılanmamasının katılımcıların

memnuniyeti üzerinde ne derece etkili olduğu ve demografik faktörler açısından bu değerlendirmenin farklılık gösterip göstermediği belirlenmeye çalışılmıştır.

Araştırmaya katılan kullanıcılara otomatik katlanır aynaya sahip olma ile ilgili yönelttiğimiz soruda kadın katılımcıların tamamı aynanın zaten olması bu özelliğin beklen bir ihtiyaç olduğu fakat erkek katılımcılarda heyecan verici bir özellik olduğu sonucuna varılmıştır.

Ayna üzerindeki diğer özellikler demografik incelenmeyerek katılan tüm katılımcıların ortak yorumlarının sonuçları ile irdelenmiştir. Kapıların kilitlenmesi durumunda aynaların bu bilgi ile kapanması durumu katılımcılarda beklenen temel bir özellik olarak yorumlanmaktadır. Fakat buna ilave olarak anahtar üzerinde buton üzerine basılı tutarak ya da ikiz basarak aynaların kapanması durumu katılımcılar üzerinde bir etkisi bulunmamaktadır. Nötr bir özellik olarak yorumlanmıştır. Kapı kilitleri açıldığında aynaların bu bilgi ile açılması temel özellik olarak sonuçlandırılmaktadır. Fakat katılımcılar ile yapılan mülakatlarda bu durumun dar alanlarda problem oluşturabileceği olarak yorumlanmıştır. Motor çalıştırıldığında aynaların açılması yapılan araştırma sonucunda heyecan verici bir özellik olarak yorumlanmıştır. Katılımcılar bu özelliğin olmasında mutluluk duymaktadır. Aynaların katlanma yönleri ve katlanma dereceleri şekil 5' de gösterilmiştir. Gösterildiği gibi yatay ve dikey yönde olabilmektedir. Bu özellik araştırmaya katılanlar üzerinde yapılan değerlendirmede doğrusal özellik grubunda değerlendirilmiştir ve müşteriye ne kadar fazla verilirse müşteri bu doğrultuda memnuniyet duymaktadır.

Şekil 5. Ayna katlanma tipleri

Müşterilerle yapılan mülakat sonucu aynaların dikey olarak katlanması estetik olarak memnuniyet derecesini arttırmaktadır. Son olarak araştırmada otomatik katlanma özelliğinin kullanıcı tarafından kontrol edilebilmesi özelliği yorumlandığında, bunun müşterilerde heyecan oluşturacağı ve memnuniyet etkisi olarak belirlenmiştir.

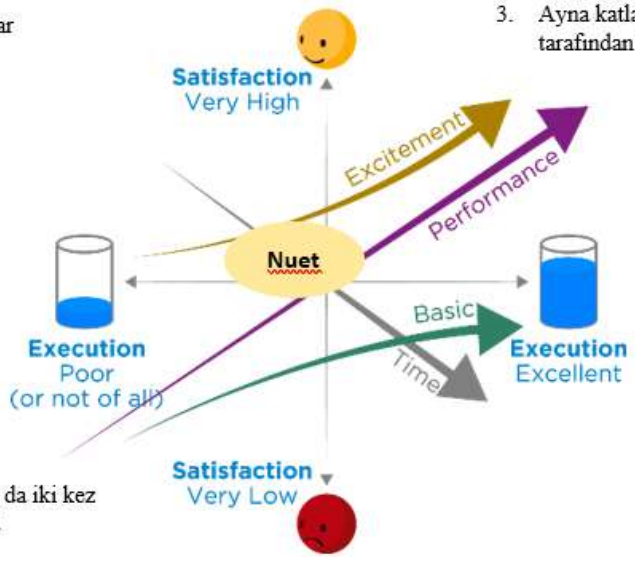
Özetle, aşağıdaki tabloda özelliklerin etkileri görülmektedir, tablo 3.

Heyecan verici özellikler:

1. Otomatik katlanır ayna
2. Motor çalıştırıldığında aynaların açılması
3. Ayna katlanma özelliğinin kullanıcı tarafından kontrol edilmesi

Beklenen özellikler:

- Dikey ve tam katlanır aynalar



Nötr özellikler:

- Kilit butonu basılı tutarak ya da iki kez basarak aynaların katlanması

ABSTRACT

Laser welding is an advanced technology welding method based on the principle of melting the materials using a laser beam. In this study, overlap laser welding was implemented to DP1200 steels with a thickness of 1.2 mm. For effective process parameters were determined as 5 levels: laser power (2200 W - 2350 W - 2500 W - 2650 W - 2800 W), scanning speed (40 mm/s - 47.5 mm/s - 55 mm/s - 62.5 mm/s - 70 mm/s) and laser angle (70° - 75° - 80° - 85° - 90°). Central Composite Design experimental design was used these process parameters. The effect of laser power, scanning speed, and laser angle on the maximum shear force after the tensile test was analyzed by the Response Surface Method. The mathematical equation was created and process parameters were optimized: results were laser power 2800 W, scanning speed 40 mm / s, laser angle 70°. A stronger welding and high shear force have been obtained with the increase of laser power, decrease of scanning speed, and decrease of laser angle parameters due to high energy input.

Keywords: Laser welding, Process parameters, Response surface method, Tensile test, Overlap welding

1. INTRODUCTION

Laser welding technology is one of the advanced methods: the densified laser beam that has high energy moves locally to the desired point, and then materials are welded via melting [1]. The laser welding method has preferred due to high energy density, high penetration, narrow heat-affected zone, and being fast properties [2]. It is widely used in the production of new generation automobile body parts [3]. Laser welding is used in the production of various structural components in the automotive industry: B-pillar, bumper, motor compartment rail, high impact-resistant auto parts, front and side panels, door reinforcements, side beams, and wheel arches [4–9]. Dual-phase (DP) steels that have mechanical strength, high hardness, and formability consist of ferrite and martensite phases. Due to these properties, DP steels generally use in the automotive industry [10–12].

Several studies conducted on laser welding have shown that is an effective method in obtaining good welding quality [13–17]. Gao et al. [18] investigated welding properties of pulsed Nd: YAG (Neodymium-doped Yttrium Aluminum Garnet) laser welding and conventional gas tungsten arc welding (TIG) for Ti6Al4V titanium alloy. Residual distortions, welding geometry, microstructure, and mechanical properties were compared. During the tensile test, with the infrared camera, the development of plastic strain was recorded and analyzed. Compared with TIG, the welded joint of laser welding has the characters of small overall residual distortion, fine microstructure, narrow heat-affected zone (HAZ), high Vickers hardness, high ductility. They concluded that Pulsed Nd: YAG laser welding is more suitable for welding thin Ti6Al4V titanium alloy plate. Rossini et al. [19] carried out dissimilar butt laser welding implementation for AHSS in car body production: Twinning Induced Plasticity (TWIP) steels, Dual Phase (DP) steels, hot stamping boron (22MnB5) steels, and Transformation Induced Plasticity (TRIP) steels were used. The weldments were characterized via metallography, microhardness, and tensile tests, digital image analysis, the fractographic examination. They explored that dissimilar weld joints between DP, 22MnB5, and TRIP steels obtained good mechanical properties, while TWIP steel exhibits poor mechanical strength due to intergranular fracture occurs along with the weld bead. Liu et al. [20] researched that laser welding of DP780 steel and Al5052 overlap joint to optimize the weld width and lap-shear force. Mathematical relationships between the process parameters which were laser power, welding speed, and defocus distance were detected via Response surface methodology and optimal parameters were determined. They found that welding speed and defocus parameters were significant by means of ANOVA analysis.

Systematic studies on DP1200 steels with overlap laser welding are very limited in the literature. The aim of this study is to determine the mathematical relationship between laser welding process parameters (laser power, scanning speed, laser angle); process parameters were optimized according to tensile test results by the Response Surface Method

2. MATERIALS AND METHOD

In this study, DP1200 dual phase steel steel plates with dimensions of 100 mmx300 mmx1.2 mm were used. Their chemical composition is in Table 1. The mechanical properties of the material as follows: yield strength 900-1100 Mpa, tensile strength 1180-1350 Mpa, elongation 6%.

Table 1. Chemical Composition of the material (wt%)

Material	C	Si	Mn	Al	P	S	Cr+Mo	Nb+Ti
DP1200	0,23	1	2,9	0,15-1	0,05	0,01	1	0,15

Fiber laser welding operations were carried out using CW (Continuous Wave) laser beam produced; wavelength was 1070 nm, the laser beam diameter was 100 µm, the maximum laser power was 6 kW. The process fiber was 0.2 mm, the collimator lens was 100 mm, the focus lens was 200 mm, and the focal distance was 190 mm. The movement of the laser beam was provided by robot integration and fiber optic cable connection. The 6-axis KUKA robot is controlled by a servo motor on a rotary table, which has a CNC control unit and software, shown in Figure 1. There is a nozzle for shielding gas at the welding point and the Argon gas temperature is between 5-25 ^{o}C, the flow rate is 12 lt / min.

Figure 1. Fiber laser welding unit and KUKA robot

The laser welding has implemented in the form of overlap welding, overlap distance, and plate dimensions are shown in Figure 2. Five levels value ranges were determined for laser power (2200 W - 2350 W - 2500 W - 2650 W - 2800 W), (40 mm/s - 47.5 mm/s - 55 mm/s - 62.5 mm/s - 70 mm/s) and laser angle (70° - 75° - 80° - 85° - 90°) process parameters in the laser welding process, were selected commonly used values in the automotive industry (Table 2). Response Surface Method Design Experiment has created for laser welding application, the experimental design is in Table 3. Energy Input formula is based on laser power and scanning speed parameters, it is in Equation 1.

$$\text{Energy Input} = (\text{Laser Power})/(\text{Scanning Speed}) \quad (1)$$

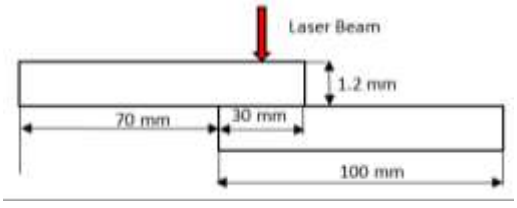

Figure 2. Overlap welding distance and plate lengths on side view

Table 2. Laser welding test parameters and ranges

Parameters	Units	Level				
		Level 1	Level 2	Level 3	Level 4	Level 5
Laser Power	W	2200	2350	2500	2650	2800
Scanning Speed	mm/s	40	47.5	55	62.5	70
Laser Angle	degree	70	75	80	85	90

Table 3. Response Surface Method Experimental Design

Experiment No	Laser Power (W)	Scanning Speed (mm/s)	Laser Angle (degree)	Energy Input (J/mm)
1	2350	47.5	75	49.47
2	2650	47.5	75	55.79
3	2350	62.5	75	37.60
4	2650	62.5	75	42.40
5	2350	47.5	85	49.47
6	2650	47.5	85	55.79
7	2350	62.5	85	37.60
8	2650	62.5	85	42.40
9	2200	55	80	40.00
10	2800	55	80	50.91
11	2500	40	80	62.50
12	2500	70	80	35.71
13	2500	55	70	45.45
14	2500	55	90	45.45
15	2500	55	80	45.45
16	2500	55	80	45.45
17	2500	55	80	45.45
18	2500	55	80	45.45
19	2500	55	80	45.45
20	2500	55	80	45.45

After the laser welding process, the tensile test specimens were manufactured by laser cutting from the plates, the specimen sizes are shown in Figure 3 [21]. Tensile tests were carried out in UTEST-7014 brand universal tensile compression test device equipped with Celtron brand load cell and MF (Mess- & Feinwerktechnik) brand automatic extensometer. Tensile test was applied to at least 3 specimens for each parameter group at 3 mm/min speed, the results were averaged. Optimization was made for the Response surface design in Minitab according to the Maximum Shear Force obtained from the tensile test, the optimum parameter values were determined.

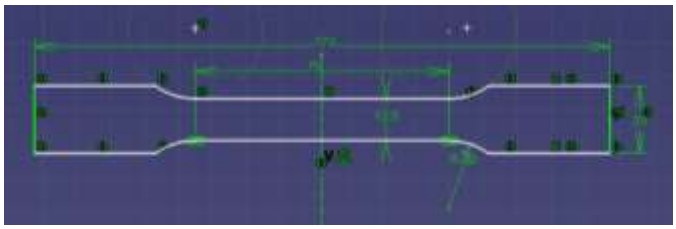

Figure 3. Tensile Test Specimen Size

3. RESULTS

The maximum shear force and elongation values obtained as a result of the tensile test were given in Table 4. An optimization study has been made using the Response Surface Method for maximum Shear Force: Effect ratios of scanning speed, laser angle and laser power were 48.10%, 11.96% and 2.26%, respectively. The model was an accuracy rate of 85.37% (Table 5). As a result of the optimization, an equation that estimates the maximum shear force was obtained (Eq (2)). Optimum parameters were found in Minitab by Response Optimizer solution: laser power was 2800 W, scanning speed was 40 mm/s, laser angle was 70 degree, and maximum shear force was 6.927 kN (Table 6).

The shear force tends to increase at high laser power and low scanning speed. Good bonded was observed at high laser power, high energy input resulted in good penetration. The effect of laser power and scanning speed on the shear force can be seen in the contour and surface map (Figure 4). As the laser power increased the shear force increased, as the scanning speed increased the shear force decreased. The contour map and surface map were shown in Figure 5 for laser

power and laser angle: the shear force was increased as increasing the laser power and the reducing the laser angle. High laser power and low laser angle parameters were produced better performance in terms of maximum shear force. The relationship between scanning speed and laser angle was depicted in Figure 6 on contour map and surface maps. Shear force was found to be good at low scanning speed and low laser angle parameters.

Table 4. Maximum shear force and elongation values for each experiment

Experiment No	Laser Power (W)	Scanning Speed (mm/s)	Laser Angle (°)	Energy Input (J/mm2)	Maximum Shear Force (kN)	Elongation %

4. CONCLUSION

Laser welding was performed in DP1200 dual-phase steel sheets in an overlap configuration and was investigated the effect of different level process parameters on the maximum shear force. The main conclusions are the following:

The effect of laser power, scanning speed, and laser angle on the maximum shear force was analyzed by the Response Surface Method and a mathematical equation was created to predict shear force. Process parameters were optimized: results were laser power 2800 W, scanning speed 40 mm/sec, laser angle 70 °. The penetration of the laser welding is good bonded related to the energy input of the laser beam, the irradiation time, and thermal diffusion effects. With increasing the laser power, energy input increased; obtained larger melt pool width and stronger weld. Due to the scanning speed increased, the irradiation time decreased, so shear force was low value. The maximum shear force was reached a low laser angle.

ÖZET

Otomotiv endüstrisinin gelişmesiyle birlikte araçlarda bulunan sistemlerin takibi alışılmış bir durum olmaktadır. Araç üzerinde bulunan özellikle hareketli sistemlerin çalışma durumları, hem ürünün hem de aracın servis ömrüne ve fonksiyonelliğine etki etmesi sebebiyle endüstrinin önemli araştırma konularından biri haline gelmiştir. Araç sistemleri üzerine yapılan araştırmalar sayesinde istatiksel veriler toplanabilmekte ve böylece ürün geliştime süreçlerine katkı sağlanabilmektedir. Bahsi geçen araç sistemlerine örnek olarak, motordan aldığı tork ve dönme hareketini araç tekerleklerine veya ilgili ekipmanlarına iletmekle görevli kardan milleri gösterilebilir. Tüm araç sistemlerinde olduğu gibi kardan milleri de, aracın kullanım koşullarından etkilenmektedir. Kullanım esnasında aracın kapasitesinden fazla zorlanması, kardan mili üzerinde yüksek tork veya kardan mili mafsallarında yüksek sıcaklık etkisi olarak ortaya çıkmaktadır. Bu bağlamda kardan mili ömrüne ve fonksiyonelliğine etki eden bu süreçlerin tespit edilebilmesi ve kayıt altına alınabilmesi hem bir ihtiyaç hem de müşteri talebi olarak karşımıza çıkmaktadır. Bu çalışma kapsamında, benzeri etkilerin tespiti ve takibi için kardan mili üzerine adapte edilebilen, tork ve sıcaklık verisinin toplanarak kablosuz iletim aracılığıyla gerçek zamanlı takibini sağlayan bir yöntem ve sistem açıklanmaktadır.

Anahtar Kelimeler: Kardan Mili, Tork Ölçümü, Sıcaklık Ölçümü

EXTERNAL SYSTEM DESIGN FOR REAL TIME MONITORING OF TEMPERATURE AND TORQUE DATA ON THE DRIVESHAFT

ABSTRACT

With the development of the automotive industry, it is familiar to track the systems in the vehicles. It has become one of the important research topics of the industry due to the fact that the working conditions of the rotational parts on the vehicle affect the service life and functionality of both the product and the vehicle. Thanks to researches on vehicle systems, statistical data can be collected and thus, product development processes can be contributed. As an example of the mentioned vehicle systems, driveshafts tasked with transmitting the torque and rotation movement received from the engine to the vehicle wheels or related equipment. As with all vehicle systems, driveshafts are also affected by the operating conditions of the vehicle. It can be seen as overloading of the vehicle beyond its capacity during operation, high torque on the driveshaft or high temperature effect on the driveshaft joints. The detection and recording of these processes that affect the life and functionality of the driveshaft emerges as both a need and customer demand. Within the scope of this study, a method and system that can be adapted to a driveshaft to detect and monitor similar effects, providing torque and temperature data acquisition and real time monitoring through wireless transmission is described.

Keywords: Driveshaft, Torque Measurement, Temperature Measurement

1. GİRİŞ

Günümüz endüstrisinde başta gelen sektörlerden biri olan otomotivde, ana sanayilerin beklenti ve ihtiyaçları her geçen gün artmaktadır. Sürekli artış gösteren tedarikçi sayısıyla beraber pazardan pay alabilmek zorlaşırken, otomobil üreticilerinin kaliteli ve yeni ürün beklentileri, tedarikçi firmalarda ürün geliştirme süreçlerinin hızlanmasını sağlamaktadır. Ürün geliştirme sürecindeki en önemli başlangıç noktalarından biri ana sanayi beklenti ve ihtiyaçlarının çok iyi şekilde tespit edilmesidir.

Otomotiv ana sanayi ve tedarikçileri, son kullanıcıya ulaşmadan önce ürünlerini belirli testlere tabi tutmaktadır. Çevresel etkilere, ürünün güvenliğine, saha performasına veya fonksiyonelliğine ait çıktılar, bu testler sayesinde elde edilirken, ilk ürün tasarım ve üretim süreçlerine de girdi sağlamaktadır. Bahsi geçen testlerde ürün üzerinden çıktıların

sağlanabilmesi, veri toplanması veya kayıt altına alınması bu noktada bir ihtiyaç konusu olmaktadır. Bu sebeple, ana sanayi ve tedarikçi firmalar ürün geliştirme süreçlerine bu doğrultuda yön vererek müşterilerinin beklenti ve ihtiyaçlarını karşalayabilecek ürünler ortaya koymak için çalışmalarını sürdürmektedir.

Kara taşıtlarında motor tarafından üretilen ve vites kutusu üzerinden taşınan gücün, ortaya çıkardığı döndürme momentini ve hareketini, sabit ya da değişken açısal pozisyonlarda ileten aktarma organı, kardan mili olarak adlandırılmaktadır [1]. Kardan millerinin çalışması, aracın özelliklerine ve kullanım şartlarına bağlı olarak değişmektedir. Kullanım esnasında aracın kapasitesinden fazla zorlanması, kardan mili üzerinde yüksek tork veya kardan mili mafsallarında yüksek sıcaklık etkisi olarak görülebilmektedir. Bu aşamada, aracın gerçek çalışma koşulları hakkında bilgi sahibi olmak büyük önem taşımaktadır.

Literatürde bulunan çalışmaların birinde (Usamentiaga, 2013), döner parçalar üzerinden yapılan ölçümlerde sıcaklık verisinin nasıl sağlanacağına dair geliştirilmiş bir teknik anlatılmaktadır. Nesnelerin yaydığı kızılötesi radyasyon yoğunluğunun esas alındığı bu çalışmada, kızılötesi ölçüm cihazlarıyla beraber belirli mesafelerdeki ölçümlere imkan sağlanmaktadır. Kardan mili üzerinden yapılan, "Development of a Rotating Shaft Torque Sensor for Automotive Application" isimli benzer ölçüm tekniklerinden birinde (Turner, 1988), dönen bir şaft üzerinden yapılan tork ölçümüne ait geliştirilmiş teknik ve bu tekniğe bağlı çalışan sensörün içeriğinden bahsedilmektedir. Döner bir şaft üzerinden yapılan, optik fiber sensörler veya gerinim ölçerlerin kullanıldığı çalışmada (Silva, 2017), yüzey akustik dalga sensörleri yardımıyla kablosuz olarak gerinim izleme yöntemi açıklanmaktadır. Çalışma kapsamında ticari kullanıma hazır çözümlerin değerlendirilmesi ön planda tutulurken testler, termal bir oda ve bir tork test cihazında tamamlanmaktadır.

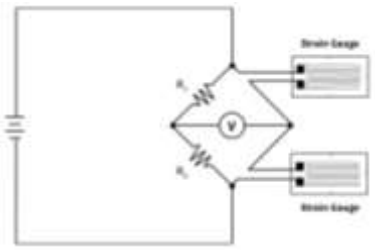
Gerçek koşulların simüle edildiği saha testlerinde, araç özelliklerinin ve yol koşullarının kardan mili üzerindeki etkilerini görmek adına veri toplanması önemlidir. Bu çalışma kapsamında, ağır seri bir araçta kullanılan ve yüksek hızda dönen bir kardan miline adapte edilebilen, tork ve sıcaklık verisinin toplanmasını ve kablosuz iletim aracılığıyla canlı takibini sağlayan bir sistem veya veri toplama yöntemi açıklanmaktadır. Bu sisteme benzer şekilde ticari ölçüm sistemleri bulunsa da, zorlu çevresel koşullarda çalışmaya uygun olmamaları, enstrümantasyonlarının uzmanlık gerektirmesi ve yüksek maliyetlerinin bulunması gibi dezavantajları bulunmaktadır [5].

2. ELEKTRONİK TASARIM

Kardan mili, motorda üretilen dönme hareketini ilgili ekipmana iletirken üzerinde belirli kuvvetler oluşmaktadır. Kardan millerinden bu kuvvetleri taşıyabilecek kadar güçlü ve güvenli olması beklenirken aynı zamanda ham madde maliyeti ve yakıt tasarrufu gibi sebeplerden dolayı hafif olması beklenmektedir. Dolayısıyla kardan mili tasarımları yapılırken uygulanacağı araca bağlı parametrelerden yararlanılarak optimum fonksiyonel limitlere sahip bir ürün ortaya konmaktadır. Kardan milinin çalışması sırasında üzerinde oluşan kuvvetlerin ölçülmesi ve takibi, hem araca bağlı parametreler için geri bildirim oluşturmakta hem de aracın uygulaması hakkında bilgiler vermektedir.

2.1. Tork Ölçüm Sistemi

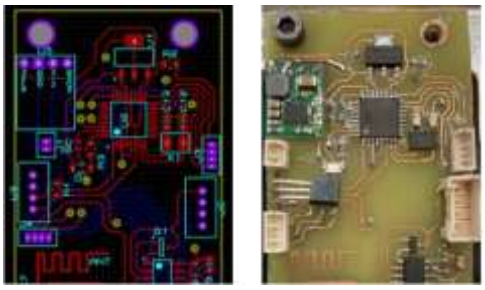
Kardan mili borusu, gerinim akışlarının en net gözlemlendiği bölge olması sebebiyle tork ölçümü için uygun nokta olarak belirlenmiştir. Bu noktaya Şekil 1'de gösterildiği gibi yarım köprü uygulaması 1000 Ω'luk 2 adet tekli gerinim ölçer ile yapılmıştır. Boru üzerindeki tork akış yönü düşünülerek gerinim ölçer konumları boru eksenine 45 derece, kendi aralarında ise 90 derece olacak şekilde konumlandırılmıştır.



Şekil 1. Gerinim ölçer yarım köprü uygulaması [6]

Belirlenen yarım köprü gerinim ölçme tekniğine bağlı olarak elektronik ölçüm devresi tasarlanmıştır. Elektronik devre üzerinde gerinim ölçerlerin referans olarak kullandığı 1000 Ω'luk iki direnç yardımıyla wheatstone köprüsü oluşturulmuştur. Gerinim ölçerlerden gelen sinyalin yükseltilmesi için ticari bir işlemsel kuvvetlendirici entegre kullanılmıştır. Güçlendirilen sinyal, mikrodenetleyici üzerinde işlenerek dijital bir sinyale dönüştürülürken ölçüm devresinin ihtiyacı olan güç, lityum iyon bataryalar tarafından sağlanmıştır. 50 mW seviyesinde güç ihtiyacı olan elektronik ölçüm devresi için test boyunca güç sağlayabilmesi adına 5 adet 1000 mAh'lik batarya paralel olarak

bağlanmıştır. Elektronik devrenin şematik ve baskı tasarımı Proteus Professional yazılımı kullanılarak yapılmıştır. Tork ölçüm devresi tasarımı ve prototip üretimine ait görsel Şekil 2'de verilmektedir.

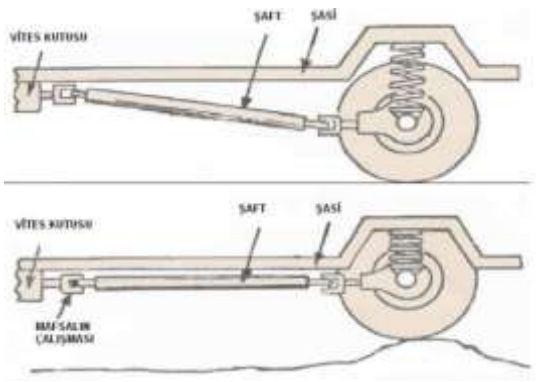


Şekil 2. Tork ölçüm devresi tasarım ve prototip üretim görseli

Ölçüm devresi üzerindeki mikrodenetleyici yardımıyla belirli matematiksel işlemlere tabi tutulan dijital sinyaller devrenin kablosuz iletişim bölümü yardımıyla el terminali, telefon, tablet veya bilgisayar benzeri görüntüleme cihazlarının iletişimine açılmaktadır.

2.2. Sıcaklık Ölçüm Sistemi

Engebeli veya kavisli bir yol üzerinde seyir halindeki bir aracın şasisinin ön ve arka bölümü, yol üzerindeki tümsek, çukur veya kavislere bağlı olarak farklı hareket etmektedir. Örneğin, arka tekerlekleri tümsek üzerinde duran bir araçta diferansiyel ve vites kutusu arasındaki mesafe, aracın durağan halindeki mesafeye göre farklılık göstermektedir. Bu durum Şekil 3'te verilen görselle örneklendirilmektedir. Kardan milleri, yol koşullarına bağlı olarak aracın arka bölümünün aşağı ve yukarı hareketine imkan sağlayacak kayıcı ve döner mafsallara sahiptir. Bu mafsalların çalışma durumu kardan mili servis ömrüne doğrudan etki etmektedir [7].



Şekil 3. Yol koşullarının araç şasisi ve kardan miline olan etkisi [8]

Yol koşullarına bağlı mesafe değişimlerinin karşılanması kardan milinin görevleri arasında gösterilmektedir. Kardan mili mafsalları, bu görev esnasında yüksek tork ve dönme hareketine maruz kalmaktadır. Sürtünmenin etkisiyle mafsal üzerinde oluşan kinetik enerji, ısı enerjisine dönüşerek malzeme yüzeyinden sıcaklık olarak dışarı atılmaktadır [9].

Çelik, hiç yanmaz malzeme grubuna girmesine rağmen, sıcaklık etkisinde fiziksel, kimyasal ve mekanik özelliklerinde değişimler gözlenmektedir [10]. Bu durum kardan mili mafsallarında görülen sıcaklık etkisiyle ilişkilendirildiğinde, kardan mili fonksiyonelliğine etki ettiği görülmektedir. Bu sebeple kardan mili mafsal bölgesinde oluşan sıcaklığın takibine de ihtiyaç duyulmaktadır.

Kardan mili mafsallarında bulunan istavroz rulmanı, mafsal üzerinden yapılacak sıcaklık ölçümü için en uygun nokta olarak belirlenmiştir. İçinde montaja imkan sağlayan mekanik yapılar, rulman ve gres yağı bulunması sebebiyle, sıcaklık sensörünün istavroz rulmanı üzerine vidalı, kaynaklı vb. yöntemlerle montajlanması istavroz rulmanının fonksiyonelliğini bozacağı düşünülmüştür. Bu sebeple, yarı iletken mimarisine sahip, içerisinde bulunan germanyum ve silisyum atomlarının sıcaklığa verdiği ters direnç tepkisi prensibine bağlı çalışan temaslı bir sıcaklık sensörü sistem için uygun görülmüştür [11].

Sıcaklık sensörü içinde bulunan atomların doğal yapısı gereği sıcaklık etkisinde ortaya koydukları elektriksel direnç değişmektedir. Bu sayede oluşan gerilim farkı mikrodenetleyici tarafından anlamlandırılıp ölçüm devresinin kablosuz veri aktarım kısmına gönderilmektedir. Ölçüm devresinin 20 mW'lık güç ihtiyacı 500 mAh'lik seri bağlı iki lityum iyon

batarya tarafından sağlanmıştır. Elektronik devrenin şematik ve baskı tasarımı Proteus Professional programı üzerinden yapılmaktadır. Sıcaklık ölçüm devresi tasarımı ve prototip üretimine ait görsel Şekil 4'te verilmektedir.

Şekil 4. Sıcaklık ölçüm devresi tasarım ve prototip üretim görseli

Hem tork ölçümü hem sıcaklık ölçümü için tasarlanan elektronik kartların büyüklüğü, şekli ve montaj konumu büyük önem taşımaktadır. Elektronik kart tasarımlarına bağlı bu parametreler ilerleyen süreçte kartın kendisinin, sensörlerin ve güç ünitelerinin kardan mili üzerine entegrasyonunu sağlayan mekanik yapılarla uyumlu bir montaj sağlaması gerekmektedir. Aksi takdirde bu sistemlerin kardan mili dönme çapı, NVH karakteristiği, ağırlığı gibi önemli parametrelere etki ettiği bilinmektedir.

3. MEKANİK TASARIM

Kardan milleri aracın altında, dış ortama açık bir durumda konumlandırılmış mekanik bir aktarma organıdırlar. Dış ortama açık olmaları sebebiyle araç altında, dışarıdan gelebilecek fiziksel etkilere maruz kalmaları kaçınılmazdır. Araçların kullanım ömrü boyunca farklı coğrafyalarda, farklı arazilerde yol alması da bu fiziksel etkilerin artmasına sebep olmaktadır. Aksamlar üzerinde biriken kir ve toz, oluşan nem etkisi, çamur içinde bulunan tuzların korozyon etkisi veya küçük çakılların atması sonucu oluşan fiziksel darbelerin tümü bu zorlayıcı koşullara örnek olarak gösterilmektedir.

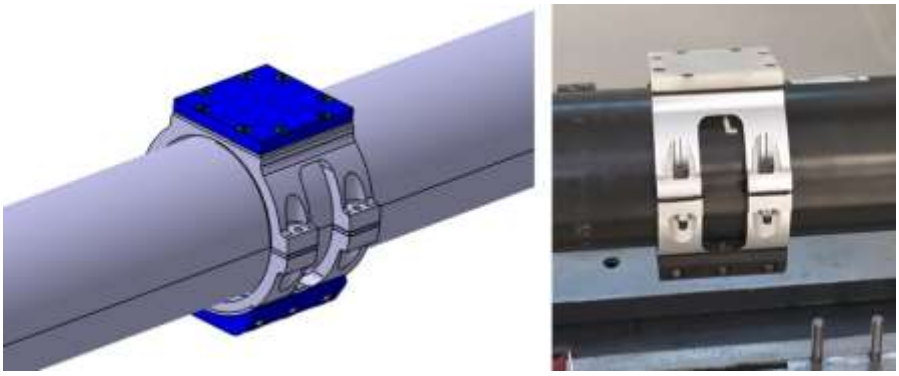
Bahsi geçen koşulların varlığı, kardan mili üzerine entegre edilmesi düşünülen tork ve sıcaklık ölçüm sistemlerine bir koruma sağlanması ihtiyacı doğurmaktadır. Bu kapsamda, akrilik ve silikon bazlı bir çok kaplama tekniğinin nem ve toza karşı direnç oluşturduğunu ve elektronik devreler üzerinde kullanıldığı görülmektedir. İlk aşamada yapılan denemeler belirli seviyede başarılı olsa da zorlayıcı ürün testlerinde istenilen izole ortamı oluşturamamıştır.

Sürüş sırasında araç altı, zorlayıcı etkilerin en yoğun görüldüğü ortamdır. Elektronik devrelerin bu etkilerden tamamen korunması, ürün fonksiyonelliğine ve uygun mekanik montaja imkan sağlaması için tasarlanan mekanik yapılar açıklanmaktadır.

3.1. Tork Ölçüm Sistemi

Gerinim akışının en net gözlemlendiği kardan mili borusu, tork ölçümü için en uygun bölge olarak seçilmişti. Buna bağlı olarak boru üzerine yerleştirilen gerinim ölçerin elektronik devre ile iletişimine imkan sağlayan, aynı zamanda gerinim ölçerleri koruyan bir mekanik yapı üzerine çalışmalar yapılmıştır.

Boru formuyla iç yüzeyinde gerinim ölçeri koruyan ve dış yüzeyine elektronik devre ve güç ünitelerinin konumlandırılmasına imkan sağlayan iki parçalı mekanik tasarım yapılmıştır. Şekil 5'te ürün montajlı haline ait katı model tasarımları ve prototip üretim görseli verilmektedir.



Şekil 5. Kardan mili boru üstü tork ölçüm sistemi

Araç üzerine oluşan fazla ağırlıkların yakıt tüketimine olan negatif etkileri bilinmektedir. Bu sebeple otomotiv sektöründe de çelik malzemeler için hafifletme çalışmalarında sıkça kullanılan, çelik malzemeden 3 kat daha hafif olan alüminyum malzeme, koruyucu yapılanma için uygun görülmektedir [12].

Yüksek hızda dönen kardan millerinde simetrik denge son derece önemlidir. Elektronik devre kartı ve güç ünitelerini üzerinde barındıran alüminyum koruyucu yapının da eksenel olarak dengede olması beklenmektedir. Koruyucu parça üzerine simetrik olarak açılan iki bölmeden birine elektronik devre kartı konumlandırılırken diğerine güç ünitesi sabitlenmiştir. Simetrik denge göz önünde bulundurularak tasarlanan kapaklar yardımıyla elektronik devre kartı ve güç ünitesi dış etkilere karşı korumaya alınmıştır.

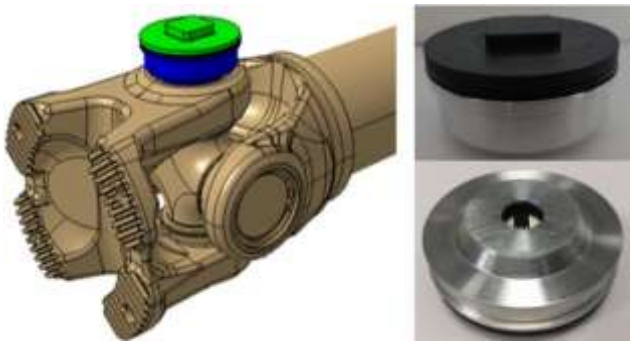
Koruyucu yapılanmaya ait kapaklar, elektronik devre kartı ve güç ünitesinin fiziki etkilerden korunmasını sağlarken, yapıya ait ağırlığın da simetrik olarak dağılmasına imkan vermektedir. Alüminyum koruyucu parçanın hem bu kapaklarla hem de boruyla arasında yerleştirilen contalar da sızdırmazlığı sağlamaktadır.

3.2. Sıcaklık Ölçüm Sistemi

Servis ömrü boyunca farklı arazi koşullarıyla karşılaşan ve zorlanma sonucu yüksek sıcaklık etkisine maruz kalan kardan mili mafsalları, istavroz gövdesi ve istavroz rulmanlarından oluşmaktadır. Bu sıcaklık ölçümü tekniği için istavroz rulmanının tabanı uygun bölge olarak seçilmişti.

Mekanik yapılanma, sıcaklık ölçüm elektronik devre kartını ve güç ünitelerinin içinde konumlandırılacağı şekilde istavroz rulmanı ve kulaklı kardan mili parçalarının yapısına uygun, dairesel formda tasarlanmıştır. Yine tork ölçüm sistemi mekanik yapılanmasında olduğu gibi parçanın hem santrifüj etkisinden hem de fazla ağırlığından kaçmak adına alüminyum malzeme tercih edilmektedir.

Alüminyum parçanın istavroz rulmanı tabanına yapıştırılması için yapıştırıcı seçimi yapılmıştır. Kardan mili üzerinde titreşim düşünülerek silikon bazlı, benzerlerine göre daha sünek yapıda endüstriyel bir yapıştırıcı tercih edilmiştir. Şekil 6'da prototip ürün görselleri ve katı modelin mafsal üzerine montajında gösterildiği şekilde mekanik parça, altında bulunan yapışma yüzeyi yardımıyla yüksük üzerine konumlandırılmıştır. İstavroz rulmanı ve parça arasında oluşan dairesel boşluğa sıcaklık sensörü konumlandırılarak temaslı veri okuması gerçekleştirilmiştir.



Şekil 6. Kardan mili mafsalı sıcaklık ölçüm sistemi

Mekanik yapılanma içinde bulunan elektronik devre kartları iki sistem için de kablosuz veri nakli prensibinde çalışarak canlı veri takibine imkan sağlamaktadır. Tork ölçüm sisteminde olduğu gibi sıcaklık ölçüm sisteminde de elektronik devre kartını ve güç ünitesinin dış ortamla izolasyonunu sağlayan, yüksek sertlikte ve sıcaklık dayanımlı plastik malzemeden tasarlanan kapaklar bulunmaktadır. Kapağın altında bulunan contalar ise ürünün çalışma koşullarına uygun şekilde sızdırmazlığı sağlamaktadır.

4. BULGULAR

Geliştirilen kardan mili ekipmanları için ana sanayi beklenti ve ihtiyaçlarını karşılamak veya son kullanıcı için ürün kalitesini arttırmak amaçlanmaktadır. Benzer çalışmalar kapsamında ana sanayi ihtiyaçları için tasarlanmış ürünler, prototip aşamasındayken bir dizi teste tabi tutulmaktadır. Bahsi geçen tork ve sıcaklık verisi toplama sistemlerinin çalışma durumu, fonksiyonelliği ve veri kalitesi görmek adına bir yol haritası çıkartılarak testler planlanmıştır.

4.1. Tork Ölçüm Sistemi

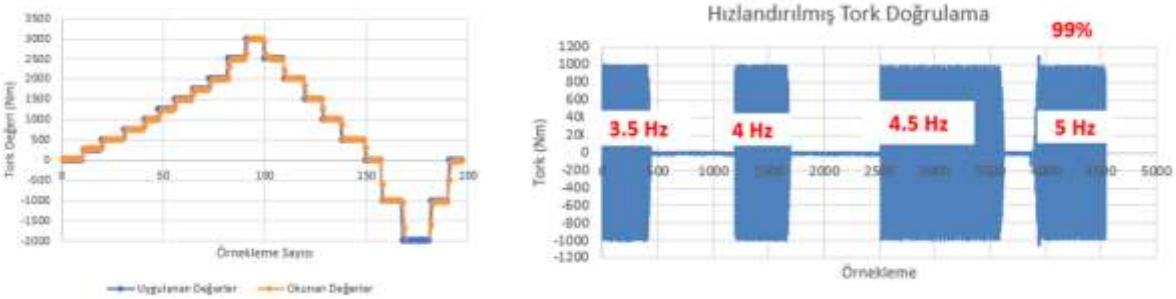
Kardan mili tork verisi toplama sistemine ait planlanan testlerde ürünün araç altındaki gerçek yol koşullarını simüle eden dinamik dayanıklılık testleri ve ölçüm kalitesi görme amacıyla statik torsiyon testleri yer almaktadır. İlk aşamada

ürünün sahadaki kullanım şartlarına bağlı olarak hazırlanan test haritasında ürünün, araç altındayken verdiği fiziksel tepkiler, veri okuma veya aktarma kalitesi ve kardan miline olan etkileri incelenmektedir. Şekil 7'de test aşamasındaki kardan mili üzerindeki ürünün görseline yer verilmektedir. Görsel içeriğinde kardan mili ölçüm sistemleri için özel olarak tasarlanmış, veri toplama, izleme, istatiksel hesaplama ve kayıt altına alma gibi özellikleri bulunan Windows tabanlı arayüze de yer verilmektedir.

Şekil 7. Boru üstü tork ölçüm sistemi dinamik testi ve veri toplama

Test sırasında kardan miline tork, devir ve açı gibi araç altında karşılaşabileceği etkiler uygulanmaktadır. Bunun sonucunda boru üzerine entegre edilmiş ürün ise, test sırasında santrifüj ve titreşim gibi bir çok etkiye maruz kalmaktadır. Bu etkiler altında gösterdiği mekanik direngenlik sayesinde ölçüm verileri doğru şekilde okunabilmiş ve kablosuz veri aktarımı aracılığıyla canlı takibi sağlanmıştır.

Ürün tasarımında beklenen hedefler doğrultusunda ±3500 Nm'lik aralıkta %0,5'lik ölçüm doğruluğu sağlanmıştır. Buna bağlı olarak ürün ölçüm hızı ise 5 Hz'lik yükleme frekansında ±1000 Nm'lik aralıkta %99 doğrulukla çalışmıştır. Test sonuçlarına ait iki grafik Şekil 8'de gösterilmektedir.



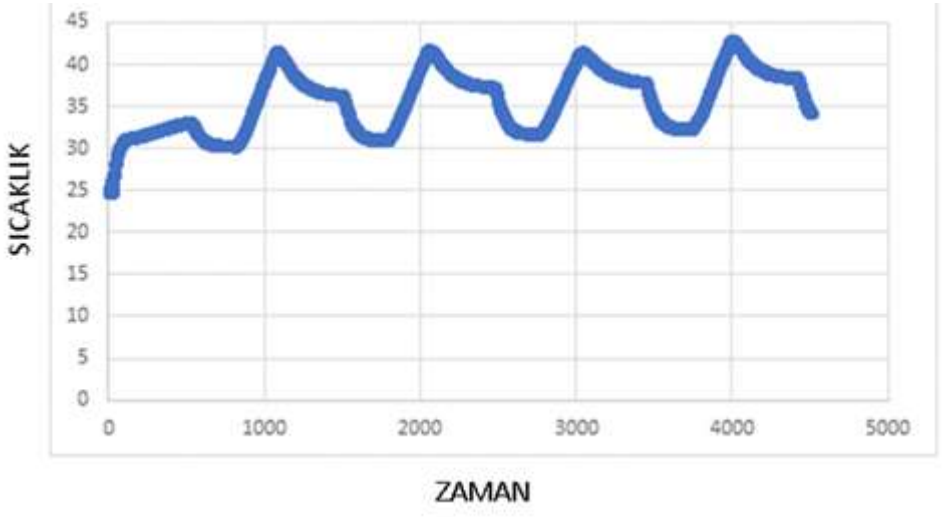
Şekil 8. Kardan mili boru üstü ölçümlerine ait sonuçlar

4.2. Sıcaklık Ölçüm Sistemi

İstavroz rulmanı tabanından sıcaklık ölçümü için tasarlanan sisteme ait testlerde ürünün veri toplama kalitesini ve fonksiyonelliğini test etmek amacıyla devir altında toz, nem ve sıcaklığa bağlı çevresel koşulları simüle eden bir yol haritası belirlenmiştir. Bu bağlamda sistem, kardan mili komplesi ile beraber çamur testine tabi tutulmuştur. Şekil 9'da test edilmekte olan sistem görülmektedir.

Şekil 9. Mafsal üstü sıcaklık ölçüm sistemi çevresel testi ve veri toplama

İstavroz rulmanı tabanına yapıştırılan sıcaklık ölçüm sistemi çamur testi sırasında ölçüm verilerinin toplanmasını sağlamaktadır. Anlık test verilerine bakıldığında hem test cihazı tarafından uygulanan ek sıcaklık hem de dönüş sırasında sürtünme kaynaklı oluşan sıcaklık net bir şekilde görülmektedir. Belirlenen test hedefleri doğrultusunda sıcaklık ölçüm sistemi kardan mili üzerindeki fonksiyonlarını kaybetmeden ±2 °C ölçüm doğruluğuyla testi tamamlamıştır. Test sonuçlarına ait sıcaklık ölçüm grafiği Şekil 10'da gösterilmektedir.



Şekil 10. Kardan mili mafsal üstü ölçümlere ait sonuçlar

5. SONUÇLAR VE ÖNERİLER

Tork ve sıcaklık ölçüm sistemi, saha koşullarını simüle eden testlerde fonksiyonelliğini koruyarak, canlı veri toplanmasına ve takibine olanak sağlamıştır. Ölçüm sistemi tarafından toplanan veriler, ticari yazılımlarla eş zamanlı olarak toplanan verilerle kıyaslanmıştır. Toplanan verilerin doğruluğu, sıcaklık için -20/+80 °C ölçüm aralığında %1 hata payıyla sağlanırken, tork için ±3500 Nm'lik ölçüm aralığında %0,5 hata payıyla sağlanmıştır.

Tork ve sıcaklık verisinin eş zamanlı tespiti amacıyla geliştirilen sistem, çalışma koşulları için belirlenen ölçüm aralığı ve ölçüm doğruluğu hedeflerini başarılı bir şekilde gerçekleştirmiştir. Bahsi geçen sistemlerin hem firma için doğrulama testlerinde hem de saha testlerinde kardan miline ait veri toplama ihtiyacının karşılanmasında çözüm olabileceği düşünülmektedir.

TEŞEKKÜR

Bu çalışmaya verdikleri destekten dolayı Tirsan Kardan Ar-Ge Merkezi ve Test Merkezi'ne sonsuz teşekkürlerimizi sunarız.

TICARI ARAÇ KARDAN MILLERINDE KULLANILAN AKUSTIK MALZEMELI SES DAMPERLERININ SES YUTUM ÖZELLIKLERININ GÜRÜLTÜ KARAKTERISTIĞI ÜZERINE ETKISI

Muzaffer Kasaba, Efe Işık

[1,2,] Tirsan Kardan A.Ş. Ar-Ge Merkezi
[1] Correponding Author: Efe Işık, e.isik@tirsankardan.com.tr

ÖZET

Kardan milleri, motordan gelen güç ve dönme hareketini arka akslara ileten aktarma organlarının en önemli üyelerinden biridir. Ayrıca, güç ve hareket aktarımı sırasında yol koşullarına bağlı olarak açı ve boy değişimi imkanı sağlar. Hareket ve güç aktarımı sırasında kardan mili gürültü ve titreşim yaratır. Bu gürültü ve titreşimin problemini giderebilmek için kardan mili içerisine monte edilen ses damperleri kullanılmaktadır. Yapılan çalışma, araçlarda kullanılan kardan millerinin meydana getirdiği gürültü ve titreşimin düşürülmesini sağlayan, kardan milinin içinde konumlandırılan ses damperi ile ilgili yapılan deneysel çalışmaları kapsamaktadır. Bu çalışmada, farklı ses damperleri kullanılmıştır. Öncelikle kullanılacak ses damperlerinin empedans tüpü yardımı ile ses yutum özellikleri belirlenmiştir. Daha sonra kardan millerine montajı gerçekleştirilen ses damperleri için araç üzeri çalışma koşulları benzetilerek gürültü testleri gerçekleştirilmiştir. Son olarak kardan millerinin elde edilen gürültü karakteristikleri ile ses damperlerinin yutum özellikleri arasındaki ilişki kurulmuştur.

Anahtar Kelimeler: akustik, gürültü ve titreşim, kardan mili, kritik hız, NVH, ses damperi.

EFFECT OF SOUND ABSORPTION PROPERTIES ON NOISE CHARACTERISTICS OF ACOUSTIC MATERIAL NOISE DAMPERS USED IN COMMERCIAL VEHICLE DRIVESHAFTS

ABSTRACT

Driveshafts are one of the most important members of the driveline that transmits the power and rotational motion from the engine to the rear axles. In addition, it provides the opportunity to change the angle and length depending on the road conditions during power and motion transfer. The driveshaft creates noise and vibration during movement and power transmission. In order to eliminate the problem of this noise and vibration, noise dampers mounted inside the driveshaft are used. The study covers the experimental studies on the noise damper located inside the driveshaft, which reduces the noise and vibration caused by the driveshafts used in the vehicles. In this study, different noise dampers were used. First of all, the sound absorption properties of the sound dampers to be used were determined with the help of the impedance tube. Then, noise tests were carried out for the noise dampers, which were mounted on the driveshafts, by simulating the working conditions on the vehicle. Finally, the relationship between the noise characteristics of the driveshafts and the absorption characteristics of the sound dampers has been established.

Keywords: acoustics, noise and vibrations, driveshafts, critical speed, NVH, noise dampers.

1. GİRİŞ

Kardan mili, motorda üretilen gücün ve dönme hareketinin, diferansiyele ve diferansiyel aracılığı ile tekerleklere kadar iletilmesini sağlamaktadır. Kardan mili kaynaklı titreşim ve gürültü, düzgün bir yolda sürüş esnasında tecrübe edilen ve artması durumunda müşteri şikâyeti yaratan bir problemdir.

Ses ve titreşim ölçülebilir ancak gürültü sadece sübjektif olarak değerlendirilebilmektedir. Hareketli parçalara sahip olan tüm makinalar, normal çalışma koşullarında dinamik kuvvet üretirler. Makinanın mekanik davranışı aşınma, çalışma koşullarındaki değişiklikler, yük değişimleri gibi sebeplerle değişebilmektedir. Makinanın dinamiği ve kuvvetlerin nasıl titreşim yarattıklarını anlamak aslında titreşim kaynaklarını anlayabilmek için gerekli en önemli anahtardır.

Kardan mili, çeşitli kullanım koşullarında ortaya çıkan diğer aktarma organları kaynaklı oluşan gürültü ve titreşimi araç kabini içerisine iletebilmektedir. Diğer yandan kardan mili kaynaklı titreşim ve gürültünün tespit edilememesi, çok maliyetli üretim duruşlarına ve son kullanıcı müşteri memnuniyetsizliğine sebep olur.

Otomotiv sektöründe titreşim oluşması istenilmeyen bir durumdur. Çünkü titreşim demek, enerjinin boşa harcanması ve istenmeyen ses ve gürültünün oluşması anlamına gelmektedir. Örneğin, motorun titreşim hareketi, elektrik motorlarındaki titreşim ya da mekanik bir cihazda oluşan titreşimler istenmeyen titreşim grubuna girmektedir. Bu tip titreşimler, dönen cisimlerin balanssız olmasından, düzensiz sürtünmeden, dişli kutusunda karşılık dişlilerin birbirine çarpmasından vs. gibi sebeplerden oluşmaktadır.

Ses ve titreşim oldukça yakın kavramlardır. Ses, basınç dalgaları titreşen yapılardan oluşmakta, basınç dalgaları da yapıların titreşimini oluşturmaktadır. Bu sebeple gürültü seviyesi düşürülmeye çalışırken titreşim genliklerinin de düşürülme çalışmaları eş zamanlı olarak yürütülmelidir.

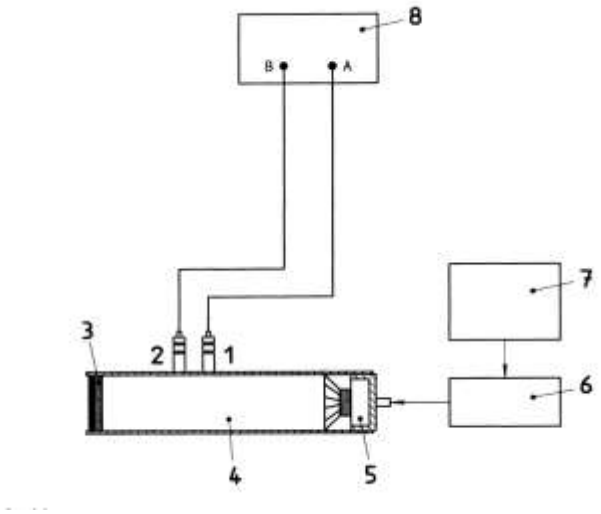
Kardan milinin meydana getirdiği gürültü ve titreşimin sönümlenmesini sağlamak için çelik boru içinde genellikle karton ses damperleri kullanılmaktadır. Bu ses damperlerinde gürültü ve titreşim sönümlemesi yetersiz olmakla birlikte montaj ve depolama işlemlerinde de bazı problemler ile karşılaşılmaktadır. Kartonun sert bir malzeme olması nedeni ile çelik boru içine yerleştirilmesi esnasında güç gerektirmekte ve bu durum seri üretimde zaman almaktadır. Aynı zamanda kartonun boru içine yerleştirilmesi sırasında karton malzemede deformasyon meydana gelebilmektedir. Bu durum da malzeme kaybına neden olmaktadır. Diğer yandan karton malzemeli ses damperi depolama sırasında iklim koşullarından etkilenebilmektedir. Karton malzemeli ses damperi yağmur, kar gibi dış etkilerden olumsuz etkilenerek kartonda deformasyon meydana gelebilmektedir. Üretim sırasında ise karton ses damperi ısıdan ve boru büzme işleminde kullanılan yağdan etkilenmektedir. Kaynak işlemi sırasında karton malzemenin alev alma riski bulunmaktadır. Sonuç olarak kardan millerinin içine konumlandırıldığı ses damperlerinde geliştirmelere gidilmekte, bu nedenle yukarıdaki değinilen dezavantajları ortadan kaldıracak ve mevcut sistemlere çözüm getirecek yeni yapılanmalara ihtiyaç duyulmaktadır.

Koruk ve arkadaşları (Koruk ve diğer., 2014) farklı kalınlıklarda karton ses damperinin titreşim ve akustik performansı hakkında nümerik, deneysel ve analitik çalışmalar yapmışlardır. Bu çalışmada öncelikle farklı kalınlıkta ses damperleri kullanılarak, kayıp faktörleri ve doğal frekansları modal analiz ile belirlenmiştir. Serbest ses alanında akustik ölçümler yapılarak, kardan miline adapte edilen farklı kalınlıktaki karton ses damperlerinin kardan mili gürültü karakteristiği üzerine olan etkisini araştırmışlardır. Gürültü ve titreşim kontrolü amacıyla, Clerk ve Sing (Clerk ve diğer, 2003) karton ses damperinin dairesel kesitli, kardan mili borusuna yerleştirilmesi sonucu gürültü ve titreşim etkisini belirlemek için bir çalışma yapmıştır. Çalışmada karton ses damperi kullanılan kardan milinin modal davranışını önemli ölçüde değiştirdiği gösterilmiştir. Ses damperi, sistemdeki modların çoğuna modal katılık katarken, modal kütlenin artışı da belirli bir kabuk türü mod gözlemlenmesine sebebiyet vermiştir. Moetakef ve arkadaşlarının (Moetakef ve diğer, 2003) yapmış olduğu çalışmada, sınırlı sönümleme kabiliyeti nedeniyle, karton ses damperlerinin etkisinin sınırlı olduğunu ve kardan milinden yayılan gürültüyü engelleyemediği veya etkili bir şekilde azaltamadığını belirtilmiştir. Bu nedenle polimer ses damperlerinin kardan mili gürültü ve titreşim sönümleme performansı ele alınmaktadır. Deneysel araştırmalara göre, kardan milinden yayılan gürültünün azaltılmasında polimer malzemeden ses damperlerinin karton ses damperlerine göre daha etkilidirler. Polimerler, şaftların akustik güçlendirici etkisini önlemek veya azaltmak için yüksek sönümleme özelliğine ihtiyaç duyulduğunda ses damperi olarak kullanılabilir. Kasaba ve arkadaşları (Kasaba ve Arslan, 2017) yaptıkları çalışmada kardan millerinde farklı kalınlıklarda polimer malzemeden ses damperi kullanarak polimer malzeme kalınlığının kardan mili gürültü karakteristiği üzerine etkisini incelemişlerdir.

2. TEORİ

2.1. Empedans Tüpü

Durağan dalga aparatı olarak da bilinen empedans tüpleri, malzemelerin ses yutma katsayılarını belirleyen aparatlardır. Empedans tüpünde ölçüm yapabilmek için gerekli düzenek Şekil 1.'de verilmiştir.



Şekil. 1 Empedans tüpü test düzeneği

Şekil 1.'de 1 ve 2 numara mikrofon, 3 numara test örneği, 4 numara boru, 5 numara hoparlör, 6 numara ampflikatör, 7 numara sinay üreteci 8 numara da data toplama sistemidir. Testi yapılacak numune 3 numaralı bölgeye yerleştirilir. Sinyal üretecinden yutum katsayısının öğrenilmek istendiği frekanslarda sinyal üretilir. Ampfilikatörden geçen sinyal hoparlör vasıtası ile tüp içerisine verilir ve tüp içerisinde durağan dalga oluşur. Durağan dalga üzerinden mikrofonlar ile ses sinyalleri okunarak data toplama sisteminde işlenir. Daha sonra transfer matris yöntemi ile ses yutum katsayıları elde edilir.

Empedans tüpünün boyutları EN ISO 10534-2 standardına göre belirlenmiştir. Ölçüm yapılabilecek en yüksek frekansa göre iki farklı boru çapı belirlenmiştir. Boru boyutlarını belirlemek için Denklem 1. Kullanılmıştır. 1000 Hz'e kadar olan ölçümler için belirlenen empedans tüpü Şekil 2.'de 1000 Hz ile 4500 Hz arası olan ölçümler için belirlenen empedans tüpü Şekil 3.'de verilmiştir.

$$f_u \; x \; d < 0{,}58 \; x \; c_0 \tag{1}$$

Burada f_u ölçüm yapılabilecek Hz cinsinden üst frekans sınırı, d metre cinsinden boru iç çapı c_0 ise m/s cinsinden ses hızıdır.

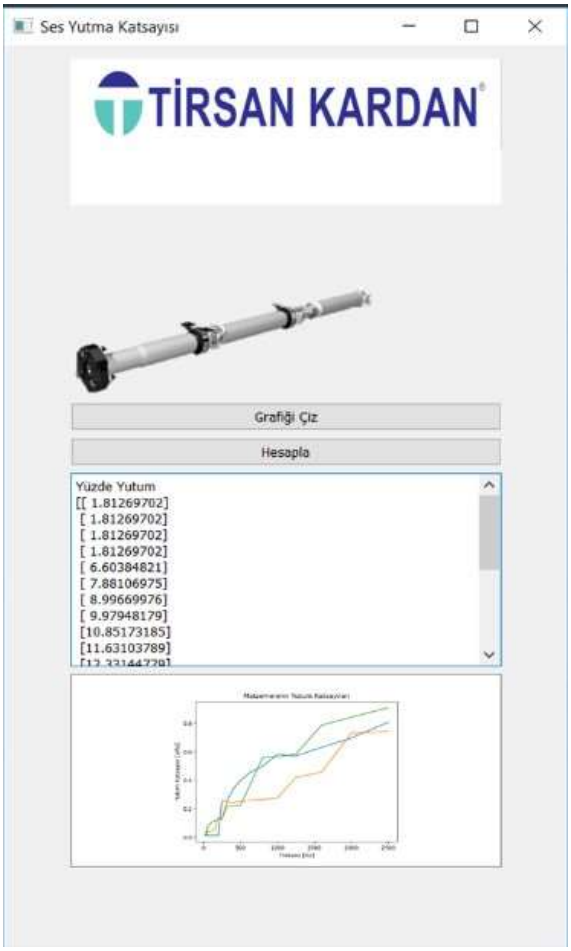
Şekil 2. 1000 Hz'e kadar olan ölçümler için empedans tüpü

Şekil 3. 1000 Hz ile 4500 Hz arası ölçümler için empedans tüpü

Empedans tüpü ile testlerin yapılabilmesi amacı ile firmamız bünyesinde EN ISO 10534-2 standardına göre Şekil 4'teki empedans tüpü tasarlanarak üretilmiştir.

Şekil 4. Firma bünyesinde üretilen empedans tüpü

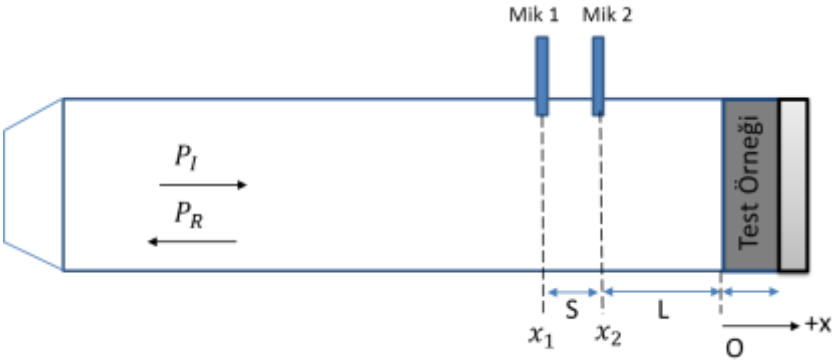
Ses verilerini toplamak amacı ile ¼ inch PCB mikrofonlar kullanılmıştır. Veri toplama sistemi olarak da Siemens LMS Scadas, yazılım olarak da Siemens Test Express yazılımı kullanılmıştır. Elde edilen ses verilerinden ses yutma katsayılarını hesaplamak için transfer matris metodu kullanılmıştır. Metodu uygulamak amacı ile PYTHON programında Şekil 5'deki arayüz geliştirilmiştir.



Şekil 5. PYTHON programında geliştirilen transfer matris yöntemi arayüzü

2.2. Transfer Matris Metodu

Transfer matris metodu, mikrofonlardan okunan basınç değerleri ile malzemenin ses yutma katsayısını hesaplayan yöntemdir. Denklemler Şekil 5. üzerindeki ölçüler referans alınarak türetilmiştir.



Şekil 6. Empedans tüpü şematik gösterimi

Gelen ve yansıyan dalgalar;

$$P_I = P^{\wedge}_I e^{ik_0 x} e^{-iwt} \quad (2)$$

$$P_R = P^{\wedge}_R e^{ik_0 x} e^{iwt} \quad (3)$$

Mikrofon 1 ve 2'deki basınç değerleri;

$$P_1 = P_I(x_1) + P_R(x_1) = P^{\wedge}_I e^{-ik_0 x_1} + P^{\wedge}_R e^{ik_0 x_1} \quad (4)$$

$$P_2 = P_I(x_2) + P_R(x_2) = P^{\wedge}_I e^{-ik_0 x_1} + P^{\wedge}_R e^{ik_0 x_1} \quad (5)$$

Transfer Fonksiyonları;

$$H_I = \frac{P_I(x_2)}{P_I(x_1)} = \frac{P^{\wedge}_I e^{-ik_0 x_2}}{P^{\wedge}_I e^{-ik_0 x_1}} = e^{ik_0 s} \quad (6)$$

$$H_R = \frac{P_R(x_2)}{P_R(x_1)} = \frac{P^{\wedge}_I e^{ik_0 x_2}}{P^{\wedge}_I e^{ik_0 x_1}} = e^{-ik_0 s} \quad (7)$$

$$H_{12} = \frac{P_2}{P_1} \quad (8)$$

X=0'da yansıma katsayısı;

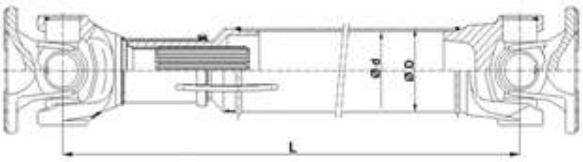
$$R = \frac{H_{12} - e^{ik_0 s}}{e^{ik_0 s} - H_{12}} \quad (9)$$

Yutum katsayısı;

$$\alpha = 1 - R^2 \quad (10)$$

2.3 Kritik Hız

Araç uygulamalarına bağlı olarak kardan millerinin çalışacağı hız aralıkları değişkenlik göstermektedir. Kardan milleri motor ve diferansiyel kaynaklı yüksek hız aralıklarında fonksiyonelliğini koruyarak güvenli şekilde çalışabilmelidir. Bahse konu güvenli çalışma aralığı gerekliliği, kardan milinin kritik hızının aktarma organlarının maksimum dönme hızından daha büyük olması zorunluluğunu doğurur. Kardan milinin kritik hızı Denklem 11 ile hesaplanır (SAE, 1991). Bu çalışmada testler kardan milinin en yüksek gürültü seviyesine ulaştığı kardan milinin kritik hızında gerçekleştirilmiştir. Kritik hız testi şirket bünyesinde bulunan test merkezindeki kritik hız cihazında yapılmıştır.



Şekil. 7. Kardan milinin şematik gösterimi

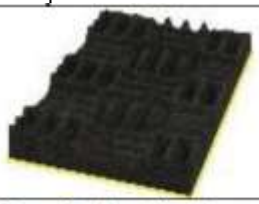
$$n_{kritik} = 1{,}22.10^{8}\frac{\sqrt{D^2 + d^2}}{L^2} \tag{11}$$

Burada n_{kritik} kritik hız, D_{mm} boru dış çapı 130 mm, d_{mm} boru iç çapı 118 mm, L_{mm} mafsallar arası mesafe ise 1 metre olarak denklemde yer almıştır. Testlerin gerçekleştirileceği kardan milleri denklemde kullanılan boyutlarda üretilmiştir.

3. DENEYSEL ÇALIŞMALAR

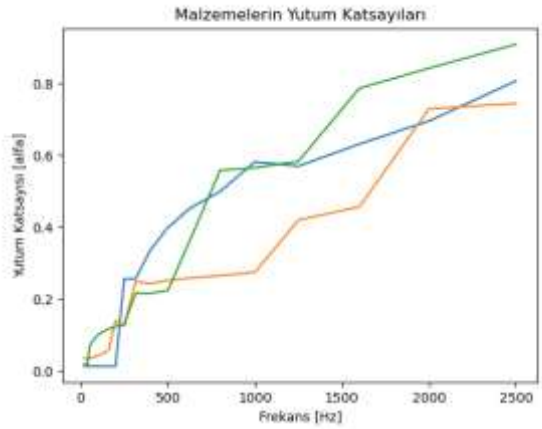
Deneysel çalışmaların ilk bölümünde 3 farklı malzeme kullanılmıştır. Malzemeler Tablo 1'de verilmiştir.

Tablo 1. Ses damperi olarak kullanılan malzemeler

Düz akustik sünger	Pramit akustik sünger	Poliüretan köpük

Empedans tüpünde gerçekleştirilen deneyler sonucunda 3 malzeme için de ses yutum katsayıları belirlenmiştir. Belirlenen değerler frekans bandında Şekil 8'de verilmiştir. Grafikte turuncu eğri düz akustik sünger, mavi eğri piramit akustik sünger, yeşil eğri de kardan millerinde kullanılan poliüretan köpüğe aittir. Tüm malzemelerin frekans arttıkça yutumların arttığı en yüksek yutumun ise en yoğun olan poliüretan köpükte olduğu görülmüştür. Karton ses damperinin fiziksel yapısından dolayı empedans tüpünde ses yutma katsayısı ölçümleri yapılmamıştır. Fakat karton ses damperine alternatif olarak kullanılacak malzemeler ile kıyaslanması adına gürültü ölçümlerinde karton ses damperli kardan millerinin de gürültü testleri yapılmıştır.



Şekil. 8. 3 farklı malzeme için ses yutum katsayısı-frekans eğrileri

Bu çalışmada ağır ticari araç kardan miline empedans tüpü ile ses yutma katsayıları belirlenen ses damperleri ve karton ses damperi Tablo 2'deki gibi adapte edilmiştir.

Tablo 2. Ses damperlerinin kardan millerine adapte edilmesi

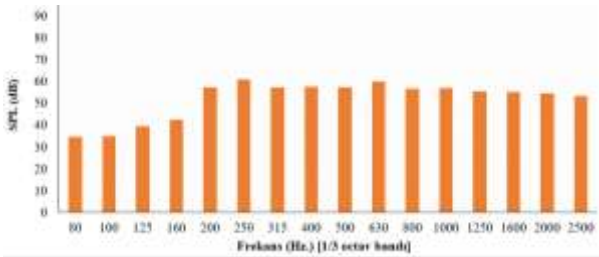
			
Karton ses damperi	Düz akustik sünger	Piramit akustik sünger	Poliüretan köpük

Gürültü testleri gerçekleştirilmiş ve gürültü karakteristikleri elde edilmiştir. Deneylerde kullanılan farklı malzemeden ses damperleri çap ve uzunluk olarak aynı boyutlarda alınmıştır. Gerçekleştirilen testlerde bir adet ¼'' serbest alan mikrofonu kullanılmıştır. Mikrofon kritik hız cihazının üzerinde, kritik frekansın çeyrek dalga boyu kadar uzağa konumlandırılmıştır.

Şekil. 9. Kardan milinin kritik hız test cihazı üzerinde gösterimi

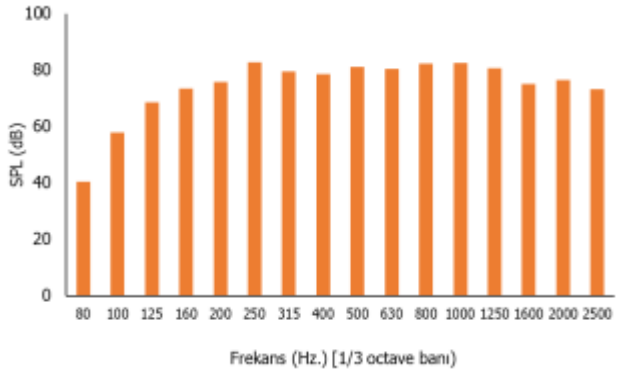
Testler şartlandırılmış akustik oda kullanılmadan tespit edilen test merkezi fon gürültüsü karakteristiği altında gerçekleştirilmiştir. Kardan milinde farklı ses damperleri kullanılarak aynı test koşullarında gürültü karakteristikleri belirlenmiştir. Fon gürültüsü ve kritik hız test cihazı çalışma koşulları sabit tutulmuştur. Gürültü testleri yapılırken, kardan mili kritik hız cihazına bağlanarak araç üstü durumu simule edilmiştir. Ağır ticari araç kardan milleri kritik hız test cihazına bağlantı flanşlarından sabitlenmiştir. Kardan mili kritik hız test cihazında belirlenen kritik devir 3500 devir/dk' da döndürülerek 10 sn süreyle ses basıncı sonuçları alınmıştır. Şekil 9' da kardan milinin kritik hız cihazı üzerinde şematik gösterimi verilmiştir.

Fon gürültüsü, test merkezi içerisindeki testin yapılacağı alanda test başlamadan önce ¼'' serbest alan mikrofonu ile ölçülen gürültüdür. Sağlıklı ölçüm alabilmek için fon gürültüsü ile ölçümü alınan cihazın gürültüsü arasında 10 dB fark olması gerekmektedir [12]. Tespit edilen fon gürültüsü karakteristiği 1/3 oktav bandında Şekil 4' de verilmiştir. Testin yapılacağı sırada toplam fon gürültüsü 68 dB olarak ölçülmüştür. Tespit edilen fon gürültüsü tüm testlerde sabit tutulmuştur.



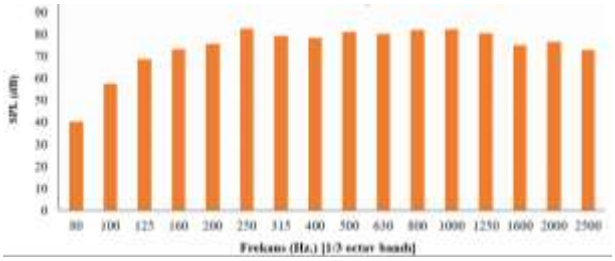
Şekil. 10. Fon gürültü karakteristiğinin 1/3 oktav bant gösterimi

Empedans tüpü ile ses yutma katsayıları belirlenen farklı malzemeden ve karton ses damperleri aynı özellikte ağır ticari araç kardan miline yerleştirilmiştir. Gürültü ölçüm sonuçları Şekil 11-14' de verilmiştir.



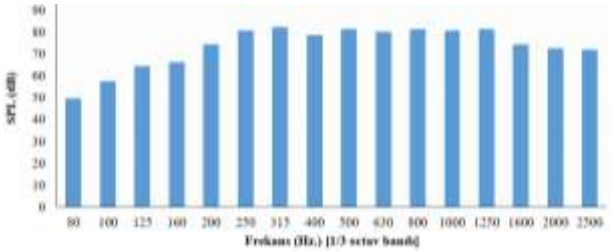
Şekil. 11. Karton ses damperli kardan milinin gürültü karakteristiğinin 1/3 oktav bant gösterimi

Şekil 11' de görüldüğü üzere kardan milinde karton ses damperi kullanılmış ve araç üzeri konumu simule edilerek kritik hız değerinde gürültü ölçümü sonuçları elde edilmiştir. Kardan milinin kritik hız değerine denklem 11 kullanılarak ulaşılmıştır. Elde edilen sonuçlara göre ortalama 92 dB ses basıncı ölçülmüştür.



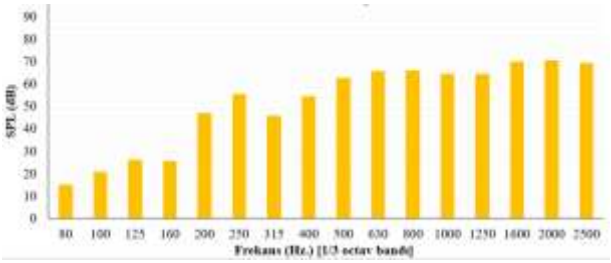
Şekil. 12. Düz akustik sünger ses damperli kardan milinin gürültü karakteristiğinin 1/3 oktav bant gösterimi

Şekil 12' de görüldüğü üzere kardan milinde düz akustik sünger ses damperi kullanılmış ve araç üzeri konumu simule edilerek kritik hız değerinde gürültü ölçümü sonuçları elde edilmiştir. Kardan milinin kritik hız değerine denklem 11 kullanılarak ulaşılmıştır. Elde edilen sonuçlara göre ortalama 88 dB ses basıncı ölçülmüştür.



Şekil. 13. Piramit akustik sünger ses damperli kardan milinin gürültü karakteristiğinin 1/3 oktav bant gösterimi

Piramit akustik sünger ses damperi kullanılarak yapılan kardan mili gürültü ölçümü sonucunda 86 dB ses basınç düzeyi elde edilmiştir. Malzeme yapısından dolayı hava kaynaklı sesi düz aksutik ses damperinden daha fazla engellediği görülmüştür. İncelediğimiz frekans aralığında poliüretan malzemeye göre daha iyi bir yutucu olan köpük poliüretan malzeme ile test yapılmasına karar verilmiştir. Son olarak kardan mili borusu içerisine poliüretan ses damperi basılarak test edilmiştir.



Şekil. 14. Poliüretan köpük ses damperli kardan milinin gürültü karakteristiğinin 1/3 oktav bant gösterimi

Yukarıda verilmiş olan diğer iki test ile aynı koşullarda poliüretan ses damperi test edilmiştir. Poliüretan ses damperi ile ortalama 80 dB ses basıncı ölçülmüştür. Karton ses damperine göre 12 dB, düz akustik sünger damperine göre yaklaşık 10 dB, pramit akustik ses damperine göre 6 dB iyileştirme sağlanmıştır.

4. SONUÇ

Ses damperi olarak kartonun kullanılması, boru kaynaklı kardan mili gürültüsünün borunun titreşimlerinden kaynaklandığı yani yapı kaynaklı ses olduğu görüşüne sebep olmuştur. Bu bilgiler ışığında titreşimi kartona göre daha iyi sönümleyebilecek, yapı kaynaklı sesi daha iyi engelleyebilecek poliüretan köpük ve aksutik süngerler ile testler yürütülmüştür. Yürütülen deneysel çalışmalar ile deneylerde kullanılan 3 farklı malzemenin empedans tüpü ile ses yutma katsayıları belirlenmiştir. En iyi yutum özelliği poliüretan köpükte, sonra akustik pramit süngerde en sonra akustik düz süngerde olduğu görülmüştür. Aynı malzemeler, aynı özelliklerde kardan millerinde ses damperi olarak kullanılmış ve gürültü ölçümleri gerçekleştirilmiştir. Gürültü düzeyi en düşük kardan mili poliüretan köpük ses damperine sahip kardan mili olduğu belirlenmiştir. Sonuçlardan görüldüğü gibi malzemelerin yutum özellikleri iyileştikçe kardan milinin gürültü düzeyi azalmaktadır.

Tablo 3. Ses damperi olarak kullanılan malzemeler

Sıra	Kullanılan Ses Damperi	Ortalama Ses Basınç Seviyesi
1	Karton Ses Damperi	92 dB
2	Düz Akustik Sünger Ses Damperi	88 dB
3	Pramit Akustik Sünger Ses Damperi	86 dB
4	Poliüretan Köpük Ses Damperi	80 dB

TEŞEKKÜR

Bu bildiri çalışmalarının gerçekleştirilmesi sırasında bize olanak sağlayan ve destek olan Tirsan Kardan Ar-Ge ve Test Merkezi' ne teşekkür ederiz.

OTEKON'un sürekliliğini sağlayan tüm kongre düzenleyicileri ve katılımcılarına ayrıca teşekkür ederiz.

ABSTRACT

The development of a vehicle consists of many stages and architecture studies can be considered as the main and the beginning of the engineering process. Based on the vehicle performance targets suspension type is selected and therefore K&C (kinematics and compliance) analysis are realized to meet vehicle objectives. The objective of this paper is to conduct a reliable virtual analysis methodology based on steering output of the front suspension of a passenger vehicle which can correlate with the physical measurements taken from the K&C bench testing. A complete front suspension assembly is created within Adams/Car environment, which includes McPherson suspension, an anti-roll bar and steering subsystem. Based on the reference vehicle, the Adams model is created with rigid bodies based on their precise hardpoints in design position. The aim of the study is to gather high correlation with steering test output taken from K&C bench testing of which specifically, front steer angle change, wheel center locus, front camber angle combined with spin angle change, camber angle change and Ackerman error.

Keywords: Kinematics and Compliance, Steering analysis, McPherson front suspension, Adams/Car assembly

1. INTRODUCTION

The complete front suspension multi-body model is generated within Adams/Car to conduct steering analysis for the selected parameters. The reason for the model generation is to use virtual tools more efficiently in development process and hence shorten the development time for the future work decreasing the need for physical tests. As the K&C characteristics are used as key indicators for behavior of the vehicle such as comfort, performance, ride and handling, it is important to generate results virtually (Yi, Park, and Hong 2014). The paper consists of the model generation and CAE analysis comparison with the results from bench testing. Model generation is divided into two segments as full vehicle static correlation and front suspension steering kinematic correlation.

As a first step, parameters related to vehicle are defined, and measured to have the static correlation that enables to conduct meaningful analysis for the further steps. These parameters can be stated as wheelbase, mass, tire stiffness, tire radius under loading and center of gravity height.

As a second step, physical test bench measurements from K&C are gathered to compare with the Adams model results to validate the virtual model. In this step hardpoints of front suspension components as well as material characteristics are defined and inserted into the model. With the help of the correlation, the model is ready to serve further steering kinematics and optimization studies to improve steering characteristics.

2. VIRTUAL MODEL

Adams/Car is used to create a whole front suspension assembly. The subcomponents of the McPherson suspension assembly; lower control arm, spindle, shock absorber, spring, top mount and subframe are defined with precise hardpoints and mass, material, and moment of inertia values. Toe angle and camber angle is defined as suspension parameters.

For the steering subsystem, a steering wheel with a rack-pinion steering system, specifically consisting of a steering column with a 2-cardan joint solution and a steering box with tie rod is used. The subcomponents are created based on the hardpoints and material type, mass information and moments of inertia are inserted for each subcomponent. The parameters of steering system such as maximum rack displacement, maximum steering angle and pinion to rack reduction gear is defined.

The anti-roll bar is also created within the virtual model to be used especially for opposite wheel travel simulations for future work (Harzheim and Warnecke 2010). To see the effect on compliance analysis, translational and rotational stiffness of suspension bushings are defined in the model, transposing from technical drawings to vehicle coordinates. The complete Adams/Car model of the passenger vehicle is seen in Figure 1. Virtual test bench of Adams/Car called suspension test rig is used to conduct the analysis.

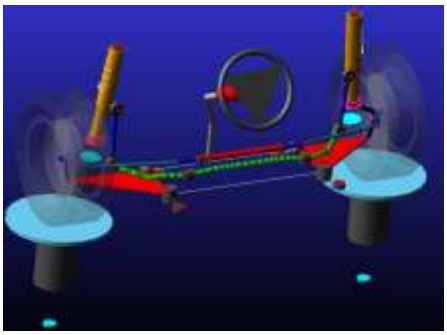

Figure 1. Adams/Car Assembly Model

Static correlation upon vehicle is achieved before conducting K&C analysis. Because the theoretical design parameters can not meet exactly the physical vehicle, the values related to vehicle are corrected in Adams model based on the measurements (Yahya Oz 2018). These values include sprung mass, center of gravity height, axle load, wheelbase, wheel mass and tire radius. However, the hardpoints for the whole virtual model are used as in the theoretical design position.

3. K&C RESULTS

Using the Adams/Car suspension test rig, one can choose to realize different suspension tests including parallel wheel travel, opposite wheel travel, steering and static load cases. In this paper the focus is on steering tests and therefore the virtual model is checked to have correlation with the measurements taken from physical K&C test machine.

3.1. Steer Angle Change

Both the virtual model and the measurement data can be seen in Figure 2. This graph shows how much the wheels are steered with given input of the full left and full right of steering wheel in degrees, which can be denoted also as steering ratio. The study shows a decent correlation and it means that the kinematics of steering wheel are processed well upon the mechanical connection through wheels based on the rotation of pinion gear which is transferred as the linear motion of rack gear and hence to the tie rods and spindle.

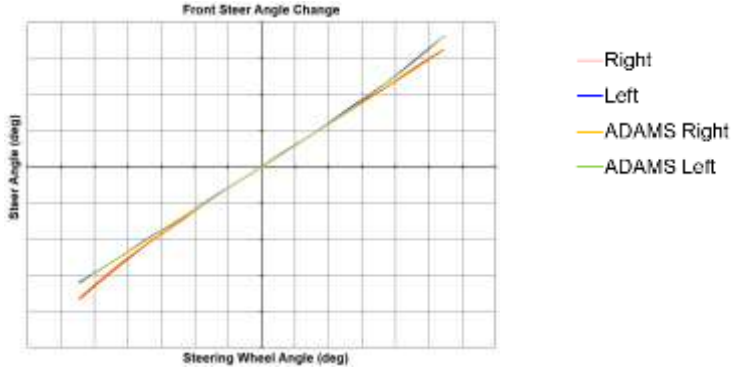

Figure 2. Steer Angle vs Steering Wheel Angle

3.2. Wheel Center Locus

The wheel center, while in turning maneuver, does not keep its position as it is due to suspension geometry. In the following Figure 3 the displacement of wheel center in lateral direction based on longitudinal direction is seen. Since the wheel center displacements are well correlated with the Adams model, it is feasible to indicate that the wheel kinematics based on the steering input is properly defined.

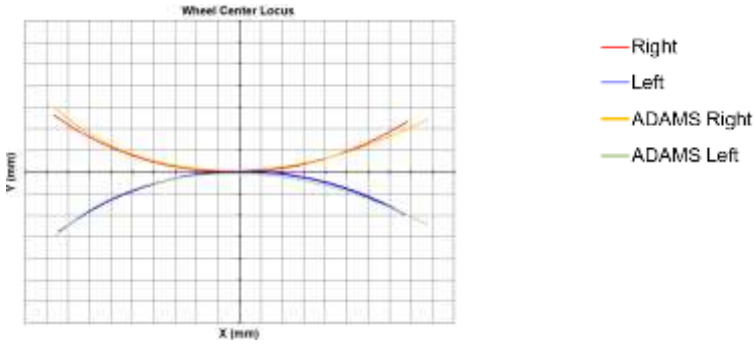

Figure 3. Wheel Center Locus

3.3. Camber Angle Change

Camber angle is one of the main wheel alignment parameter and is defined as the angle of which the wheel plane vertically makes with respect to the vehicle axis. It is positive when the top of the tire is leaning outward and negative when the top of the tire is leaning inward. The Figure 4 shows the effect of steering wheel input against the change on camber angle. This is considered a relatively successful model simulating the behavior of the wheel; however, the left side camber variation shows the ADAMS model can be further improved with respect to the physical results.

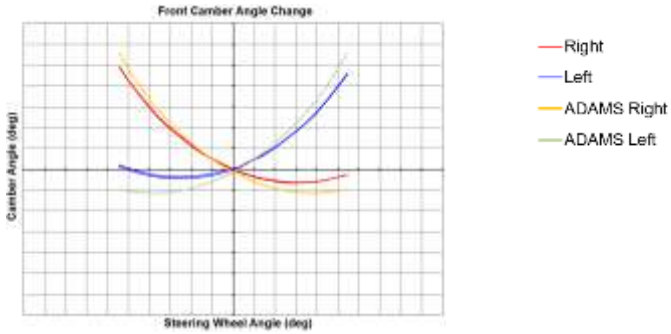

Figure 4. Camber Angle Change

3.4. Camber Angle and Spin Angle Change

Similar behavior is seen for the camber angle and spin angle change based on the steer angle generated on the wheel comparing to camber angle change based on steering wheel angle change. The correlated graphic is seen in the Figure 5.

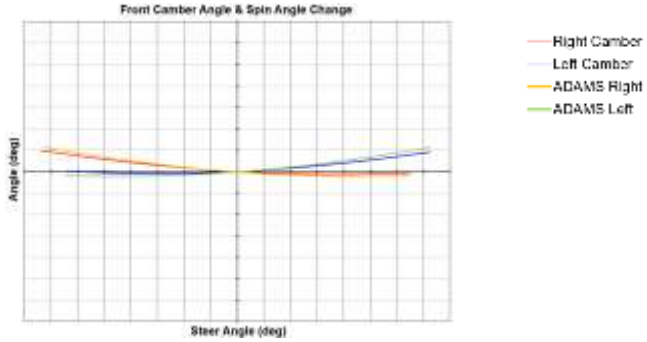

Figure 5. Camber Angle and Spin Angle Change

3.5. Ackerman Error

Ackerman error is calculated based on the ideal steer angle generated from Ackerman geometry and the actual steer angle. In ADAMS, the Ackerman error for the inside wheel is zero because inside wheel is used for the turn center calculation. Positive Ackerman error indicates that the steer angle is greater comparing to ideal steer angle. The

Ackerman angle is using a key role especially on larger steer angles (Mitchell, Staniforth, and Scott 2006). The results show considerably good correlation with large steer angles despite poor correlation on lower angles.

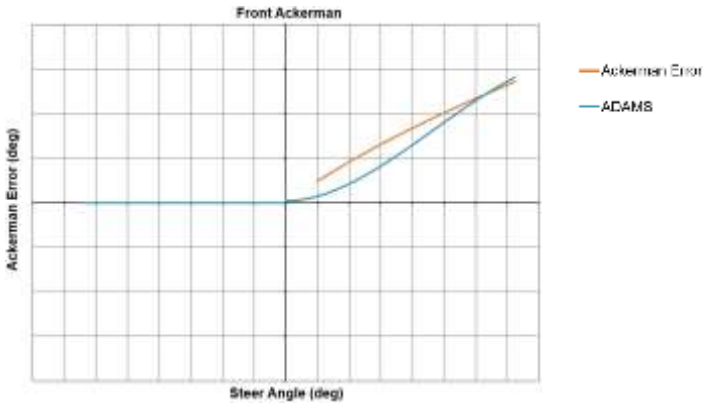

Figure 6. Ackerman Error

4. CONCLUSIONS

In this paper main selected steering kinematics is presented with a comparison of Adams multi-body model of a complete front McPherson suspension and the results obtained from K&C test machine. In general, the correlation of the virtual and physical results is satisfactory. This helps to try new settings virtually and get the results without further physical testing, therefore reducing the development time and costs.

ABSTRACT

Modeling and system optimization of electric vehicle battery system with high sensitivity enables vehicle producers to design more long runner electric vehicles on the roads. Artificial Intelligence is one of the potential for Automotive technologies which also enables the system modeling more precise, clear and time and cost saving instead making experimental test load. In parallel, Artificial Neural Network (ANN) is the potential concept to consolidate with dynamic systems to make more precise parameter assumption with the support of wide experienced data pool. In this study, the electric vehicle powertrain system is modeled as 1-D and battery State of Charge (SoC) status are observed based on system inputs. After that, the modeled battery system is subjected to Design of Experiment (DOE) study using Latin Hypercube distribution which enables to have system behavior data in wide range which provides the data pool for ANN model. Obtained data pool from DOE including the vehicle weight, roll friction coefficient and wind speed effecting SoC behavior is modeled with ANN structure in Python language. Trained ANN model, also called 'Digital Twin' of the system, is used to estimate battery SoC status in modeled electric powertrain system. According to results of the performed methodology, ANN adaptation considerably approaches to estimate best SoC status within acceptable limits for the battery. This methodology creates opportunity to estimate realized system model results in design phase instead to making too much several experimental study causing time and cost consuming.

Keywords: Electric Vehicle, Electric Vehicle Battery System, State of Charge (SoC), Artificial Neural Network, Digital Twin, Latin Hypercube distribution

1. INTRODUCTION

Nowadays electric vehicle technology considerably focuses on battery storage systems and increasing battery life in electric vehicles. Battery management in electric vehicles has high importance to provide both optimized electric consuming and safe driving. Increased battery life and balanced 'Depth of Discharged' (DoD) are set the desired system design of 'State of Charge' (SoC) status of an electric vehicle. SoC explains the instant situation of the battery in terms of percentage in the running vehicle. SoC is affected by the key parameters of the vehicle directly based on different impact levels and managed by 'Battery Management System' (BMS). Figure 1 explains the modeled electric vehicle powertrain main sections as electrical and mechanical system sections.

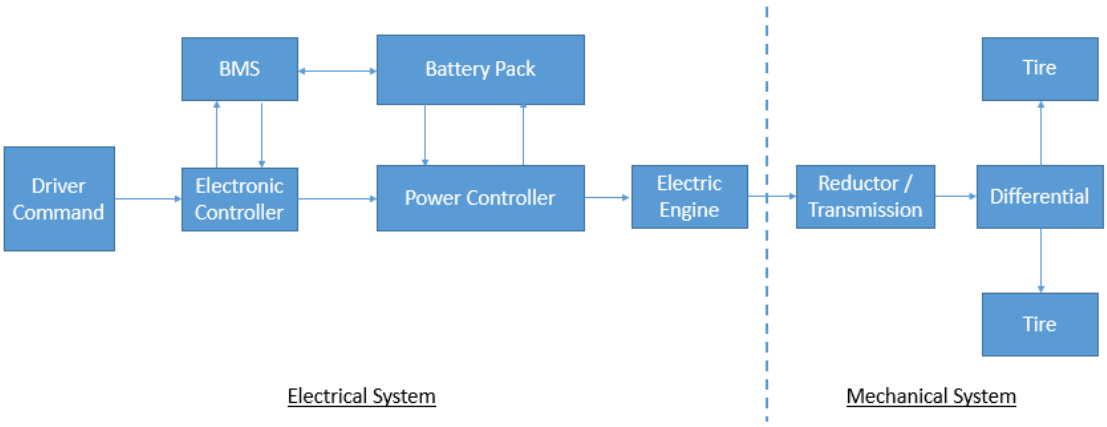

Figure 1. Powertrain System in the Electric Vehicle Analysed in the Study

Artificial Neural Network (ANN) represents the biological brain by making interacting with each artificial neurons and transmit the signals to the other in the physical models. In general, the information flow between the neurons can be provided just the signal can exceed the threshold value. Figure 2 shows the classical ANN model consists of; Input, Hidden and Output layers. Hidden layers represent the non-linear transformation section that strength the model consistency for the input values. Hidden layers strength the model estimation in case the more non-linear data exist in the pool.

Recently Artificial Intelligence (AI) studies have started to take place in engineering problem solving area both in system or design point of views. Artificial Neural Network models have one of the major possible area that representing the physical model of the real system. Nowadays 'Digital Twin' concept is leading virtual representative method for engineering systems that provides to make predict in behalf of the model behavior. ANN modeling is one of the methodology to create 'Digital Twin' for the physical models and provide physical prediction without using either real model or physical model so called 1-D model.

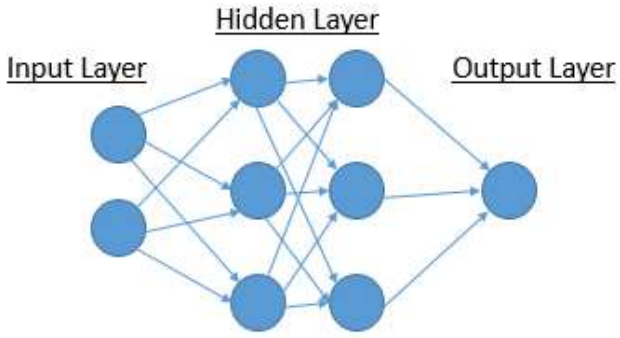

Figure 2. Information Flow in ANN

Figure 3 explains the methodology followed in this study. The electric vehicle powertrain system was first modeled via 1-D model library by indicating the key parameters in BMS by using LMS AMESim. As next step, the system model was defined with parameter tolerances, and totally 100 experimental set was defined by using Latin Hypercube method in order to have more sensitive distribution that provides precise input for ANN model. As next step, the obtained results from 1-D model was transferred to ANN model, so that the model predict the estimated battery SoC based on the input data. This methodology enables to eliminate too many real vehicle testing and 1-D modeling by using 'Digital Twin' that making model predicting.

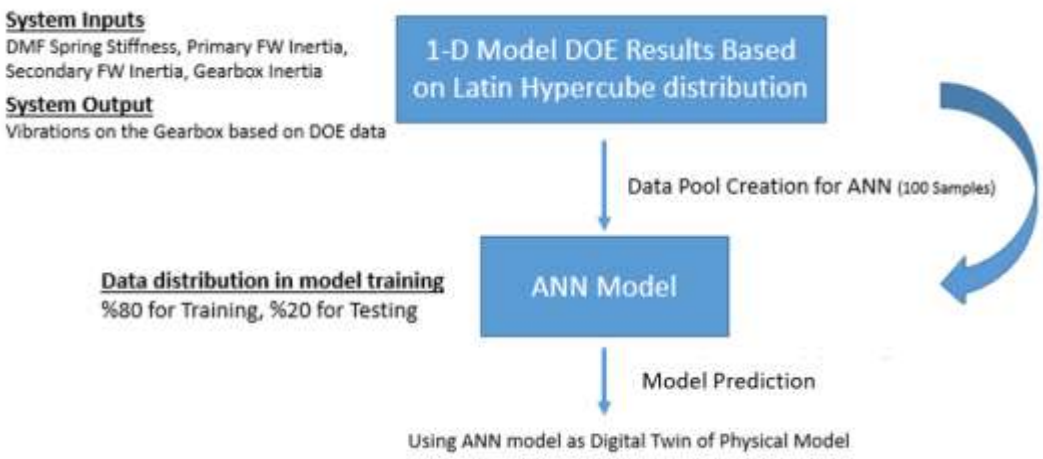

Figure 3. General Flow Followed in the Study

2. VIRTUAL MODELING

This section explains the virtual modeling study of the real product. Virtual model, also called physical model, was created as 1-D model in AMESim programme. Figure 4 shows the modeled powertrain system. In this study, as system parameter totally 3 different values were taken into account. These parameters are in order; Vehicle total weight (tonne), Rolling friction coefficient and Wind speed (m/sn).

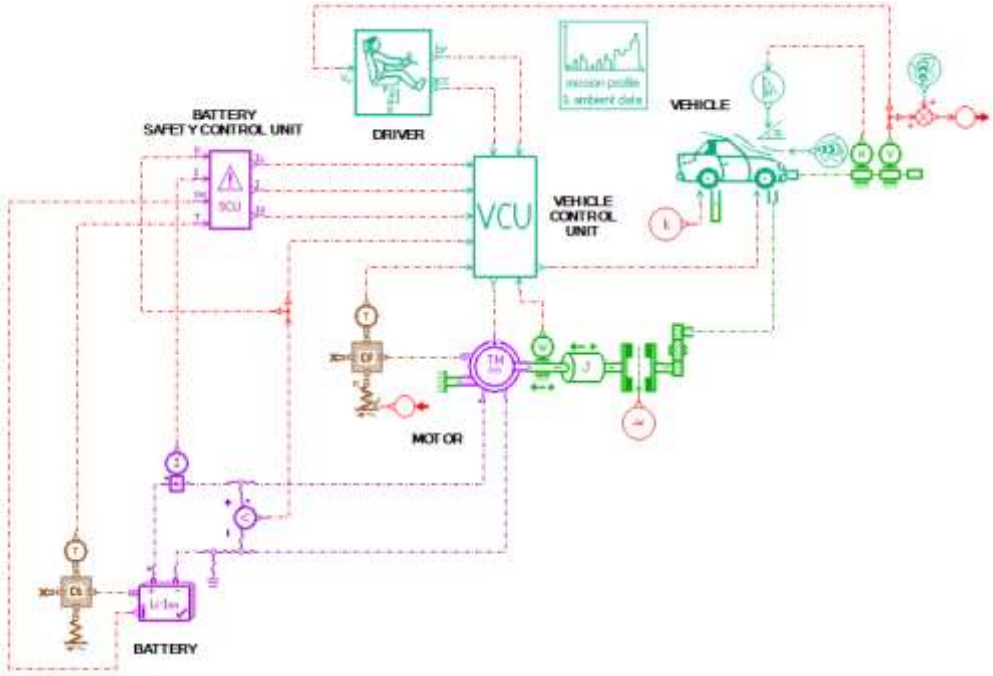

Figure 4. AMESim 1-D Model with DMF

Based on the input data (vehicle weight, rolling friction coefficient, wind speed), the output was defined as battery State of Charge (SoC) reading by Battery Management System (BMS). Figure 5 shows the main tasks and functions of the BMS. State of Charge (SoC) prediction has high importance on for drivers to estimate milage capacity. This sensitivity and importance SoC composed the motivation during this study by using ANN model prediction. Table 1 shows the parameters within the tolerance values of key parameters.

3. ARTIFICIAL NEURAL NETWORK MODELING

3.1. Digital Twin Concept

Digital twin represents the virtual twin of a physical model and can allow the make prediction based on the real or virtual model. In this study, in order to create base information data for 'Digital Twin', the virtual model was modeled as 1-D and DOE (Design of Experiment) study was performed by using Latin Hypercube distribution methodology. Figure 6 explains the 'Digital Twin' concept by comparable with real and virtual systems.

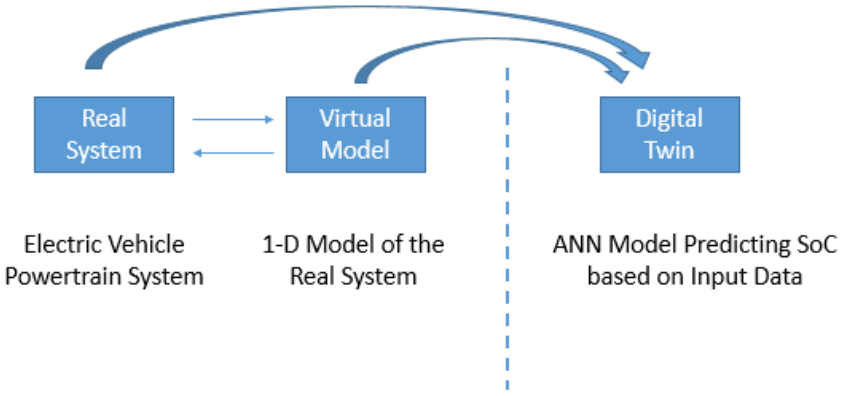

Figure 6. Digital Twin Concept Followed in the Study

3.2. ANN Modeling

In this section the ANN modeling study is introduced and explained. Figure 7a shows the DOE data used in 1-D modeling as representative for first and last five values within the 100 samples. Figure 7b indicates Latin Hypercube distribution coefficients as sample for first and last five values as the base coefficients of the value in 6a. These data were sent to ANN model and enabled the model to get read it via 'Pandas' module.

Figure 8 shows the ANN model flow performed in the study. The obtained DOE results coming from the 1-D modeling first are being read by the model, than the model is randomly splitted into two groups. First group is used for training , and covers the 80% of the data. The remain 20% of are used for testing the performance of the trained data. Afterwards, the layer definition for the Artificial Neurons (AN) is done including hidden layers according to expected performance from the model. As next step, the optimizer and loss method definition take place. 'Adam' optimization methodology and 'Mean Squared Error' are selected, after that the model fit is provided and tested to provide model prediction at last step.

Figure 9. Coded Main ANN Model for the Study

Table 2 explains the random try-out results for the defined model. In the table randomly selected three test sets are shown. After the random points are defined and found, the results are compared with the 1-D model. According to results predicted by ANN model and found by 1-D model, in average the results are found around 1.53% deviation.

This deviation ratio can be considered in model predicting because the vibration of the vehicle is distributed non-linear during the operation ranges in the vehicle.

Table 2. Trained ANN Model Random Results vs. Comparison with 1-D Modeling

	System Parameters	Value	ANN Results (SoC)	1-D Results (SoC)	Deviation (%)
1st Random Trial	Vehicle Weight (tonne)	0.965	86.10	87.24	%1.3
	Rolling Friction Coefficient	0.0234

	Rolling Friction Coefficient	0.0102			
	Wind Speed (m/sn)	0.15			
3rd Random Trial	Vehicle Weight (tonne)	1.355	81.88	80.65	%1.5
	Rolling Friction Coefficient	0.0458			
	Wind Speed (m/sn)	18.75			

5. CONCLUSION

This study makes the innovative approach to battery SoC parameter estimation by using ANN model, also represents the 'Digital Twin Concept'. The physical model of the electric vehicle powertrain system, also called virtual model, first set and run with DOE methodology based on Latin Hypercube distrubiton. Obtained data pool sent to ANN model to provide model predicting in battery SoC has major importance on for drivers to estimate milage capacity, and predicting based on the system data provides the more consistency in engineering phases. According to model results, the SoC values are predicted around with 1.53% deviation. This results can be acceptable to make model prediction and considered as 'Digital Twin' of the physical model in electric vehicle engineering.

İKİZ KARDAN MAFSALLI KARDAN MİLLERİNDE SAPMA AÇISININ HIZ DÜZGÜNSÜZLÜĞÜNE ETKİSİ

[1]Turan Solmaz, [2]Mert Can Kahyalar, [3]Muzaffer Kasaba

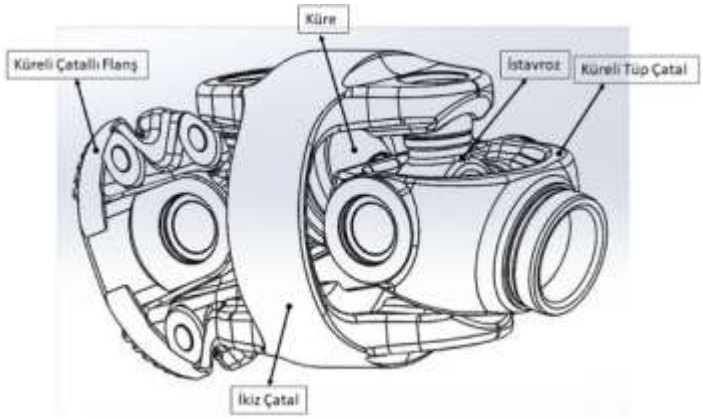
ÖZET

Kardan millerinin açısal hareketi, üzerinde bulunan mafsal grubu ile sağlanır. Universal mafsalın değişken açılar altındaki dönme hareketi nedeniyle kardan milindeki giriş ve çıkış hızları arasında bir fark ortaya çıkmaktadır. Bu fark teoride hız düzgünsüzlüğü olarak tanımlanmıştır. Yüksek hız düzgünsüzlüğünün yayında yüksek mafsal açılarına ihtiyaç duyulduğu durumlarda da ikiz kardan mafsalı kullanılmaktadır. Hız düzgünsüzlüğünün minimuma indirilebilmesi adına ikiz kardan mafsalının optimum çalışma açısının belirlenmesi çok önemlidir. Bu çalışmada küre merkezlemeli ikiz kardan milinin tasarımını gerçekleştirirken, hız düzgünsüzlüğünün minimum olduğu optimum çalışma açıları teorik ve sanal ortamda belirlenmiştir.

1.GİRİŞ

Kardan milleri kullanım yerleri ve fonksiyonel beklentileri göz önüne alındığında, farklı mafsal bağlantıları içermektedir. Mafsal bağlantılarına göre kullanım açısından ilk sırada gelen universal mafsallı kardan milleridir. Universal mafsal araç koşullarına bağlı açısal hareket sergilemekte ve bu sayede kardan milinin değişken yol koşullarına uyum sağlamasını sağlamaktadır. Ancak universal mafsalın değişken açılar altındaki dönme hareketi nedeniyle kardan milindeki giriş ve çıkış hızları arasında bir fark ortaya çıkmaktadır. Hız düzgünsüzlüğü olarak da anılan bu fark, bir diğer mafsal türü olan merkezlemeli küre yatağına sahip ikiz mafsallarda belirli bir açı aralığında çalışmak koşulu ile oldukça düşük seviyededir. Bu tür kardan milleri, içerdiği mafsaldan dolayı ikiz kardan mili olarak anılmaktadır. Şekil 1'de küreli ikiz kardan mili sistemi ve parçaları gösterilmiştir. İkiz kardan milleri son zamanlarda otomotiv sanayi gündeminden düşmeyen, artış trendi yakalayan elektrikli araçlarda ve bunun yanı sıra sektör ve literatürde mobile off-highway (MOH) olarak anılan kazıcı-yükleyici gibi yol dışı araçlarda kullanım alanı bularak yaygınlaşmaya devam etmektedir.



Şekil 1. Küreli ikiz kardan mili sistemi ve parçaları

Özen Işık tez çalışmasında kardan mili mafsallarında açı artışına bağlı olarak hız dalgalanmalarını incelemiştir. Bu dalgalanmaları çözmek adına MATLAB ode23s ve Newmark metodu olmak üzere iki farklı metot kullanmıştır. Newmark ve ode23s metotları kullanılarak giriş, orta ve çıkış şaftları için burulma açıları ve açısal hızlar hesaplanmıştır. Buna ek olarak, sisteme girdi olan değerler değiştirilerek etkileri incelenmiştir. 25º'den daha fazla açı

gerektiren uygulamalar için ikiz kardan mafsallı miller kullanılabilir. Bu sayede açı 47º'ye kadar çıkarılabilir ortaya koymuştur (Işık, 2019).

I. S. Fischer ve arkadaşları çalışmasında, çift kardan eklemin hız oranlarını hem analitik hem de deneysel olarak inceledi. Bağıl faz açısının, çift kardan milinin giriş çıkış yer değiştirme ilişkisini etkileyen en önemli değişken olduğunu bulmuşlardır.

Bağıl faz açısı şu şekilde tanımlanır: İki düzlemi ele alırsak, biri giriş ve ara millerin oluşturduğu düzlem, diğeri ise çıkış ve ara millerin oluşturduğu düzlemdir. Bu iki düzlem arasındaki açıya bükülme açısı denir. Faz açısı, ara miller üzerindeki iki kulak arasındaki açıdır. Bağıl faz açısı, faz açısı ile bükülme açısı arasındaki farktır. Fischer ve Paul, iki mafsalın mafsal açıları eşit olduğunda ve bağıl faz açısı sıfıra ayarlandığında girdi ve çıktı yer değiştirmelerindeki dalgalanmaların ortadan kalktığı sonucuna varmıştır. İki mafsal açısı eşit olmadığında bazı dalgalanmalar olacaktır. Bununla birlikte, bağıl faz açısı sıfır olduğunda dalgalanma en aza indirilir sonucuna varmıştır. (Fischer ve Paul,1991)

Jussi Sopanen Bu çalışmada, ikiz mafsallı kardan millerinin iki modeli sunulmuştur. Basit bir analitik model, çok gövdeli bir dinamik formülizasyon kullanılarak türetilir. Ticari birçok gövdeli dinamik yazılım uygulamasında uygulanan başka bir model, kardan mafsallarındaki taşıma kuvvetlerinin doğrusal olmayan tanımlarını içerir. Her ikisi de ara şaftın esnekliğinin açıklamalarını içerir. Bu modeller, sabit mıknatıslı senkron elektrik motoru (PMSM) ile bir simülasyonda kullanılır. Aktarma organlarının dinamiklerini etkileyen mekanik ve elektriksel ideal olmayanlar incelenir. Modellenen ideal olmayanlar arasında eşit olmayan eklem açıları, kardan mafsallarının yanlış fazlanması, yatak boşluğu ve elektrik motorundaki akım ölçüm hatası yer alır. İki kardan mili modelinden elde edilen sonuçlar karşılaştırılır ve iyi bir uyum elde edilir. Sonuçlar, elektrik motorunun mekanik ideal olmayanların neden olduğu iletim hatasını düzeltmeye çalıştığını göstermektedir. Bu da dalgalanan torka ve istenmeyen dinamik yüklere yol açar (Sopanen,2003).

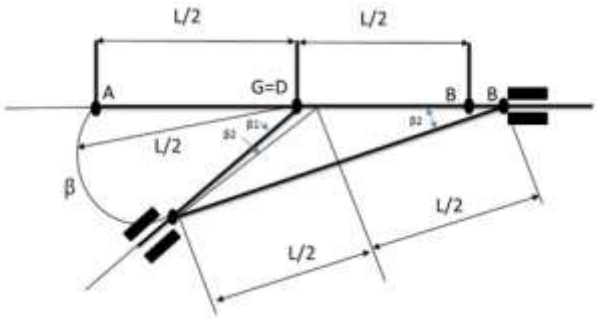
Bu çalışmada küre merkezlemeli ikiz kardan milinin tasarımını gerçekleştirirken, hız düzgünsüzlüğünün minimum olduğu optimum çalışma açıları teorik ve sanal ortamda belirlenmiştir.

2.TEORİ

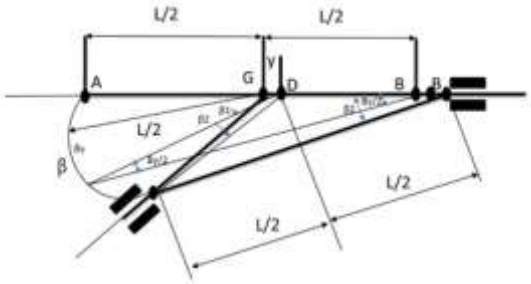
Prensip olarak ara mil kullanılmadan iki kardan mafsalının sırt sırta Genelde yön verilebilen aksların yani ön aksların tahrikinde kullanılır. İkiz kardan mafsalları ile 47° kadar bir sapma açısına ulaşılabilir. β eğim açısı altında çalışırken bu mafsalda birbirine eşit olmayan β_1 ve β_2 açıları oluşur ve hareket düzgünsüzlüğü ortaya çıkar. Bu kesişme noktasının (M noktası) sabit yatak tarafına y kadar kaydırılması ile düzgünsüzlük giderilmiş olur.

Fark açısı $\Delta\beta = \beta_1 - \beta_2$ büyüklüğü ve düzgünsüzlük derecesinin belirli bir sınırda tutulabilmesi, ancak mafsal ortasının dönme ekseni ortasının tersi yönde y değeri kadar sabit mil tarafına doğru yer değiştirmesi ile mümkündür. Düzgün hareket iletimi için gerekli olan y değerinin büyüklüğü L mesafesine, seçilen bir sapma açısı β_Y değerine bağlıdır: (SAE,1971)

Şekil 2. İkiz Kardan Mafsalında sapma açısı



Şekil 3. İkiz Kardan Mafsalı hız düzgünsüzlüğü hatası



Şekil 4. İkiz Kardan Mafsalı hız düzgünsüzlüğü hatasının giderilmesi

$$y = \frac{L}{2}\ x\ \left(\frac{1}{\cos\frac{\beta_y}{2}} - 1\right) \tag{1}$$

$$x = L\ x\ \left(\frac{\sin\left(90+\beta-\sin^{-1}\frac{\sin\beta}{2\ x\ \cos\frac{\beta_y}{2}}\right)}{\frac{\cos\beta}{2}}\right) \tag{2}$$

Amaca uygun olarak β 1 = β 2 olduğu eşdeğer bir sapma açısı β_y = 35° seçilebilir.

Mil yataklarının boyutlandırılmasında bu periyodik kuvvet ve momentlerin dikkate alınması gerekmektedir. Bunların maksimum değerleri aşağıdaki eşitliklerden hesaplanabilir:

$$F = \frac{2\ x\ M_{d\ max}\ x\ \sin\left(\frac{\beta}{2}\right)}{L} \tag{3}$$

$$B = \frac{F\ x\ (a+b)}{b} \tag{4}$$

$$C = \frac{F\ x\ a}{b} \tag{5}$$

$$f_1 = \frac{F\ x\ a\ x\ b^2}{9\ x\sqrt{3}\ x\ E\ x\ J} \tag{6}$$

$$\tan\alpha_B = \frac{F\ x\ a\ x\ b}{3\ x\ E\ x\ J} \tag{7}$$

İkiz kardan mafsalının seçimi gene motor momenti dağılımı ve diferansiyel ve dişli kutusu maksimum çevrim oranına göre yapılır. Tutunma momenti yükünden gelen zorlamanın kontrolünde aks yükü, lastik yarıçapı, yol-tekerlek arası tutunma sürtünme katsayısı ve duruma göre tekerlek istemindeki çevrim oranına bağlıdır:

Motordan tekerleklere iletilen kalkış momenti M_1 :

$$M_1 = M_{dmax}\, x\, i_1\, x\, i_{T1}\, x\, i_D\, x\, \eta_G\, x\, \frac{1}{1+v} \qquad (8)$$

Yol-Tekerlek arasındaki tutunma momenti M_F :

$$M_F = G_A\, x\, R_{Stat}\, x\, \mu_G\, x\, \frac{1}{1+v}\, x\, \eta_D \qquad (9)$$

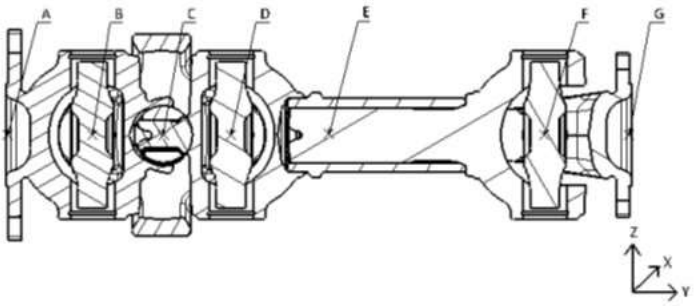
Md max Maksimum motor momentini
RStat Tekerlek statik yarıçapını,
GA Aks yükünü,
μ Yol-Tekerlek arası tutunma sürtünme katsayısını,
i1 1. vites çevrim oranını,
iT1 Transfer kutusu yavaş kademesi çevrim oranını,
iD Diferansiyel çevrim oranını
v Motor momenti dağılım oranını MÖA/MAA ve
η G , η D Genel iletim ve diferansiyel verimini ifade etmektedir.

3.ANALİZ

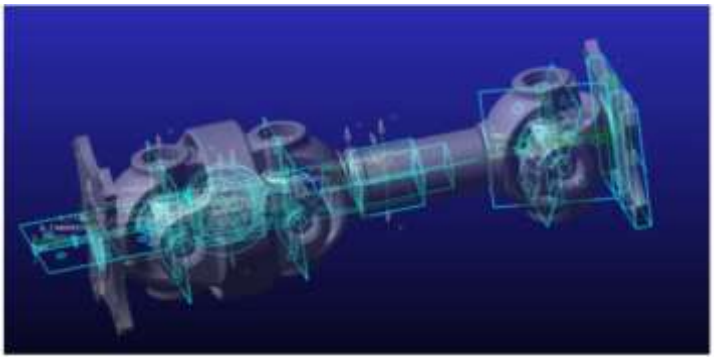
Analiz çalışmaları Adams View yazılımı ile yapılmıştır. Bu yazılımda yapılabilmesi için kardan mili Şekil 5'teki gibi modellenmiştir.

Şekil 5. İkiz kardan mili üç boyutlu modeli

Adams View'de hareketleri tanımlayacağımız mafsal tanımlayabilmek için şekil 6'daki mafsal noktaları belirlenmiştir. Tanımlanan bu noktalara döner mafsal, küresel mafsal, silindirik mafsal, primatik mafsal ve eş düzlemli mafsal tanımlanmıştır. ADAMS modeli şekil 7 de görüleceği üzere hazırlanmıştır.

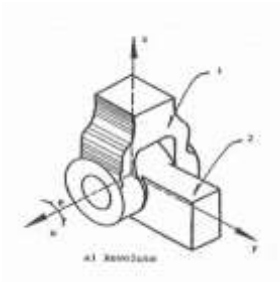


Şekil 6. İkiz kardan mili mafsal noktaları



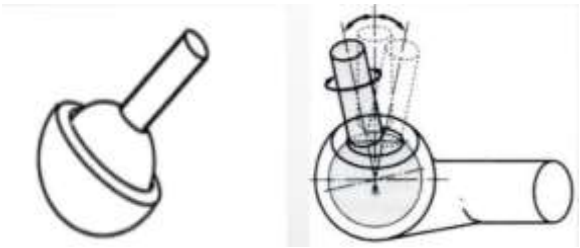
Şekil 7. İkiz kardan mafsalı ADAMS View modeli

A,B,D,F noktasına ‘’revolute jonit’’ (Döner mafsal) tanımlanmıştır. Döner mafsal, İki eş eleman birbirine göre bir eksen etrafında döner. Hareketin miktarı mafsal geometrisine göre sınırlandırılır. Bu mafsala Şekil 8’deki gibi, menteşe ya da pim mafsalı da denir. (Söylemez,2007)



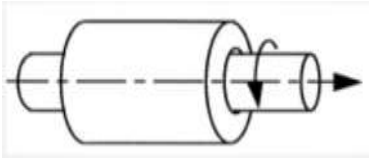
Şekil 8. Döner mafsal

C noktasıda Şekil 9’da görüleceği gibi ‘’Spherical joint’’ (Küresel Mafsal) tanımlanmıştır. Küresel mafsal Bir kürenin ekseni etrafında bir elemanın diğerine göre serbestçe dönmesini sağlar. Eş elemanlar arasında bir öteleme ve ilerleme hareketinin olmadığı bir “bilya-yuva” mafsalıdır. (Söylemez,2007)



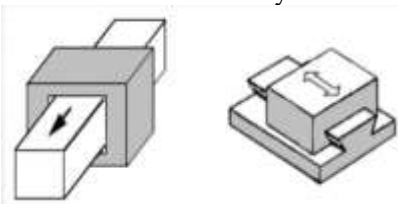
Şekil 9. Küresel mafsal

Aynı zamanda C noktasına Şekil 10'da görüleceği gibi '' cylindrical joint'' (Silindirik Mafsal) tanımlanmıştır. Bir eksen etrafında dönme ve bu eksen boyunca bir kaymaya izin verir. Bu yüzden iki serbestlik derecesi vardır. Silindirik mafsal, eksenleri paralel hem prizmatik hem de döner. (Söylemez,2007)



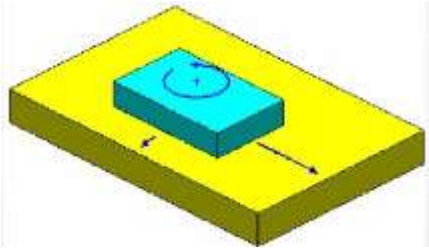
Şekil 10. Silindirik mafsal

E noktasına Şekil 11'deki görüleceği gibi ''translational joint''(prizmatik mafsal) tanımlanmıştır. Prizmatik mafsal, İki eş eleman, mafsal geometrisine bağlı olarak belirlenen bir eksen boyunca birbirine göre kayar. (Söylemez,2007)



Şekil 11. Prizmatik mafsal

G noktasına Şekil 12'de görüleceği gibi ''planer joint'' (eşli düzlem mafsal) tanımlanmıştır. Eşli düzlem mafsalı Bir düzlem üzerinde iki öteleme hareketi ve bu düzleme normal bir eksen etrafında bir dönme hareketine izin verir. (Söylemez,2007)



Şekil 12. Eşli düzlem mafsalı

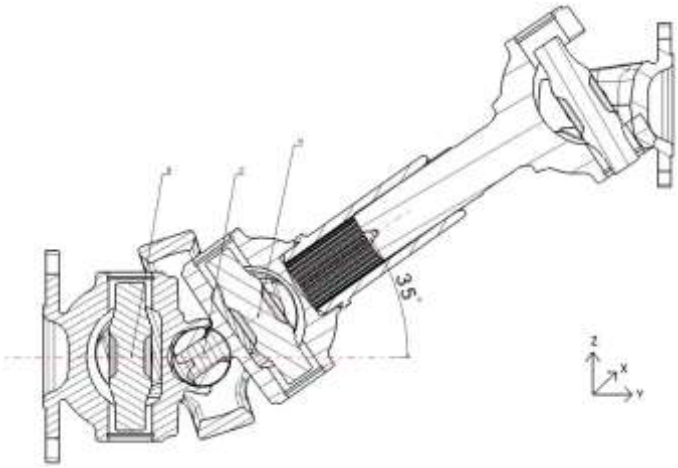
Kardan milinin dönme ekseni doğrultusunda, A noktasındaki döner mafsala aşağıdaki Şekil 13'deki gibi sabit 91deg/sec hız tanımlanmıştır.

Şekil 13. Modele uygulanan açısal hız

G noktasında bulunan eşli düzlem mafsala şekil 6'da görülen global koordinatlara göre X ve Y doğrultusundaki, doğrusal hareketi için sınır koşulu uygulanmıştır. Z doğrultusunda ise tablo 1'deki gibi zamana bağlı olarak deplasman girdisi verilmiştir. Analiz sonucunda kardan mili şekil 14'deki konuma ulaşmıştır.

Tablo 1. Zamana Bağlı Olarak Deplasman Girdisi

Zaman (sn)	Deplasman (mm)
0	0
40	40
80	80
120	120
160	160
200	200

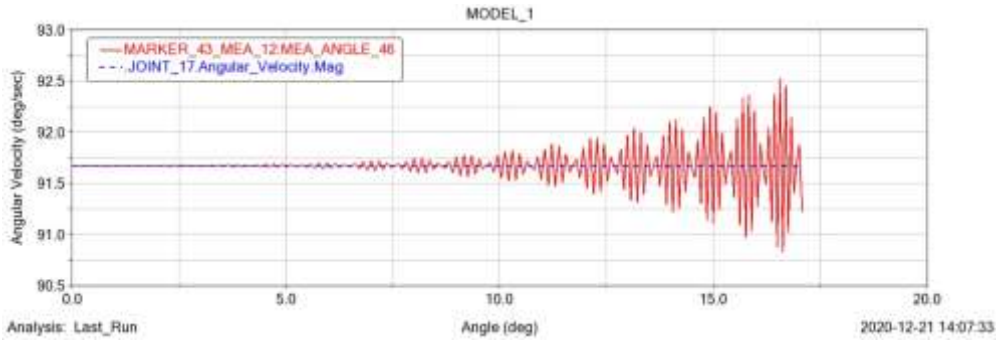


Şekil 14. İkiz kardan milinin hız düzgünsüzlüğünün minimum olduğu sapma açısı

4.SONUÇ VE TARTIŞMA

Yapılan çalışma sonucunda;

- İkiz kardan mafsalının hız düzgünsüzlüğünün görüldüğü minimum sapma açısı teorik yöntemlerle 35º olarak hesaplanmıştır.
- Teorik yöntemlerimizi doğrulamak amacıyla model sanal ortamda oluşturulmuş sapma açısı – açısal hız grafiği şekil 15'deki gibi oluşturulmuştur.



Şekil 15. Sapma açısın yarısı (β/2) – Açısal hız Grafiği

- Grafiğe göre sanal ortamda hız düzgünsüzlüğünün görülmediği maksimum sapma açısının yarısı(β/2) 17,5° sapma açısı (β) da 35° olduğu tespit edilmiştir.
- Teorik ve sanal ortamda yapılan çalışmalar sonucu göz önüne alındığında kurulan modelin doğru olduğu öngörülmüştür.
- Çalışmanın devamı için teorik ve sanal ortamda hesaplanan hız düzgünsüzlüğünü doğrulamak amacı ile test çalışmaları gerçekleştirilip sonuçlar karşılaştırılacaktır.

RESEARCH OF BULKHEAD PRODUCTS FOR CUSTOMER SATISFACTION

Hakan Kayserili, Serdar Müminoğlu

TOFAŞ Türk Otomobil Fabrikası A.Ş., Arge Merkezi,Bursa, Türkiye
Hakan Kayserili , hakan.kayserili@tofas.com.tr

ABSTRACT

It is very important to know the customer's needs and demands before starting the design of product. It is focused on Bulkhead, the part that is positioned between the cargo area and passenger zone in the commercial vehicle. The first purpose of bulkhead, it can be minimized the risks of injury and loss of life to the driver and passengers by the load coming from the luggage compartment of the vehicle to the front cabin in case of an accident. Currently, there are many types of Bulkhead that are used in light commercial vehicles. It can be classified these bulkheads in two groups. They are full closed bulkhead and partially closed bulkhead. What a customer needs and understanding of satisfaction is important for the design of a Bulkhead. In this study, it has been used Kano model as the analysis method. Thus, it can be successfully realizing the optimum product design according to customer needs. This study was carried out with drivers who have light commercial vehicles in Bursa City. In addition to the security requirements for the bulkhead, the customer was questioned about the internal sound level, aesthetics, extra functions for load volume, quality problems, prefer which type of bulkhead and ease of use. Our company tends to give priority to customer satisfaction in the vehicles it produces. This paper shows, what are the effects of Bulkhead for driver about satisfaction or dissatisfaction.

Keywords: Bulkhead, Kano model, Customer satisfaction, Bulkheads of commercial vehicle

ÖZET

Ürün tasarımına başlamadan önce müşterinin ihtiyaç ve taleplerini bilmek çok önemlidir. Ticari araçtaki kargo alanı ile yolcu bölgesi arasında yer alan ara bölmeye odaklanılmıştır. Ara bölmenin ilk amacı, bir kaza durumunda aracın bagaj bölümünden ön kabine gelen yük ile sürücü ve yolcular için yaralanma ve can kaybı riskini en aza indirebilmektir. Şu anda, hafif ticari araçlarda kullanılan birçok ara bölme çeşidi vardır. Bu ara bölmeleri genel olarak iki gruba ayırabiliriz. Komple kapalı ara bölmeler ve kısmen kapalı ara bölmelerdir. Bir ara bölmenin tasarımı için müşterinin ihtiyaçları ve memnuniyet anlayışı önemlidir. Bu çalışmada analiz yöntemi olarak Kano modeli kullanılmıştır. Böylece müşteri ihtiyaçlarına göre optimum ürün tasarımını başarıyla gerçekleştirebilme amaçlanmıştır. Bu çalışma, Bursa şehrinde hafif ticari araçlara sahip sürücülerle gerçekleştirilmiştir. Ara bölme için güvenlik gerekliliklerine ek olarak, araç iç ses seviyesi, estetik, yük hacmi için ekstra fonksiyonlar, kalite sorunları, ara bölme türü ve kullanım kolaylığı gibi tercihleri sorgulandı. Firmamız ürettiği araçlarda müşteri memnuniyetini ön planda tutmaktadır.

Bu makale hafif ticari araçlardaki ara bölmenin sürücü için memnuniyet veya memnuniyetsizlik üzerindeki etkilerini göstermektedir.

Anahtar Kelimeler: Ara bölme, kano modeli, müşteri memnuniyeti, ticari araçlarda ara bölme

1. GİRİŞ

Otomotiv sanayisinde firmalar arasındaki rekabet her geçen gün üst seviyelere çıkmaktadır. Rekabetten sıyrılabilmek için ürünlerin geliştirilmesinde müşterilerin memnuniyeti daha fazla önem kazanmaktadır. Tüm bunlar göz önünde bulundurulduğunda, işletmelerin global otomotiv dünyasında rekabetçi kalabilmesi için müşterilerin ihtiyaçları belirlemeli ve belirlenen ihtiyaçlar ürün tasarlama aşamasında dikkate alınmalıdır.

Günümüzde müşterilerin isteklerine önem verip kaliteyi optimum fiyatlarda sunan firmalar rekabette avantaj sağlayabilmektedir. Aksi durumda müşteriler tarafından tercih edilmeleri azalacaktır.

Tüm bu sebeplerlerden dolayı Dr.Noriaki Kano, müşteri ihtiyaçlarını anlamak ve önceliklerini belirleme adına yeni bir model geliştirmiştir [1].

Müşteri memnuniyetini belirlemek için kullanılan Kano modeli pek çok sanayi alanında bilinilmemektedir. Kano modelini bilen işletmeler de sınırlı seviyelerde kullanmaktadır. Kano modeli, bir ürün ya da hizmet için müşteri taleplerinin müşteri memnuniyetine farklı oranlarda katkıda bulunacağı varsayımına dayanarak,farklı demografik yapıya sahip müşteri taleplerini detaylı katagoriler içerisinde sınıflandırarak müşteri memnuniyeti ile ürün kalite performansı düzeyi arasındaki ilgiliyi ortaya koyan analiz yöntemidir [2].

Türkiye piyasasında Otomotiv Distribütör Derneği (ODD) raporuna göre 2019 yılı hafif ticari araç satış adeti 91804 tür. Bu araçların yaklaşık % 20 si arabölmeli araç kullanan müşterilerden oluşmaktadır. Diğer ticari araç kullanan müşterilere göre ara bölmeli araç kullanan müşterilerin ihtiyaçlarını arabölme tipleri belirlemektedir. Otomotiv firmaları farklı amaçlar ile alınacak olan bu araçların arabölmelerini tüm müşterilerin gereksimlerini karşılayacak şekilde tasarlanması durumunda rakiplerine karşı kendilerini daha ayrıcalıklı hale getirecektir. Bu makale de Kano modelini kullanarak ara bölmeli hafif ticari aracı olan müşterilerin ihtiyaçları yönünde ara bölme konseptleri belirlenecektir.

Uygulamanın birinci bölümünde Kano modele uygun olan arabölme hakkında olumlu ve olumsuz yönde 29 adet anket sorusu belirlenmiştir. İkinci bölümünde uygun deneklere Kano model tanıtılmış, anket soruları cevaplandırılmış ve yapılan anketlerin sonuçları Kano modeli formülasyonuna göre değerlendirilmiştir. Üçüncü bölümünde ise sonuçlardan bahsedilmiştir.

2. METHOD

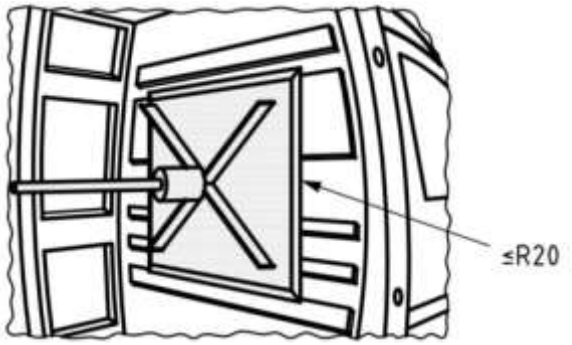
2.1. Hafif Ticari Araçlarda Ara Bölme

Aracın yük taşıma ve yolcu taşıma bölümlerini birbirinden ayıran ara bölmenin karşılaması gereken temel fonksiyonu kaza anında aracın bagaj bölümünden ön kabine gelecek olan yükün sürücü ve yolculara vereceği yaralanma ve can kaybı risklerinin minimize edilmesini sağlamasıdır. Yapılacak olan tasarımın aracın satışa sunulacağı ülkelerde geçerli olan yasal normlara uygun olarak müşterinin güvenlik beklentilerini karşılamasına ilave olarak iç ses seviyesi, estetik beklentileri karşılaması, geri dönüşümlü malzeme kullanımı, araç üstü montaj kolaylığı ve satış sonrası taleplerinde de gerekli ihtiyaçları karşılayacağının garanti edilmesi gereklidir. Şirketimizde kullanılan ara bölmeler genel olarak Şekil 1'deki 2 ana sınıfa ayrılabilir.

Şekil 1. Ara Bölmenin sınıflandırılması

Ara bölme , güvenlik açısından ISO 27956 ve ECE R126 uluslararası standartlarına göre uygun olmalıdır. Bu Uluslararası Standartlar, yolcuları yükün hareket ederek yolcuya çarpmasından kaynaklanan yaralanmalara karşı korumak için minimum gereksinimleri ve test yöntemlerini belirtir. ISO 27956 göre araç gövdesine sabitlenmiş ara bölme , şekil 2'de gösterildiği gibi tip 1 pistonu kullanılarak test edilmektedir. Piston, ara bölme sisteminin merkezine (yüksekliğine ve genişliğine bağlı olarak) uygulanmaktadır.

Test kuvveti F, aşağıdaki denklem (1) kullanılarak hesaplanmalıdır. Bu test kuvveti, şekil 3' deki gibi ara bölme sistemi üzerinde uzunlamasına yönde yatay olarak etki etmektedir. Deney kuvveti 2 saniyeyi aşmadan mümkün olduğunca çabuk arttırılmalı ve 10 sn boyunca muhafaza edilmelidir.[3]



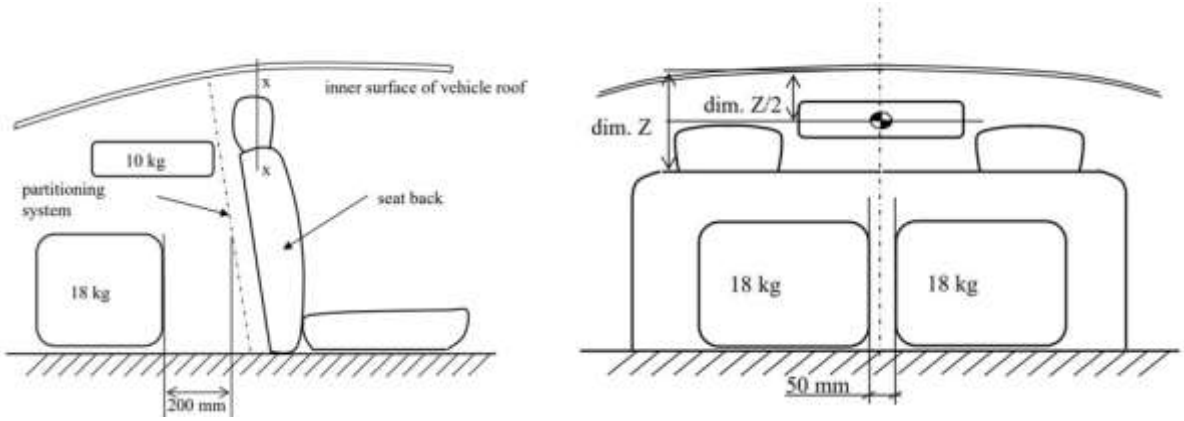
$$F = 0{,}5 \times m_p \times g \quad (1)$$

F Test kuvveti (N)

m_p Maksimum kargo yükü (kg)

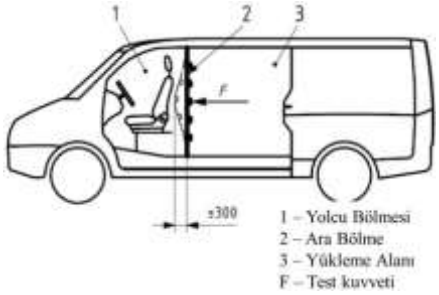
g Yerçekim ivmesi (9,81 m/s²).

Şekil 2. Tip 1 Piston



Şekil 3. Ara bölme test gösterimi

ECE R126 standardına göre araç gövdesine sabitlenmiş ara bölme, bagaj bölümündeki yüklerin ara bölmeye çarptırılmasıyla test edilmektedir. Bu testte iki adet 18 kg ve bir adet 10kg yüklerin Şekil 4'de gösterildiği gibi pozisyonlandıktan sonra bilgisayar kontrolünde olan bir piston üzerinden çarpışma sinyali iletilmektedir. Çarpışma sinyali neticesinde test edilen sistem kızak üzerinde hareket ederek belli bir miktar yol aldıktan sonra kendi ataleti ile durmaktadır. Test sonunda ara bölme bağlantılarında herhangi bir kopma olmamalı ve yolcu kabinine olan girişimin minimum seviyede olması istenmektedir. Maksimum girişim 300mm olması hedeflenmektedir. Bağlantı noktalarında negatiflik istenilmektedir.[4]



Şekil 4. Ara bölme ECE R126 test gösterimi

Ara bölmeye müşteri ihtiyacına göre güvenlik fonksiyonu dışında ilave özellikler eklenebilmektedir. Bu ilave fonksiyonu yerine getirebilmek için müşterinin ihtiyacını doğru anlayabilmek gerekmektedir. Örneğin kargo/van versiyonlu araçların yolcu koltuğunun kullanılmadığı zamanlarda daha uzun yük taşınmasına imkan sağlayan ara bölme Şekil 5'de görüldüğü gibi yapılmaktadır. Bunun için önce yolcu koltuğunun sırt kısmı öne doğru yük alanına paralel olacak şekilde katlanmaktadır. Sonrasında yolcu koltuğun arkasında olan ara bölmenin kilit mili yukarı kaldırılarak menteşe vasıtasıyla 90 derece şoför koltuğuna doğru açılmaktadır. Sonrasında ara bölmenin sabitlenmesi için kilit mili yolcu koltuğunun sırtlığındaki delik yuvasına yerleştirilmektedir.

Şekil 5. İlave Yük Hacmi Sağlayan Ara bölmeler

2.2. Kano Modeli

Kano model; 1984 yılında N. Kano ve arkadaşları tarafından geliştirilen müşteri ihtiyaçlarını kategorize etmek için kullanılan bir modeldir.

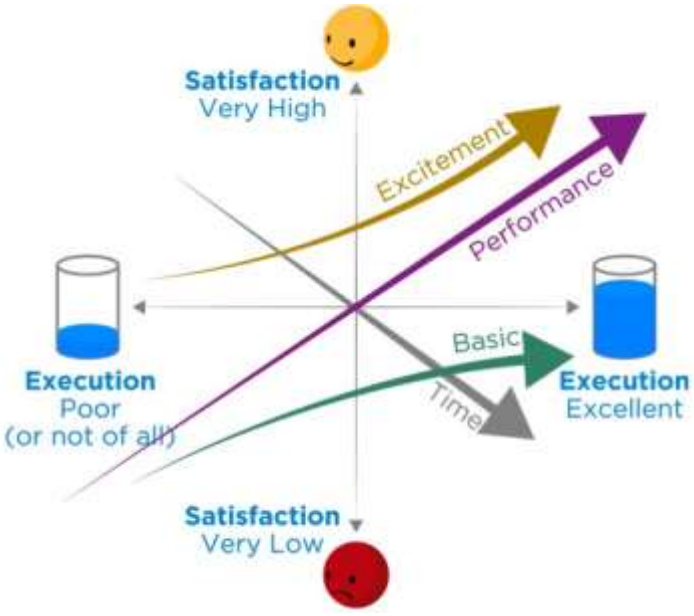
Kano modeli firmaların müşteri taleplerini yerine getirebilme derecesi ile müşterinin memnuniyeti arasındaki ilişkiyi kıyaslayarak sonuçları sunmaktadır. Kano modeli, müşterilerin bir kısmının ihtiyaçlarında küçük bir iyileşme gerçekleştirildiğinde müşteri memnuniyeti üst seviyelere çıkarken, diğer müşterilerin ihtiyaçlarında büyük bir iyileştirme yapılsa bile müşteri memnuniyeti seviyesinde neden yeteri kadar yükselme olmadığını raporlayan bir metottur.[5]

Kano modeli, müşteri gereksinimlerini, müşteri memnuniyetine olan etkileri temelinde üç temel sınıflandırmaya ayırmaktadır. Şekil 6'daki Kano Diyagramı, müşteri memnuniyeti derecesi ile müşteri gereksinimlerinin karşılanma seviyesi arasındaki bu üç tür (Temel, Beklenen ve Heyecan Verici) ilişkiyi ifade etmektedir [9]

Temel özellikler (M): Bu özellikler, müşterinin zaten üründen en basit halinde olmasını beklediği özelliklerdir. [6] Bu temel beklentilerin olması durumu müşteri memnuniyetini olumlu yönde arttırmaz ancak bu temel özellikleri azalması müşteri memnuniyetini olumsuz yönde ciddi bir şekilde etkileyecektir. [7] Örneğin, telefon konuşmasında karşıdan gelen sesin az olması müşteride memnuniyetsizliğe sebep olur, ancak telefon konuşmasında seslerin net gelmesi müşteri memnuniyetini artırmaz.

Beklenen özellikler (O): Müşterilerin ürün hakkında minimum beklentisini ne olduğunu anlatan özelliklerdir. Ürün performans değerinin minimum seviyesi olarakta açıklanır. Bu gerekler yerine getirildiğinde müşteri memnuniyetine, yerine getirilmediklerinde ise müşteride tatminsizlik yol açmaktadır. [5] Müşterilerin taleplerine göre ürünlerde geliştirmeler yapıldıkça müşteri memnuniyeti artmaktadır. Örneğin, bir arabanın frenlerinin iyi çalışması müşteri tarafından beklenen bir özelliktir.

Heyecan verici özellikler (A): Ürün özellikleri içinde olmadığı zaman müşteriler tarafından herhangi bir tatminsizliğine sebep olmayan , ancak ürün özellikleri arasında bulunduğunda da müşteriye üst seviye memnuniyet veren özelliklerdir. [7] Müşteri memnuniyeti ile ürünün performansı arasındaki bağ, yükselen bir ivmeyle ilerlemektedir. Ürünün performansı artarken müşteri memnuniyeti yüksek hızla artmaktadır. Bunun açıklaması ,ürün performansı müşteri memnuniyetini beklenilenin üzerinde sağlanmaktadır [8].



Şekil 6. Kano Diyagramı

Kano modelde yukarıdaki 3 maddenin haricinde ek olarak üç özellik sınıfı daha bulunmaktadır. Bu sınıfları açıklayacak olursak:

Sıradan özellikler (I): Müşteri tarafından elzem ihtiyacı olmayan özelliklerdir. Müşteri bu ürünün varlığından yada yokluğundan olumsuz etkilememektedir. Örneğin, sıradan bir akıllı telefonun kaleminin olması önemli bir özellik değildir[10].

Zıt özellikler (R): Müşteri tarafından talep edilen ürün özelliğinin olması durumunda bir başka özelliğinin olumsuz etkilenmesi durumudur.Müşteri, ürünün olumsuz etkilenen özelliğininde olumlu hale çevirilmesini istemektedir. [7] Örneğin, Büyük motor hacimli araçlara sahip olmak isteyen müşterilerin beklentisi, düşük motor hacimli araçlardaki gibi yakıt tasarruflu özelliğidir.

Şüpheli özellikler (Q): Bu özellikte soru doğru sorulmamış ya da müşteri soruyu iyi anlamamıştır.Bu yüzden mantıksız bir cevap verilmiştir.

Kano modelinde müşteri gereksinimlerinin ne olduğunu bulmak için konuyla alakalı anket hazırlanmalıdır.Ankette, konuyla alakalı biri olumlu ve diğeri olumsuz olan sorular olmalıdır. Örneğin , Arabada teyp olması sizi nasıl etkilemektedir, arabada teyp olmaması sizi nasıl etkilemektedir . Sorulan sorulara beş farklı yanıttan sadece biri verilmektedir. Cevaplar için beş seçenek verilmiştir.

1- Hoşlanırım
2- Öyle olmalı
3- Farketmez
4- Katlanabilir
5- Hoşlanmam

Tablo 1. Kano Modeli İçin Değerlendirme Tablosu

Müşteri İstekleri		**Olumsuz Soruya Verilen Cevaplar**				
		Hoşlanırım	Öyle Olmalı	Fark Etmez	Katlanabilirim	Hoşlanmam
Olumlu Soruya Verilen Cevaplar	Hoşlanırım	Q	A	A	A	O
	Öyle Olmalı	R	I	I	I	M
	Fark Etmez	R	I	I	I	M
	Katlanabilirim	R	I	I	I	M
	Hoşlanmam	R	R	R	R	Q

M:Temel İhtiyaçlar **O:** Beklenen ihtiyaçlar **A:** Heyacan verici **Q:** Şüpheli İhtiyaçlar **R**: Zıt İhtiyaçlar

I: Sıradan İhtiyaçlar **(M>O>A>I)**
[11]

Bir çok alanda ürün olduğundan müşterilerin her ürün için farklı talepleri bulunmaktadır. Bundan dolayı müşterilerin hangi kategorinin içinde olacağını anlamak için heyecan verici, doğrusal ve temel özellikler ana başlıkları altında iki katsayı aşadadaki denklem 2 ve 3 gibi hesaplanmaktadır. Bu katsayılar; rekabet ortamında müşteri gereksiniminin pozitif ve negatif katsayıları belirlemektedir. [12]

Pozitif katsayı memnuniyet katsayısı, negatif katsayı ise memnuniyetsizlik katsayısı olarak adlandırılmaktadır. [13]

$$\text{Memnuniyet katsayısı (P)} = \frac{A+O}{A+O+M+I} \qquad (2)$$

$$\text{Memnuniyetsizlik katsayısı (N)} = -\frac{A+O}{A+O+M+I} \qquad (3)$$

3. Araştırma

3.1.1 Araştırmanın Amacı

Araştırmanın evreni Bursa ili ara bölmeli hafif ticari kargo aracı olan müşteriler olacaktır. ODD'nin 2019 yılı raporuna göre Türkiye piyasasında satılan hafif ticari araçların adeti 91804 tür. Adetlerin bu denli yüksek olması rekabetçi olma gerekliliğini zorunlu kılmaktadır. Bu sebepten dolayı araştırmamızda , ara bölmeli hafif ticari araç kullanan müşterilerin

ihtiyaçlarını belirlenmeye çalışılmıştır. Ara bölmenin güvenlik fonksiyonu dışındaki ilave potansiyel özellikler ve bundan oluşabilecek çeşitlilikte müşteriden alınacak bilgilerin yorumlanması amaçlanmıştır.

3.1.2 Araştırma için Ara bölme Soruların Belirlenmesi

Araştırma sorularının belirlenmesi için ilk durumda ara bölmenin mevcut özellikleri ortaya koyulmuştur. Bu özelliklerden müşteriyle etkileşimde bulunacağı düşünülen kısmı seçilmiştir. Aşağıda belirtilen maddelerde görülen her özellik için olumlu ve olumsuz sorular hazırlanmıştır.

- Komple kapalı ara bölme & kısmen kapalı ara bölme
- Komple kapalı ara bölmede arkayı görmek için cam olması
- Camın boyutları hakkında
- Ekstra ses izolasyonu için ara bölmenin üzerine ilave malzeme kaplanması
- Estetik görünümü artıracak ara bölmenin üzerinde kaplama malzeme olması
- Ara bölmenin rengi hakkında
- Ara bölmenin bozuk yolda kendisinden gelebilecek ses performansı hakkında
- Uzun yükü taşıyabilmek için ara bölmenin hareketli sistemiyle yük hacmini artırmak
- Elbise askısının sayısı hakkında
- Ara bölmenin kompozit & sac malzemeleri hakkında
- Kısmen kapalı ara bölmelerde üst kısmında borulu ve ızgara (telli) kullanımı hakkında

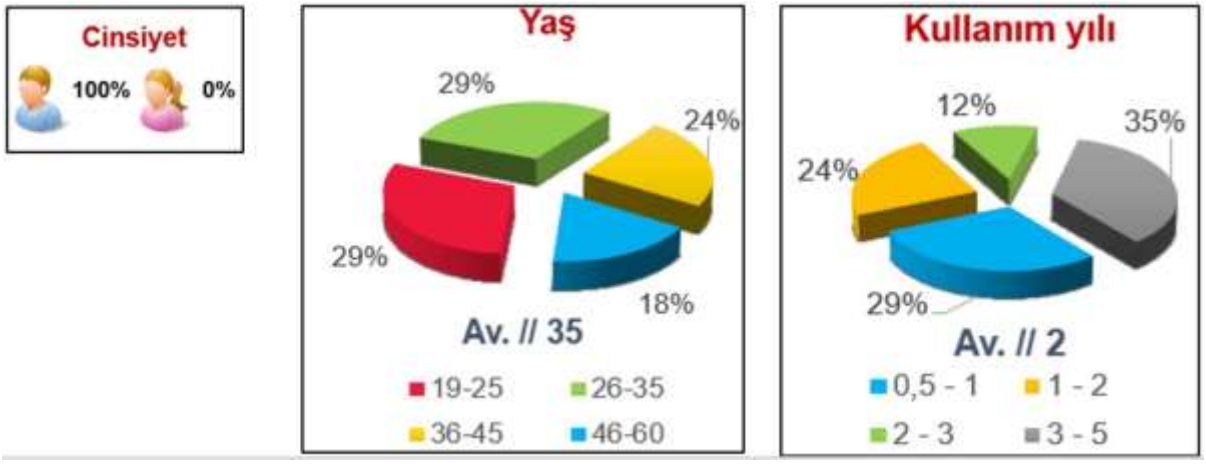
Bundan sonra rakiplerin ve şirketimizin yeni potansiyel özellikler belirlenmiştir. Aşağıda belirtilen bu özellikler hakkında olumlu ve olumsuz sorular hazırlanmıştır.

- Ara bölmede müşterinin ihtiyacı kadar yük hacminin kademeli olarak artılabilmesini sağlamasıyla ilgili
- 5 koltuklu araçta arka 3 koltuğu yatırılıp cargo tip aracı dönüştürülmesiyle ilgili

3.1.3 Araştırmanın Demografik yapısı

Araçları kullanan kişilerin cinsiyet yaş ,sektör ve kaç yıldır aracı kullandıkları bilgisi alınmıştır.Ayrıca iletişime geçilen araç kullanıcılarının çalıştıkları alanlar;

- Boya Satış
- Elektronik parçalar Teknisyenliği,
- Araç Servis ,
- Talaşlı imalat üretimi,
- Gıda Satış
- Otomasyon



Şekil 7. Demografi diyagramları

4. Araştırmanın Değerlendirmesi

Müşterilerin ihtiyaç duyabileceği modifikasyonlara ve araç homogolasyon standartlarına uygun sorular gerek duyulmaktadır.

Tablo 2: Kano modeline göre müşteri değerlendirmesi

Attributes	Category
Multi-positional bulkhead	A
Full Panel Closed for bulkhead	R
Only Bulkhead behind only driver	M
Glass on Full Panel closed bulkhead	O
Dimensions of glass on bulkhead	M-I
Isolator for increasing sound insulation on bulkhead	O
Isolator for increasing aesthetic satisfaction on bulkhead	O
Light color of bulkhead	O
No noise from the full panel bulkhead during broken road	O
Openable bulkhead for extra long luggage	I
Bulkhead with Sliding system	I
Two Dress hangers	A
Composite lightweight bulkhead	A

Her bir özelliğin kategorize edilmesinden sonra, denklem 2 ve 3'e göre ürün özelliklerinin tüketici memnuniyeti seviyesini belirlemek için verileri işlemeye devam edilmektedir. Tablo verileri tablo 3'te gösterilmektedir:

Tablo 3: Memnuniyet seviyesi

No	Attributes
1	Multi-positional bulkhead
2	Full Panel Closed for bulkhead

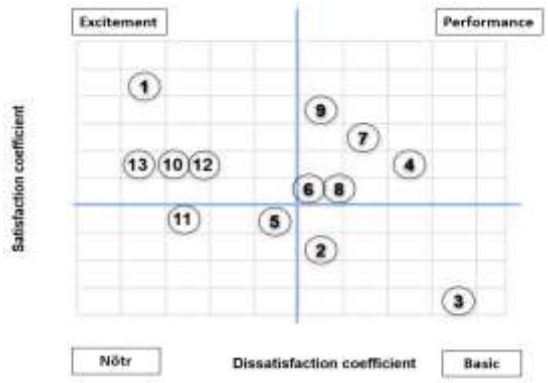
9	No noise from the full panel bulkhead during broken road
10	Openable bulkhead for extra long luggage
11	Bulkhead with Sliding system
12	Two Dress hangers
13	Composite lightweight bulkhead

Grafik 1: Memnuniyet Grafiği



Bu araştırmadan tespit edilen özellik sorularına yapılan sorgulamalarda iki adet farklı özellikte soru gerekliliği söz konusu olmuştur. Bunlardan birisi ara bölmeden sonra koltuk ayak mesafesi ikincisi ara bölme üzerinde elbise askısı pozisyon seçeneğidir. Anketin genel değerlendirmesi olarak heyecan duymuşlardır. Eğer bu şekilde olabilecek arabölme özelliklerinin var olması durumunda araçlarını daha efektif kullanabileceklerini aktarmışlardır.

5. Sonuçlar

Bu araştırmayı değerlendirdiğimizde sonuçları 4 kategoride gruplanmıştır. Ara bölmedeki özelliklerin müşteri üzerindeki etkileri aşağıdaki maddelerde açıklanmıştır.

1. **Sürpriz Özellikler / Heyecan Verici Özellikler :** Bu özellikler varsa müşteri memnuniyetini tahminlerin üzerinde arttırır, yok ise memnuniyeti olumsuz etkilemez çünkü bunlar müşterinin farkında olmadığı sürpriz unsurlardır. Bu araştırmada araç sürücülerinin ara bölmede heyecan verici olarak tanımladığı özellikler ; Birden fazla

pozisyonlanabilir ara bölme, Açıldığında bagaj hacmini artıran ara bölme, kompozit malzemeli daha hafif ara bölme, iki adet elbise askısı olan ara bölme .

2. **Daha Çok, Daha İyi / Performans Özellikleri :** Müşterinin farkında olduğu ihtiyaçları gideren özellikler sağlanırsa, memnuniyet doğrusal olarak artar, azaldıkça da müşteri memnuniyeti düşer. Bu araştırmada araç sürücülerinin ara bölmede performans olarak tanımladığı özellikler ; Komple kapalı ara bölmede cam olması , Ekstra ses izolasyonu için ara bölmenin üzerine izolatör malzemesi kaplanması, estetik görünümü artıracak ara bölmenin üzerinde kaplama malzeme olması , açık renkli ara bölme kullanılması , elbise askısının müşteriye göre uygun poziyonda olması , bozuk yolda ara bölmeden ses gelmemesi.
3. **Olmazsa Olmaz / Temel Özellikler :** Müşteri tarafından standart olması beklenen özellikler bulunmadığında memnuniyetin düştüğü , bulunduğunda da müşteri memnuniyeti etkisinde herhangi bir değişme olmaz, nötr olarak kalır. . Bu araştırmada araç sürücülerinin ara bölmede olmazsa olmaz olarak tanımladığı özellik; sürücünün arkasında bir koruyucu ara bölmenin bulunması.
4. **Fark Etmez / Nötr özellikler :** Bu kategorideki özelliklerde müşterinin özellikle alakalı herhangi bir farkındalığı olmadığı ve sonuç olarak memnuniyete herhangi bir katkısı bulunmayan özelliklerdir. Müşterinin ihtiyacı kadar yük hacmini artıran ara bölme , ara bölmedeki kullanılacak camın büyüklüğü.

ABSTRACT

Spare Wheel Carrier is the optimum reliable solution today and in near visible future to handle and also keep the spare wheel in its dedicated place for a motor vehicle in particular for Light and Medium Commercial Vehicles. The expectations of final customer in other words end user are mostly focused for easiest and quickest replacement of damaged wheel.
On the other hand national and international regulations, norms and engineering specifications to respect including safety and crash tests requirements are indispensable criteria to take into consideration for safety related products such as spare wheel carriers.
The locations of the spare wheel and its carrier accordingly are highly important for light and medium commercial vehicles due to specific requirement to have a flat surface and a maximized volume for cargo compartment in order to load the vehicle easily to its limits.
İt is assumed that the results of this research study including benchmarks is a first step to an innovative brand independent new spare wheel carrier design and development for an international deep market penetration.

Keywords: Spare Wheel, Carrier, Winch, Lifter, Hoist

1. INTRODUCTION

A spare wheel is a replacement of an active wheel for motor vehicles in case of having an irreversible blowout for any reason as exemplarily shown by Figure 1 while vehicle running or parked.
Since a replacement is an assembly of the rim and the tire, the correct nomination should be Spare Wheel instead of Spare Tire which is a mistake usually done. Motor vehicles were manufactured without spare wheel before 1904 when Thomas and Walter Davis invented it. Another synonym in various languages for spare wheel is Stepney which comes from the Stepney Street, Llanelli in South Wales where Davis brothers run their ironmongery company Stepney Spare Motor Wheel Ltd. The rims made by three different materials as conventional sheet metal, aluminum alloy and composite, a spare tire and a spare wheel, all shown by Figure 2.

Figure 1. A blowout tire [1]

(a) Sheet Metal Rim [2] (b) Aluminum Alloy Rim [3] (c) Composite Rim [4] (d) Spare Tire [5] (e) Spare Wheel [6]

Figure 2. The Rim, The Tire and The Wheel

Recent developments in automotive industry promote two alternatives to avoid spare wheel and to save both weight and related cost as tire repair kits shown by Figure 3 and puncture-proof airless tire shown by Figure 4.
Even these two alternatives seem like applicable as a technical solution, each of them still has its own issues to be solved.

Figure 3. Tire Repair Kit [7]

Figure 4. Puncture-Proof Airless Tire [8]

Tire repair kits are under mass production since both spare wheels and jacks are no longer legal requirement to carry in the vehicle. Theoretically repair kits are quicker and easier than replacing a damaged wheel. On the other hand they are not suitable for all types of puncture.

Airless tires are not in mass production yet, therefore, there is no enough data exists to prove the effectiveness and reliability of this technology. One of the expected potential issue is about the spokes which can be damaged somehow under road conditions and might be broken, ripped, cut or torn. All these damages affect the life and the functionality of the tire. The other potential issues are mostly linked to the construction of airless tires which may cause delamination of outer ring or the treads.

Considering above mentioned inconveniences, motor vehicles still carry spare wheels for the replacement of running wheels since the repair kits are not widely used in the market especially for Light Commercial Vehicles (LCV) and Medium Commercial Vehicles (MCV) due to their loaded conditions. Therefore, spare wheel is still keeping its place and significance in automotive industry and also remains important for most of the customers or end users.

The study on resilience assessment of engineered systems by dynamic Bayesian network based approach (2020) of Tong et al., the vehicles with spare wheel are considered as more resilient and functional even vehicle with flat tire can still run called under low functionality state conditions [9]

Spare wheels are classified regarding their size and also their usage mode as follows;

1. Full size matching spare wheel ;
   This spare wheel is exactly the same with those currently on the vehicle.
2. Full size non-matching spare wheel ;
   This spare wheel is a full size one, but, differs from those currently on the vehicle,
3. Full size temporary spare wheel ;
   This spare wheel is lightweight and designed to get the vehicle to the nearest garage or dealer to replace or repair the blowout tire,
4. Folding temporary spare wheel ;
   This is an inflatable and deflatable spare wheel designed to get the vehicle to the nearest garage or dealer to replace or repair the blowout tire,
5. Compact temporary spare wheel ;
   This is a smaller and lightweight spare wheel designed to get the vehicle to the nearest garage or dealer to replace or repair the blowout tire,

All vehicle manufacturers try to offer a flat surface together with a clear and proper cargo area to their customers or end users in order to facilitate loading and unloading. So, having a well-organized and available zone for spare wheel preferably out of the cargo area is one of the key issue for vehicle manufacturers including LCV and MCV manufacturers.

Famous question of hundred years appears again, best place for spare wheel, where is it ?

Even it is rarely used, the importance of the spare wheel place and its user friendship are unquestionable when the moment comes for a driver who has unpleasant flat tire trouble on the way with loaded LCV or MCV considering also distressed conditions including weather and environment which may cause various extra difficulties during replacement.
The trouble is more important for heavy commercial vehicles, heavy duty vehicles and buses because of the handling difficulty during replacement due to oversize spare wheel which is around 100 kgs. Shete mentioned this problem by his study (2015) about buses [10].

Spare wheels has been located to various places in and out of the vehicles according different designs, preference of vehicle manufacturers themselves, notion of beauty or aesthetic tendency of era etc. during last hundred years.
Spare wheel is pretty good protected from compelling conditions of outdoor environment such as wet, mud, dust, cold or heat and of course impact of little stones and gravels if it is located in the spare wheel well in trunk as shown by Figure 5.While spare wheel is in the vehicle, two additional advantages to mention are the elimination of its throw away risk during any crash and protection against theft. But, the problem occurs while trunk is loaded, in this case, trunk should be unloaded to reach the spare wheel. Another common place is rear underbody to locate the spare wheel and two solutions are available to do it.
First solution is to use a mechanism called Spare Wheel Carrier (SWC), in other words a winch system as shown by Figure 6. A mechanical carrier mechanism driven by a key which is similar to "L" or "Cross" type of wrench, spin-down and spin-up the spare wheel via its connected steel wire rope. This carrier mechanism can also be driven electrically.
Second solution is to use a cradle as shown by Figure 7. Cradle keeps the spare wheel in place and avoid throw away hazard by complete mechanically locked structure. Although cradle is more simple solution than a carrier mechanism, unfortunately heavier also due to its dimensions covering all spare wheel which causes limits for utilization.

Figure 5. Located in Trunk [11]

Figure 6. At Underbody - Carrier [12]

Figure 7. At Underbody - Cradle [13]

Spare wheel can also be mounted to various places at the rear side of the vehicle as shown by Figure 8. One of often used location is the tailgate as shown by Figure 8(a). This is a common application for SUVs and off-road vehicles assuring an easy access to spare wheel. Prominent inconveniences are partially limited rear view for driver and a weak anti-theft protection. Spare wheels mounted on trunk is another option mostly faced at 1920s to 1930s and later on retro cars as shown by Figure 8(b). An aesthetically pretentious application is the spare wheel mounted on rear bumper as shown by Figure 8(c). Advantages and inconveniences of last two solutions mentioned above and shown by Figures 8(b) and 8(c) are almost same with the one mounted on tailgate.

(a) Mounted on Tailgate [14]

(b) Mounted on Trunk [15]

(c) Mounted on Bumper [16]

Figure 8. Rear Side Spare Wheels

Other possibilities for locations of spare wheel are shown below by Figures 9, 10 and 11. Locating the spare wheel on top of the vehicle or on top of the hood are mostly applicable for off-road vehicles as shown by Figure 9. This application has no inconvenience from aerodynamic point of view for an off-road vehicle since the speed is not high and the drag coefficient is not a key parameter to consider in a first place. On the other hand center of the gravity is

another issue due to overweight of the spare wheel which is usually from 120 up to 200 kgs for off-road, heavy duty and military vehicles.
According to the study of Stanco et al. (2020), the load transfer may reach in average 1G for X and Y axis and 1,5 G for Z axis in off-road conditions [17].
Spare wheel can be located at both sides of the vehicle more precisely at both sides of the engine compartment just on the fenders as shown by Figure 10(a).This is a famous and almost generic application for the vehicles of 1930s and 1940s. The benefit of having spare wheel at sides is easy access with an aesthetic view and the inconvenience is again weak anti-theft protection.
An interesting application shown by Figure 10(b) is to hide spare wheel by locating it into fender. Unfortunately this is a complex and expensive solution even it is a brilliant idea from design point of view provided that there is enough available space behind the fender and between engine and cockpit compartments.
Another application as shown by Figure 11(a) is locating the spare wheel on top of the engine. This is one of the rare solutions which is not applicable nowadays due to lack of space in engine compartment because of the complexity and also the size of the engine.
Last application to mention in this paper is the spare wheel mounted on sidewall of the trunk as shown by Figure 11(b). This is applicable mostly for SUVs or station wagons due to availability of enough space in the trunk wall for spare wheel.

Figure 11. Spare Wheel, Others

2. EXPERIMENTAL

2.1. Problem Definition

The spare wheel is in use today and will be in use in near future for most of the motor vehicles, especially for LCVs and MCVs taking into consideration the facts mentioned in introduction. In this case, a reliable solution is needed to satisfy end user expectations in order to replace the damaged wheel in easiest and simplest way, to respect the national, regional and international regulations including crash tests requirements and also to respect engineering specifications defined by Original Equipment Manufacturer (OEM) in other words Motor Vehicle Manufacturer itself.

Safety regulations is also highly important to take into consideration for the design to keep the spare wheel in dedicated place safely with no harm to its vehicle, driver and passengers also to other individuals or vehicles in case of accident.
Staff et al. reported by their study (2012) that every year 1,3 million people die and 20 to 50 million people were injured due to motor vehicle accidents. Regarding their research done for totally 190 accidents, 338 motor vehicles and 618 individuals involved, 327 individuals (53%) were injured, and 61 (10%) died. 133 motor vehicles (39%) involved and 293 individuals (48%) injured due to unrestrained objects and 32% of objects weighed >20 kg. [24]

Rear underbody is the most preferred place by OEMs to locate the spare wheel considering market requirements and OEM tendency accordingly to offer as much as possible a flat surface and a clear ergonomic volume for cargo area of any LCV or MCV to be able to load maximum possible volume as effective load to the vehicle.

Spare Wheel Carrier seems like the best solution today according to regulations, engineering specifications, easy handling, cost, weight and occupied volume criteria.

The question is about to define the best possible location of SWC for LCVs and MCVs to dedicate more volume available to mechanism considering two drive options as mechanically by a wrench and electrically by an electric motor.

2.2. Method

As a first step, a benchmark study for SWCs conducted. The objective is to clarify and accordingly compare the volumes of SWC mechanisms used by various OEMs for various vehicle bodies.

In this benchmark study totally fourteen SWCs has been studied in terms of their weight, dimensions and volumes. These SWCs are used for four Pick-Ups, three Sport Utility Vehicles (SUV), three LCVs and four MCVs belong to eight different OEMs. Almost equal or similar sizes and weights has been taken into consideration while above mentioned four body styles chosen.

As a second step, the underbodies of 2 MCVs and 1 LCV belong to two different OEMs studied in terms of the available volume to dedicate to SWC by 2 alternative locations as bumper zone and rim center. The objective is to compare and accordingly clarify the best location considering maximum volume available for SWC.

The aim of looking for maximum available volume is certainly not to target a bigger mechanism, but, to check the available space in order to consider a potential electrical drive system means an electric motor and its gearbox addition into system. A second reason is to consider also optional sub-systems such as mechanical locking or auto spin-down systems.

2.3. Benchmark Study for SWCs

Totally four different SWC used on four Pick-Ups belong to 3 different OEMs analyzed and the results are shown by Table1. Although vehicles are very similar in terms of their sizes, weights and also their spare wheels accordingly, the volumes of SWC mechanisms are varying between 1.265 and 4940 cm^3 which means a wide fluctuation approximately 400%. But the comparison between their weights is not showing the same picture as their volumes and the weights are between 1.977 and 2.790 g.

Table 1. Spare Wheel Carrier Benchmark for Pick-Ups

Brand	OEM 1			OEM 2			OEM 3			OEM 3		
Body	PICK-UP			PICK-UP			PICK-UP			PICK-UP		
Spare Wheel Carrier												
Total Weight (g)	1.977			2.790			2.190			2.596		
Mechanism (cm^3)	1.265			3.450			2.188			4.940		
Mechanism x-y-z (mm)	100	115	110	115	200	150	153	130	110	190	130	200

Table 2 shows the results of benchmark study done for three different SWC used on three SUVs belong to three different OEMs. Their weights are between 1.375 and 2.295 g. and the volumes are between 1.676 and 3.898 cm^3. Fluctuations for both weight and volume are approximately 200% which is still wide but not as much as the results of Pick-Ups.

Table 2. Spare Wheel Carrier Benchmark for SUVs

Brand	OEM 4			OEM 5			OEM 6		
Body	SUV			SUV			SUV		
Spare Wheel Carrier									
Total Weight (g)	2.295			1.415			1.375		
Mechanism (cm³)	3.838			1.676			2.898		
Mechanism x-y-z (mm)	298	140	92	190	140	63	200	207	70

The third benchmark has been done for 4 different SWC used on four MCVs belong to 4 different OEMs and the results are shown by Table 3. The first one belonging to OEM1 is quite different than others in terms of both weight and volume because of missing clutch system which limits the applied torque to mechanism, therefore, it is better to make the comparison among the rest. Although the weight of SWCs for OEM 2, OEM 7, OEM 8 are between 2.650 and 3.030 g and very close to each other, their volumes are varying between 1.052 and 6.197 cm^3 pointing out a wide fluctuation around %600.

Table 3. Spare Wheel Carrier Benchmark for MCVs

Brand	OEM 1			OEM 2			OEM 7			OEM 8		
Body	MCV			MCV			MCV			MCV		
Spare Wheel Carrier												
Total Weight (g)	1.400			2.700			3.030			2.650		
Mechanism (cm³)	231			6.197			2.948			1.052		
Mechanism x-y-z (mm)	81	87	33	243	150	170	130	126	180	178	197	30

The last benchmark study done for three different SWCs used on three LCVs belong to two OEMs and the results are shown by Table 4. Again, the first SWC belonging to OEM 1 should be evaluated separately due to missing clutch system. Even two other SWCs are belong to the same OEM, they are pointing out a fluctuation around 250% by their volumes 2.250 and 5.646 cm^3 while the weights is almost same as 2.522 and 2.534 g.

Table 4. Spare Wheel Carrier Benchmark for LCVs

Brand	OEM 1			OEM 2			OEM 2		
Body	LCV			LCV			LCV		
Spare Wheel Carrier									
Total Weight (g)	1.980			2.522			2.534		
Mechanism (cm³)	190			5.646			2.250		
Mechanism x-y-z (mm)	81	87	27	270	255	82	178	158	80

When the both extremities in terms of the volume means the ones with low and high volumes eliminated by a very basic approach, a volume between 1.200 and 2.900 cm^3 seem like reasonable considering all fourteen SWCs analyzed.

2.4. Benchmark Study for Available Volume Comparison at Underbodies of LCV and MCV

The comparison of available volume between the rear bumper zones and the rim centers via 3Ds for two MCVs and one LCV belonging to two different OEMs are shown by Figures 12, 13 and 14.The first 3D view on the left side shows always the SWC location at rear bumper zone and second 3D view on the right side shows always the SWC location at the center of the rim for all three cases presented below.

Rear Bumper zone is the common and also conventional place to position the SWC since it easily reachable by end user.
On the other hand reinforcements and ribs at rear underbody also rear axle are limiting available volume considering SWC for most of the cases, therefore the quest of more available volume at the rim center is important to position SWC perpendicularly regarding spare wheel and additional space needs in case of having an electrical drive option.

The measurements taken from 3Ds and accordingly calculated available volumes for above mentioned three cases are shown by Table 5. Dimensions at X, Y and Z and their (-) and (+) values calculated regarding vehicle coordinate systems which has been shown below by Figures 12, 13 and 14.

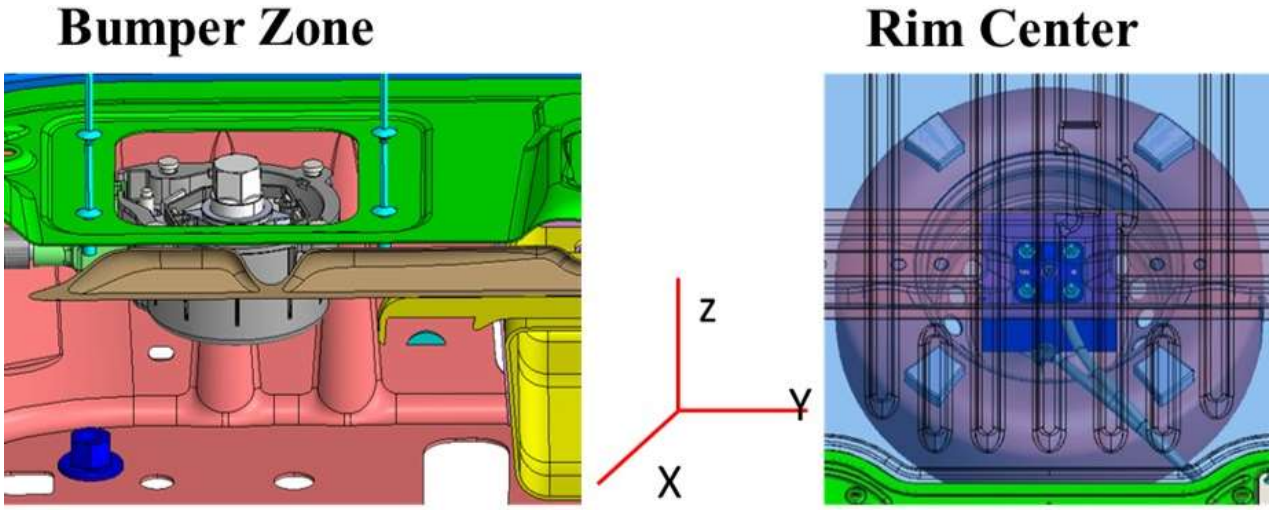

Figure 12. Spare Wheel Carrier, OEM 1 – MCV

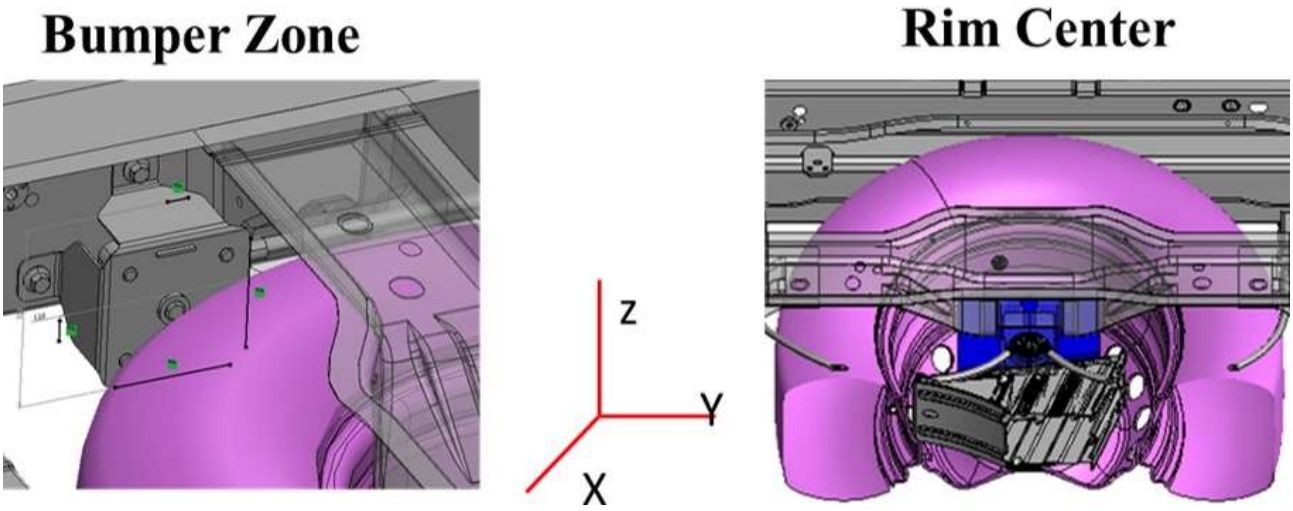

Figure 13. Spare Wheel Carrier, OEM 1 – MCV

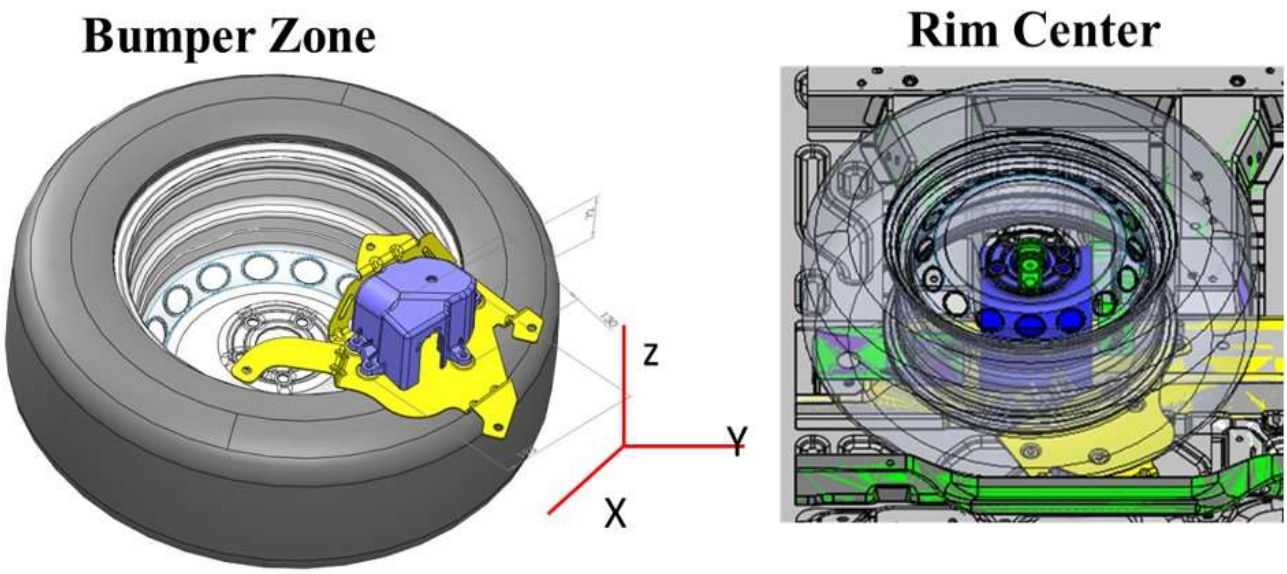

Figure 14. Spare Wheel Carrier, OEM 2 – LCV

Table 5. Available space comparison between Bumper Zone and Rim Center

		Bumper Zone Available Dimensions				Rim Center Available Dimensions									
OEM	Vehicle	X (mm)	Y (mm)	Z (mm)	cm^3	X (mm)	Y (mm)	Z (mm)	cm^3	% diff	+X (mm)	-X (mm)	+Y (mm)	-Y (mm)	Z (mm)
1	1	108	114	120	1477	190	220	120	5016	**340%**	95	95	110	110	120
1	2	125	65	123	999	124	200	120	2976	**298%**	110	114	100	100	120
2	1	130	195	72	1825	160	155	120	2976	**163%**	80	80	77,5	77,5	120

The available volumes at the center of the rim are clearly higher than the rear bumper zone and the results are between 163% and 340% for studied 3 vehicles. Table 5 shows that it is possible to achieve up to 5.000 cm^3 available volume regarding to underbody design to dedicate to the SWC at the rim center. Approximately 3.000 cm^3 observed by two different vehicles of two different OEMs can be accepted as an average achievable and available volume at the rim center to be at safe side while designing the SWC package.

3. CONCLUSION

Obviously there is more available volume for SWCs at the rim center considering its shape comparing rear bumper zone.
It is possible to achieve approximately 200% available volume to dedicate to the SWC regarding rear bumper zone if 3.000 cm^3 considered as available volume in average at the rim center regarding Table 5. This available volume is providing several opportunities to the designers such as presenting optional drive systems both mechanical and electrical by the help of the additional volume for electric motor and its own gearbox.

An electrically driven SWC is certainly a new approach for passenger, light and medium commercial vehicles considering its today's limited usage only for heavy commercial vehicles.

Another potential advantage for designers is the communization and/or carry-over opportunities of the SWC box design for various vehicles of various OEMs in order to present more competitive price to the market by the support of high production quantities and carry-over sub-components.

The rim center is potentially a better location for SWC rather than the rear bumper zone except being closer to the bumper for mechanical drive access. The rim center can be considered as the optimum positioning at the underbody of vehicle for SWC mechanism assuming a flexible torque transmission system as a flexible shaft application to neutralize above mentioned inconvenience in future in case of driving the SWC mechanically.

Some of prominent technical advantages to mention by virtue of being just in the center of the rim are mostly based on the opportunity for cancellation or at least reduction of quantities of several subcomponents such as conduit, plastic

elbows and plastic clips. This cancellations or reductions for length and/or quantity will help also to both lightweight the SWC and reduce its cost accordingly.

ABSTRACT

Interior lighting is gaining great importance as not only ambient lighting systems providing comfort and elegance, but also as supporting and functional systems linked with ADAS such as blind spot detection or front collusion warning. Interior lighting is also currently experiencing a big trend towards new light sources by considering new autonomous vehicle and interior designs. The most important components in interior lighting are the front ceiling light, rear ceiling light and trunk lamps. These products are now produced with high technology to enhance style, safety and convenience within the vehicle. Some suppliers offer variety of HMI solutions varying from tactile and capacitive buttons to more advanced systems including haptic feedback. Trunk lamp, puddle light, door projector light, glove box lamp are other frequently used interior lighting components in modern vehicle. In addition to interior lighting lamps, ambient lighting improves feeling of comfort and elegance with different color options and light intensity. Interior ambient lighting have a direct impact on the quality perception of materials execution, surface finish or color & gloss properties. Ambient lighting can be easily applied in many parts of the vehicle such as cup holder, footwell area, dashboard panel, door panel map pocket, door handle and headliner. Moreover, ambient lighting with functionality is a feature to increase perception and support safety.

Keywords: Interior Lighting, Functional Ambient Lighting, Multipurpose Lights, Spotlights

1. INTRODUCTION

Automotive lighting is one of the most complex discipline and has a dramatically growing interest for the automotive industry. Illumination was simple 20 and 30 years ago, and interior lighting was purely functional. In most vehicles today, we see that the interior lighting is not limited to just a few lamps. One reason for this is that until a decade ago, interior lighting was actually provided by a central main lamp in headliner. This situation has come to a very different point in today's vehicles. Present-day automotive engineering considers the automotive interior lighting to be an important quality communication channel [1-2]. We see multifunctional front ceiling lamps, functional ambient lighting with ADAS systems and interior lighting lamps with advancing technologies in many parts of the vehicle.

The technical complexity of interior lighting systems is also frequently underrated, since the integrated electronics are not externally apparent. However, due to the development of advanced technology, once simple lighting systems have evolved into highly intelligent interior lighting systems. Design and technical requirements have also considerably increased. Today, interior lighting in automobiles is used in many areas in the vehicle. New lighting types like front dome lamps with HMI (Figure 1.) or ambient lighting are becoming more and more common.

Figure 1. Advanced Overhead Consoles with HMI Interface

Interior lighting improves feeling of safety for the driver and it affects the driver positively. In the Figure2 below, you can see how different types of interior lighting can be used in a vehicle.

Figure 2. Different interior lights in a modern vehicle

2. INTERIOR LIGHTING

2.1 INTERIOR LIGHTING FUNCTIONS AND THEIR LIGHTING REQUIREMENTS

Interior lighting increases the feeling of safety and security for the customer and provides a pleasant atmosphere in the vehicle. There are no binding legal regulations for the lighting of passenger compartment. The various interior lighting functions have been developed in a harmonization process between the automakers and the lighting supplier, taking into account the lighting quality criteria that shown below Figure 3. The main challenge of lighting development today is the ability to find an optimal balance between lighting performance (light distribution, luminous flux, brightness level) and perceived quality in combination with the development time and cost ratio [3]. To find the balance, product development teams at OEMs should correctly define perceived quality requirements. Therefore, all design and system solutions have to be executed in a way that the customer will perceive the interior lighting at high quality criteria [4].

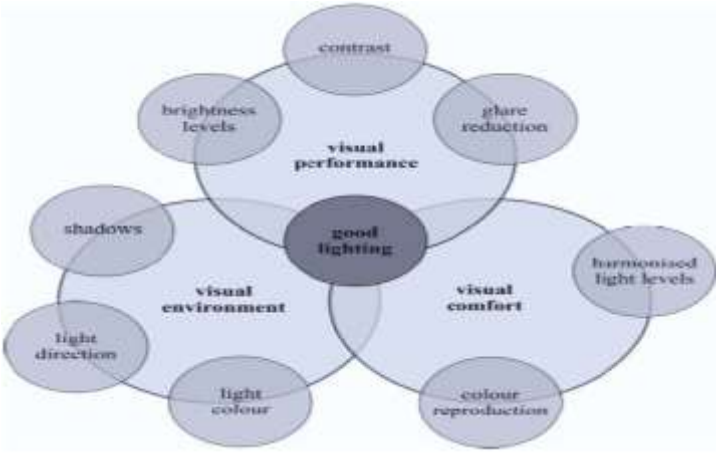

Figure 3. Quality criteria for interior lighting

According to this quality criteria, good lighting is achieved by three main criteria as visual performance, environment, and comfort. Brightness level, contrast and glare effects visual performance directly. Glare is the loss of visual performance or discomfort produced by an intensity of light in the visual field and it distract the customer. Shadows, hot spots, direction of lights and color type of light are key points to improve visual environment. In order to provide visual comfort, there should not be a noticeable difference between light levels, harmony between colors and homogeneity should be emphasized. Interior lighting of many vehicles in the market has been analyzed in four different categories [5].

Table 1. Typical Function Table of Interior Lighting

	Purpose of Usage		
Typical Functions	**Entry/Exit**	**Functional Lighting**	**Ambient Lighting and Orientation**
	Courtesy Light	Interior Main Light(Dome Light)	Cupholder
	Door Lock	Reading Light	Cubby bin
	Footwell	Make up/Vanity Light	Door Handle
	Door Warning	Glove box lamp	Door Map Pocket
		Trunk lamp	IP Panel
		Puddle lamp	Footwell
		Door projector lamp	
Performance Criteria	*No shadow *Average luminosity 1-10 lx *Neutral light colour *Average colour rendering(CR>50) *Low glare *Homogeneous illumination	*No shadow *Clear delineation of the illuminated area *For reading/working luminosity 50-100 lx *For interior/make up luminosity 10-20 lx *For trunk and glovebox luminosity min 10 lx *No glare *homogeneous illumination	*Low luminosity expectation between 0,1 cd/m2 and 2 *illuminance dependent on interior color *No glare *Different color options

2.2 LIGHTING PERFORMANCE STUDY OF AN INTERIOR LIGHTING COMPONENT

Regarding to the lighting performance criterias that are mentioned in above table, we should verify the product before production. We can do this verification in two ways. Initially, we should perform virtual optical analysis to understand the lighting values meet or not meet with our specification or performance norms. Secondly, we should perform a dark room test on physical component to understand lighting values meet the lighting target in terms of homogenous and optical values. We generally use optical softwares such as Ansys or Lucidshape to perform virtual optical analysis.

The following Figure 4 shows us a luggage area of the premium vehicle. In this trunk area, two trunk lamps are located at lateral sides with a certain height. If this lighting source is bulb, this lighting component includes housing, outer lens and a traditional bulb. This traditional bulb has 50 lumen flux and it emits yellowish color. We need to understand optical values to verify our design and choose proper trunk lamp.

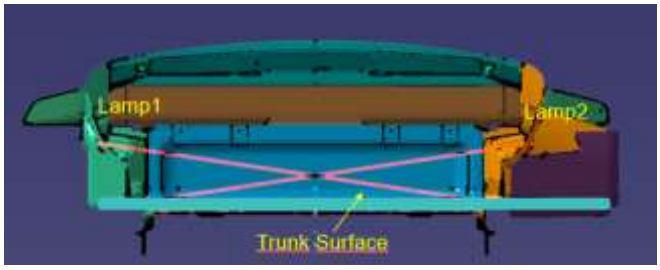

Figure 4. Trunk area of premium vehicle

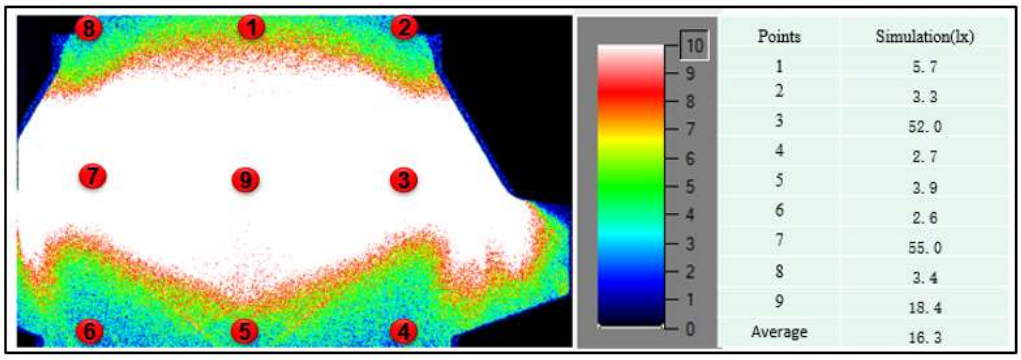
If we consider the trunk floor surface as a square, we must evaluate the optical values for 9 points separately as shown in Figure 5. Our target is to provide better homogeneous distribution on the surface. Although we could not provide minimum value of 10 lux at all points, the average value is above 10 lux. As a result, we met our requirements in this way.



Points	Simulation(lx)
1	5. 7
2	3. 3
3	52. 0
4	2. 7
5	3. 9
6	2. 6
7	55. 0
8	3. 4
9	18. 4
Average	16. 3

Figure 5. Optical Values of Trunk Lamp

Even if the optical values are proper in terms of lighting target, how the light looks is also an important parameter to validate the quality criteria. For this purpose, a render showing how it looks from the human eye is required. You can see the human vision render of this trunk lamp in Figure 6. Visible patterns of light, light leaks and glare should not be observed on trunk surface in human vision render.

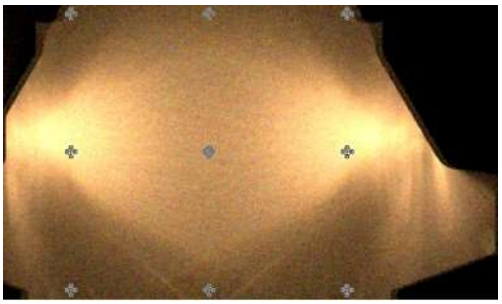


Figure 6. Human Vision Render of Trunk Surface

3. AMBIENT LIGHTING

Automakers are more and more using ambient lighting with advanced technologies inside their vehicles. And it is increasing trend in recent years. It is not only makes the passenger compartment attractive but could increase safety and the digitalization. Ambient lighting provides an indirect illumination of the passenger compartment in low light settings, such as during the night. It delivers an emotional atmosphere and provides the reduction of the driver's fatigue levels. It helps us to perceive the surrounding space [6]. Additionally, creating mood affect at night and daytime and theater like effects like welcome and goodbye messages are examples for remarkable user experience of ambient lighting [7].

On the other hand, ambient lighting has a psychological effect on the driver. An experimental study done by Lighting Engineering Group shows that ambient lighting improved drivers' perceptions of a vehicle's interior. The results showed that ambient lighting, although being in a peripheral position in the driver's field of view, has several significant positive influences on space perception, interior attractiveness, perceived safety, functionality and perceived interior quality [8].

3.1 COLOR OPTIONS ON AMBIENT LIGHTING

Color selection is very important in ambient lighting. There are two types of ambient lighting in terms of color. LED is used as the light source and the LED type is determined according to the desired color.

3.1.1 Single Color (SC) Ambient Lighting

Ambient lighting is obtained by the use of different color temperatures of LED from 2300K to 6000K. Cool light is more preferred in ambient lighting and interior lighting components.

3.1.2 Multi Color (RGB) Ambient Lighting

Upcoming next big trend in interior lighting is to use RGB Light Emitting Diodes (LED)s to provide orchestrated effects and living room feeling for autonomous and robot cars including daylight performance [9]. By using RGB LEDs, a more dynamic and attractive ambient lighting effect can be created in different color options. RGB LEDs bring possibilities for multi-color tunability to the LED lighting designer.

RGB LEDs can create just about any visual color, but creating the right color is a major challenge. Some methods are used to overcome the problems in color consistency both among individual LED packages and in large scale luminaires. One of the most used method is gamut calibration. The gamut of an RGB LED light source is defined as a triangle within the color space. The shape of the triangle as shown in figure 4, the gamut, depends on the color points of each individual LED.[10]

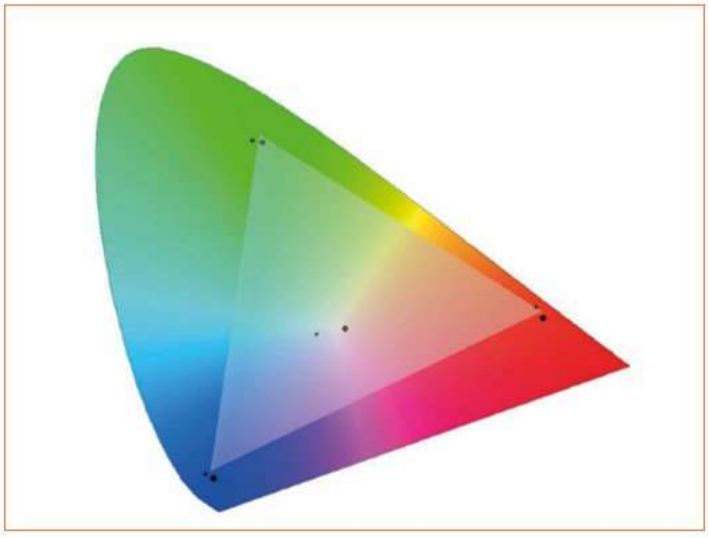

Figure 7. Gamut of the target light source: The triangle defined with vertices at points corresponding to each of the R, G, and B LEDs

3.2 TYPES OF AMBIENT LIGHTINGS

Automakers are more and more using ambient lighting with advanced technologies inside their vehicles. And it is increasing trend in recent years. It is not only makes the passenger compartment attractive but could increase safety and the digitalization. Ambient lighting can be easily applied in many parts of the vehicle such as cup holder, footwell area, dashboard panel, door panel map pocket, door handle and headliner. Different lighting characteristic can be used in the application of ambient lighting. This characteristic of light is explained below.

3.2.1 Direct Lighting

Direct lighting is when a light guide or other type of source is clearly visible to human eye. The light source can be point and linear, but the light source is clearly visible to the human eye. (Figure 4). The direct light solution costs more than indirect due to optical concerns on the lens.

Figure 8. Sample of direct light

3.2.2 Indirect Lighting

Indirect lighting is used for creating illuminated areas while keeping the light source hidden from human eye. As show below picture, there is a lightguide at backside of housing of door panel and light rays only go to the class a surface of door panel. Light source is invisible from human eye (Figure 5)

Figure 9. Sample of indirect light

3.2.3 Dynamic Ambient Lighting

Thanks to freely controllable RGB LEDs, the dynamic light features the dynamic flow of lights along a light rod. Dynamic light especially suitable for the visual display of functions and warnings inside the vehicle. Light guide or strip can be light up with individual color and brightness.

Figure 10. Sample of Dynamic Ambient Lighting

3.2.4 Decorative Ambient Lighting

Ambient lighting can be applied to aesthetic surfaces with different patterns, colors or brand signatures. It can offer different intensity of illumination in both daylight and night mode. IMD and IMF are processes used for decorative purposes.

Figure 11. Sample of Decorative Ambient Lighting

4. FUNCTIONAL AMBIENT LIGHTING

Ambience lighting has become more popular in the automotive sector with the developing technologies. In the past, ambient lighting was all about aesthetics. Today, new innovations combine emotion and functionality. With the development of ADAS functionalities, lighting is not only used for ambient lighting but also for interaction between the car and the driver [11]. Ambient lighting is now incorporated into new functions such as innovative turn- and brake-lighting applications, blind spot, speed limit, backlit displays and more. Unlike traditional ambient lighting, functional ambient lighting is a feature to increase perception and support safety as well as reaching elegance, attractive and an emotional atmosphere. Ambient lighting with functions, which is now becoming a trend, is listed below.

4.1 Functional Ambient Lighting with Blind Spot Detection

This function works compatible with Blind Spot Detection. When BSA is activated, there will be color transitions, flashing warning lights at the related door panel lamp. There's an ambient light guide that covers the entire of the dashboard and continues through the door panels to create a beautiful visual effect and warn the driver. The yellow section of the guide acts as a warning indication for blind spot detection. It works with signals that comes from Left and Right Blind Spot Detection. An automaker announced that it has integrated this function ambient lighting in its new model [12].

Figure 12. Functional Ambient Lighting with Blind Spot Detection

4.2 Functional Ambient Lighting with Front Collision Warning

A model at Figure 9 has interior ambient lighting with Collision Function. There is new ambient lighting fixtures to create a single continuous line of light throughout the vehicle. New ambient lighting features are actually integrated into the driver assistance programs. So for example, blind-spot monitoring would warn you of a possible collision by projecting a bright red animation throughout the cabin.

Figure 13. Functional Ambient Lighting with Front Collision Warning

4.3 Functional Ambient Lighting with Door Function

There is an interior ambient lighting with door function at Figure 10. When the door is open the ambient lighting changes to red. It is a useful function to see the handle on the door panel, especially when the vehicle is stopped at nighttime.

Figure 14. Functional Ambient Lighting with Door Function

4.4 Functional Ambient Lighting with Entry and Leaving Scenario

There may be color transitions, flashing lights or different colors during entering and leaving the car. When open the door and entering the car, ambient lighting will turn to red color, in the other case-it will turn to blue color. The function works by receiving the speed signal that comes from Body Computer Module.

Figure 15. Functional Ambient Lighting with Entry&Leaving Scenario

5. CONCLUSION

Interior lighting has become more functional and aesthetic with the development of new technologies. Currently there is no direct regulation for interior ambient lighting in EU. We know that which the performance criterias are used in to develop interior lighting components and these criterias are specific for each function. These performance criterias should be considered in order to achieve the best result in interior lighting. We have also observed how the lighting performance of a trunk lamp belonging to a premium vehicle is determined. Besides these, ambient lighting is an important and growing part of the interior lighting category. The usage of ambient lighting increases comfort and orientation inside the vehicle during both at daytime and night drive, which can be almost seen as standard for premium cars. Additionally, we can say that safety and comfort have increased remarkably with the ambient lighting gaining a functional feature.

ABSTRACT

In new product development studies, design parameters are determined according to certain standards of automobile manufacturers. It is expected that the fuel consumption of the vehicle will be reduced every day in the automotive sector, which is constantly developing. Accordingly, many changes to the vehicle are applied to each new model. The main goal of the component parts located at the bottom of the vehicle is to reduce fuel consumption by reducing the aerodynamic drag coefficient. Durability is an important factor in products developed for this purpose. Parts that can meet the coefficients determined by the aerodynamic units of automotive manufacturers must have an effective strength at the design stage. Otherwise, customer dissatisfaction will occur when the part cannot meet the loads on the part. In addition, these parts, which are connected to the underbody of the car, encounter challenging conditions such as rough roads, stone chipping, rainy weather, and puddles. In this study, the behavior of the part in wading through water was examined in detail. With the effect of aerodynamic forces on the part, the changes in the strength of the part were improved by the numerical analysis method. The condition of the part produced under the improved conditions in the water passing tests was observed. This part of the work carried out in order not to have any problems with the driving experiences of the passengers depending on all kinds of road conditions will give an idea for the engine underbody development studies. In this way, it is aimed to reduce customer satisfaction and warranty costs in models produced with proven parts.

Keywords: Under engine shield, numerical analysis, strength, water passing test

1. INTRODUCTION

Due to the need to reduce carbon dioxide emissions in cars, improving fuel efficiency is an important field of study in the automobile industry. (URL1: EU 2021) There are two main approaches to improving fuel efficiency, one is to improve the combustion process in the engine (Alla, 2002). The other is to reduce the overall aerodynamic drag coefficient of the vehicle while driving (Dwight & Peter, 2010). Due to the reduction of friction, many computational fluid dynamics (CFD) calculations are performed during the project phase. Then, verifications are provided with prototypes created for the wind tunnel (Yuan & Wang, 2017). Deformation effects caused by aerodynamic friction are verified by fluid-structure interaction analysis, necessary changes are made in product designs and the strength of the part is increased (Kesti and Olsson, 2014).

In addition to these two main approaches, many factors come to the fore for automobile underbody shields. There are many studies in the literature on the rough road conditions, puddles in the rain, stone splashes on the components, lightweight of the components, and their costs. The roughness of the road has a negative impact on automobile manufacturing costs and consequently on traffic safety. Repair and maintenance costs are continuously evaluated using vehicle-road interaction models. (Zaabar, Chatti 2011). The effect of rough road conditions on the underbody is verified by software and tests. Electric vehicles are becoming more common day by day, and most of the electric vehicles developed contain a lithium-ion battery pack mounted in the underbody. When these batteries are punctured, lithium usually reacts with air, causing fire or explosion (Larsson et al, 2016). Therefore, serious design changes are made against random stone splash fractures of the underbody components (Chu ver et al, 2018). In addition, the weight of the vehicle directly affects the energy consumption (URL2), so the underbody components are expected to be light. For this reason, high-performance and low-weight polymer composite studies are carried out on the underbody components. Metal components with high rigidity in the materials of the underbody components are gradually being replaced by lightweight composites (Lyu & Choi, 2014). As the materials become lighter and lose their rigidity, more serious design and analysis studies are developed against external effects, and the components are placed on the vehicle.

Puddles formed in wet weather are also an important development issue for underbody components. Driving through deep puddles, referred to as wading, is a driving situation associated with many potential problems for automobiles. Sudden loads on the underbody components of the vehicle force the parts at the fixation points. The ingress of water can block the air supply in internal combustion cars, which ensures the continuous movement of the engine. To lower the center of gravity in electric cars, batteries are usually placed close to the floor. Therefore, these parts should be carefully developed for puddle situations (Idoffsson, 2019). In traditional approaches, prototype vehicle testing is used to examine damage to the vehicle's underbody linings and engine compartment due to the driving through puddles. Issues are usually detected too late in the development process, and last-minute changes bring additional costs to the business (Khapane et al., 2017).

In this study, a finite element model of an under-engine shield part was created utilizing structural analysis software. In the case that the assembly of the car, in which this model is also included, enters the puddle, the pressure exerted on it was determined by the aerodynamic unit and included as the input parameter to the study. The deformations in the under-engine shield were calculated against the pressure parameter obtained in this way. With these deformations obtained before the prototype stage, it was ensured that the weak areas of the part were detected. Finite element models of alternative prototype proposals were created for these weak areas. The same calculations were repeated with the same inputs each time for the different alternatives and it was tried to decide the most suitable alternative. While focusing on cost and lightness, of course, at the decision stage, a prototype suitable for strength was obtained. The product development phase was advanced by completing the process with the part that gave positive results in the driving through deep puddle test.

2. MATERIAL and METHOD

Modeling of the car's driving through water was carried out by the aerodynamics unit. In this part of the study, the definition of pressure as the input parameter on the part and the numerical analysis will be emphasized. Then information about the driving through puddle test will be given.

2.1. Driving Through Puddle Test

With this test, the behavior of the car in puddles formed in rainy weather is determined. Minimal splash of water occurs as a car moves through the water at low speeds. If the car travels in the water at such low speeds, the Weber number and Froude number are low (White, 2011). A bow waveform in front of the car, if the car stops or slows down, water from the raised bow wave hits the underbody components. An automobile can pass through high-water levels at low speeds, and in this case, most of its subcomponents are submerged (Khapane et al., 2017). The Weber and Froude numbers are high while the automobile moves at high speeds; a high degree of splash occurs. As the speed of the car is increased and the height of the water level is increased, the movement of the components in the underbody of the vehicle does not occur in the form of sinking. During such a ride, water hits the underbody components of the vehicle and proceeds. Here, the severity of the impact depends on the actual vehicle speed and the water depth. Figure 1 shows the performing of the driving through puddle test.

Fig 1. Performing of the driving through puddle test

In the test carried out here, a water pool is created at a certain height level. The expectation for the under-engine shield part is that no deformation occurs when the car moves at different speeds from puddles of different heights. As a result of the test, the subcomponents are examined and deformations that may occur are reported.

2.2. Mathematical Model and Finite Element Method

The first mathematical model was modeled by the surrounding parts and the design criteria of the material used. Since manufacturability, good mechanical properties, and lightness are preferred in this part, this criterion has been considered in material selection.

Finite Element Analysis (FEA) is the simulation of any physical phenomenon (Logan, 2011) using numerical methods called the Finite Element Method (FEM) and a network structure. It is widely used in engineering to reduce the number of physical prototypes and experiments to develop better products faster and to optimize components at the design stage. By using finite element methods, problems that may occur during the service of the products are detected in the pre-prototype stage. In this way, when the product development process is preferred, it is prevented from testing the prototype with the traditional method and producing prototypes again. As a result of the analysis, a successful prototype is chosen, and time and cost savings are achieved according to the project schedule. The analysis was carried out dynamically and in nonlinear conditions. The detail of the created model is shown in Figure 2.

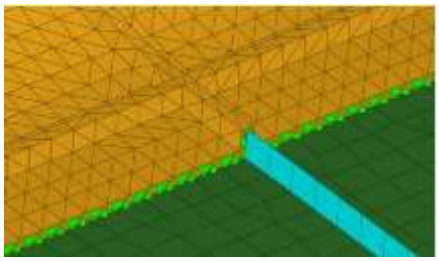

Fig 2. Combination of shell and solid elements

There are a few issues to be considered in the finite element model to ensure the accuracy of the analysis results. One of them is that the mesh structure accurately represents the geometry. Another criterion is that the quality of the element remains within the desired limits. The limit values are specified in Table 1. Unreduced square elements (S4) are used as shell elements. The unreduced triangular elements (S3) were used as transition elements and, if necessary, not exceeding five percent of the total number of elements. To observe the damage correctly, part of the under-engine shield, which is normally modeled with shell elements, is modeled with solid elements. As seen in Figure 2, the "Shell to solid coupling" contact definition has been made to transfer the freedoms between shell elements and solid elements. For solid elements, due to the complexity of the geometry, tetrahedral elements (C3D10M) are used for the under-engine protector. However, second-order elements were used for the accuracy of the results and since it increases the rigidity. In the modeling of bolts and other parts, C3D8 and C3D6 element types were used. Figure 3 shows the followed method of the analysis and the situation regarding the surrounding parts.

Table 1. Finite element model element qualities

	Limits
Triangle Ratio	$\leq 5,0$
Skewness Ratio	$\leq 20,0$
Aspect Ratio	$\leq 3,0$
Distortion Ratio	$\leq 45,0$
Quadrant Ratio	$\geq 0,6$

Using the correct material properties is one of the most important criteria for the accuracy of the analysis. The plastic material definitions in the material library as the under-engine shield material have been provided. Elastic-plastic material definitions are also included in the material modeled as isotropically [15].

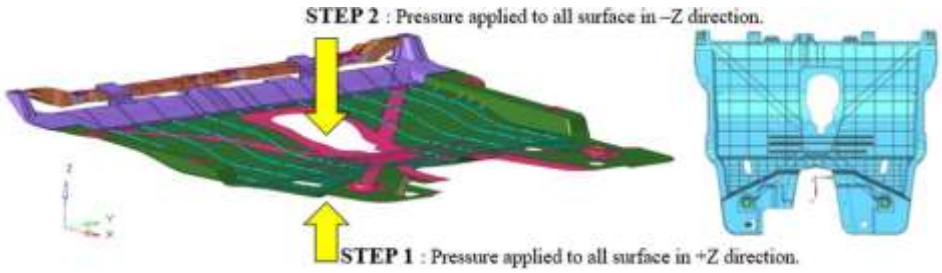

Fig 3. Finite element model created and defined boundary conditions

Because it will affect the analysis results, the peripheral parts are included in the model and the limitations are provided by independent joints of the zero-dimensional elements (COUP_KIN) from these parts and the bolt fixations on the under-engine shield and are kept in six directions of freedom. Detailed modeling has been made in the critical regions where the results will be examined. As shown in Figure 3, aerodynamic pressures on the part were applied on the under-engine shield in positive and negative directions, respectively, at the surface normal. The results obtained were examined and development studies were initiated.

3. ANALYSIS RESULTS OF THE FIRST DESIGN

When the finite element analysis simulating the puddle test was performed, it was observed that the piece had a high displacement result in the +/- Z directions due to its lightness. If Figure 4 is examined, when water originated pressure is applied on the part, displacements occur on the part. A movement that occurs in this way will cause strain on the fixation points.

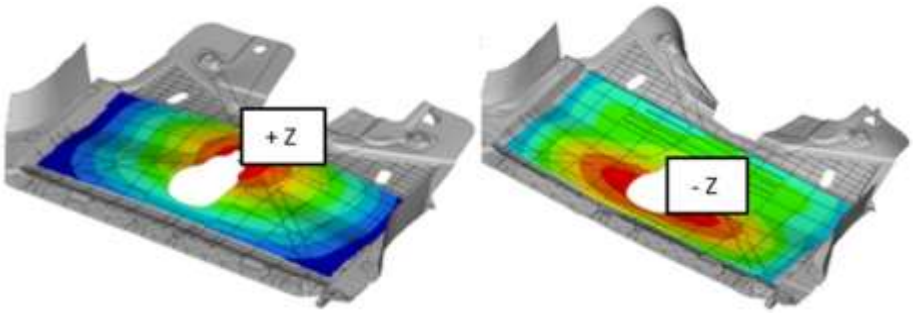

Fig 4. The displacement of the part in the + Z direction on the left and in the -Z direction on the right

If Figure 5 is examined, as a result of the displacements seen in Figure 4, it is seen that the stress values occurring in the part in 2 of the 5 fixation points of the part, seen below, exceed the limit where the flow will occur in the material. These stress values that will occur in the relevant parts of the part must be reduced. As the water comes on the part from the front side, as seen in Figure 5, the fracture may occur according to the stresses in 2 of the 3 fixations located at the front. The improvements to be made must be in this part.

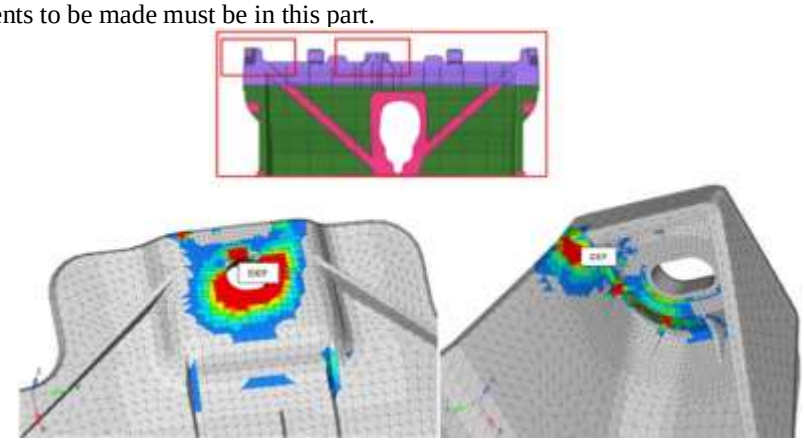

Fig 5. Detection of deformation areas

If the driving through water puddle test were to be carried out with the prototype of a design to be created in this way, fractures could occur in the relevant parts. In this part of the study, inappropriate areas of the piece have been identified. Analyzes will be repeated on new alternatives with necessary improvements depending on these regions.

4. IMPROVEMENT STUDIES

Improvement studies will be included in this part of the study. In these studies, improvements have been made for the 3 fixations in the front area of the under-engine shield part. Among these improvements, prototype parts will be produced by choosing an alternative that is suitable for compliance with the time schedule and is cost-effective. If Figure 6 is examined, 6 alternative improvement studies modeled are seen.

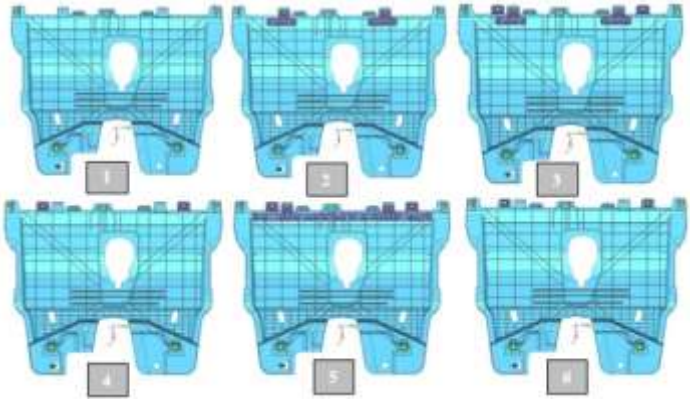

Fig 6. Alternative studies

If Figure 6 is examined in detail, in proposal 1, changes have been made in the plastic part as seen in Figure 7. In addition to the changes made on proposal 1, new suggestions have been studied. 2 new metal brackets are included in proposal 2, 2 new metal brackets, and 2 metal mounting brackets are added in proposal 3, 2 new metal mounting brackets are included in proposal 4, 1 in proposal 5 is a long one metal bracket and 2 metal mounting brackets modeled, proposal 6 included 2 new plastic mounting brackets.

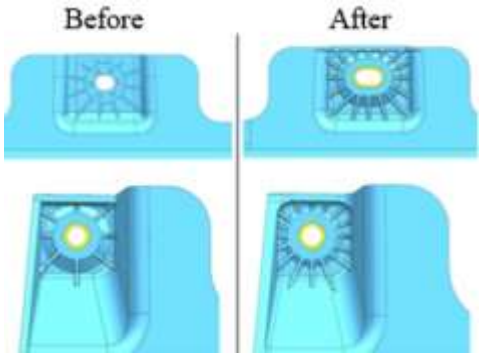

Fig 7. Design changes made to the plastic part

As can be seen in Figure 7, the number of ribs in the plastic part has been increased, and a metal bush has been added to the middle fixation point.

4.1. Analysis Results of Alternative Studies

In Table 2, all analysis results of the 6 alternative solutions are shown comparatively. As can be seen from all these figures and tables, important differences have been achieved with the use of metal brackets. In addition, as a result of the design changes made in the plastic part, the part has become able to be driving through puddle test. 89% improvement in the + Z direction and 71% improvement in the -Z direction with only plastic part changes.

Table 2. Analysis comparative analysis results of all alternatives

Alternatives	Displacement Reduction % +Z	Displacement Reduction % -Z	PEEQ +Z Improvement %	PEEQ -Z Improvement %
Solution 1	8,66	15,38	89,44	71,56
Solution 2	22,2	30,5	97,36	92,66
Solution 3	21,8	29,6	97,06	93,58
Solution 4	15,9	18,2	96,77	89,00
Solution 5	24,1	31,7	98,53	97,24
Solution 6	21,2	24,5	97,65	85,32

Figure 8 shows the analysis results of alternative solution suggestions. The figure shows only the left fixation point of all alternatives. Left and middle fixations are added for each analysis because this is the fixation point where fractures may occur.

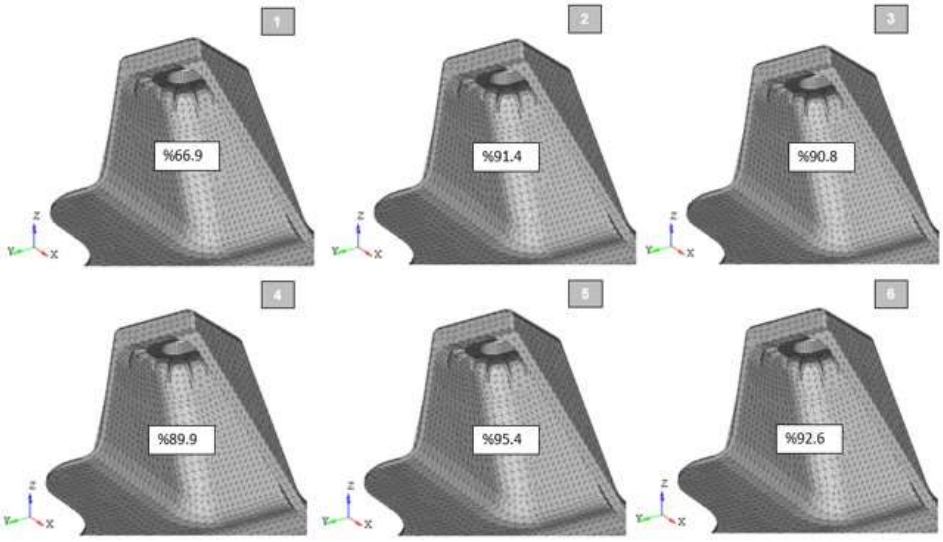

Fig 8. Improvements provided in the left fixation in alternative solutions

Figure 9 shows the analysis results because of the design alternative improvements made in the previous case. From here, it was observed that the middle fixation point came to the structure that provides stiffness and that stresses were obtained at values not exceeding the yield limit.

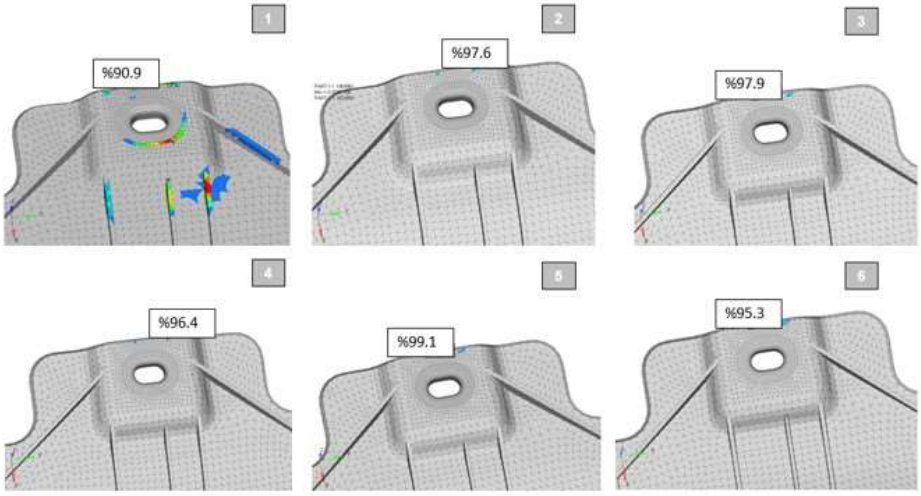

Fig 9. Improvements in the middle fixation in alternative solutions

As a result of all these studies, the engineer must decide on the most appropriate solution. After obtaining the parts that can pass tests such as verification and puddle according to the analysis results, the time plan and cost issues suitable for the project come to the fore. It is already clear that plastic modifications made on the part will not stretch the timetable too much. However, in the other alternatives, there will be an extra metal bracket mold, and an extra fixture to perform

the fixation. To avoid such a high cost, the part should be initialized to include plastic changes. Later, the development study should be verified by physical tests to be carried out by the project schedule, and then the product development process should be completed when positive results come there.

4.2. Driving Through Puddle Test Result of the Preferred Alternative

Models with sufficient improvements were examined in line with the analysis results. A proposal that can produce the prototype and final part in the most appropriate time for the project progress was preferred. Figure 10 shows the piece created with these changes. Driving through puddle test was carried out with the project vehicles to which this part was attached.

Fig 10. Generating the preferred alternative

The test was repeated continuously with different conditions. In these tests, which were repeated at different water levels and different speeds of the vehicle, no deformation was observed on the part or at the fixation points, as can be seen in Figure 11.

Fig 11. The positive result obtained as a result of the driving through puddle test

Thus, the product development process was completed by deciding on the product suitable for the progress of the project, the test results of which were concluded.

5. CONCLUSIONS

There are many tests carried out by automobile manufacturers under challenging conditions. With a test simulating a vehicle passing through puddles in rainy weather, the underbody components are continuously improved. In this study, the development process of a plastic protective part located in the under of the engine was explained in a short time. The importance of making calculations and making decisions in pre-prototype stages with numerical analysis is emphasized. If separate prototypes were produced for each alternative and the tests were repeated separately, it would have been a difficult and costly process to manage. With a project managed in this way, the product was put into use on time and by the conditions. Even if automobile users want to avoid conditions such as rough road conditions and puddles, they may not always find the opportunity. Thanks to this study, the possible problems that the users may experience in the puddles that they enter in such rainy weather have been eliminated.

ACKNOWLEDGEMENTS

We would like to thank the Farplas team for their support during the production of prototypes in our work.

ABSTRACT

Both design and survivability requirements should be optimally met in land vehicle design. Weight parameter stands out as the most important design constraint; therefore land vehicles, especially amphibious land vehicles need to be designed with using lightweight materials. Aluminum alloys (AA) offer lightweight solutions with their superior mechanical properties in ballistic applications. In this study, ballistic performance of aluminum alloys, particularly application areas of aluminum alloys in land vehicles have been investigated in a detailed manner. Comparative ballistic performance results of aluminum alloys in miscellaneous studies have been included. It has been seen in the results of the study that the use of appropriate aluminum alloy according to the threat level and type is very important for light armored vehicle design. Also, the type and thickness of aluminum alloys vary according to their position on the vehicle. Aluminum alloys will maintain their importance as very important materials in light combat vehicle design in the future as it is today.

Keywords: Aluminum, alloy, ballistic, land vehicle.

1. INTRODUCTION

Aluminum, titanium and magnesium based alloys are among the lightweight engineering alloys. When the use of those three alloys as armor material is examined, aluminum alloys are more advantageous [1]. The main reason for this is the properties of aluminum alloys which are high strength-to-weight ratio and ease of fabrication (ductile, malleable, tough, durable, high degree of workability, excellent thermal conductivity and high corrosion resistance) [1,2]. In addition, especially the cost and availability of titanium and magnesium alloys, are really compelling [3].

Aluminum alloys play an important role in lightweight armored vehicle design with the combination of low density and high strength, thus having a high specific strength. When the design requirements are met, high structural strength, ballistic protection, better transportability can be achieved with the use of these materials [4]. Turkish Armored Amphibious Assault Vehicle (AAAV) which has aluminum hull aiming to reduce the weight can be seen in Figure 1.

Figure 1. Armored Amphibious Assault Vehicle (FNSS Company) [5]

2. ALUMINUM ALLOY APPLICATIONS IN MILITARY VEHICLES

Weight reduction in land vehicles has been achieved by using high strength aluminum alloys and titanium instead of steels. There are many vehicles made of aluminum in the last few decades. Aluminum alloys were used in the hull and turret systems of the Soviet BMP-3, in the UK FV 510 Vehicle (in the hull). Futhermore USA, is the first country to use aluminum as an armor material in military vehicles [3] in 1960's.

The M113 Armored Personnel Carrier (APC) (Figure 2) was put into service in 1960 for transporting infantry forces. This vehicle which are air-transportable, air-droppable, amphibious operation ability, cross-country travel over rough terrain, and high-speed travel on pavement has effective deployment ability. Aluminum 5083 alloy was used in original M113 and its hull armor. This armor provided ballistic protection against small arms and fragments. On the contrary, it was insufficient to some extend against rocket-propelled grenades (RPGs) and mine blasts [3].

Figure 2. M113 Armored Personnel Carrier [6]

The M551 Sheridan Light Tank (Figure 3) which was designed in the early 1960's is an amphibious military vehicle used in different military operations. Use of aluminum hull and spaced aluminum armor was seen in this vehicle [3].

Figure 3. M551 Sheridan Light Tank [7]

Bradley Fighting Vehicle (Figure 4) was produced with the purpose of infantry transportation as providing covering fire to pin down enemy troops [3]. Its hull was made of Al 5083-H131 (MIL-DTL-46027) and Al 7039-T64 (MIL-DTL-46063) was used in the upper half of the vehicle.

Figure 4. Bradley Fighting Vehicle [8]

Aluminum alloy bar-armor system has been installed on a U.S. Army RG31 vehicle (Figure 5) against RPGs. These lightweight bars (half weight of the steel solutions) does not allow for a situation that impedes operational capability. Also they have a good maintainability and usability [9].

Figure 5. RG31 Vehicle [9]

3. BALLISTIC PROPERTIES OF ALUMINUM ARMOR ALLOYS

Aluminum alloys provide weight reduction in armor design compared to armor steels as previously explained. Projectile kinetic energy (KE) to penetrate versus the thickness of the plate for several armor materials are shown in the Milne-de-Marre graph (Figure 6). Aluminum-based armors provide lighter solutions than steels against KE ammunition with an impact energy of ~104 J according to the graph [1]. Strength of some 7xxx series alloys is comparable to that of mild steel having a specific strength three times higher [4].

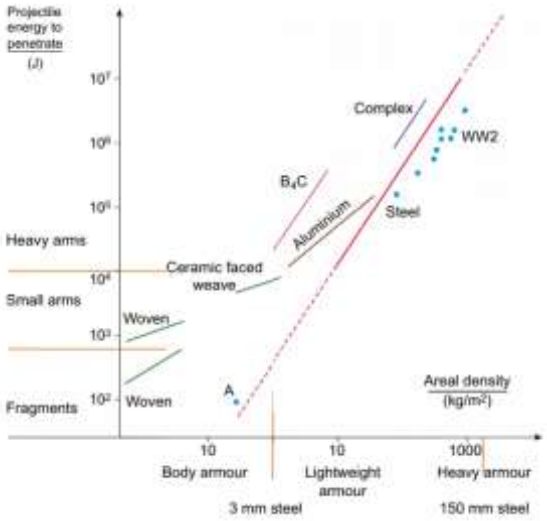

Figure 6. The Milne-de-Marre graph [1,10]

More particularly, AA5083 alloy has a wide range application area in land system platforms (such as the Paladin Self Propelled Howitzer and armored personnel carriers) [11]. 5083-H131 has been used in the M1113, the M109 and the USMC Amphibious Assault Vehicle (AAV) in the past. Lighter weight, ease of weldability for manufacturing, performance against fragmentation based threats and excellent corrosion resistance are the prominent features of this alloy [12]. AA7039 with the same density as AA5083 has higher strength and lower corrosion resistance and was used on the upper half of the Bradley fighting vehicle. AA5059 is another potential alternative armor material which has promising properties [11].

Tensile properties (specially yield strength) have an significant effect upon damage mechanism of aluminum armor plate against armor piercing (AP) projectile. Ballistic resistance of aluminum-zinc (7xxx) and aluminum-copper (2xxx) for AP projectile is higher than that of other aluminum armors [4]. For the armor piercing threats, higher strength AAs (such as AA7039, AA2219 and AA2519) were used in some armored vehicles such as the M2 Bradley Fighting Vehicle and the USMC Expeditionary Force Vehicle. Higher strength property of these alloys improves ballistic protection against AP threats. However, corrosion resistance of these alloys is much lower than AA5083-H131 because of stress corrosion cracking tendency of AA7039 and from pitting and exfoliation in AA2519. Although AA5083-H131 has significant material properties, it provides insufficient ballistic protection against strong AP threats compared to AA7039 alloys due to its lower strength. AA5059-H131 which is magnesium-based non-heat treatable alloy can be considered in some armor applications instead of AA5083-H131 since it has better mechanical properties, most notably higher strength. Moreover, AA5059-H131 has superior corrosion resistance compared to AA7039. Chemical composition and mechanical properties for various AAs are seen in Tables 1 and 2, respectively [12]. And finally, AA 2149 has come to scene as an emerging armor material which was first designed and improved in US Army Lab [13].

Its better performance in AP and fragment simulating projectile (FSP) was well documented, however 2139 alloy may have some constraints in welding operations [13-14].

Table 2. Minimum mechanical requirements for military specification aluminum armor alloys [12]

Property	**5083**	**5456**	**5059**	**7039**	**2219**	**2519**
Yield Stress (ksi)(0.2% offset min.)	35.0	35.0	44.0	51.0	46	58.0
Ultimate Stress (ksi)	45.0	45.0	57.0	60.0	62.0	68.0
Percent Elongation	8	8	8	9	7	7

Ductility, fracture toughness and tensile properties are important blast resistance properties against Mine Blast and IEDs (Improvised explosive device) for aluminum armors. 5xxx series are more prominent in terms of the blast resistance properties. Against fragments, resistance of 2xxx aluminum armor alloys is better than 7xxx alloys. 5xxx alloys show best protection for thickness below 1.5". Tendency of spalling which is detachment or delamination of a layer of armor plate in the area surrounding the projectile hole for high strength heat treatable aluminum armor plate should also be considered in armored vehicle design [4].

It is very difficult to use only one type of alloy to provide desired military vehicle requirements. If the zone specific ballistic performance criteria are determined, lightweight solutions and required ballistic solutions can be acquired [15]. For example, 5xxx series may provide a more suitable solution in some part of the military vehicle such as lower hull, on the other hand 2xxx or 7xxx series which are higher strength aluminum alloys would be more appropriate in upper side of the hull design [4].

The following results have been achieved in significant experimental studies on aluminum alloys.

AA7085-T7XXX which is an aerospace grade aluminum alloy was investigated for ballistic performance by using two tempers. Against AP projectiles, ballistic performance of two tempers were better than AA7039 specification and also first temper showed better ballistic performance than AA2139 specification. Against FSPs which are a kind of projectiles that are flat-nosed, right circular cylinders, while performance of first temper was between the specifications for AA7039 and AA2139, second temper FSP performance was comparable to AA7039 [16].

Ballistic performance of AA7056 that is used as armor was evaluated. 7056-T721 (a lower strength, higher ductility variant, for underbody blast protection kits), 7056-T761 (a high-strength variant, for use as an appliqué against direct-fire threats) and modified AA7056-T751 (original blast temper) were used in the study. AA7056 showed ballistic performance similiar to AA7085 against the AP projectiles (US 0.30-cal. APM2, 0.50-cal. APM2, Soviet 14.5-mm BS41) at equal thicknesses [17].

4. CONCLUSION

There are different suitable aluminum alloys for various ballistic applications. The properties of aluminum alloys have a very significant role in determining ballistic performance. Each alloy has a ballistic application area in accordance with its own characteristics. Lightweight ballistic solutions are obtained with aluminum alloys when the material solutions are properly selected regarding the design needs. When the aluminum alloys are used as hull materials some significant vehicle design requirements (speed, maneuverability and survivability) can be met effectively. Aluminum alloys will maintain their importance as very important materials in light combat vehicle design in the future as it is today.

ÖZET

Şehir içinde ve şehirlerarası yolculuklarda, farklı konfor arayışları ve gereksinimler oluşmaya başlamıştır. Bu çalışmada araçta bulunan soğuk ve sıcak içeceklerin (araçta depolanan veya tüketilen içecekler) müşteri tarafından beklenen sıcaklık seviyelerinin korunarak, müşteride olumlu etki yaratması amaçlanmıştır. İçecekleri sıcak veya soğuk tutma konusunda müşteri alışkanlıkları araştırılmıştır. Çalışma, araç içindeki sıcaklığa ve yolun uzunluğuna göre sıvıların zaman içerisinde sıcaklık değişimleri göz önünde bulundurularak, bu bölgeler için en uygun yerleşime ve en uygun sıcaklığın sağlanmasına dayanmaktadır. Bu kapsamda orta konsol üzerinde bulunan bardaklık ve saklama alanlarının verimliliği, ilave fonksiyonlar eklenerek artırılmaya çalışılmıştır. Bardaklık alanının ve orta konsol üzerindeki kolçak altı saklama alanının ısıtılması veya soğutulması için aracın mevcut klimasının alternatif çalışmaları ve kullanım esasları belirlenmiştir.

Anahtar Kelimeler: Orta Konsol, Soğutmalı Kolçak, Isıtmalı Bardak Tutucu, Araç Klimaası

HEAT & COLD CUP HOLDER ON CENTRAL CONSOLE DESIGN OPTIMIZATION CUSTOMER RESEARCH

ABSTRACT

With short rides in the city or long rides in the city and between the cities, different comfort searches are beginning to occur in the driver. In this study, to create a positive effect for cold & hot beverages in the vehicle (drinks stored and consumed in the vehicle). Customer habits regarding keeping drinks hot or cold have been researched. The study is based on the most appropriate placement and providing the appropriate temperature for these regions, considering how much temperature the fluids change according to the temperature inside the vehicle and the length of the road. In this context, the efficiency of the cup holder and storage areas on the center console has been tried to be increased by adding additional functions. Alternative studies and the usage principles of the current air conditioner of the vehicle have been determined for the cooling of the temperature that will come to the cup holder area and the under armrest storage area on the center console.

Keywords: Center Console, Cooled Armrest, Heated Cup Holder, Automotive HVAC

1. GİRİŞ

Çalışma, araç içindeki sürüş konforunu artırmak ve aynı zamanda aracın hali hazırdaki donanımının en iyi şekilde kullanılarak yeni özelliklerin sürücü ve yolcuya sunulması için yapılmıştır. Kapsam olarak sürücü ve yolcunun araç içinde tükettiği içeceklere, bu içeceklerin hangi zaman aralıklarında ve koşullarda tüketildiklerine odaklanılmıştır. Araç içindeki sıcaklıklara göre içeceklerin zamana göre davranışları ölçülmüş ve buradaki durum müşteri tarafından beklenen durum ile karşılaştırılmıştır.

Araç içerisinde içecekleri özellikle soğuk tutma için farklı alternatifler bulunmakta ve birçok farklı firmanın araçlarında son kullanıcıya bu özellik verilmektedir. İçeceklerin sıcak tutulması ise yeni yeni oluşturulmakta olup hala çok yaygın olarak kullanılmamaktadır. Araç ile gelen özelliklerin yanında satış sonrası olarak kabul edilen ve çoğu zaman araç üreticisi firmaya ait olmayan USB veya 12V'tan beslenen elektronik aletler bu ihtiyacı karşılamak için kullanılabilmektedirler.

Yapılan çalışma ile sürücünün uzun ve kısa süreli araç kullanımı deneyimi ile mola ve/ya günlük ihtiyaçlarına göre hangi içecekleri öncelikle tükettikleri, bunları araç içine konumlandırırken nelere önem verdikleri, sürüş sırasındaki ihtiyaçlarına göre beklentilerinin neler olduğu birebir görüşmeler ile ortaya çıkartılmıştır. Sonrasında yapılan prototipler ile son durum yine birebir görüşmeler ile müşteri beklentilerinin karşılanıp karşılanmadığı doğrulanmıştır.

Prototip çalışması ile ilgili olarak sedan binek araç orta konsolu ve araç kliması üzerinde değişiklikler yapılarak en uygun çözüm için sıralı denemeler yapılıp, en iyi, en uygun ve anlamlı çözüme ulaşmak hedeflenmiştir.

2. DENEYSEL ÇALIŞMA

Çalışmanın başlangıcında sürücülerin araç içi davranışlarını anlamak ve mevcut içecek koyma alanlarının verimliliğini ölçmek için saha çalışması yapılmıştır. Yapılan görüşmelerde sürücülerin sıcak veya soğuk tüketilen içeceklere göre 3 farklı alandaki geri bildirimleri toplanmıştır.

Ön kapı panelinin soğuk/ılık tüketilen içecekler için öncelikli olarak kullanıldığı tespit edilmiştir. Sürücüye yakın ve açık bir alan olması nedeniyle, bu alanda ayrılmış bölmelerin sürücü ve yolcu için oldukça önemli olduğu gözlemlenmiştir. Günümüzde çoğu araç üreticisi ön kapı panelinde öncelikli olarak 1,5 lt'ye çıkan veya 2 adet 0,5 lt'lik su alacak şekilde gözler yapmaktadır. Bu yaklaşımın müşteri talepleri ile örtüştüğü saha araştırmasının sonuçlarıyla da doğrulanmış oldu.

Torpido üzerindeki yolcu eşya gözünün ise daha çoğunlukla içecek yerine gündelik olmayan eşyaların koyulması ve uzun süre dayanan yiyeceklerin yerleştirilmesi şeklinde kullanıldığı geri bildirimi alınmıştır. Özellikle sadece sürücünün araç içerisinde olduğu sürüşlerde, araç hareket halindeyken kapalı bir eşya gözü içinden bir içecek alınmasının konforlu ve güvenli olmadığı, bunun yerine alternatif çözümlere ihtiyaç olduğu iletilmiştir. Hali hazırda araçlarda verilen soğutmalı eşya gözlerinin ise kullanışsız olduğu ve bazı müşteriler tarafından da gerekli olmadığı yönünde geri bildirimler alınmıştır.

Orta konsol bardaklık bölgesi özellikle sıcak içeceklerin araç içinde konumlandırılması için öncelikli olarak tercih edilmektedir. Buradaki geri bildirimler: Sürüş esnasında sürücü ile yolcunun yan yana oturdukları durumlarda, yan yana koyulmamış arka arkaya koyulmuş olan içeceklerinin karışması; mevsime göre sürüş uzadıkça araç içindeki içeceklerdeki ısı kaybının müşteride yarattığı memnuniyetsizlik; sürücünün içeceğini görememesi veya ulaşmasının zor olması durumlarında sürüş konforunda azalma olarak iletilmiştir.

Temel 3 alan içindeki olumlu ve olumsuz müşteri beklentilerine bakıldığında, sürücü ve yolcu için ek bir fonksiyonun anlamlı olacağı düşünülmüştür. Orta konsol üzerindeki bardaklıkta sıcak veya soğuk tutma özelliğinin olması KANO metodu ile değerlendirildiğinde, müşterilerin bu özelliği çekici bulacakları sonucu çıkmıştır.

Araç içi içecek kullanımı ile ilgili yapılan anket sonuçlarına göre, araçlarda öncelikli olarak su tüketilmekte ondan sonra ise kahve tüketimi gelmektedir. Diğer meşrubatlar ve çay daha sonraki sıralarda yer almaktadır.

Su ile ilgili olarak; Yaz aylarında özellikle soğuk su tercih edilmektedir.

Kahve ile ilgili olarak; arabası ile işe gelen sürücüler sabah işe geldikleri yol boyunca sıklıkla kahve tükettiklerini ilettiler. Buna benzer durumlarda günümüzde birçok kişi artık araçlarında sıcak içecekler ile seyahat etmektedir. Bu süre zarfında sıcak olarak alınan içeceğin soğuma süresinin kısa olması kullanıcının içeceğini daha hızlı içmesine veya içeceğin hızlı soğuması nedeniyle içeceğin tamamını içememesine sebep olmaktadır.

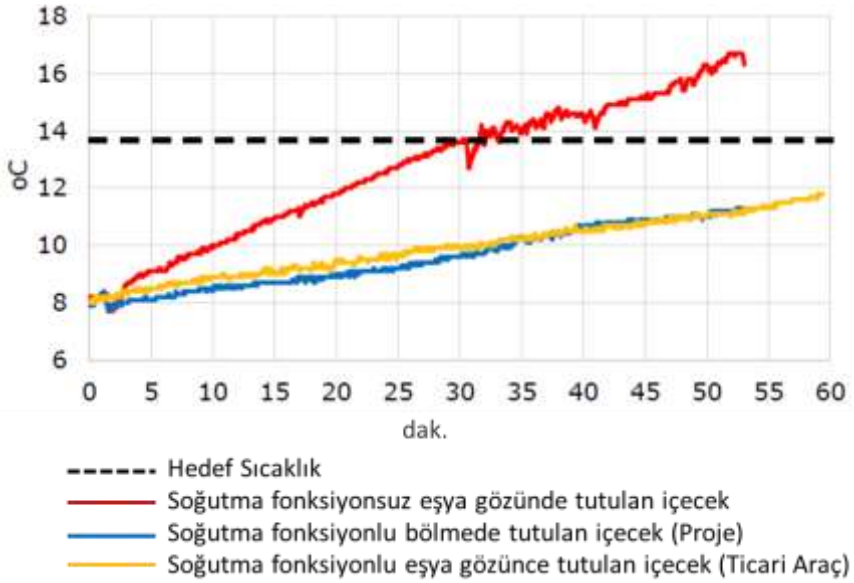
Araç içindeki kahve ve benzeri sıcak içecekler ile su ve benzeri soğuk içeceklerin en uygun sıcaklık değerlerinin literatür araştırmaları, sıcak içecek kahvenin 57.8 ^{o}C'de [1], soğuk içeceklerden suyun 15 ^{o}C'nin altında, sodanın ise 10 ^{o}C altında kalması durumunda içecek memnuniyetinin sağlandığını belirtmektedir. 4 kişilik bir müşteri deneyimi ekibi ile birlikte yapılan tadım testlerinde de benzer sonuçlar alındığından projemizin hedef değerleri de bu doğrultuda belirlenmiştir.

Araç içinde içeceği sıcak tutmak için bazı satış sonrası çözümler veya yoğunlukla olmasa da araç içi çözümler bulunmaktadır. Bu tarz uygulamalarda elektronik peltier pedler [4] kullanılmakta ve araç aküsünden elektrik enerjisi alınarak sıcaklığı koruma veya kapalı bir alan içini ısıtarak ısıtma uygulamaları bulunmaktadır. Fakat bu çalışmalar maliyet açısından yüksektir ve aracın elektronik sistemine bir yük getirmektedir.

Soğuk havanın alınması ve taşınması ile ilgili olarak; Araçlarımızdaki klima ünitelerinde, hava akışını ilk olarak buharlaştırıcı denilen soğutucu özellikli ısı değiştirici [3] üzerinden geçer ve soğur, bu havanın en soğuk olduğu ve tüm

araçlardaki eşya gözü soğutma için soğuk havanın alındığı bölgedir. Buharlaştırıcı çıkışındaki ısı sıcaklıkları 5 ºC ile 10 ºC arasında değişmektedir. Soda için içecek konfor sıcaklığı, klimanın en soğuk çıkışının da altında kaldığı için projemizde soğutma olarak 15 derecelik su soğutması hedeflenmiştir. Hedef belirlenmesinde ticari araç soğutmalı torpido eşya gözü sıcaklığı da 17 derece olarak ölçülmüş ve hedefin uygun seçildiği doğrulanmıştır. Alınabilecek soğuk hava debisi klima fan seçimi ile doğru orantılıdır. Genel kullanım koşullarında fan minimum seviyede kullanıldığı için çalışmamızda da en düşük fan debisi ile performans optimizasyonu yapılmıştır. Soğuk havayı eşya gözüne taşıyacak, gerekli hortum boyuna bağlı olarak, ısı kayıpları dikkate alınarak, yeterli hava debisini verebilecek hortum çapı ve klima çıkış çapı seçilmiştir.

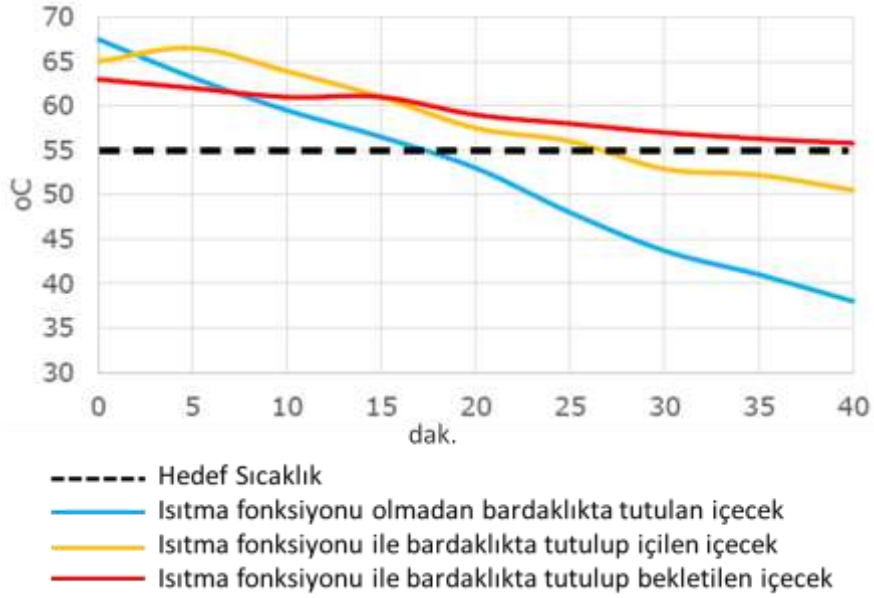
Soğuk içecekler bir bardaklık içinde soğutulmaya çalışıldığında, soğuk hava çıkışı ile içeceğin sıcaklığının istenen değerde tutulamadığı ve bundan dolayı da açık bir bardaklık kullanılmasının uygun bir çözüm oluşturamadığı görülmüştür. Burada test edilen yöntem, araç kliması çalıştırılmadan, sıcak ya da soğuk hava seçiminden bağımsız olarak kolçak altındaki kapalı bölmeye soğuk havanın taşınmasıdır.



Şekil 1. Soğuk İçecek Sıcaklık Değişimi

Soğuk içecek performans testi 22 ºC'de ayarlı kabin iç sıcaklığında, sürüş şartında yapılmıştır. İçecekler 8 ºC'de tutulan makinadan alınarak teste başlanmıştır. 40 dakikalık bir süre sonunda, soğutma fonksiyonu olmayan bir eşya gözünde tutulan su soğukluk özelliğini kaybetmektedir.17 ºC'de soğutmalı eşya gözlü araçta 1 saat süre sonunda suyun sıcaklık değeri 12 ºC'nin altında kalmıştır. (Şekil 1) Aynı içecek projemizdeki soğutma performansına sahip bölmede, 15 ºC'lik bir üfleme sıcaklığı ve 10 m3/h'lik akış debisiyle yine 12 ºC nin [2] altında kalmıştır. Havanın taşınması için 3 mm kalınlık ve 17 mm iç çapı olan 800 mm EPDM hortum kullanılmıştır ve projede klima çıkışında ölçülen sıcaklıklar 8 ºC – 10 ºC dir. Bu değerler 5 derecelik bir ısınma ile bölmeye ulaşmaktadır.

Sıcak havanın alınması ve taşınması ile ilgili olarak; Klima ünitesinde buharlaştırıcı çıkışında belli bir miktar hava bir klape yardımı ile karışım odasına alınır. Karışım odası, içinde 90 ºC de motor soğutma suyunun dolaştığı klima radyatörünün bulunduğu bölgedir. Bu bölge çıkışı en yüksek sıcaklıkların alınabildiği kısımdır. Sıcaklık potansiyeli yüksek olsa da yeterli hava debisi açısından kritiklik içermektedir. Çünkü klape konumuna bağlı olarak karışım odasındaki basınç da değişmektedir ve bu da sistemde ilave bir hava emiş fanı kullanılmadan klimadan alınabilecek sıcak hava debisini etkilemektedir. Araçta, maksimum soğutma ihtiyacı olduğunda, bu klape karışım bölgesine hava akışını kapatacağı için, içecekleri sıcak tutma fonksiyonu sıcak hava ihtiyacını da karşılayamayacaktır. Bu sebeple çalışmamızda, en kötü ve en yaygın kullanım koşulu olan en düşük fan debisinde karışım klapesinin farklı çalışma açıları için performans ölçümleri yapılarak, sistemin 60 ºC üzerinde hava sağlama hedefini hangi dış ortam ve çalışma şartlarında sağlandığı belirlenmiştir. Sıcak hava kaynağı ile bardaklık arasındaki gerekli hortum boyu, ısıl kayıplar hesaplanarak uygun debi seçimi ve bu debi için gerekli hortum çapı ile klima çıkış ağzı çap ölçüsü belirlenmiştir.



Şekil 2. Sıcak İçecek Sıcaklık Değişimi

Sıcak içecek performans testi 22 ºC'de ayarlı kabin iç sıcaklığında, sürüş şartında yapılmıştır. Başlangıç durumunda içecekler makinadan 65 ºC – 70 ºC sıcaklıklarda alınmıştır. Isıtma fonksiyonu olmayan bardaklıkta tutulan kahve sıcaklığı 15 dakika içinde konfor sıcaklığı olan 55 ºC'nin altına düşmektedir. Klimadan alınan sıcak hava ısıtması ile sıcak içecek sıcaklıkları 40 dakikaya kadar konfor sıcaklığı üzerinde tutulabilmektedir. (Şekil 2) Klima çıkışında 65 ºC'lik bir kaynaktan alınan sıcak hava, bardaklık çıkışında 50 ºC – 55 ºC düşmektedir. Yeterli ısıtma 15 m3/h ve üzeri hava debisi ile sağlanabilmektedir. Tasarımda 1200 mm hortum boyunda istenen debinin sağlanması için 22 mm iç çap seçilmiştir.

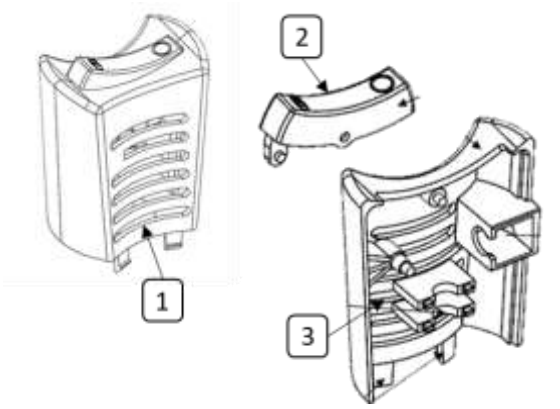
Yapılan testler sonrasında sıcak içecekler için uygun sıcaklığı korumak üzere klimadan faydalanılabileceği görülmüştür. Buradaki etken durum, araç kliması çalıştırılmadan, sıcak ya da soğuk hava seçiminden bağımsız olarak bardaklık içine doğru sıcaklıktaki havanın taşınmasıdır.

Torpido eşya gözü yerine orta konsol kolçak altındaki göz, sürücülerin yolculuk halinde daha kolay ulaşmasını sağlamak için seçilmiştir. Müşteriler ile yapılan görüşmelerde de suyun en çok kapı paneli ve orta konsolda saklandığı geri bildirimi alınmıştır.

3. SONUÇLAR VE ÖNERİLER

Bardaklık bölgesi ile ilgili olarak, klima ünitesinden gelen hava yardımı ile sıcak içeceğin soğuma süresini uzatan mekanik ve modüler bir yapı bardaklık içine gelecek şekilde tasarlanmıştır. Tasarım ile beraber hava çıkışını açıp kapayarak sistem kullanılabilmektedir. Bu sayede sıcak hava kontrollü bir şekilde dışarıya verilmektedir.

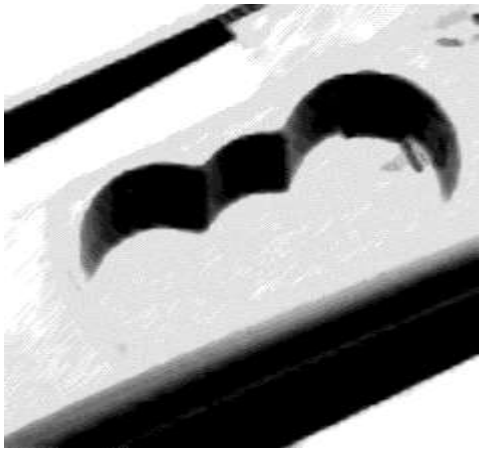
Yapı mekanik çalışacak şekilde tasarlanmış olup, her hangi bir elektronik donanım öngörülmemiştir. (Şekil 3)



1	Yönlendirici Mekanizma
2	Açma Kapama Tuşu
3	İç Kısım Izgara Yapısı

Şekil 3. Bardaklık Hava Dağıtım mekanizması

Mekanizma bardaklık bölgesine takılmakta ve klima ünitesinden çekilen sıcak hava alt bölgede bulunan kanaldan sistem içerisine gelmektedir. Açma kapama işlemi buton ile yapılmıştır. Hava delikten girdikten sonra kapalı ve sızdırmaz bir alanda kalmakta bundan sonra yanal ızgaralar sayesinde bardaklık içine iletilmiştir. Bardaklık içinde yuvarlak hat sebebiyle havanın bu bölgede kalması hedeflenmiştir. (Şekil 4) Mekanizma bardaklığın ortasına konumlanacak olup, her iki bardaklık bölgesine eş hava dağıtacak şekilde tasarlanmıştır.



Şekil 4. Bardaklık bölgesi tasarımı

Tasarım ile ilgili detaylar için patent başvurusu yapılmıştır. [5]

Kolçak altındaki saklama alanı için de bir vana yardımı ile soğuk havanın içeriye girmesi kontrol edilmektedir. Bu bölge ile ilgili sızdırmazlık, kolçağın kumaş yüzeyi ile saklama alanı arasında baskı oluşturması ile sağlanmıştır.

Sıcak ve soğuk bölgeler klima üzerinde farklı konumlardan alınıp, yine araç içinde farklı yerlere verildiği için bu özelliklerin ayrı ayrı veya beraber araçta ek bir özellik olarak kullanılabileceği görülmüş ve prototip ile doğrulanmıştır. Buradaki etken durum aracın klimasına donanım eklemeden, klima kasası üzerinde tasarım değişimleri ile ek özellikler verilmesidir. Bunun klima fonksiyonları üzerinde herhangi bir kayba neden olmadığı doğrulanmıştır.

Yapılan tasarımlar prototip seviyesinde araca uygulanmış ve müşteri deneyimi çerçevesinde kullanımı sonrası olumlu yorumlar almıştır. Yorumlarda sıcak içecek sıcaklığının uygun bir derecede tutulduğu belirtilmiş ama içeceklerin dış kaplamalarının da sıcaklık sürelerini etkilediği görülmüştür.

Deney gurubu olarak uzman kullanıcılara gün içerisinde 3 farklı zaman diliminde şehir içinde uzun ve kısa mesafeleri oluşturacak şekilde yol yaptırılmıştır. Bu sıradaki deneyimleri ve beklentileri analiz edilmiştir. Gelen yorumlardaki kritikler alttaki gibi iletilmiştir.

- Sistemin mevcut bardaklık konumunda olması olumlu karşılanmıştır.
- Sistemin açma kapaması olması talep edilmiştir.

- Soğuk içecekler için kolçak altı saklama alanı torpido eşya gözüne göre daha olumlu bulunmuş olup, sürücünün sürüş sırasında kullanımı için uygun görülmüştür.
- Sürüş sırasında oluşabilecek ıslık sesi ile ilgili olarak, havanın iletildiği boruların malzemesi güncellenmiştir.
- 2 adet bardaklık olan araçlarda her 2 bardaklık için farklı çalışma olması (sıcak havanın bir tarafa gelip birine gelmemesi şeklinde) geri bildirimi gelmiştir.
- Şehir içi koşullar için sıcak içeceklerin 40 dakikalık süre boyunca uygun sıcaklıkta korunması yeterli bulunmuştur.
- Kolçak altı saklama alanında içeceklerin soğuk tutulabildiği görülmüş olup ancak araç çalışmadığında buradaki sistem durduğundan araca ilk binişte soğuk bir içecek deneyimi sağlanamamıştır.

Yapılan çalışmalar neticesinde bardak ısıtıcısı olan mevcut sistemlerde elektronik ped yardımıyla ısıtma işlemine alternatif olarak araç içinde bir bileşen olan araç klimasının efektif kullanımı ile maliyet avantajlı ve sürücü ile yolcuya değer katan bir sistem oluşturulmuştur.

TEŞEKKÜRLER

Yapılan çalışmalarda yer alan müşteri deneyimi ekibinden Arzu Yaman ve Özde Özdemir'e geri bildirimleri için, prototip hazırlık aşamasındaki teknik desteklerinden ötürü İsmail Mutlu'ya, mentörlük ve destekleri için Özgür Öztürk'e teşekkür ederiz.

ÖZET

Müşteri ihtiyaçları çeşitlenmesi, pazar ihtiyaçlarının farklılaşması araçlardaki ürün çeşitliliğinin artmasına ve her çeşit ürün için ayrı ayrı yatırım yapılmasına sebep olmaktadır. Bu bildiride orta konsol parçasında 4 çeşit ürün için ayrı 4 ana kalıp yapılması yerine, versiyon lokmaları ile modüler bir yapı kurularak tek bir ana kalıpla versiyon lokmaları değiştirilerek 4 çeşit ürünün elde edilmesi ile sağlana verimlilik anlatılmaktadır. Üretim adetlerine göre ana kalıp üzerinde kablosuz şarj ve radyo kontrol düğmelerinin olup olmamasını yöneten versiyon lokmaları ana kalıp üzerinde değiştirilerek üretim çeşitliliği yönetilmektedir. Bu yöntem ile yatırım maliyetlerinde (%50) verimlilik sağlanabilmektedir. Ayrıca 4 ayrı büyük kalıbın üretimde tutulması yer kaplamasının önüne geçilmiştir. Paralelde birim maliyet etkileri de adetlere göre düzenlenip proses zamanına göre düzenlenerek, az adette üretilen parçalarda birim maliyet artışı sağlanmıştır.

Anahtar kelimeler;

Plastik enjeksiyon kalıbı, versiyon lokması, ürün çeşitliliği,

MANAGEMENT OF PRODUCT VARIETY WITH FEWER MOLDS USING OF VERSION SOCKETS

ABSTRACT

The variation of customer needs and the differentiation of market needs cause the product variety in vehicles to increase and separate investments for each type of product. In this paper, instead of making 4 separate main molds for 4 different products in the center console part, the efficiency achieved by creating a modular structure with version inserts and by changing the only version inserts on a single main mold is explained. Production diversity is managed by changing these version inserts that manage whether there are wireless charging and radio control buttons on the main mold according to the production quantities. With this method, 50% efficiency can be achieved in investment costs. In addition, keeping 4 separate large molds in production is prevented from covering large space. In parallel, the unit cost effects were arranged according to the number of pieces and arranged according to the process time, resulting in a unit cost increase in parts produced in less quantities.

Keywords:

Plastic injection tool, version inserts, product complexity.

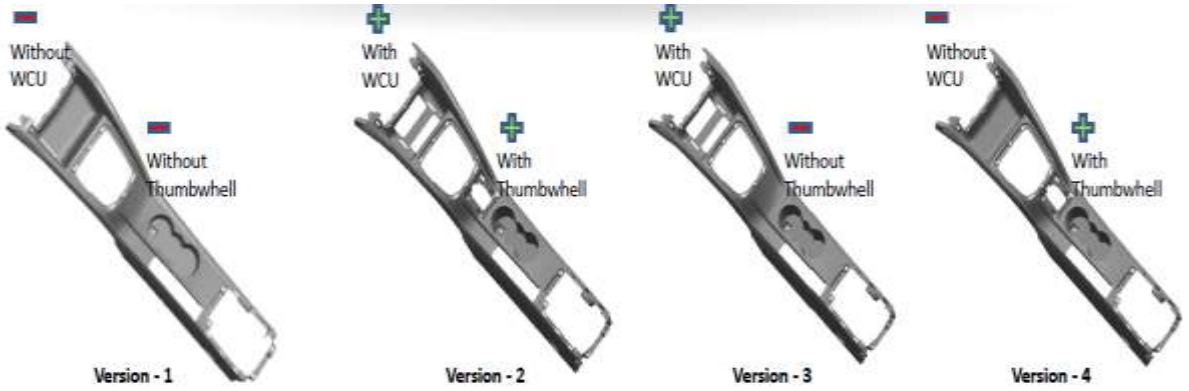
1. GİRİŞ

Ürün çeşitliği yönetmek için yapılan daha önceki çalışmalar kalıp sayısını arttırarak (her versiyon için ayrı kalıp yaparak) ya da parça sayısının arttırılarak tak çıkar sistemler oluşturarak giderilmektedir. Bu durum hali hazırda pahalı olan plastik enjeksiyon kalıp yatırım maliyetlerini [1] arttırmaktadır. Ayrıca kesme kalıpları ile bazı basit boşaltmaların yapılıp parça çeşitliğinin yönetildiği görülmektedir. Fakat kesme operasyonu karmaşık yüzeyleri olan formlu bölgeler için kullanılamamaktadır, kullanım alanı sınırlıdır. Ayrıca plastik parçalar kesme ve işleme operasyonlarına her zaman uygun değildir. Özel işleme teknikleri ve aletleri gerektirmektedir [2].

Bu bildiride parça çeşitliliğini, optimize edilmiş yatırım maliyetleri ile yönetilmesini sağlayan versiyon lokması kullanımından bahsedilmiştir. Özellikle büyük maliyetli plastik enjeksiyon prosesine uygun [3], üzerinde opsiyon olarak az sayıda üretilecek olan versiyonlar için kullanılabilecek bir yöntemdir. Parça çeşidine göre, versiyon üretim miktarlarına göre bu tip yöntemin avantajları (yatırım maliyet kazancı, kalıp sayısı azaldığı için alan kazancı), uygulama alanlarını nasıl genişlettiğinden bahsedilmektedir.

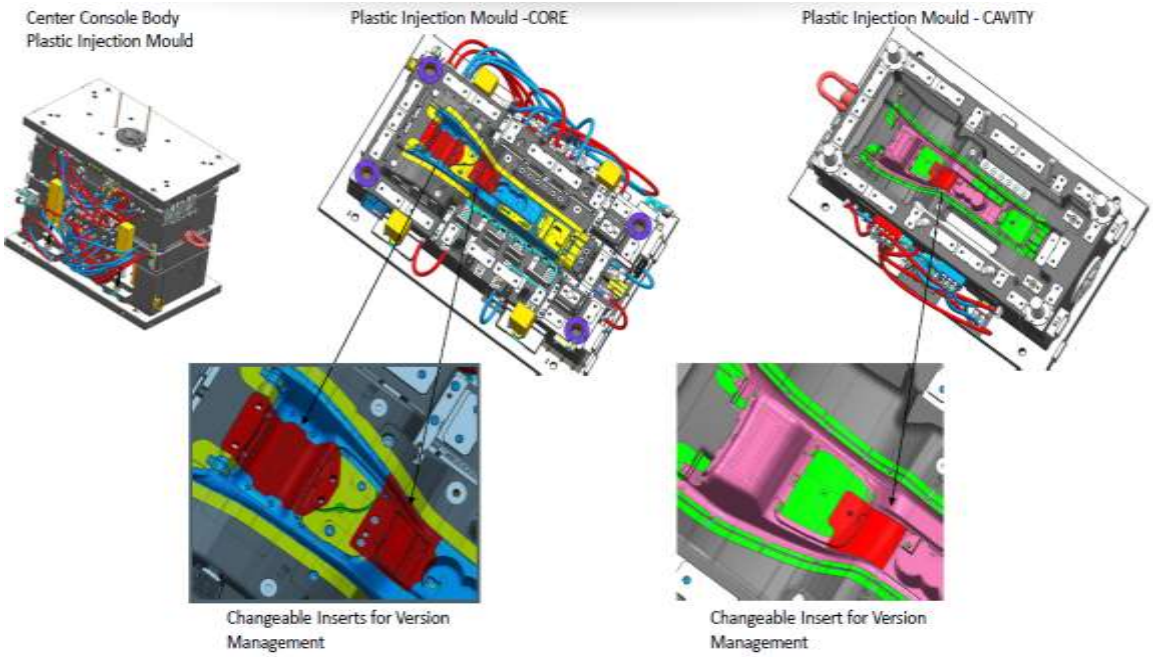
2. ANA BÖLÜM

Bu çalışmanın başlangıcında orta konsol üzerine iki özelliğin, kablosuz şarj ünitesi (WCU Wireless Charge Unit) ve radyo kontrol düğmesi (Thumbwheel) pozisyonlanıp yerleşiminin yapılması talep edilmiştir. Bu iki özellik standart olmayıp müşteri taleplerine incelendiğinde toplam üretim adedine göre düşük adetlerde olduğunu varsayalım. Her iki özelliğin yerleşimi için, konsol üzerinde gerekli olan boşluklara ve formlara ihtiyaç duyulmaktadır (Bknz Şekil-1). Bu özelliklerin olmadığı üretimin yüksek orandaki konsolda ise bu bölgeler estetik açıdan sürekli ve kapalı olmalıdır. Bu durum her bir ürün çeşidi için (baz kapalı – kablosuz şarj üniteli – radyo kontrol düğmeli – hem kablosuz hem radyo kontrol düğmeli) 4 ayrı plastik enjeksiyon ana konsol kalıbı yapma ihtiyacı doğurmaktadır. Otomotivde çok sayıda parça basan plastik enjeksiyon kalıpları özel çelik malzemeden üretilip, uzun işleme sürelerin tabi tutularak maliyetleri oldukça yüksek bir şekilde üretilmektedir [1]. Bu tip bir paçada kalıp maliyetinin 200.000 birim olduğunu düşünürsek, projeye getireceği maliyet 800.000 birimi bulacak ayrıca 4 ayrı büyük kalıbın belli bir alanda saklanması gerekmektedir.



Şekil 1. Orta Konsol Çeşitleri

Az sayıda üretilecek olan üst versiyon özelliklerinin konsol üzerinde yerleşimini sağlayacak, bu özellikler istenmediği zaman estetik bütünlüğü sağlayacak, orta konsolun ilgili bölgelerine takılıp çıkarılarak 4 ayrı ana konsol yapısını elde edilmesini sağlayan versiyon lokması tasarımı [4] ve her versiyon proses simülasyonları [5] yapılarak gerçekleştirilmiştir (Bknz-Şekil-2).



Şekil 2. Versiyon lokmalı kalıp

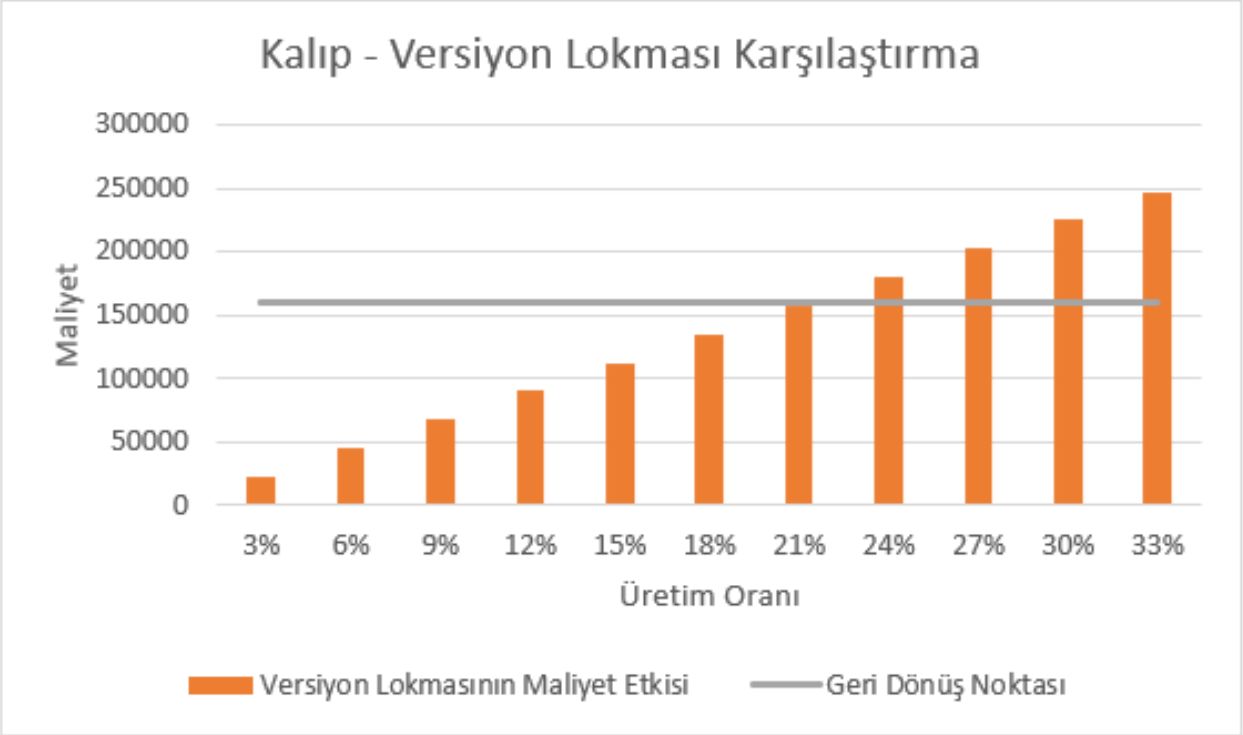
Versiyon lokması tasarımı, yerleşimi yapılacak parçanın ihtiyacına göre çeşitlenebilmektedir. Plastik enjeksiyon prosesinde oluşabilecek hatalar [6] düşünülerek tasarım yapılmalıdır. Ana gövde üzerinde sadece bir boşaltma yapılacak ise erkek çelikte bir versiyon lokması çalışmak yeterlidir. Fakat bağlantı elemanları için formlu girintili bir yapı oluşturulacaksa hem erkek kalıpta hem de dişi kalıpta versiyon lokması tasarımına ihtiyaç duyulmaktadır. Bu durumda versiyon lokma sayısı ve kalıp hazırlama süresi artmaktadır. Versiyon lokma yatırım maliyetleri tasarıma göre çeşitlilik gösterse de ortalama 40000 birim olarak alınabilir.

Tek bir özelliğin (Ör. Kablosuz şarj ünitesinin) talep edildiği ömrü boyunca üretimin %3 nü kapsayan bir özelliğin versiyon lokması yönetimi ele aldığımıza ve toplam üretim adedini 500.000 bin olarak varsaydığımızda, kablosuz şarj ünitesinin üretimi için kalıp dönüşümünden parça başına 1.5 birim maliyet artışı gelmektedir. Bu maliyet artışının araç ömrü boyunca getireceği maliyet 500.000 x 0,03 x 1.5 = 22.500 birimdir. Yeni kalıp maliyetinden bu etki ve versiyon lokması maliyeti çıkarıldığında oluşan fark (200.000 – 22.500 – 40.000 = 137.500 birim) oldukça yüksektir.

Kablosuz şarj adetlerinin artması kalıp değişim sayısını artmasına ve karşılanacak maliyetinin artmasına sebep olmaktadır. Bu versiyonun üretimin %30 una çıktığını varsayarsak birim maliyete etkisi sabit 1,5 birim olarak almamız durumunda yönetim maliyeti 500.000 x 0,3 x 1,5 =225.000 birime denk gelmekte ve başata yapılacak yatırımın üzerine çıkmaktadır.

Bu karşılaştırma kalıp maliyetine göre belli bir üretim oranından sonra geri dönüş yapmadığını, ana kalıp maliyet miktarına göre ikinci kalıba veya versiyon lokması çözümüne karar verilmesi gerektiğini göstermektedir. Ayrıca versiyon üretim miktarı arttıkça kalıp değişim sayısının üretim hattı üzerindeki etkisi de ayrıca değerlendirilmelidir.

Aşağıdaki grafik-1 de 200.000 birimlik bir ana kalıpta, birim maliyet etkisinin 1.5 birim olduğu, %21 üzerinde bir üretim oranına sahip versiyon yaratmak istendiğinde kazanç sağlanmadığı ve daha yüksek üretim oranlarında ikinci kalıbın tercih edilmesi gerektiğini göstermektedir.



Tablo 1. Maliyet Karşılaştırması

Aynı plastik parça üzerinde iki ayrı özellik için yerleşim istenmesi durumunda (Ör: kablosuz şarj ve radyo kontrol düğmesi) ihtiyaç duyulan kalıp sayı dört adede çıkmakta ve kalıp yatırım maliyetleri dört katına çıkmaktadır. Bu yerleşim için versiyon lokması düşünüldüğünde ise elde edilecek yatırım kazancı daha da aratmaktadır, çözüm daha anlamlı hale gelmektedir.

Talep edilen özellikleri üretim oranlarını olacak %3 kablosuz şarj- %3 radyo kontrol- %9 hem kablosuz şarj hem de radyo kontrol olacak şekilde varsayarsak. Versiyon lokmaları için yapılacak yatırımı iki tip için yaklaşık 80.000 birim olacaktır.

Aracın ömrü boyunca getireceği maliyet yükü ise;

Kablosuz şarj için 500.000 x 0,03 x 1.5 = 22.500 birim

Radyo kontrol Düğmesi için 500.000 x 0,03 x 1.5 = 22.500 birim

Her iki özellik olan versiyon için 500.000 x 0,09 x (1.5 +1.5) = 135.000 birim

Toplamda oluşan maliyet yükü ana kalıp ve versiyon lokması yatırımı dahil 460.000 birim olmaktadır. Fakat her versiyon için ayrı kalıp yapılması durumunda yapılacak yatırım 800.000 birim olacağında yaklaşık %50 kazanç sağlanmaktadır.

3. SONUÇLAR VE TARTIŞMA

Bu çalışma ile düşük üretim oranlarına sahip özelliklerin ana plastik parça üzerine yerleşimi için ekonomik yatırım kazancı sağlayan versiyon lokması kullanımı özetlenmiştir. Kullanım adetleri arttıkça, versiyon lokması yönetim maliyetleri, ana kalıp yatırımına göre değerlendirilerek karar verilmelidir. Versiyon lokmalarını formlu yüzeyleri yönetmekte sağladığı esneklikte açıkça görülmektedir.

TEŞEKKÜR

Bu çalışma da tasarımların edüstriyelleşmesi ve devreye alınması çalışması FOMPAK Automotive Plastik & Intreior tarafından, kalıp imalatı KAREL KALIP SAN. A.Ş tarafından gerçekleştirilmiştir. Her iki firmaya da projede yapmış oldukları çalışmalardan için teşekkür ederiz.

AERODYNAMIC INVESTIGATION OF AN E-SCOOTER & RIDER SYSTEM THROUGH COMPUTATIONAL FLUID DYNAMICS APPROACH

Sercan Acarer[1], Ersen Arslan[2,3], Çağlar Uyulan[1]

ABSTRACT

Micro-mobility in cities increasingly becomes widespread as demand to environmentally-friendly technologies escalates. Electric kick scooters (e-scooters) are at the heart of this concept and has been undergoing a strong evolution in recent years. Even if battery life and system integration aspects are being studied as major headlines, aerodynamics received little attention due to its relatively minor role. However, this may not be completely true. For instance, the legal limit of the e-scooter speed being 25 km/h in some EU countries. Thus, moderate wind speeds can go up to 30 km/h and this makes a quite interesting value of 55 km/h as a relative speed in such a blunt body. Therefore aerodynamics may impose a major impact on the motor requirements as well as generating notable forces on the rider and lateral lean of the scooter. The objective of this study is to investigate longitudinal and lateral aerodynamic loads on an e-scooter and its generic rider. Experimentally validated steady-state Computational Fluid Dynamics (CFD) simulations are used for this purpose. Seven cases at different wind speed and angle conditions are considered. Drag and leaning torques are presented. Then, detailed wake structures, shear forces and surface streamlines on the rider are revealed and discussed. The results aim to serve as a reference data to be used by the e-scooter community. However, these results are limited to steady-state conditions and transient behaviour and stability analysis is required for future studies.

Keywords: Aerodynamics, Computational Fluid Dynamics (CFD), e-Scooter, Personal Light Electric Vehicle.

1. INTRODUCTION

Aerodynamics can be regarded as the most common physics phenomena that need to be analysed in the design stage of any vehicle that is running through the air. Depending on the case, there may be a considerable amount of force interaction with the air, in terms of drag or lift. Indeed, the drag force is the one to consider for the land mobility vehicles, as it may have effects on the system. Throughout history, many researchers and engineers have tried to find the best aerodynamic design to meet their project needs like power demand, speed limits, stability etc. In this study, the aerodynamic investigations through numerical calculations will be addressed for an electric kick scooter that belongs to the Personal Light Electric Vehicle (PLEV) category. For these types of vehicles, power efficiency and safety are the main topics for designers, and aerodynamics plays a key role in both.

Although there is no single definition for micro-mobility, it means the category of vehicles weighing up to 350 kg and having a speed limit of 45 km/h and used for personal transportation [1]. PLEVs are often used for wheeled vehicles partially or motorized for transporting a single person. Electric kick scooters (also known as e-scooters) are stand-up scooters that are propelled by an electric hub motor inside the scooter wheels. While there is still not an exact class defined for e-scooters, L1e (Light two-wheel powered vehicle) will the best alternative according to the EU vehicle category [2]. Nowadays the popularity growth of these vehicles together with e-bikes is beyond argument. Successful evolutions in battery technologies, such as higher energy density lithium-ion batteries, not only have made electric cars become feasible but also boost the micro-mobility products with more affordable and light power sources. This unbundling trend of car usage into these micro-mobility vehicles can be explained with several reasons: The environmental awareness and electrification trends in the industry, shared mobility trend in personal transportation, first and the last-mile gap in public transportation and serious level of automobile traffic in city centres. This quick evolution in the transport industry has led to some issues like safety, environmental sustainability, and energy efficiency. Also, the regulations and the technical standards for the micro-mobility vehicles are still under development and they need some more time to supply adequate references for the whole eco-system. Manufacturers adapt their background and insights

in designing the vehicle, but some points are to be ignored to catch up with the demand and put the product on the market as soon as possible.

One of these ignored points is aerodynamics. Especially for the e-scooters, the effect of wind on the rider and the vehicle is generally being underestimated since the speed is low and the frontal area is assumed to be exceedingly small. Depending on each country's regulation, the upper limit of e-scooters on public roads is limited. For example, the legal limit of the e-scooter speed is 25 km/h in some EU countries. At first, this value seems to be quite low and easily be ignored for the aerodynamic effects. However, the weather may also contribute to the relative speed between the vehicle and surrounding air. The moderate wind speeds can go up to 30 km/h [3] and this makes a quite interesting value of 55 km/h as a relative speed. As a standalone vehicle, the frontal area in any direction is neglectable. Depending on the physical size of the rider, this value can go up to 0.8 m2 - 0.9 m2 by considering the vehicle with the rider. Eventually, the effect of wind on the system needs to be analysed for various aspects.

There are some interesting kinds of literature about the aerodynamics of micro-mobility vehicles, mostly for the ones that are used for racing. The researchers principally used CFD (Computational Fluid Dynamics) tools to investigate the drag acting on the vehicle and rider as a system and tried to search for either the best design of the vehicle, the best orientation of the human body or sometimes even the best clothing worn by the rider [4-7]. Most of these are about bikers, and their interaction with their surroundings like other bikers, motorcycles, etc. Other kinds of literature focus on wind drag solely on the human body for various positions [8]. Unfortunately, there is a lack of investigations that focus mainly on the cases for electric kick scooters and their rider as a system.

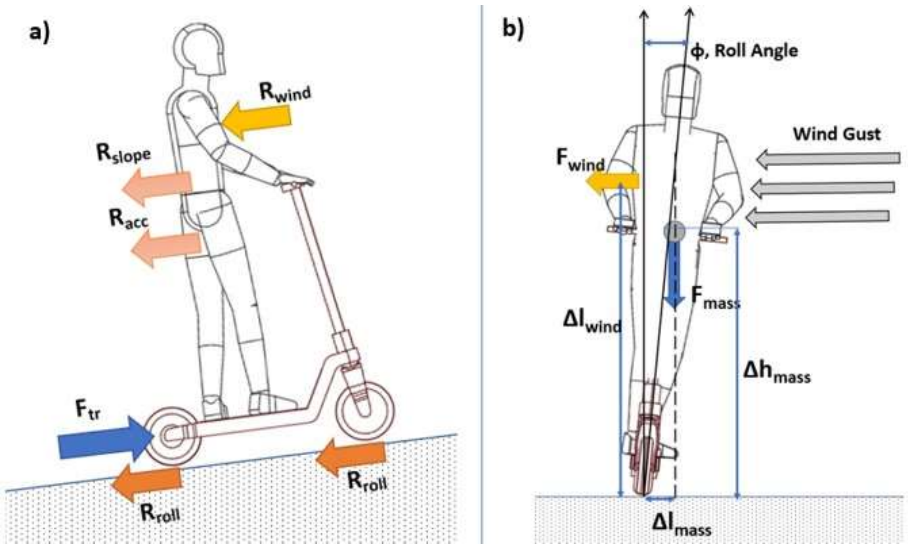

Figure 1. Problem Schematics: a) Power Consumption, b) Lateral Stability

In this study, the effect of wind loading on the e-scooter with its rider is aimed to be investigated through CFD analysis. The fundamental purpose of this investigation is to understand how much power is needed to overcome the aerodynamic resistance and to find out the most critical case in terms of wind angle for a specific type of human posture riding an e-scooter. The force balance equation can be written according to the general loadings shown in Figure 1. as below:

$$F_{tr} = R_{roll} + R_{slope} + R_{acc} + R_{wind} \quad (1)$$

where F_{tr} is the traction force on the tire with the hub motor, R_{roll} is the rolling resistance forces on the front and rear tires, R_{slope} is the gravitational force due to slope while hill-climbing, R_{acc} is the force needed to accelerate the vehicle with the rider and R_{wind} is the drag force due to wind. Most of the time e-scooter electric drive systems are designed or selected by considering only the hill-climbing force R_{slope} which indeed the most dominant force to overcome. On the other hand, drag force R_{wind} can significantly contribute to this equation under specific conditions which may occasionally happen.

The roll effect of cross moderate wind loadings will also be checked to understand how safe is to ride an e-scooter in windy weather. Wind can blow in any direction onto the rider, but it will be the most dangerous case when it is blowing in the side directions which may cause rolling instability of the ride as shown in Figure 1.b. The moment of the wind drag will try to roll the rider onto the ground. The rider can adjust the centre of gravity to the right or the left, up to a certain angle (Φ) to balance this force according to the equation below:

$$F_{wind} . \Delta l_{wind} = F_{mass} . \Delta l_{mass} = F_{mass} . \Delta h_{mass} . \tan \Phi \quad (2)$$

here F_{wind} is the wind force, Δl_{wind} is the distance from the ground to the aerodynamic centre, F_{mass} is the total weight of the rider and scooter, Δl_{wind} is the distance from the aerodynamic centre, Δh_{mass} is the distance from the mass centre of the system to the ground, respectively. Φ is the roll angle of the rider and Δl_{mass} is the offset distance of the mass in the horizontal plane.

2. PROBLEM DEFINITION

Longitudinal dynamics and stability analysis of two-wheeled vehicles have important aspects from the point of view of energy consumption, safety, handling, and comfort, respectively. Ride stability that exploits models with geometry and mass distribution for achieving self-balance can be investigated and a proper traction motor can be selected or designed after solving the aerodynamic drag forces on the system. Wind gust has negative effects on the traction and stability of two-wheeled vehicles. While it causes energy consumption originated from aerodynamic drag force in straight road driving condition, it may induce yaw and roll modes which can lead to the instability of the vehicle. A schematic view of the corresponding wind loading case is as shown in Figure.2.

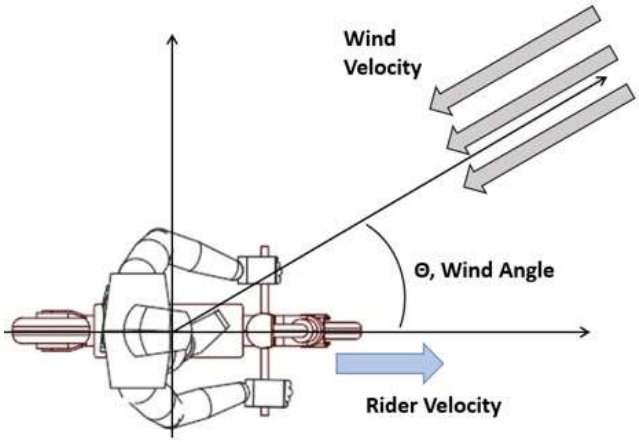

Figure 2. Top view of the problem, rider and wind velocity

2.1. Target Vehicle and Simulation Conditions

The target vehicle and its dummy rider of the analysis presented in this study is an example of a commercial electric scooter model that has around 20 kg mass under no-load condition. The dimensions of the target electric scooter with its rider are shown in Figure 3. The diameter of the front and rear tires of the scooter is 10 inch and the vehicle has no suspension. The orientation of the rider on the scooter is fixed to a very common posture that most people have while using a scooter on public roads. The dummy human is around 1.7m tall.

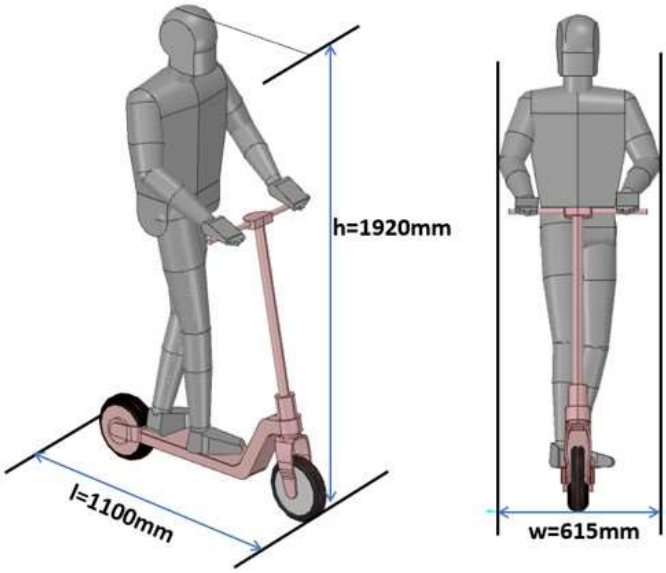

Figure 3. Outer dimensions of the dummy rider on the scooter

The loading scenarios have been grouped under two categories; namely the power consumption and lateral stability. In the power consumption case, the electric scooter is assumed to move straight ahead at a constant maximum legal speed of 25 km/h; it is driven into various wind speeds in the upwind direction (wind angle θ is zero) shown in Figure.2. The design of experiments (DoE) for the power consumption scenario is given in Table 1. The maximum wind speed in the design experiment is selected as moderate wind speed and its value is equal to 30km/h.

Table 1: Design of experiments for the power consumption analysis scenario.

	Case 1	Case 2	Case 3	Case 4
Wind Speed (km/h)	0	10	20	30
Scooter Speed (km/h)	25	25	25	25
Inlet Velocity in CFD (km/h)	**25**	**35**	**45**	**55**

In the lateral stability case, the electric scooter moves straight ahead at a constant maximum speed legal speed of 25 km/h; it is driven into a crosswind region with different impinging wind angles shown in Figure 2. The relative yaw angle of the vehicle concerning incoming flow changes from 0º to 90º. The design of the experiment (doe) for the lateral stability analysis case is given in Table 2.

Table 2: Design of experiments for the lateral stability analysis scenario.

	Case 5	Case 6	Case 7
Wind Angle, θ (degree)	30	60	90
Wind Speed (km/h)	30	30	30
Scooter Speed (km/h)	25	25	25
Inlet Velocity in the X direction(km/h)	51	40	25
Inlet Velocity in the Y direction(km/h)	15	26	30

3. CFD SIMULATIONS:

CFD simulations provide the required flow field estimations described in the preceding sections for the e-scooter. ANSYS Mesher and Fluent 19.1 are employed to generate computational mesh and CFD computations, respectively for the seven cases described in Table 1 and Table 2. In creating the computational grid, around 30 wedge-shaped boundary layer elements with y+ around 1 (maximum lower than 3) are generated on the walls with a growth rate of 1.2. The solver utilizes the cell-centred finite volume (FVM) method to discretize the Reynolds-averaged Navier-Stokes (RANS) equations. The well-known k-omega Shear Stress Transport (SST) [9] is employed for turbulent closure of the RANS equations. The employed mesh and the CFD models are validated in the Ahmed Body case [10], which is a representative test case for blunt bodies (such as ground vehicles and the scooter considered in this paper). The results are presented in Figure 4. CFD can predict 5 and 12.5-degree slant angles very well. There are 2 experimental data for the 30-degree slant angle case. The high drag case is highly unstable due to side vortices and placing a vertical plate downstream of the body can stabilize this (the low drag case). CFD can predict the low drag case very well. The probable reason for not predicting the unstable high drag case can be explained by the steady solution of the flow-field as well as employing RANS equations which are not eddy-resolving. Nevertheless, the stable characteristics of such a blunt body can successfully be predicted by the CFD.

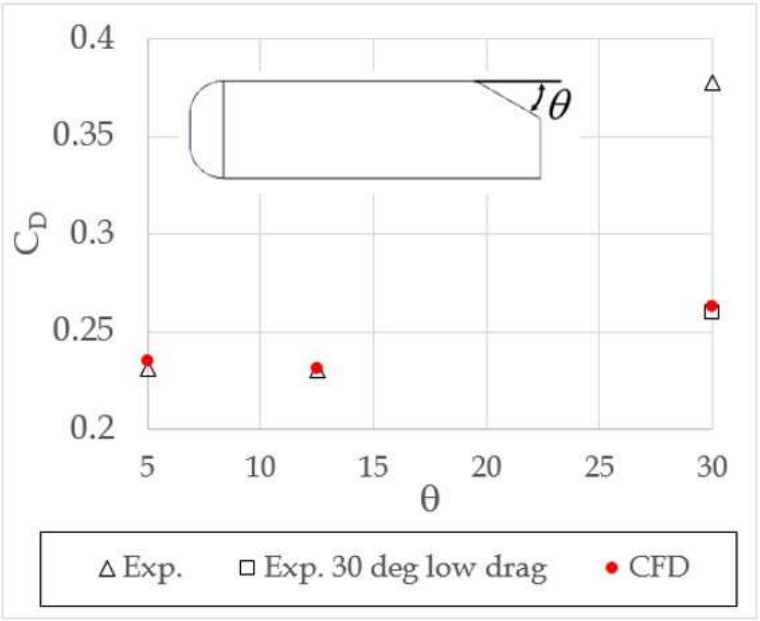

Figure 4. Comparison of experimental and CFD data on the Ahmed Body Test Case [10]

Figure 5 presents the computational mesh and the boundary conditions for CFD simulations. A quite large space is left between the scooter and the domain boundaries. The ground is assumed as inviscid and a uniform wind is specified at the velocity inlets to eliminate uncertainties arising from the atmospheric boundary layer [11]. Inlet turbulence intensity is specified as 0.5% with a turbulent length scale of 5 cm. Roughness throughout the scooter and dummy human surfaces are specified as 0.5mm. Figure 6 presents the snapshots from the computational mesh created based on the above considerations. A total of 28 million tetrahedral volumes are generated with a smooth transition from the e-scooter to the far field.

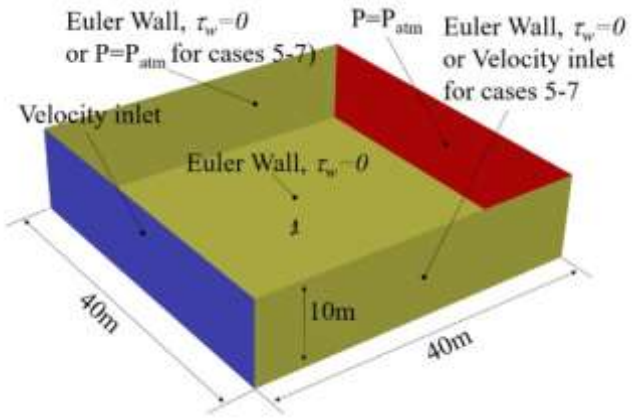

Figure 5. The computational domain and the boundary conditions

To tabulate drag coefficient (C_D) values, several reference areas are considered. For the overall C_D, the projected area normal to the oncoming wind vector is considered together with the resultant wind speed and drag force. The longitudinal C_D is calculated based on the frontal area and the longitudinal component of the drag force. Finally, the lateral C_D is estimated by considering the lateral area and the lateral component of the drag force. The corresponding areas are presented in Figure 7. The first subfigure (upwind direction) corresponds to the first four cases and longitudinal C_D calculations for cases 5-7. The last subfigure (sidewind direction) corresponds to lateral C_D calculations of cases 5 to 7. The second, third and fourth subfigures correspond to overall C_D calculations of cases 5, 6 and 7, respectively. The results are presented in the next section.

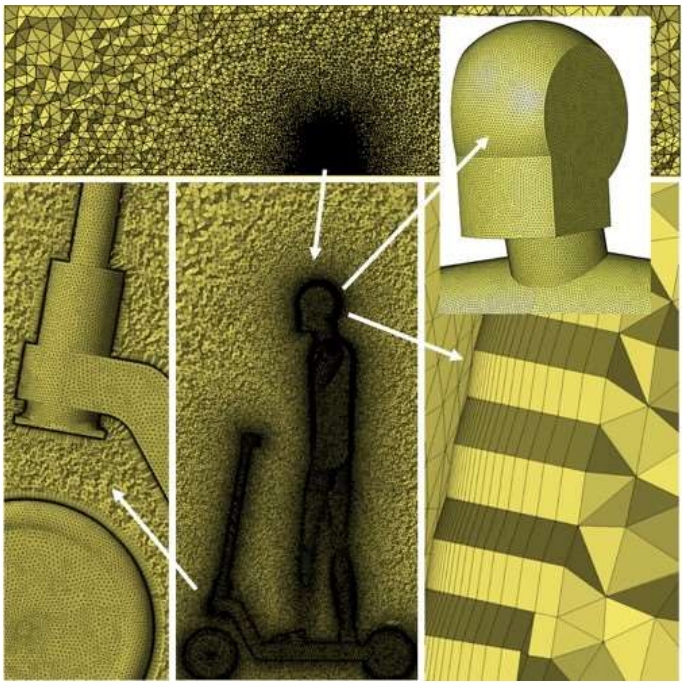

Figure 6. The computational mesh

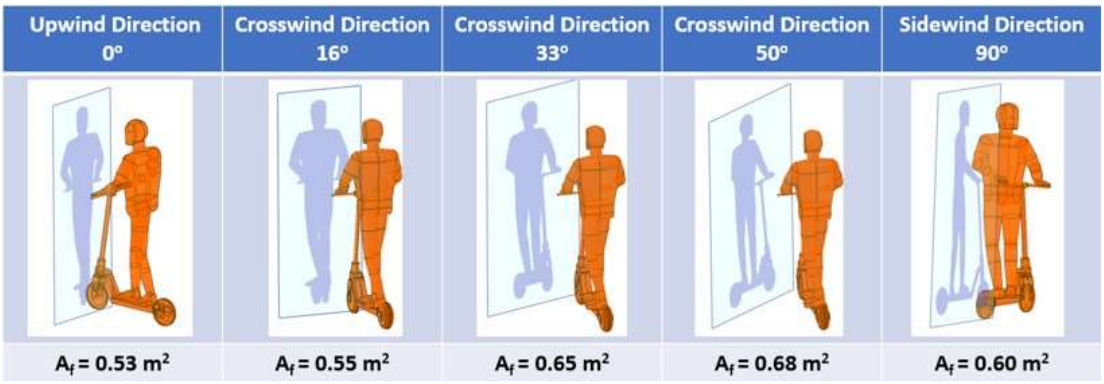

Figure 7. Frontal area values of the e-scooter and its rider for different projection planes

4. RESULTS

The results based on CFD described and validated in the prior section is presented in this section. Table 3 presents overall results (forces and moments).

4.1. Drag Coefficient

For cases 1 to 4, overall C_D values of 0.76 - 0.79 are predicted. Considering the C_D of a human is approximately 0.8, these results for riding position human together with the small-frontal-area scooter seem expected. The overall C_D rises to 0.80-0.81 when the wind is approaching with an angle. This is because lateral area increases and a higher force is realized. However, the higher force is balanced by the higher area for case 6, and C_D remains similar with cases 1-4. The lateral C_D values rise from 0.25 in case 5 to 0.74 in case 7. These are not isolated C_D values for lateral flow and cannot be employed for this purpose. These are just the realized values for this multi-component (and non-linear) wind flow. An isolated lateral flow case (no driving speed and lateral wind) could be expected to give a C_D approximately 0.8 (though this is not simulated).

Table 3: Overall aerodynamic force and moment results.

	Power Consumption cases				Stability cases		
CASE NUMBER	1	2	3	4	5	6	7
Wind angle [deg]	0	0	0	0	30	60	90
Wind angle relative to the moving scooter [deg]	0	0	0	0	16	33	50
Longitudinal drag [N]	12.5	24	40	58	56	43	23
Lateral drag [N]	1	1	2	2.5	20	33	32
CD	0.79	0.78	0.78	0.76	0.81	0.78	0.80
CD_Longitudinal					0.78	0.75	0.60
CD_Lateral	NA	NA	NA	NA	0.25	0.51	0.74
Lateral moment [N.m]	1	1	2	3	14	22	23

4.2. Drag Force and Lateral Moment

The longitudinal drag force goes up to a maximum value of 58 N for 30 km/h wind speed and 25 km/h vehicle speed case in this simulation. Assuming the R_{slope} is around 90 N while climbing a hill with a slope of 10° angle for a total system mass of 90 kg, the drag force becomes very comparable and becomes the second major resistant force according to Eq.1.

For the lateral drag, the effect of wind on the rider has a maximum forcing value of 33 N. Accordingly, the lateral moment values are around 23 N.m for the 6. and the 7. analysis cases. To interpret this result in terms of stability (balance) for the rider, Eq.2 is to be checked. For a person weighing 70 kg, the offset distance of the centre of gravity in

the horizontal plane should be around 3.5 cm. On the other hand, if the rider is lighter and is 50 kg in weight, then the required offset value to balance the ride increases to a value of 5 cm. The corresponding roll angle of the rider body is around 3°.

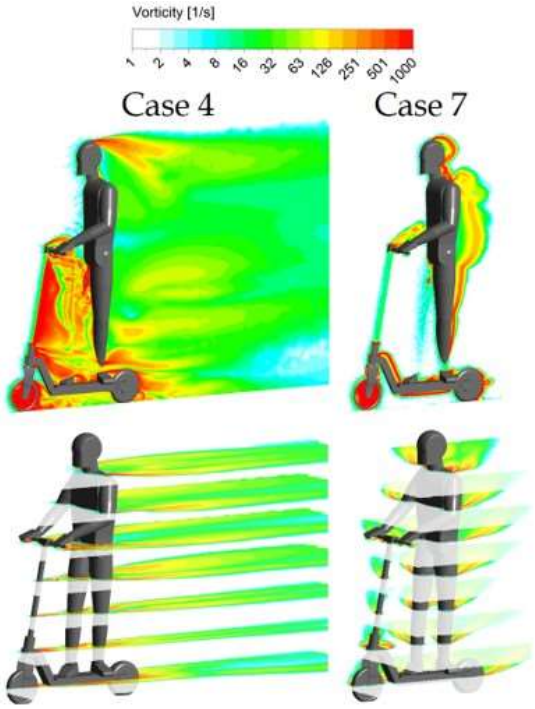

Figure 8. Vorticity fields for case 4 (left) and case 7 (right)

4.3. Other Field Outputs

Figure 8 presents the wake vorticity field of the scooter for the maximum longitudinal drive speed (case 4) and the maximum lateral wind exposure (case 7). Near-symmetrical vorticity fields can be seen for case 4, while the wake is inclined in the direction of the wind in case 7. An interesting result is that more vorticity is generated on the strut of the scooter than the human. Therefore, some sort of streamlining in this region (and possibly downstream of the human) can significantly enhance the instability of the flow and the drag force.

Figure 9 presents skin friction contour, skin streamlines and 3D streamlines for cases 4 and 7. Skin friction is higher in case 4 relative to case 7. This is probably because the wind speed relative to the scooter is smaller in case 7 relative to case 4, which is a likely scenario during riding. In case 4, the belly of the dummy human has the lowest skin friction (and highest pressure) as stagnation point is this region. However, the stagnation point moves to the arm of the dummy human in case 7. The bottom of Figure 8 presents the wake streamlines. A strong wake region is evident for case 4, while this becomes smaller and inclined in the direction of oncoming flow for case 7, which is probably due to lower wind speed (and correspondingly low Reynolds number) as discussed above.

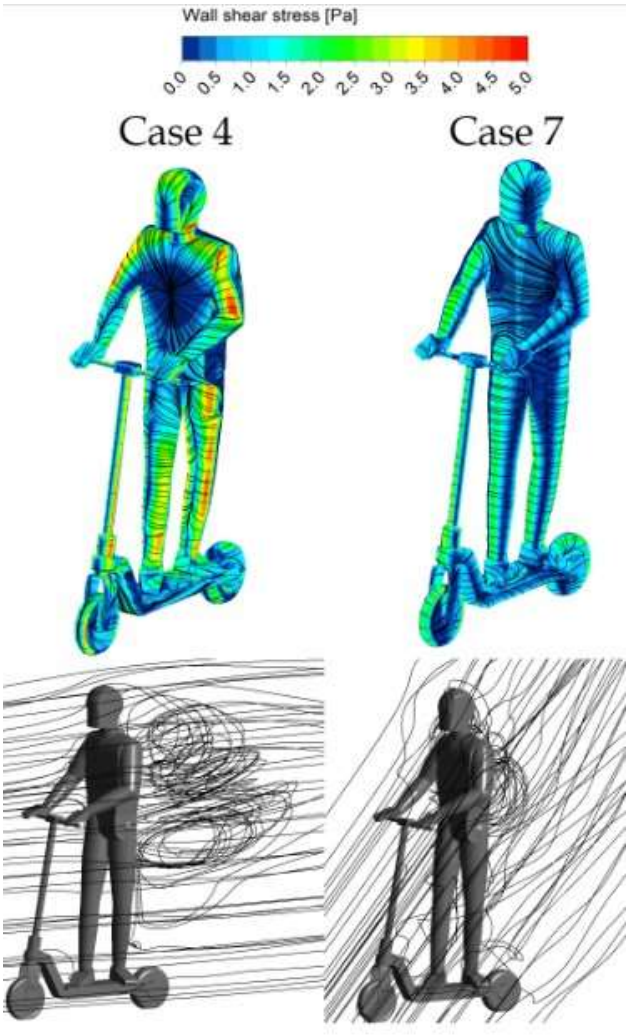

Figure 9. Surface streamlines and shear stress contour (top) and streamlines (bottom) for case 4 (left) and case 7 (right).

5. CONCLUSIONS

In this study, the effect of the wind gust disturbance exerted with various loading scenarios on the e-scooter & rider system was investigated through steady-state CFD analysis. These loading conditions are important for determining the power consumption in a straight road and the limit magnitude and direction of the lateral wind force vector that leads to instability of the system. This study provides ample input while building the mathematical model of the system to select the most suitable electric motor and to optimize controller parameters. In addition, the effect of moderate wind loading (up to 30 km/h) on the ride has been analysed in terms of riding safety and it seems to be weak. sufficient to analyse the nonlinear dynamical responses and system stability under transient loading conditions. This study can be extended to capture unstable modes from a fully coupled lateral dynamic model by evaluating time-dependent wind gust disturbance profile through transient CFD analysis for nonlinear stability investigations.

ACKNOWLEDGEMENTS

The authors would like to thank FİGES engineering company, HOP! e-scooter sharing company and Dr.Tarık Öğüt for their support of this work.

KABLOSUZ ŞARJ ÜNİTESİ KURULUMU & TASARIM KRİTERLERİ

Özgür BOZCA
[1] TOFAŞ Türk Otomobil Fabrikası A.Ş., İstanbul Cad. No: 574, 16110 Bursa, Türkiye
[2] Sorumlu Yazar: Özgür BOZCA, ozgur.bozca@tofas.com.tr

ÖZET

Kablosuz Şarj Ünitesi, uyumlu elektronik cihazları 15 W 3A ila Qi Şarj standardına [2] kadar şarj eden bir endüksiyon şarj cihazıdır. Bu cihazı, araçlarda konumlandırmak için henüz bir standart oluşturulmamıştır. Bununla birlikte, literatür araştırması, cihazın orta taban konsolun, torpido ile birleştiği bölgede, konsol önüne konumlandırıldığı yönünde bir eğilim olduğunu bize göstermiştir. Bizim durumumuzda ise sorun; halihazırda seri üretimde olan bir araçta , aracın diğer işlevlerini etkilemeden uygun bir yerleşim bulmak ve tasarımı diğer bileşenlerle minimum müdahale / modifikasyonla optimize etmektir; böylelikle imalat ve montaj kolaylığı sağlamanın yanı sıra düşük yatırım maliyetleri hedeflerine de ulaşmak mümkün olacaktır. Nihai karar olarak, cihaz, orta taban konsoluna sabitlenen plastik bir taşıyıcı tasarlanarak, konsolunun önüne, IP'nin altına yerleştirildi. Bu bildirinin amacı ise , orta taban konsolunda, mevcut kablosuz şarj ünitesi ile ilgili kurulum ve tasarım kriterlerini sağlamaktır.

Anahtar Kelimeler: Orta Konsol, Orta Taban Konsol, Kablosuz Şarj Ünitesi Kurulumu

WIRELESS CHARGING UNIT INSTALLATION & DESIGN CRITERIA

ABSTRACT

The Wireless Charging Unit is an induction charging device that will charge power electronic compatible device up to 15W 3A to Qi Charging standard. No standard for positioning this device was yet established in the vehicles. However, the literature survey showed a trend of positioning the component in front of the center floor console where it interfaces with the dashboard. In our case, the problem is to find a proper placement in an already serial – production car, without effecting the other functions of the vehicle and optimize the design with minimum interference/modification with other components; thus allowing an ease of manufacturing, and assembly and so; as well as reduced investment costs [1]. As the final decision, the device was positioned in the front of the center floor console, below the IP, designing a plastic carrier which is fixed to the center floor console.
So, the objective of this document is to provide installation and design criteria about the available WCU onto the floor center console.

Keywords: Center Floor Console, Wireless Charging Unit Installation, WCU

1. GİRİŞ

Günümüzde akıllı telefonların ve telefon uygulamalarının da hayatımızın önemli bir parçası olmasıyla birlikte, telefonları şarjlı tutmak her tüketicinin oldukça önem verdiği bir konu haline geldi. Otomotiv alanındaki gelişmelere bakıldığında da kullanıcıya her daim telefonunu kablosuz olarak şarj etme imkânı veren araca entegre padler neredeyse standart hale geldi. Mevcut araçta ise şarj için orta konsol ön bölgesinde bulunan 12V, çakmaklık ya da USB girişleri kullanılmaktaydı, bu da ön bölümde bulunan eşya gözünün bu girişlere bağlanan kablo ya da ara şarj kitlerinden ötürü verimli kullanılmasını engellemekteydi. (Şekil-1). Bu tespit, paralelde yürütülen KANO [2] çalışması esnasında birebir yüz yüze müşterilerle yapılan görüşmelerde müşterilerin şikayetleriyle de örtüşüyordu. Bu olgudan yola çıkarak, hali hazırda üretimde mevcut araçlar için kablosuz şarj sisteminin de araca entegre edilmesi kaçınılmaz oldu.
Başlayan çalışma ile üniteyi araç üzeri konumlandırma için gereken kısıtlar ve yine ünite şarj performansının optimize edilebilmesi için gereken şartlar belirlenmiş oldu.

Şekil-1- Mevcut konsol ön eşya gözü

2. ANA BÖLÜM

Çalışma başlangıcında, ergonomi uzmanları ve mühendislik tasarım uzmanları bir araya gelerek, araç içinde fiziksel olarak, torpido ve konsol üzerinde olası tüm pozisyonlar; telefonun sürücü ve ön yolcuya olan mesafesi, kolay ulaşılabilirliği ve telefon ekranının, sürücü tarafından görülebilir olması baz alınan kriterler olarak belirlenerek bir liste tanımlandı. Bu ilk değerlendirme sonucunda, orta konsolun (Şekil-2) ön bölgesi ve yine arka bölgede kolçağın altındaki eşya gözü potansiyel alanlar olarak öne çıktı. Konsol orta bölgesinde mekanik el freni ve bardaklıkların bulunması, ünite dik olarak konumlansa bile bir çok fonksiyonun etkilenmesi sebebiyle alternatif olmaktan çıktı. Torpido ön orta göğüs bölgesi, (Şekil-3) ise; klima kumanda paneli, dörtlü çakar grubu, hava üfleçleri gibi komponentler bulunduğundan ergonomik olarak uygun değerlendirilmesine rağmen farklı bir çok kompleksite oluşturduğundan aynı şekilde olumsuz olarak değerlendirildi.

Şekil-2- Orta Konsol

Şekil-3- Torpido ön orta göğüs

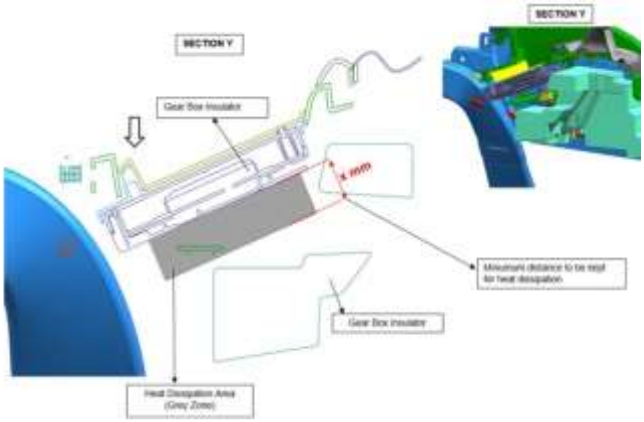
Çalışmanın ikinci fazında ise seçilen bu bölgeler CAD ortamında incelenerek şarj ünitesi (Şekil-4), bu bölgelere pozisyonlandı. Arka eşya gözünün içine pozisyonlandığı durumda, (Şekil-5) ünitenin buraya sığmadığı, sığması için gözün yanlara doğru genişlemesi gerektiği, ancak koltuklar ile olan sağlanması gereken minimum mesafe kriterlerinin sağlanamadığı görüldü ve değişmesi gereken çevre parça sayısı da fazla olacağından yüksek maliyetler nedeniyle bu alternatiften vazgeçildi. Daha önce bahsi geçen telefon ekranı görünebilirliğinin olmaması da olumsuz faktörlerden biriydi. Bazı lüks segment araçlarda şarj ünitesinin/pad inin bu bölgeye konumlandırıldığı örnekler yine de var.

Şekil-4 - Şarj Ünitesi

Şekil-5 – Şarj ünitesi arka göz konumlandırılması

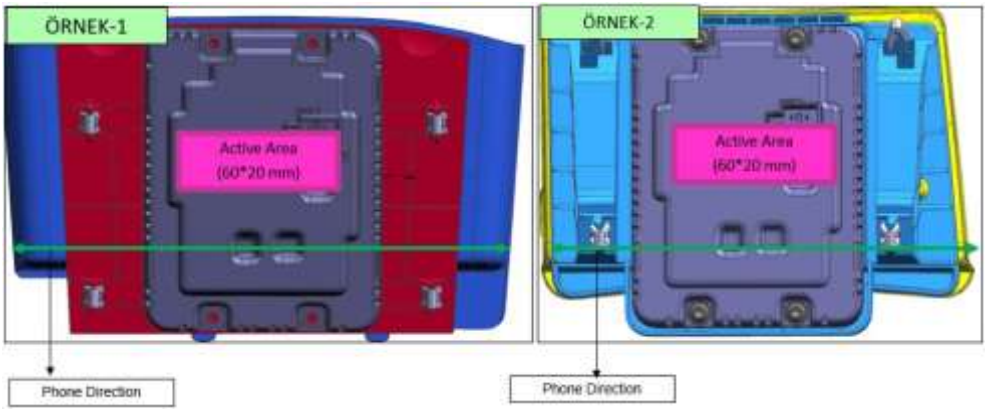
Ünite, ön göz bölgesine x eksenine paralel olarak konumlandırıldığında ise, ünitenin konsol gövdesi ve klima ünitesinden çıkan arka ayak hava kanallarıyla girişim yaptığı, ancak Z eksenindeki konumundan dolayı gözün içinde saklı kaldığı dolayısıyla ünite üzerindeki şarj ledinin görülmediği fark edildi. Diğer bir problem ise; konsol ön eşya gözünü oluşturan duvarlardaki minimum kalıp çıkma açısından ötürü, Z ekseninde derinleştikçe, Y ekseninde yan duvarlar arası mesafenin azalması ve bu konuma konumlanabilecek telefon çeşitliğinin de sınırlanmasıydı.
Belirtilen sebeplerden ötürü; ünitenin açılı pozisyonlanmasına çalışıldı ve bir çok iterasyondan sonra hem telefon ekranının , hem ünite led ışığının görülebilir olduğu , ve çevre parçalara minimum müdahaleyi mümkün kılan bir konum belirlendi. Çevre parçalarla özellikle ünitenin alt tarafında kısmın, ünite ısındığından ve bu ısının atılması amaçlı belli bir bölgenin boş bırakılmasına karar verildi.

Şekil-6-Konsol üzeri konumu



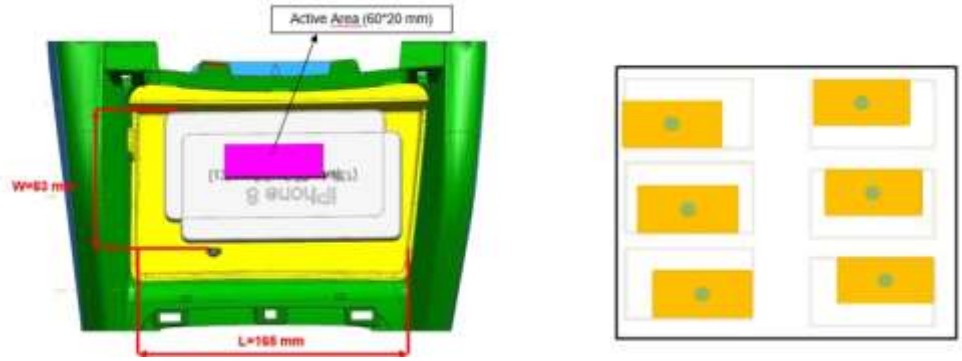
Şekil-7 -Konsol üzeri Y kesiti

Bu konumlama çalışması esnasında bir diğer önemli nokta ise, seçilen ünite içindeki manyetik bobinlerin konumu nedeniyle, ünite üzerinde aktif şarj alanının aşağıdaki görselde belirtildiği gibi oluşmasıydı. Bu nedenle, telefonun aktif alanla kesişebilmesi için, telefonun yeşil ok doğrultusunda yani 60 mm olan kenara paralel olarak konumlaması gereklidir.



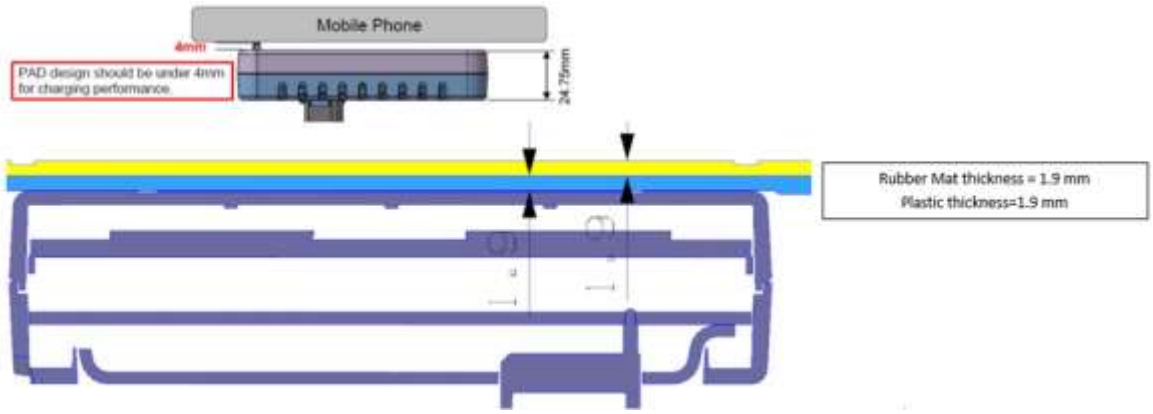
Şekil -8 – Aktif şarj bölgesi ve telefon oryantasyonu

Kablosuz şarj özelliği olan telefonlar dikkate alındığında ise iphone-8 in en küçük boyutlara 138.4x67.3 mm, sahip olduğu görüldü, bu telefonun da şarj ünitesi üzerinde oluşan aktif alan ile kesişmesi için pad boyutlarının 198.4 mm x 87.3 mm den büyük olmaması gereklidir.



Şekil-9 – Mevcut Araç – PAD ölçüleri ve 198,4*87.3 mm alanda -iPhone konumu

Ünite şarj performansı dikkate alındığında ise ünite ve şarj edilecek telefonun arasındaki mesafe 4 mm yi geçmemelidir, telefonla direkt temas eden pad kısım kaydırmaz özellikli elastomerik kauçuk, üniteyi taşıyan plastik ise üst kısmı düzlemsel olması gerektiğinden ve geometrisinden ötürü çarpılmaya müsait olduğundan, yapılacak moldflow analiz sonuçlarına göre talk ya da cam fiber katkılı PP-PA ya da PC-ABS seçilebilir



Şekil 10- Elastomer pad ve plastik taşıyıcı kesiti

3. SONUÇLAR VE TARTIŞMA

Çalışma esnasında, zorlayıcı olarak öne çıkan konu, üniteye mevcut araç içinde yer bulabilmek oldu. Bunu gerçekleştirebilmek için telefon ulaşılabilirliği, ekran ve uyarı led ışığının görülebilirliği ile ilgili kısıtları belirlemiş olmak çalışmanın kazanımlarından oldu. Yine şarj edilebilecek telefon çeşitliliğini arttırmak için gerekli olan boyutların belirlenmesi çalışmanın bir diğer çıktısı oldu. .

Ünitenin en ya da boyuna göre hangi oryantasyonda konumlanıyorsa, telefonun nasıl konumlanması gerektiği belirlendi.

Parça için malzeme seçimli ve , ünite performansını sağlamamak için parça et kalınlıklarının ne olması gerektiği bilgisi edinildi. Pad dediğimiz kauçuk parçanın çizilmez özellikte olması, yine altta kalan taşıyıcı parçanın üst yüzeyinin tercihen desenli olması deneyimleri kazanıldı.

Gelecek çalışmalar için; üniteyi taşıyacak ara bir parçaya ihtiyaç duyulmayacağı; ünitenin direkt olarak konsol gövdesine bağlanması fikri öne çıktı.

ABSTRACT

The energy management of electric vehicles is today a key aspect in the design in order to optimize the sizing of components, the cost of the product, of course the environmental aspects and finally the user experience of the final customer.
Thermal management is a main contributor to this Global Energy Management approach in EV and it is the reason why we experience more and more complex thermal systems in these types of New Energy Vehicles. This is due to the multiple objectives allocated to thermal systems and organic solutions to be optimized. To address this complexity, Digital Twins based on Modeling & Simulation are very relevant methods and performant tools to run efficiently architecture evaluation, component sizing and control design.
We propose to focus in this paper on the use of functional energy modeling to ensure the link between the system architects' model and multi-physical simulation models and to design the thermal system supervisor. The application to an EV (electric vehicle) illustrates the modularity of the methodology as well as its flexibility in response to the variability of equipment and objectives.

Keywords: Digital Twins, Energy Management, MBSE, Thermal Management, MBD

1. INTRODUCTION AND MAIN SECTIONS

The thermal synthesis of electric and hybrid vehicles is becoming more and more complex. This is due to the multiple objectives allocated to thermal systems and organic solutions to be optimized according to cost, space and performance. One example is the case of the refrigerant circuit, initially dedicated to the cabin, which is increasingly used to cool the battery. Similarly, the water circuit, initially dedicated to the internal combustion engine, must also provide cooling for the electric motor and power electronics at different temperature levels. There is also an increase in the use of heat pumps for electric vehicles, as well as fuel cells requiring specific cooling. As a result, the control of thermal management is becoming a major challenge for tomorrow's vehicles to ensure better range but also for greater safety and comfort for passengers.
To meet this complexity, the use of Model-Based provides a response element at the engineering level (with Model-Based System Engineering) and at the design level (with Model-Based Design) for the evaluation of architectures using simulation and for the sizing of components (Fiani et al., 2016).
Recent work in the description of complex systems, carried out as part of a CIFRE thesis (Mökükcü, 2018), has made it possible to propose a methodological approach for developing a functional energy model describing, in a modular way and using only the mathematically necessary models, the different components, sources and consumers and their interconnections (Fiani, 2017; Mökükcü, 2018).Applied to the mobility of a hybrid vehicle, the tools have made it possible to link the different levels of modeling (functional and multi-physical) but also to connect the different levels of control (Mökükcü et al., 2017).
In this paper, we propose to present the extension of this approach for the treatment of heat exchange in electric and hybrid vehicles. The main extensions are the functional representation of heat exchange and distribution groups such as heat transfer fluid circuits, refrigeration circuits and heat exchangers between these circuits.
This functional model has a double target: to ensure the link between the system architects' model and the multi-physical simulation models and to design the thermal system supervisor in order to optimize exchanges in relation to the thermal comfort needs and the operating and safety constraints of the equipment.
The results of a demonstrator (electric vehicle) will be presented to illustrate the modularity of the methodology as well as its flexibility in the face of equipment and targets variability.
The design of complex systems requires multi-view and multi-business processing. This is what justifies the decomposition into subsystems. It is therefore necessary to break down the system in relation to the business organization (§2.1) while ensuring the integration and satisfaction of uses (§2.2). We propose to develop each

subsystem, complex in itself, by iteratively addressing two levels of modeling to design the structural architecture and its functioning (§2.3).
Functional energy modeling concepts that provide the modularity necessary for system integration (§3) will be used to develop and test each of the subsystems (§4.1 & §4.2). These concepts then make it possible to connect subsystems, check their interrelationships and optimize overall energy management (§4.3).

2. ORGANIZATION AND COMPOSITION

2.1. Breakdown by business line

The development of complex systems faces two opposing constraints. To address complexity, it is necessary to design the system as a whole and to address all the interrelationships between its components. Conversely, the development of a complex system requires breaking it down and assigning responsibility for its components to several teams, each specialized in its field.

Figure 1: A breakdown by business line**.**

For vehicles, it is usual to define two complementary subsystems: the powertrain managing the electromechanical powers and the thermal synthesis which manages both the thermal comfort of the cab and the thermal conditioning of the equipment (Fig. 1). This decomposition is justified by the business lines and reinforced by a natural frequency separation (fast electro-mechanical dynamics and slow thermal dynamics).
To ensure the proper contribution of each of the subsystems to the purposes of the overall system and to ensure interrelation during final integration, one solution is to:

- Carry out a global preliminary study specifying the subsystems using functional modeling; with a low modeling granularity, it is both possible to consider the vehicle as a whole and to avoid a precise definition of the components before their choice;
- Ensure coordination of subsystems, both at the organizational level and at the level of the overall vehicle supervisor**.**

2.2. Overall functional modeling

Functional energy modeling has been created to represent a complex system as a whole (Mökükcü, 2018). and evaluated in the case of a hybrid vehicle (Fiani,2017; Mökükcü,n.d.). Based on energy links and using a low modeling granularity, this representation allows systems in simulation to be evaluated from the early design stages.
The entire vehicle model (Fig. 2) represents the energy exchanges required to meet mobility and thermal comfort targets. In addition to these two effectors, the model includes electromechanical transformation, heat exchange with an external source, energy storage and a distribution block to spread energy between different consumers according to a predefined strategy. The modeling concepts will be presented in §3.

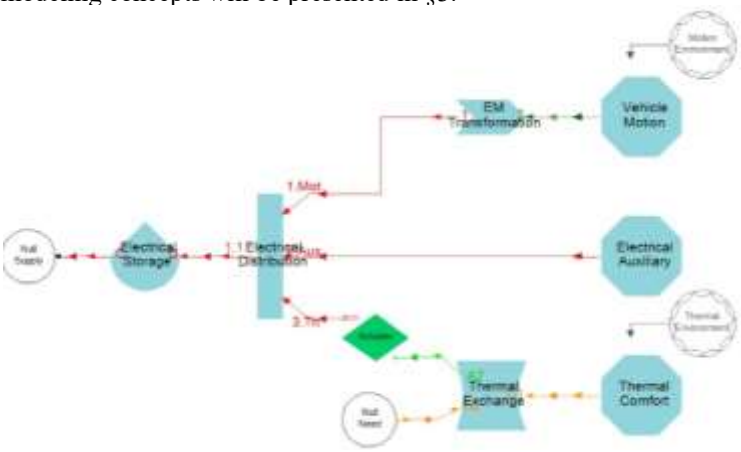

Figure 2: Simplified functional energy model of an electric vehicle

The results in Figure 3 represent the main system variables: missions (vehicle dynamic and cabin temperature), power distribution and the state of charge of the energy storage unit. The simulation model allows to make a first energy analysis with an estimate of the overall consumption during a WLTC cycle with different external temperature levels.

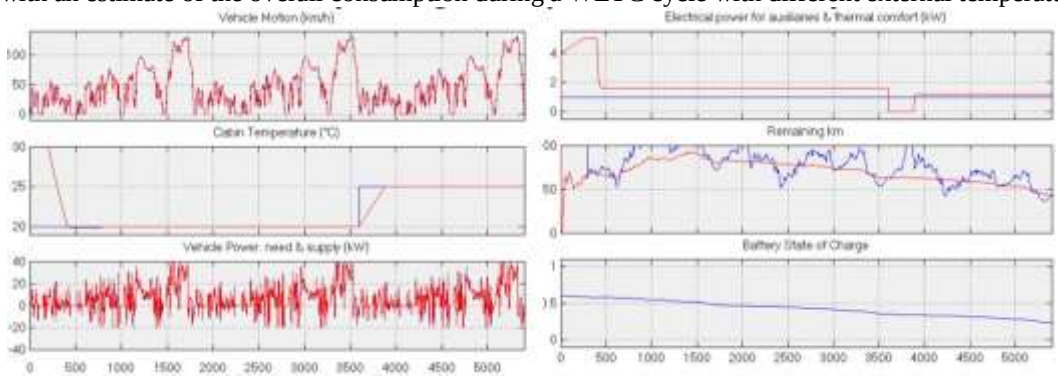

Figure 3: Energy management of mobility and thermal comfort

In addition to an initial verification of functional choices, this model makes it possible to specify the specification of subsystems by providing dynamic power profiles to be produced, stored or distributed.
Moreover, the use of modular formalism facilitates integration and ensures relationships between subsystems.

2.3. Canonical composition of subsystems

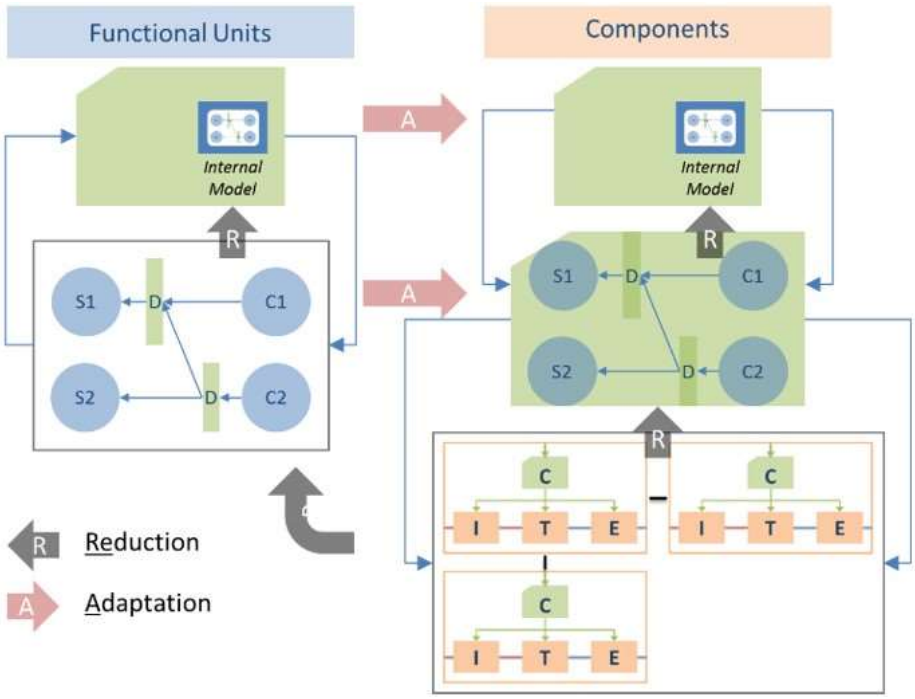

Figure 4: Canonical composition of subsystems

The functional model represents the exchange of energy flows between the different components. The flow controller of each subsystem can be extracted from it and connected to the controlled components (Mökükcü et al., 2017). The principle is to replace the simplified model included in the functional blocks with a link to the physical component controllers.
We deduce a canonical composition for each subsystem (Fig. 4) with:

- A technological or organic architecture with its control;
- An assembly of components (functional blocks) with flow management;
- A finalization block allowing overall coordination at the vehicle level.

The final architecture thus obtained includes three interconnected system levels, each representing the entire system from a specific point of view.

3. MODELING CONCEPTS

The concepts introduced in previous work have been demonstrated on the hybridization of motor vehicles with electrical and mechanical consumers (Mökükcü, 2018). From a modeling perspective, this work is based on the theories of systemic modeling (Degenne&Moigne, 1978) and the use of modular functional blocks (components) to represent a complex energy system by simple assembly (§3.1). Figure 5 shows an example of such a coupling with the formalism adopted in this work. The model allows to control the energy flows of a hybrid vehicle (mechanical - green highlighting - and electrical - red highlighting -). The distribution blocks (rectangles) allow the necessary energy to be allocated to consumers on the sources (electrical and fuel) according to a predefined priority. They also make it possible to distribute the energy produced to consumers (in this case mobility and electrical auxiliaries) according to a predefined strategy. These distribution blocks may contain either heuristic logic or a more advanced optimization algorithm (Fauvel et al., 2014).

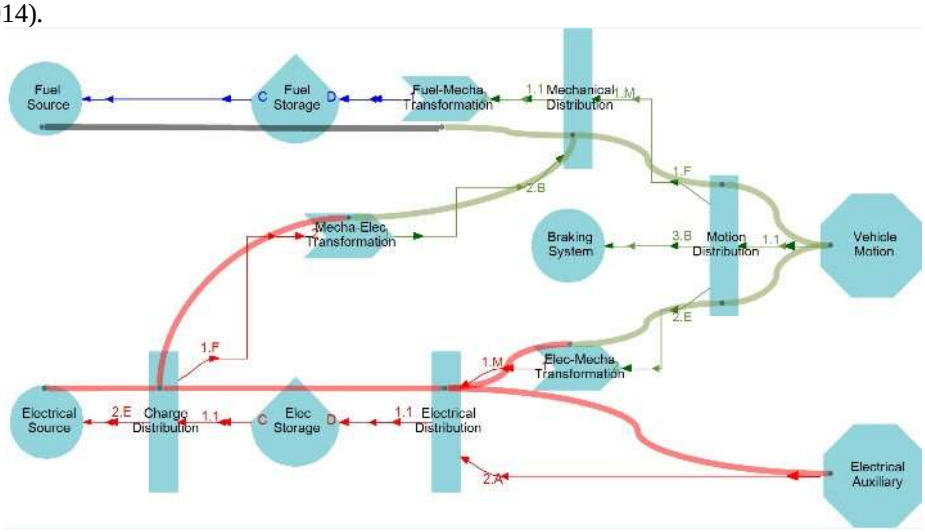

Figure 5: Electromechanical functional model of a PHEV

In order to simultaneously process thermal synthesis (application introduced in §2.2), it is necessary to extend the modeling concepts to heat exchanges (§3.2) and in particular:

- Heat exchange between two circuits (air, water, refrigerant);
- The dissipation or recovery of heat losses from an energy transformation; example of a conventional propulsion system that requires thermal conditioning but can also provide heat for air conditioning.

3.1. Components for effective assembly

The use of components is made to meet a need for modularity: to connect functional elements without pre-defining the source or consumer to which it must be connected. The element therefore reacts to the flows it receives (Fig. 6) and not to the nature of the component to which it is connected. This black box representation favors, by construction, the definition of the relations between blocks.

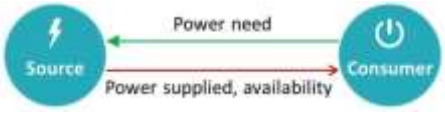

Figure 6: Energy flows between components

The nature of the flows exchanged is of the EMI type (Energy, Matter or Information). The flow is bidirectional, with demand (from consumer to source) and supply (from source to consumer).

Each component provides an elementary service with a set of consistent functionalities. In addition, the components are reusable and ensure a modular approach to the architecture with better readability, thus addressing the complexity of the controlled systems.

The main components are presented in the table below with their pictogram inspired by (Odum & Odum, 2000). They represent functional units that potentially correspond to a technological solution.

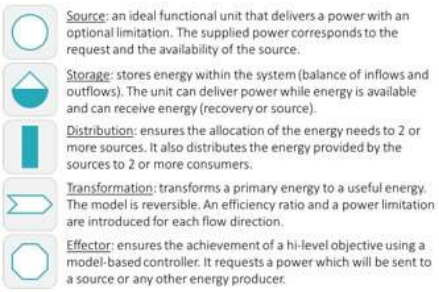

Figure 7: Diagram of the cooling circuits of an electric vehicle

3.2. Extension of functional concepts - Heat exchange between circuits

Thermal management is commonly based on exchangers between conditioning circuits (water, air, refrigerant). As a first approximation, the circuits can be represented by thermal energy distributors with a possible energy cost (to run pump, compressor, fan, etc.).
On the other hand, the exchange between two circuits cannot be represented by the blocks introduced in §3.1.

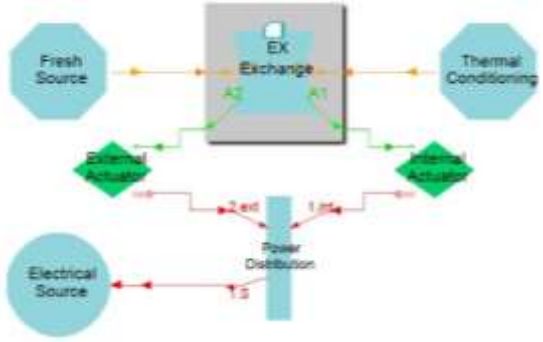

Figure 8: Heat exchange between two circuits and associated energy cost

The new component presented in Figure 8 represents this type of exchange with:

- Symmetrical treatment of the two thermal ports: no distinction between the two circuits to which the exchanger will be connected;
- The desired heat exchange is ensured by conditioning the circuits: use of actuators with energy cost.

The exchanged power is given by: $$P = \varepsilon . min(c_p . Q) . (T_1 - T_2) \quad (1)$$
Where P is the exchanged power, ε the efficiency of the exchange, T, cp and Q are the temperature, calorific capacity and flow rate of each of the circuits.

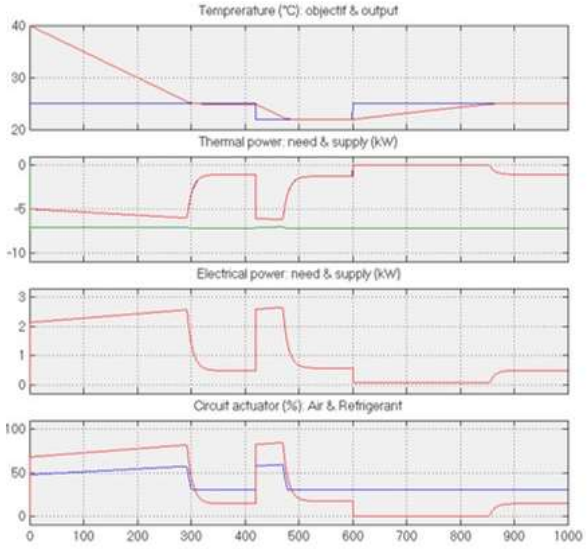

Figure 9: Thermal conditioning of an equipment by exchange with a cold source

The scenario in Figure 9 illustrates how this functional block works. The temperature of the system to be conditioned (axis 1) is controlled to its set point by energy exchange with the cold source (axis 2). The circuits are conditioned by actuation (axis 4) which induces an energy cost (electrical power - axis 3).

4. DEMONSTRATION ON A HYBRID ELECTRIC VEHICLE

In accordance with the process suggested in §2, this paragraph presents the results of the design of the two subsystems (powertrain and thermal synthesis), their integration and the verification of their relationships.
Subsystem design and physical-control connection: following the specification (§2), each subsystem is treated separately following the same steps:

- Detailed functional energy modeling corresponding to organic-functional choices;
- Connection to the multi-physical model and control (details of structural relationships).

4.1. Powertrain and vehicle movement

The functional energy model is the one in Fig.5 corresponding to a PHEV.

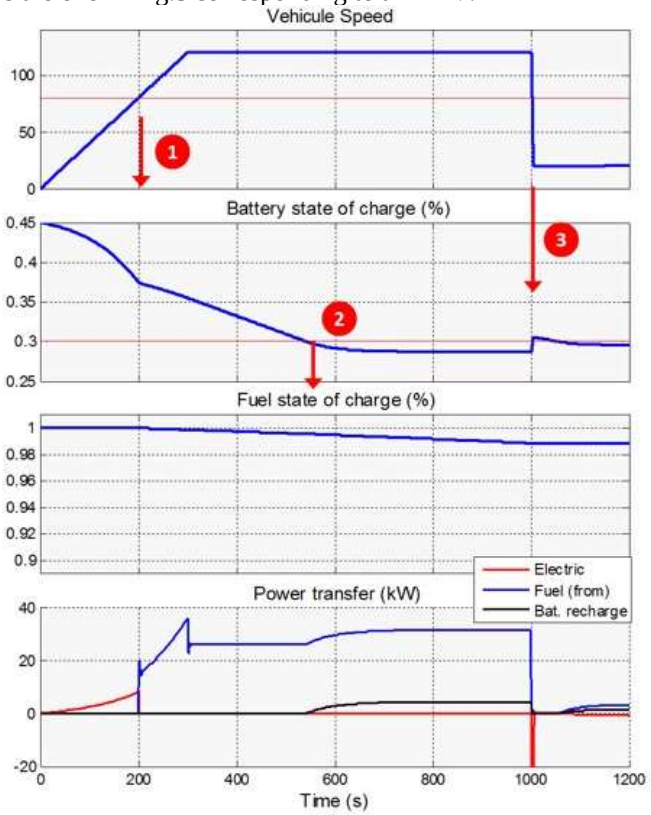

Figure 10: Energy management principles for the mobility of a PHEV

The basic scenario in Figure10 illustrates the energy management strategy chosen for the powertrain. During start-up, the electrical source is used to move the vehicle until a speed limit of 80km/h is reached (event 1); the power is then supplied by the conventional network (fuel). When the storage capacity reaches a lower limit (event 2), the storage unit is recharged by the fuel network via an electromechanical transformation (black signal from axis 4). Finally, during braking at the end of the scenario (event 3), the braking energy is recovered and used to recharge the storage unit.

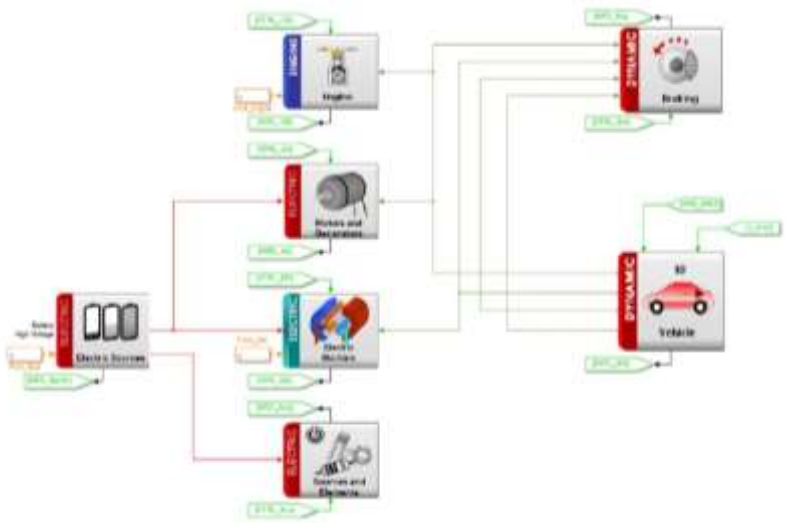

Figure 11: Electromechanical model of the powertrain

The multi-physics model in Figure 11 represents the main technological units of a hybrid powertrain: the vehicle dynamics, the braking system, the various engines (internal combustion engine, electric traction motor and alternator), the power battery as well as a set of electrical auxiliaries representing various vehicle consumers.

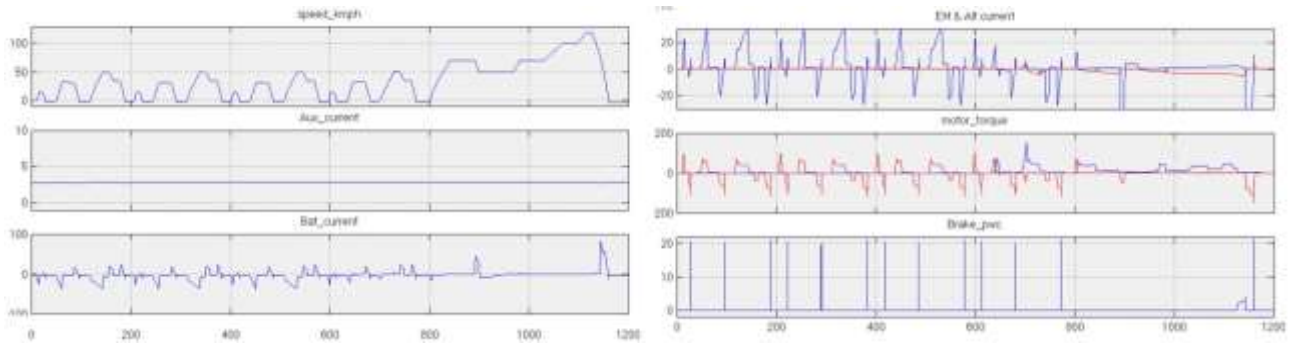

Figure 12: Energy behavior of a PHEV over a NEDC cycle

The multi-physical model was connected to the functional energy model according to the method introduced in (Mökükcü et al., 2017). The functional model becoming the model for the vehicle's energy management strategy.
Figure 12 shows the simulation evaluation results for a NEDC consumption cycle. We find the physical signals (speed, currents, torques, braking pressure) and a behaviour that validates the strategy designed using the functional model.

4.2. Thermal synthesis

In the case of an electric vehicle, cooling is provided either by direct exchange with outside air or by exchange with a cooling circuit (Fig.13).

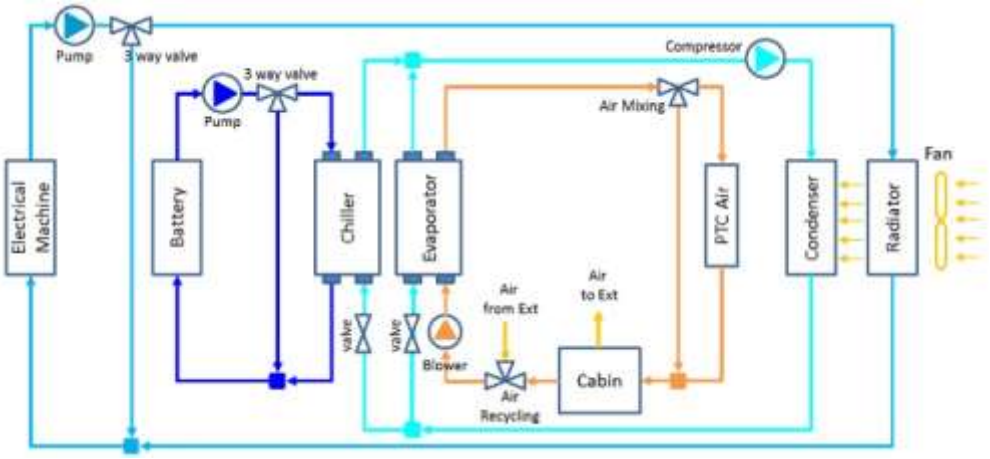

Figure 13: Diagram of the cooling circuits of an electric vehicle

The separation into several circuits results from the temperature level constraints of the elements to be cooled. This leads to complexity due to the need to optimize sizing and operation by pooling the sources of costs: the refrigerant is used to cool the cabin and the battery; the outside air is used in all circuits.
The functional model in Figure 14 represents this subsystem and reproduces its main functions:

- Cooling of electrical and electronic components by exchange with outside air;
- Cooling of the battery and passenger cabin by exchanging with the refrigerant circuit;
- Exchange between the refrigerant circuit and the outside air.

The circuits are represented by heat (or cold) distributors with an energy cost that will later be connected to the powertrain.

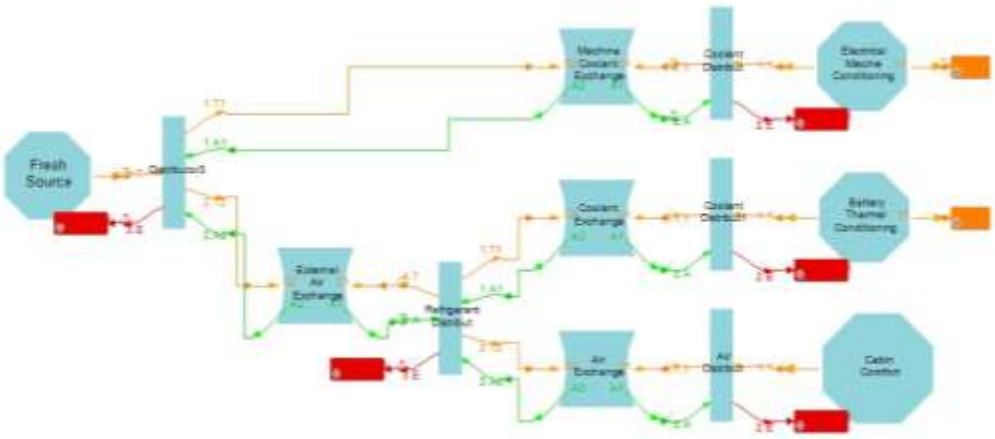

Figure 14: Functional energy model representing the thermal synthesis of an EV

The functional model was connected with the thermo-fluid model representing in detail the different thermal circuits.

Figure 15 shows, on a simple scenario, the compromise to be addressed in the case of an energy limitation. We placed ourselves in an unfavorable case (outside temperature of 45°C, steep slope 10%). Two cases are presented: on the left with a cabin prioritization and on the right with an electric machine prioritization. The axes present the different signals: temperatures (cab, battery and machine), main actuators (axis 4, compressor and fan) as well as the distribution of flows in the refrigerant circuit (axis 5, cab and battery).
Without the use of sophisticated algorithms, functional modeling has allowed the control of the system to be mastered, including with (deliberately) underestimated sizing.

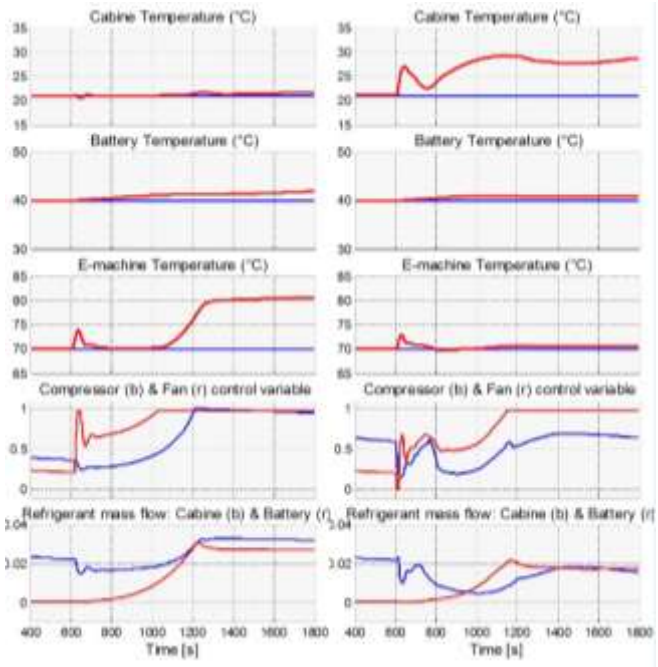

Figure 15: Cooling boundary management

4.3. Verification of interrelationships and energy optimization

This last part is devoted to the integration of the models of the two subsystems and to the overall verification of the vehicle's properties. It was done in the case of an electric vehicle (Fig.16) with:

- Physical links (electrical and thermal) between the two subsystems;
- Control links between each subsystem and its flow control (extract from the functional energy model);
- EMI links between the two flow controllers and information links with the overall coordination of the EV.

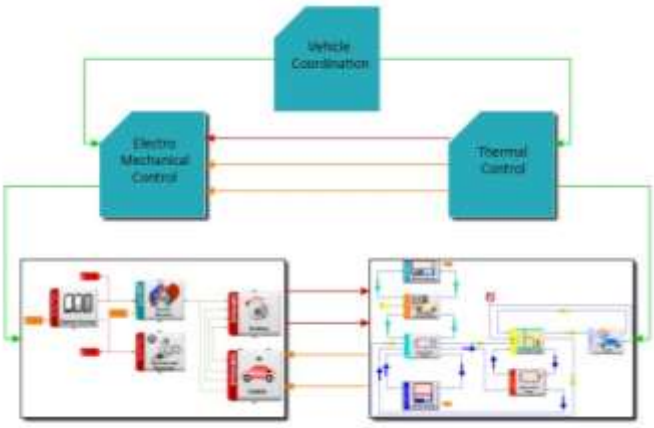

Figure 16: Model of an EV integrating mobility and thermal synthesis

The results presented below correspond to the EV's behaviour with a WLTC cycle. The second cycle is carried out with a slope of 6%, thus increasing the mechanical power and cooling requirements.

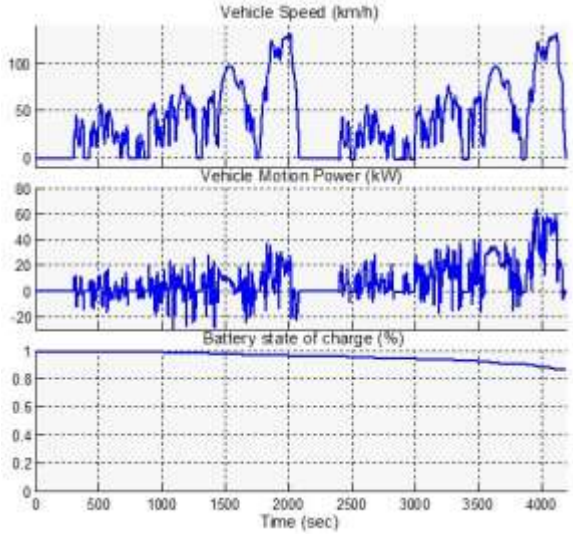

Figure 17: Mobility of the EV with a WLTC cycle

Figure 17 shows the main mobility variables: speed, battery charge state and power used by mobility. There is an increase in power (axis 2) in the second cycle corresponding to the slope driving.
Figure 18 shows the heat exchanges for two control configurations: high priority to cooling the electric machine (left) and better weighting for thermal comfort (right). The results are discriminating during the second cycle (slope driving) where, only the second strategy makes it possible to achieve all the objectives of thermal synthesis.
An additional use of this global model is the presetting of the coordination module with a possibility of optimization: control parameters, dimensioning of components...

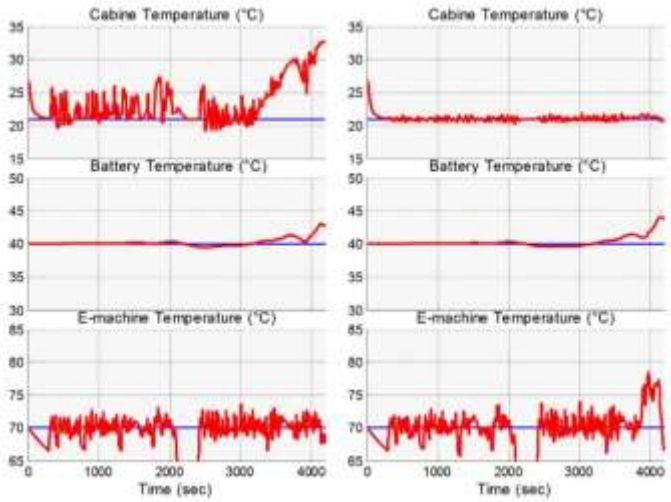

Figure 18: EV thermal exchanges with two control configurations

5. CONCLUSION

A methodology for modeling and evaluation in simulation of complex systems has been introduced and evaluated on an electric vehicle taking into account mobility and thermal synthesis.
Based on two connectable modeling concepts (multi-physical and functional energy), this methodology:

- Allows system evaluation from the early design stages;
- Ensures the consistency of the decomposition into subsystems by pre-defining their contributions to the overall system and facilitates the integration of their model;
- Provides the energy flow regulation model essential for the proper functioning of the system.

In addition, the method ensures modularity (which facilitates implementation) and flexibility.

ABSTRACT

City logistic is one the most polluting segments of the transport sector. Moreover, commercial vehicles generate higher traffic noise than passenger cars. Therefore, new regulations which aim CO_2 free transportation is one of the main considerations by policy makers. The number of electric vehicles (EV) has been increased especially over the last decade due to the strict regulations which aim to limit CO_2 emission. In-wheel solutions became a popular research and development area because of lowering total vehicle weight, eliminating many powertrain and suspension components which leads to obtain cost reduction opportunities. Thanks to in-wheel technology, furthermore larger design space is achievable that is employed to implement additional battery pack to increase the vehicle range. Beside mentioned, in-wheel e-machines are known for modular possibilities, lower center of gravity (CoG), increased range and energy efficiency. In this study, retrofitting a light commercial vehicle (LCV) with in-wheel e-drive and suspension systems is represented. Thanks to the benefits of in-wheel technology, the impact on range, weight and cost of the vehicle are mentioned. Main design considerations during adaptation of in-wheel systems and how to operate them efficiently is presented.

Keywords: Electric vehicle, retrofitting, in-wheel systems, thermal management

1. INTRODUCTION

Electric vehicles (EV) have substantial advantages such as zero emission, low noise operation, high efficiency of energy conversion compared with conventional vehicles in which internal combustion engine (ICE) is used for the propulsion [1]. Thanks to faster torque response, e-machines are easier to be controlled than ICE. Moreover, wide range of speed control characteristics of e-machines can lead to the elimination of some mechanical parts such as clutch, gearbox which provides to simplify vehicle structure [2].

Since e-machine is the core component of EV, it has significant influence on power, structure, cost and reliability of the vehicle. According to the different installation locations of e-machine inside EV, there are mainly two types of electric propulsion systems such as centralized drive with a single e-machine or distributed drive with at least two in-wheel e-machines (IWM) [3]. IWMs were introduced already 120 years ago by Porsche. However, they had limited applications due to technology and power-supply limitations. Since electric powertrain solutions have a rapid growth especially over the last two decades, there are also some examples of in-wheel e-drive solutions in modern vehicles. Today, IWMs have already been produced massively, in tens of millions of units per year. Thanks to technical developments that reach specific torques, in-wheel e-machine technology can now be adopted in the automotive industry [4].

Besides in-wheel e-drive system, applications of in-wheel suspension system are introduced to the modern vehicles with the goals of saving vehicle space by eliminating some mechanical parts of conventional suspension systems while improving travel conditions and reducing noise, vibration and harshness (NVH). The suspension system can be defined basically as a mechanism which physically separates the vehicle body from the wheels. The major function of the suspension system is to minimize the acceleration originated vertically which is transmitted to the passengers [5].

City logistic is one of the most polluting segments of the transportation and commercial vehicles generate much more noise than passenger cars [6]. The ultimate goal of this study is to represent retrofitting a light commercial vehicle with in-wheel e-drive and suspension systems that provide sustainable city logistics and improve mobility, accessibility and quality of life. Implementation of in-wheel e-drive and in-wheel suspension systems to a light commercial vehicles brings substantial benefits such as reducing the number of powertrain components under engine hood and the parts of conventional suspension system that provides extra space to implement additional battery pack or to be used for the

storage. Reducing the vehicle complexity and mass production cost becomes easier to reach with those modular systems.

In this study, the process of retrofitting a light commercial vehicle with in-wheel e-drive and suspension systems is represented. Thanks to the benefits of in-wheel technology, the impact on range, weight and cost of the vehicle are mentioned.

2. IN-WHEEL SYSTEMS

LCV (Figure 1), being retrofitted as part of the EU funded Sys2Wheel project, is an electric vehicle with in-wheel e-drive and suspension systems. There can be various vehicle architecture topologies since IWMs can be used for front wheel driving (FWD), rear wheel driving (RWD) or four wheel driving (4WD).

Figure 1. Target vehicle

The proposed rim size for LCV vehicle is 16" which is just enough for M700 in-wheel e-machine [7]. It is not feasible to place in-wheel e-machine and in-wheel suspension in the same rim due to the limitations by rim size, e-machine size and needed travel distance for suspension. All constraints narrow down vehicle architecture just to one in which M700 e-machines are mounted to front wheels while in-wheel suspension components are mounted to rear wheels.

2.1. In-Wheel e-Drive System

Propulsion systems with in-wheel e-machines provide intrinsically larger design space, lowering total vehicle weight, reduction of many powertrain components and consequently cost reduction opportunities are generated [8]. A comparison of ICE powertrain and FWD in-wheel drive system is depicted in Figure 2.

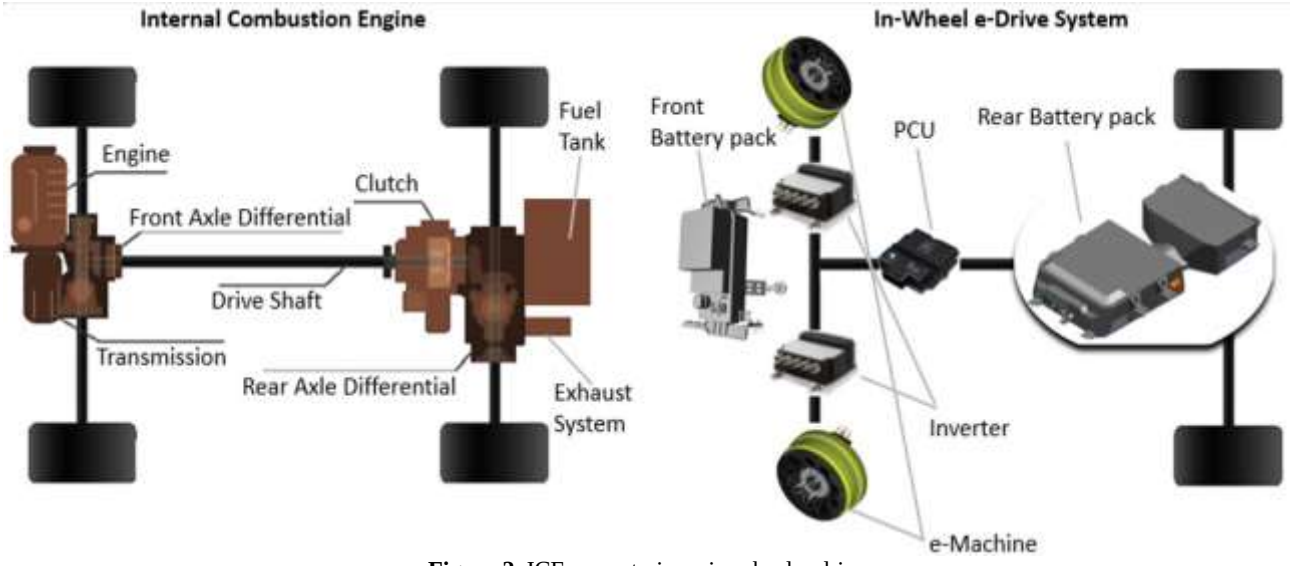

Figure 2. ICE powertrain vs in-wheel e-drive

Since the wheels are propelled directly and no mechanical transmission is required, higher energy efficiency is achieved with in-wheel e-drive system. Two in-wheel e-machines are driven by separate inverters which are controlled by propulsion control unit (PCU).

IWM has an outer rotor and relatively small air gap exists between rotor and stator as shown in Figure 3. High mechanical power outputs ranging above 110 kW is achieved by mounting two IWMs to the front wheels of the vehicle. Since the propulsion system generates large amount of heat especially on e-machines and inverters, designing a cooling layout and thermal management become a major consideration during retrofitting the vehicle.

Figure 3. Exploded view of in-wheel e-machine [7]

2.2. In-Wheel Suspension System

In-wheel suspension system is mounted to the rear wheels. The system allows dynamic behaviour along the wheel travel and chassis roll which gives stability and comfort travel. The suspension system depicted in Figure 4 consists of three main parts:

- Rigid central arm which is designed to take most of the forces applied on the wheel.
- Secondary arm designed for only one directional force.
- Upright that connects the arms to the wheel.

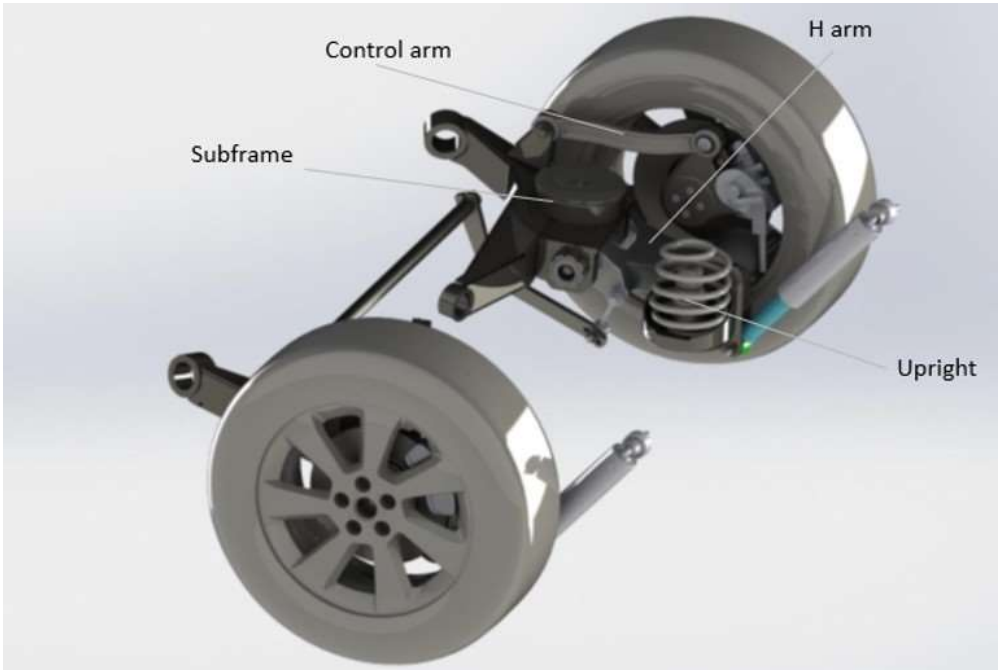

Figure 4. Exploded view of in-wheel suspension system [4]

H arm is designed to take most of the forces applied to rear wheels. It creates a dynamic compensation between camber and toe. Control arm is designed to withstand tension forces. The force in the case is a reaction created by the degree of the freedom that appears by H arm main shaft. The upright connects the arms to the wheel hub and allows H arm to pivot while passing the spring and damper reactions from the wheel to chassis. In order to mount those arms to the

original chassis rigid points, a sub-frame is designed which serves also for an additional purpose of silencing NVH and improving travel conditions.

3. OVERVIEW VEHICLE ARCHITECTURE

Retrofitting a vehicle with in-wheel e-drive and in-wheel suspension systems provides substantial benefits based on reducing powertrain and conventional suspension components and providing extra spaces which can be used for additional battery pack. A comparison study for in-wheel architecture, e-axle and central e-machine is represented in Table 1.

Table 1. Comparison study for in-wheel, e-axle and central e-machine architectures

Parameter	In-wheel	e-Axle	Central e-machine
Complexity	++	+	-
Space (Volume)	++	+	-
Cost (Transmission)	++	+	-
Cost (EM+INV)	-	++	++
System Efficiency	+	+	++
Modularity	++	+	-
Torque Vectoring	++	-	-
Comfort	+	++	++
++: good, +:not bad, needs checking, -: critical			

Packaging benefits, design flexibility, weight reduction and fuel savings are the main catalysts for implementing IWM platforms, while part of the reason for slow adoption seems to be the perceived cost related issues. When incorporating the e-machines in the wheel, some traditional mechanical powertrain components such as reduction gears, transmission, constant-velocity (CV) joints and drive shafts, are eliminated. While adding to the weight of the vehicle, mentioned components minimizes overall powertrain efficiency, since energy is being lost during the transmission.

ICE driven vehicles seem to utilize approximately 4500 drivetrain components, while Battery Electric Vehicles (BEV) end up at 3800 parts [7]. Bill of material for one with IWMs lists less than 100 components. However, it is evident that having two or four e-machines results in a higher component cost comparing with having only one and mechanical parts for transferring the drive [8]. Additional e-machines increase the price of the powertrain which leads the cost to increase by 25% [7]. A completely different result is obtained with a holistic approach analyzing the distributed IWM powertrain impact on the vehicle level.

Economic impact normalized on production costs of an average SUV for implementing direct drive IWMs bottom up to a 4WD vehicle was evaluated. Assessment of IWM benefits (packaging, powertrain mass, efficiency and battery pack cost, other benefits such as development costs, torque vectoring, ground clearance, steering functions etc.) showed an approximate financial benefit of 32,5% [7].

Based on the findings, even though the part count of IWMs in terms of basic building blocks like screws and nuts, is higher than that of an e-axle, the vehicle-level benefit greatly outweighs this. In terms of maintenance, the increased part count of IWMs does in fact reduce the number of serviceable elements to a minimal, as it reduced the number of friction elements that are subject to wear and tear throughout the vehicle lifetime. As the volumes for the components grow, typical processes allow part cost to drop to suitable levels to enable price parity or even price benefit on a powertrain level to existing technologies (assuming future-looking cost).

In this study, ideal vehicle architecture by considering rim size is defined in which two IWMs are mounted to front wheels while in-wheel suspension components are mounted to rear wheels. PCU controller is considered as main controller for the propulsion system which consists of two M700 IWMs driven by two inverters.

It is crucial to identify which parts are carry over from the donor vehicle (coloured green) while red colour indicates new parts or need to be modified (Figure 5). Visual bill of materials (BOM) study is performed after defining the locations of in-wheel systems in the vehicle.

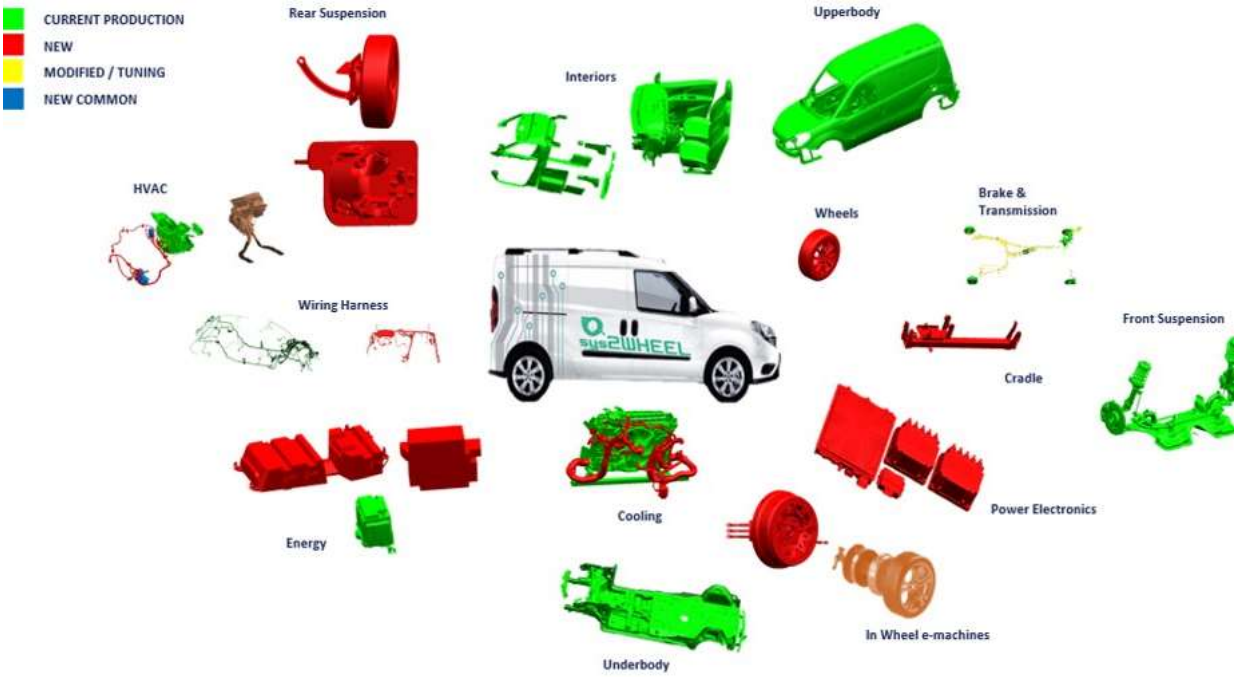

Figure 5. Visual BOM study

3.1. High Voltage (HV) Battery Design

One of the important activities carried out during retrofitting the vehicle is designing two separate battery packs. Available volume analysis for each battery pack is performed. One battery pack is located under vehicle body while the other one is located under engine hood as shown in the following figure due to increasing the range beside balancing center of gravity (CoG) of the vehicle. The total battery capacity hereby reaches to 89 kWh. The range of the vehicle is expected to be increased by ~20% with that additional battery pack under engine hood thanks to in-wheel drive technology.

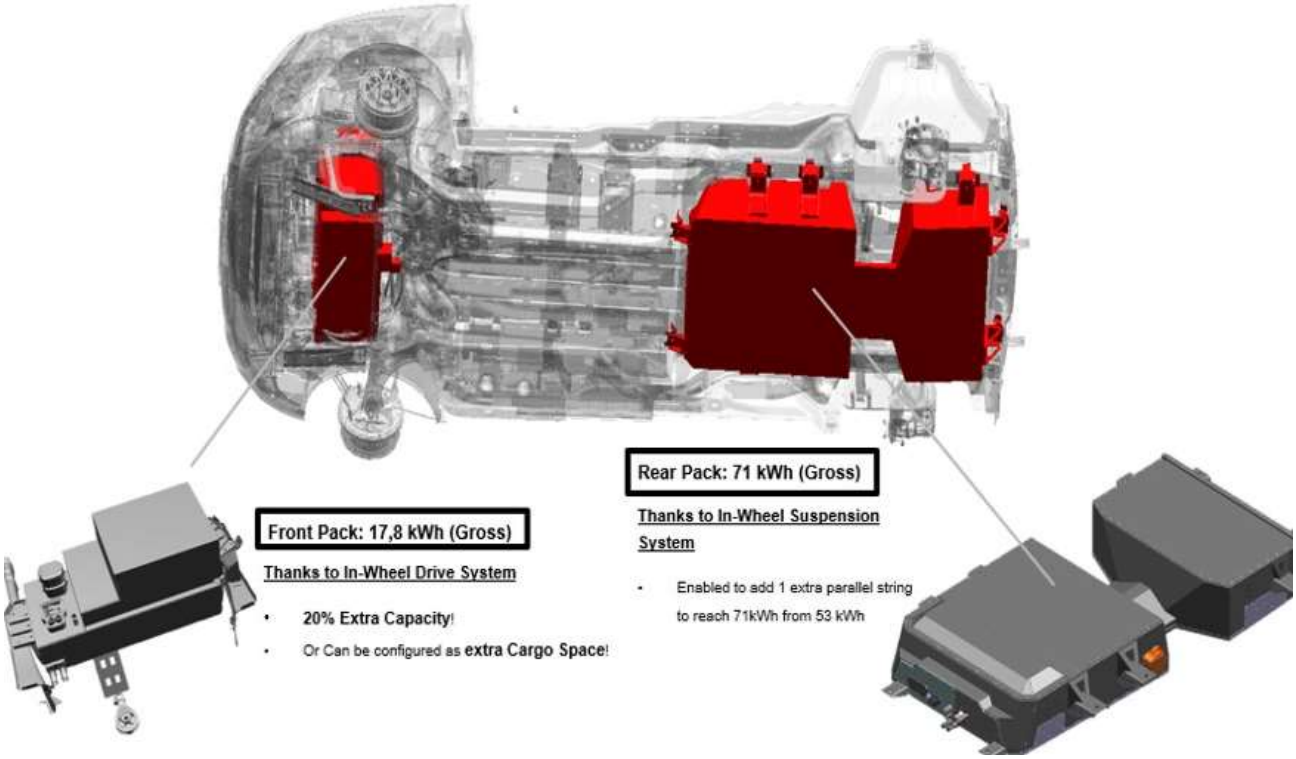

Figure 6. Location of HV battery packs

3.2. Integration of HV Components

Positioning of HV components such as DC/DC converter, onboard charger, e-machines, inverters, PCU, battery packs, A/C compressor etc. is one of the major activities since there are hoses of cooling layout and one of the battery pack mounted under engine hood where HV components are to be placed. Battery pack under engine hood is designed with an idea of providing some fixation points on itself in order to mount some HV components closer to each other. Hence, HV wiring harness and also coolant hoses can be designed as short as possible. The inverters are located at the bottom of battery pack to make them closer to e-machines as shown in the following figure.

Figure 7. Placement of inverters and e-machines

Mounting of in-wheel e-machines to the donor vehicle, which is designed for central e-drive, requires a new mechanical adaptor named as knuckle, designed to fix e-machines to vehicle chassis as depicted in the following figure.

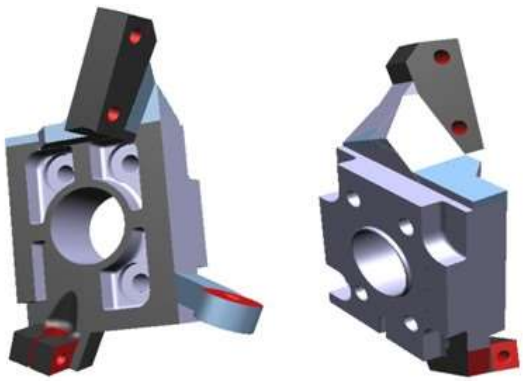

Figure 8. Knuckle parts

Positioning the rest of HV components such as DC/DC converter, onboard charger, power distribution unit (PDU), cooling system components are fulfilled in detail. In case of placement the components, some significant points are considered as below:

- Keeping HV components as close as to HV battery under engine hood to shorten the paths of HV cables,
- Keeping wiring harness of the signalization as short as possible,
- Avoiding any interference with vehicle body parts and providing enough space for coolant hoses,
- Positioning HV components for considering the coolant water inlet /outlet,
- Mountability and serviceability

3.3. Thermal Management Architecture

Thermal system design and cooling layout definition are key points to sustain optimum temperature for all HV components. Loop water temperature is regulated according to high voltage components' best efficiency working temperatures. Furthermore, cooling layout is designed attentively since packaging and using the space inside engine compartment efficiently are significative to finalize the battery pack under engine hood. Finalization of thermal architecture is illustrated in the following figure.

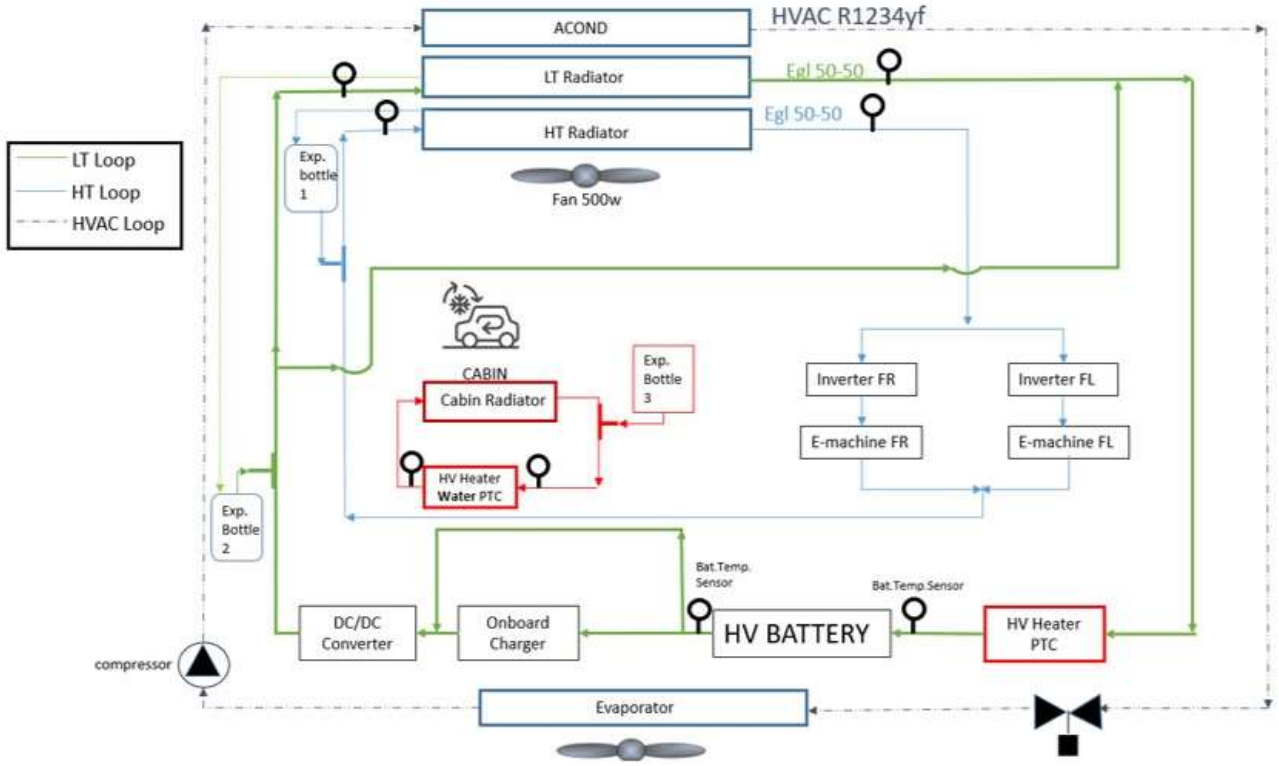

Figure 9. Thermal management architecture

Three cooling circulations are designed for the thermal management of the vehicle. High temperature (HT) circulation is employed to stabilize the operating temperature of inverters and e-machines which are mostly needed to cool down during driving the vehicle.

Low temperature (LT) circulation is utilized for providing optimum temperature for HV batteries and the rest of HV components such as DC/DC converter and onboard charger. A heater is placed before HV battery cause of considering cold weather condition. There are several two-way valves and those are being used for switching the coolant flow through different circulation lines when the specific by-pass conditions are met. Heaters and circulation pumps are controlled by electric vehicle control unit (EVCU) software.

According to the finalization of thermal management architecture, vehicle cooling layout studies are performed attentively since there isn't so many space left especially under engine hood. Therefore, coolant hoses can have interference with the rest of vehicle parts.

For retrofitting vehicle, the same vehicle body is being used with donor one. However, the transformation of traditional vehicle to a particular EV based on in-wheel e-drive and in-wheel suspension systems requires some modifications and new designs for brackets and fixing structures to mount new parts onto the vehicle body.

The vehicle has to have also completely new thermal management architecture and cooling layout. Every single part is evaluated for mounting point of view and relevant brackets are designed and prototyping process is completed. Finally, full vehicle integration is finalized as shown in Figure 10.

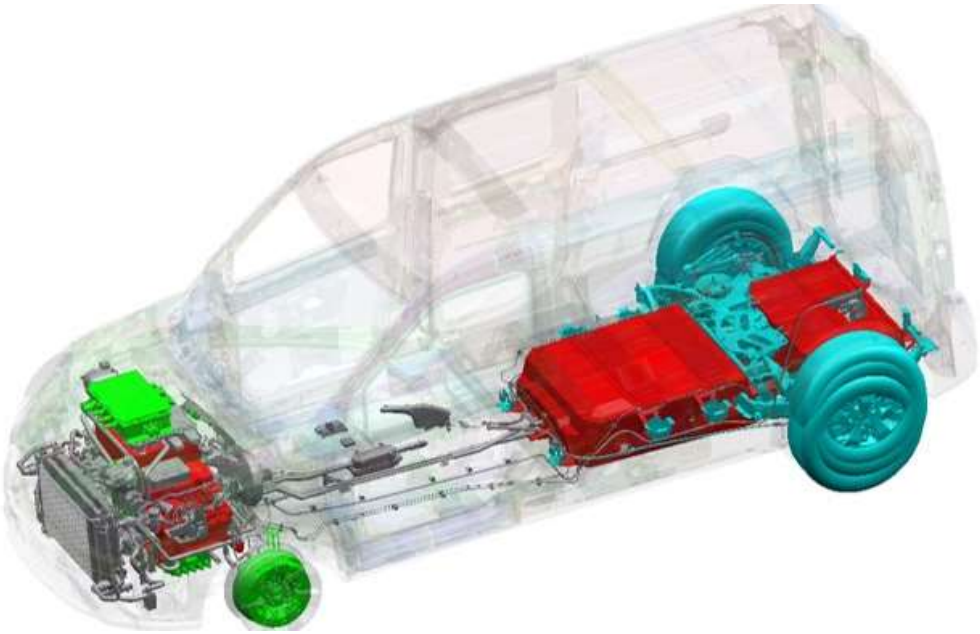

Figure 10. Full vehicle integration

3.4. Vehicle Network Architecture

Network architecture can be different depending on implementing time sensitive networking (TSN) or not. Due to using various electronic control unit (ECU) such as EVCU, PCU and gateways network architecture may be varied. Regarding to capability of each ECU, some management such as torque vectoring, thermal management etc. can be handled on specific ECUs. Moreover, some gateways can be eliminated if those ECUs are capable to provide required interfaces such as local interconnect network (LIN), pulse width modulation (PWM), Ethernet, controller area network (CAN) etc.

Since the number of electronic control units is being increased especially over the last decade, one of this study objective is to implement TSN which provides faster and more reliable data communication inside the vehicle. TSN communication is employed between battery management system (BMS) and EVCU as depicted in Figure 11.

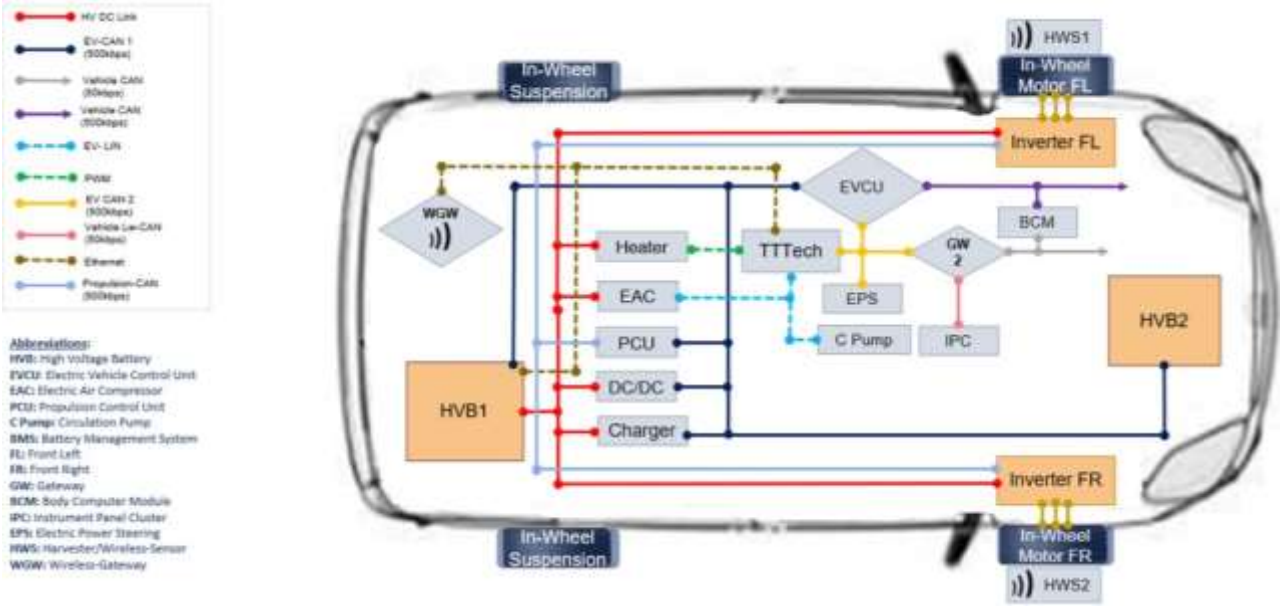

Figure 11. Vehicle network architecture

TTTech TSN controller mainly has Ethernet interface role between BMS & EVCU and WiFi-gateway & EVCU communications. It is also utilized to provide CAN, PWM, LIN interfaces for the rest of the vehicle network communication.

In addition to high voltage (HV) battery pack under vehicle, a front battery pack is placed under engine hood where ICE and associated powertrain components were located in the donor vehicle before.

PCU controller is defined as main controller for the propulsion system which consists of two M700 e-machines driven by two inverters. Harvester units are mounted to collect and transmit data from the front wheels. This information is used as an input for advanced control algorithm.

Heaters and circulation pumps are involved for the cooling system and they are controlled by thermal management algorithm inside EVCU. EVCU is also acting as supervisory controller on top of the whole system.

4. CONCLUSION

In this study, retrofitting a light commercial vehicle with in-wheel e-drive and suspension systems are represented. Thanks to in-wheel technology, reducing the vehicle complexity and mass production cost becomes easier to reach. Moreover, eliminating ICE and associated powertrain components under engine hood in the donor vehicle provides extra space that could be employed for the storage or implementing additional battery pack.

Additional battery pack with 18 kWh capacity is designed and placed under hood which directly contributes to increase the vehicle range. The range is expected to be increased by ~20% with that additional battery pack. Besides increasing the range, it provides an improvement on balancing CoG due to main battery pack is mounted under vehicle body close to rear wheels. Thanks to in-wheel suspension system, it is achieved to eliminate conventional rear suspension components which leads to enlarge the battery pack under vehicle body.

Thermal management is one of the major consideration during retrofitting the vehicle. It is crucial to have optimum temperature inside the cooling circulations in order to ensure the efficiency of HV components. Moreover, coolant hoses are designed carefully since using the space under engine hood has an impact on finalizing the front battery pack.

As a future work, performance comparison of donor vehicle and retrofitting one is proposed. In this regard, IWMs and in-wheel suspension systems could be evaluated from a different perspective. As such, in-wheel powertrain opens opportunity for novel vehicle designs and architectures, adding safety and control functions.

ÖZET

Mevcut ürün geliştirme sürecinde, klima gazını şartlandıran klimatik bankolarında yapılan, borulardaki basınç kayıplarını ölçen performans testleri, yüksek geliştirme maliyetlerine neden olmaktadır. Yüksek maliyetleri nedeni ile de proseslerin iyileştirme sürecinde, parça geometrisinin her bir iyileştirme adımı sonrasında değil, sadece son ürün doğrulaması olarak yapılıyordu. Bu da son testlerde oluşan olası problemlerde hem zaman kaybı hem de maliyetli testlerin tekrarlanması sonucunda proje maliyetlerine olumsuz etkilemektedir. Bu çalışmada boru için basınç kayıplarını, klimatik banko gerektiren klima gazı ile yapmak yerine basit düzenekler ile hava ile değerlendirileceği fiziksel bir doğrulama süreci geliştirilmiştir. Hava kullanımı durumunda yeni basınç kayıp hedeflerin belirlenmesi için de AMESIM programında boruların modellenmesi ve model sonuçlarının kalibrasyonu yapılmıştır. Yeni doğrulama yöntemi ile ilk proses parçasında banko testleri olmadan gerekli iyileştirmeler belirlenmiş ve sonuç ürün banko testlerinin problemsiz sonuçlandırılması sağlanmıştır.

NEW PERFORMANCE EVALUATION PROCESS FOR HVAC INTERNAL HEAT EXCHANGER

ABSTRACT

In actual product development process, pressure drop performance of internal heat exchanger measured with final product on high cost validation bench with complete refrigeration system without any interim physical check. Possible negatives results time losses and higher spending. In the study, a new validation test developed with using air as a fluid which aids simple bench test using pressured dry air already exist in production plants. All internal design changes from of tool to of tool of process parts can be validated with this new method. To define pressure-drop targets with air, AMESIM 1D model developed and calibrated. New process applied on MHEV program with a sufficient final validation result.

Keywords: Internal heat exchanger, Pressure drop, Product development cost, 1D AMESIM, Air test bench

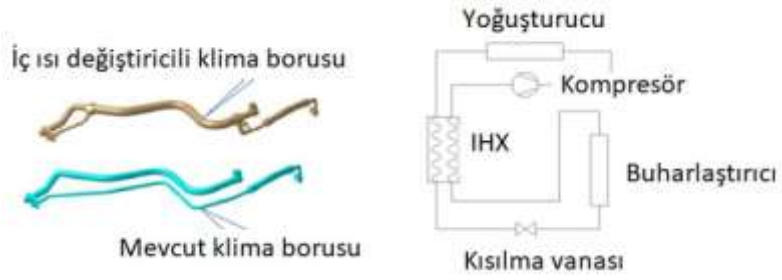
1. GİRİŞ

Otomobil firmaları R1234yf gazına geçiş süreci ile araçların klima sistemlerinde de performans arttırıcı çözümleri devreye almak zorunda kaldı. R1234yf ile sistem kapasitesindeki düşüşü telafi etmek için otomobil firmalarının tercih ettiği en yaygın uygulama, sıvı hattı ile emiş hattı arasında ısı transferi sağlayan iç ısı değiştiricisi (IHX) ilavesidir.

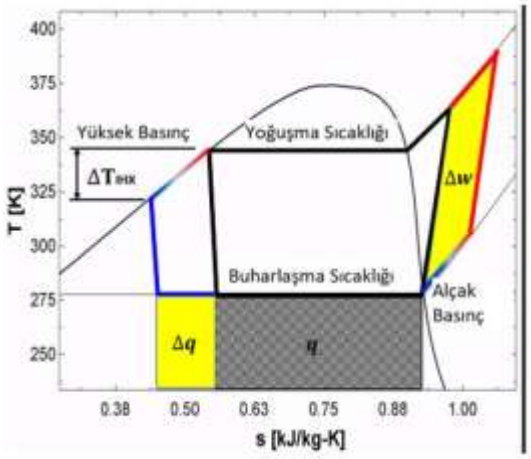
Performans etkisinin yanında özellikle, benzinli turbo motor araçlarda su soğutmalı yoğuşturucuya geçiş ile birlikte IHX kullanımı da zorunlu hale gelmiştir. Kurutucu/filtre ile entegre yapıda olan geleneksel boru-kanatçık tipi yoğuşturucularda, aşırı soğutma boruları da bulunmaktadır. Plaka-plaka tip olan su soğutmalı yoğuşturularda ise kurutucu/filtre ayrık bir parçadır ve sistemde aşırı soğutma ancak iç ısı değiştirici kullanımı ile sağlanabilmektedir. IHX kullanılmadığı durumda ise kısılma vanasına çift fazlı akış girme riski bulunmaktadır.

IHX şekil 1'deki gibi iç içe geçmiş iki borudan oluşmaktadır. İçteki borudan emiş hattından gelen soğuk buhar kompresöre doğru akarken, dışarıdaki borudan da yoğuşturucudan çıkan doymuş sıvı termostatik genleşme valfine doğru akar. IHX'in görevi ise buharlaştırıcıdan çıkan soğuk buharı kullanarak, termostatik genleşme valfine giren sıvının daha fazla soğumasını sağlamak ve bu sayede buharlaştırıcıdaki ısı alma kapasitesini arttırmaktır. Şekil 2'deki iç

ısı değiştiricili bir termodinamik çevrimde aşırı soğuma ile buharlaşma entalpisindeki artış Δq ile, karşılığında ise yoğuşturucudan atılması gereken ısıdaki artış Δw ile gösterilmiştir [1].



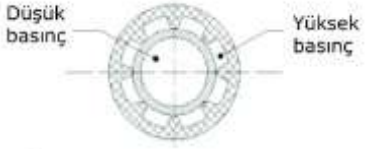
Şekil 1. araçlarda iç ısı değiştiricisi uygulaması



Şekil 2. iç ısı değiştiricisi ile termodinamik çevrim [1]

Huguang ve diğerleri [2], IHX kullanımı ile kompresördeki enerji tüketiminin %16 oranında azaltılabildiğini belirledikleri araç üzeri testlerinde, IHX'in soğutma kapasitesine pozitif etkisinin araç rölantide iken daha yüksek olduğunu gözlemlemişlerdir. Rölantide çalışan araçta IHX'li klima sistemi ile 2.5 ºC daha soğuk hava üflerken, sürüş şartında ilk 30 dakikada iyileşme görülmemiştir. Akyol ve diğerleri [3] çalışmasında ise R1234yf yüklü bir sistemin soğutma kapasitesi, sisteme 400mm'lik bir IHX iç ısı değiştirici ilave edildiğinde, kompresör yüksek devirde iken %3.5, rölantide kompresör düşük devir iken ise %11 arttığını ölçmüştür.

Seybold ve diğerleri [4] yaptığı çalışmada 350 mm'lik bir IHX kullanımı ile soğutma kapasitesinin %7 oranında arttığını tespit etmiştir. IHX boyu 700mm'e çıkarıldığında soğutma kapasitesi ancak %8'e çıkmıştır. Bu sonuç, IHX kapasite seçiminin optimumda olması gerektiğini göstermiştir. Bunun en önemli nedenlerinden biri de basınç kayıplarının optimize edilmesidir. Mastrullo ve ark. [5] düşük basınç gaz akışındaki basınç kayıplarının STK soğutma tesir katsayısını daha fazla etkilediğini belirlemişlerdir. Yu-Lin [6] tez çalışmasında ise düşük basınç hattında zig-zag iç boru yapısı oluşturulması veya iç yüzeye ilave kanatçık eklenmesi durumlarında ısı transferinde artış sağlanmasına rağmen, düz boru geçildiğinde sistem STK'sının daha yüksek olduğunu ölçmüştür. Isı değiştirici düşük basınç hattı tasarımında yaygın çözüm hem basınç kayıplarını hem de sıcak motor bölmesine ısı kayıplarını önlemek için iç taraftaki düz borudur.



Şekil 3. İç ısı değiştiricisi iç içe geçmiş boru yapısı

Yüksek basınç hattı ise Şekil' 3 de ki gibi, ısı transfer yüzeyini arttıracak kanatçıklı bir yapıda ekstüzyon çekilmekte ve alçak basınç hattı üzerine kaynatılmaktadır. Yaygın olarak 10 ile 15 arasında mikro-kanal yapıda üretilmektedir. Yüksek basınç tarafındaki basınç kayıpları STK üzerinde etkisi düşük olsada, mikrokanal yapısı ve IHX giriş ve çıkış bölgelerinden flanşlardaki dirsek geçişler ani genleşme ve daralmalar nedeni ile proseste oluşacak geometrik sapmalardan çok fazla etkilenmektedir. Sistemde oluşacak bir tıkanıklık teorik beklentinin üzerinde STK'yı düşürebilir.

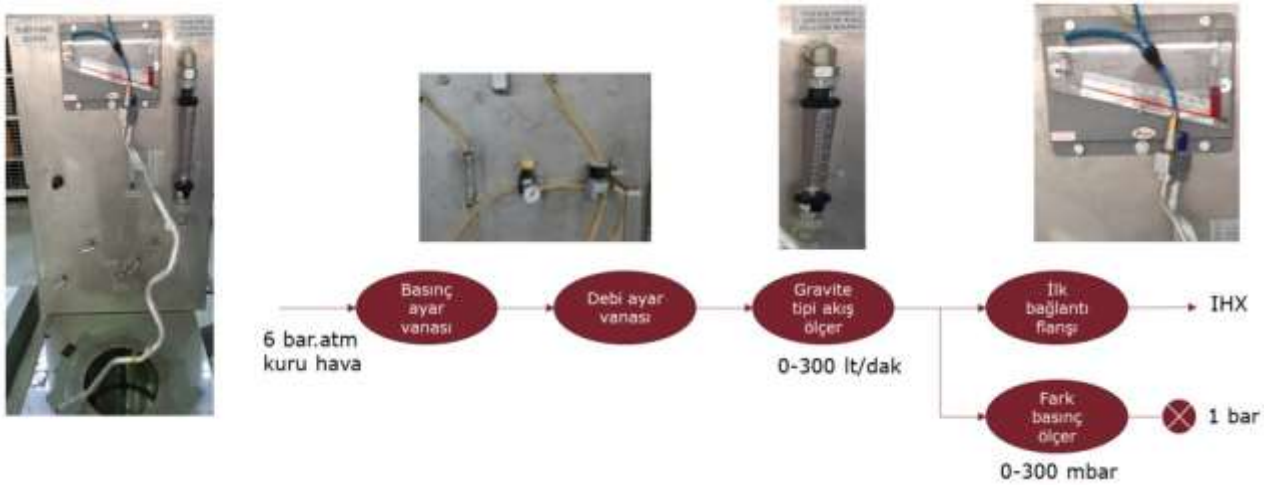
Şekil 4. Soğutucu gaz ile iç ısı değiştirici doğrulama testleri giriş şartları

IHX ürün performans doğrulaması, kapalı bir soğutucu gaz çevrimi ile, giriş ve çıkışta akışkan koşullarının Şekil 4'deki gibi kontrol edilebildiği büyük ölçekli bankolarda yapılmaktadır. Yüksek basınç sıvı ve düşük basınç buhar hattındaki basınç kayıplarını ve toplam ısı transferi hedefleri kontrol edilmektedir. Düzeneklerin hazırlanması ve testler toplamda, 1 haftalık bir süre ve yüksek maliyetler ile yapılmaktadır. Performans doğrulamaları, maliyetlerinin yüksek olması sebebi ile proses geliştirme sürecinde değil, son ürün onay testleri olarak planlanmaktadır. Proses geliştirme süreci ise parçalar üzerinden fiziksel ölçü kontrolleri ile ilerlenmekte, tasarım parametrelerin uygun seçilip seçilmediği, proseste yapılan iyileştirmelerin performans çıktısı için yeterli olup olmadığı bilinmemektedir.

Çalışmamızda, literatürden farklı olarak, mikro kanal yapısı ve giriş/çıkış flaş dirsekleri ile ölçüsel sapmaların kritik olduğu yüksek basınç hattında, prosesten kaynaklı hataların, erken fazlarda ölçülebilmesi hedeflenmiştir. Maliyet ve süreyi minimize etmek içi boru içinden akışkan olarak soğutucu gaz yerine hava geçirilerek fiziksel basınç kayıplarının ölçüleceği bir banko geliştirilmiştir. Hava ile yapılan testlerin anlamlılığını ve hedeflerini belirlemek için de 1D AMESIM yazılımında hava akışı için modelleme yapılmıştır. Gemin [7], soğutma çevriminde IHX'in TXV duyargası öncesine taşındığı durumdaki soğutma kapasite ve COP'yi değerlendirdiği tez çalışmasında AMESIM yazılımını kullanmıştır. Fakat analizinde kullandığı 1D modeli, basınç kayıpları özelinde olmadığı için dirsekler, flanşlar gibi geometrik yapılı içermeyen düz boru kabulü ile hazırlamıştır. Komple soğutucu gaz kapalı çevriminin 1D modeli yapıldığı durumlarda, analiz sürelerini kısaltmak için düz boru kabulü yaygın olarak kullanılmaktadır. Çalışmamızda IHX elemanının basınç kayıpları özelinde olduğu için geometrik yapıların tam modellemesi yapılmıştır.

2. METOT

Şekil 5'te fabrika basınçlı hava tesisatını kullanarak, boru içi basınç kayıplarının ölçüldüğü tesisat verilmiştir. Basınç ayar vanası ise 6 bar basınçlı hava 1 bar'a düşürülmektedir. Debi ayar vanası ile akış kontrol edilmekte ve gravite tip akış ölçer ile ölçülmektedir. Akış ölçer 350 l/dak hava akışını (volumetrik) ölçebilmektedir. Akış ölçer sonrasında hat, statik basınç ölçümü için 2 paralel hatta ayrılmaktadır. İlk hattın çıkışana IHX bağlantısı yapılabilecek flanş ve girişinde açma/kapama vanası bulunmaktadır. Paralel hatta ise su manometresine ulaşmaktadır. Manometre 300 mbar'a kadar bağıl basıncı, atmosferik basınçtan farkı ölçmektedir. Su manometresinde okunan değer IHX içindeki toplam basınç kaybını vermektedir. Basınç değerleri seri hat üzerindeki manometreden okunması durumunda dinamik basınç etkisi de ölçülebilir. Test sonuçları ortamdan bağımsızdır, dikkat edilmesi gereken hava tesisatlarındaki kaçaklardır. Test başlangıcından önce IHX girişindeki vana kapatılarak ve basınçlı tesisat üzerinde ses dinlenilerek, sistemde kaçak olmadığı doğrulanmalıdır.



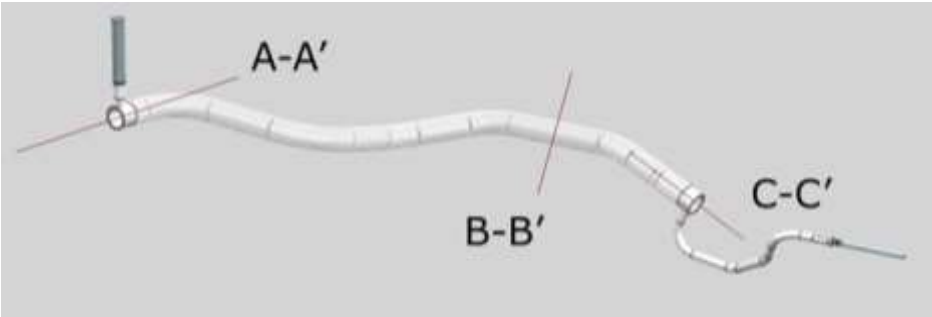
Şekil 5. Hava ile boru içi basınç kayıplarının ölçüldüğü tesisat şeması

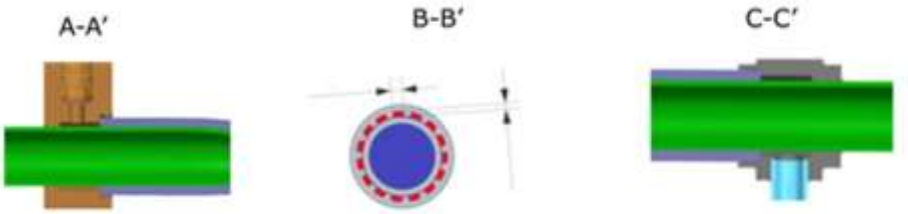
Test debisinin belirlenmesinde Reynold benzerlik ilkesinden faydalanılmıştır. Reynold benzerlik ilkesine göre soğutucu akışkan ile bankoda yapılan testlerde ulaşılan Reynolds değerini sağlayan hava debisi, 1 nolu denklem kullanılarak belirlenmiştir. Çalışmamızda türbülanslı akış koşullarında Re=9000 değeri için 50 lt/dak. hacimsel hava akış debisi giriş şartı olarak seçilmiştir.

$$Re=(u*D_h/\nu)_{R1234yf}=(u*D_h/\nu)_{hava} \quad (1)$$

Şekil. '6 da çalışmamızda değerlendirdiğimiz iç ısı değiştiricisi yüksek basınçlı sıvı hattı kritik kesit ölçüleri verilmiştir. Hat üzerindeki akış soldan sağa 4 bölgede incelenmiştir.

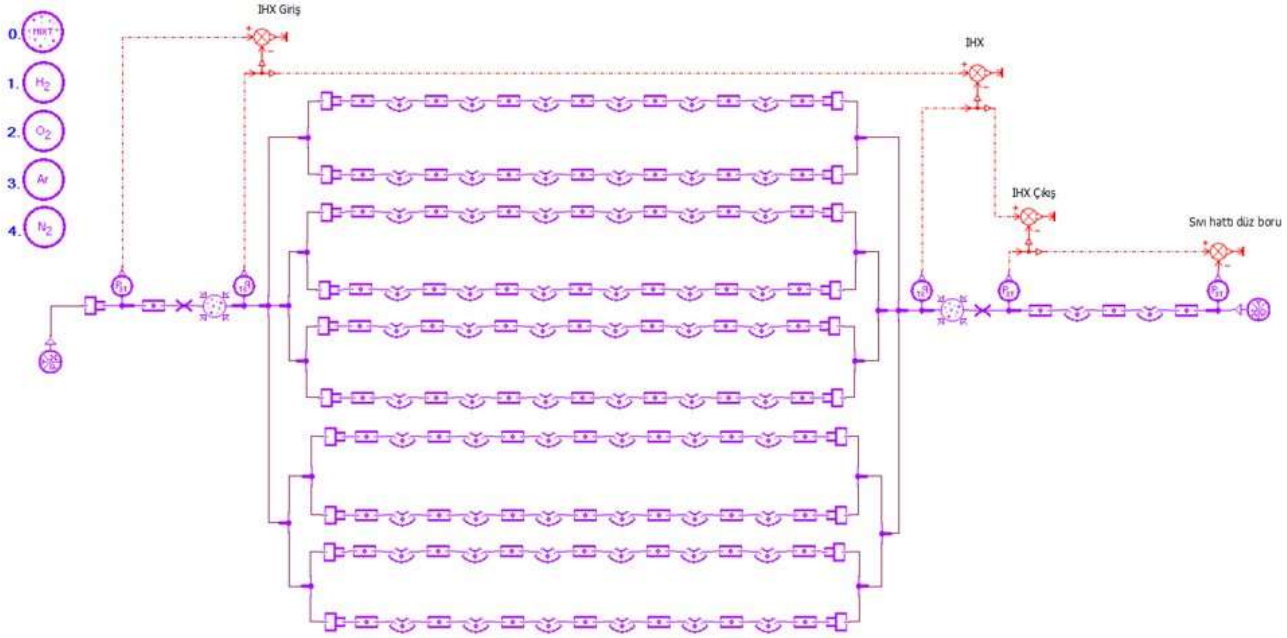
1) A-A' kesitinde belirtilen IHX'e soğutucu akışkan giriş flanşı, düz boru dar kesitten geçerek bir hacim doldurma
2) B-B' kesitinde belirtilen mikro-kanal yapılı boru içi akışı, ani daralma ile giriş ve ani genişleme ile çıkış
3) C-C' kesitinde belirtilen çıkış flanşı, hacimden düz boruya dar bir kesitten geçerek ani genişleme
4) Düz boru akışı





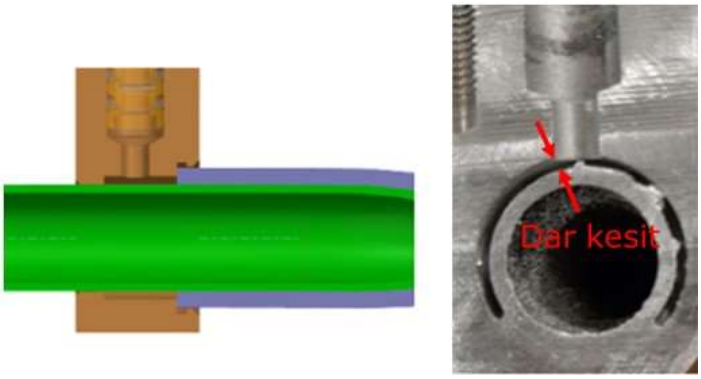
Şekil 6. İç ısı değiştiricisi kritik kesitler

Şekil 7'de akışkan hava olması durumunda yüksek basınç hattının AMESIM yazılımında 1D modeli verilmiştir. AMESIM programında, Pnömatik veya Gaz Karışımı kütüphaneleri kullanılarak modelleme yapılabilir Çalışmamızda, daire veya kare harici farklı kesitler için, hidrolik çap kullanılarak, düz boru akışları modellenebildiğinden Gaz Karışımı kütüphanesi seçilmiştir. Pnömatik kütüphanedeki adyabatik, ısı transferi içermeyen, düz boru modülünde yalnız dairesel kesit için modelleme yapılabilmektedir.



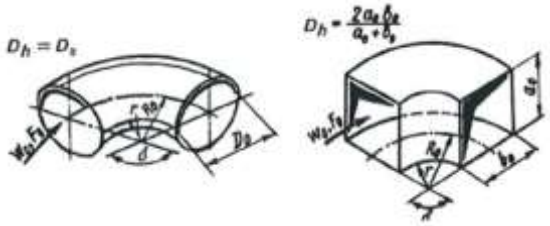
Şekil 7. İç ısı değiştirici AMESIM 1-D modelleme

Düz boru ile flanş arası geçişlerde, ani genişleme veya daralma modülleri yerine, kesit daralması modülü kullanılmıştır. Kullanım nedeni, hacim içerisinden geçen buhar hattının, Şekil 8'deki gibi düz boru girişinde, dar bir kesit oluşturmasıdır. Dar kesit modülündeki basınç kayıplarının ani genişleme veya daralmaya göre daha etkili ve test sonuçları ile daha uyumlu olduğu görülmüştür.



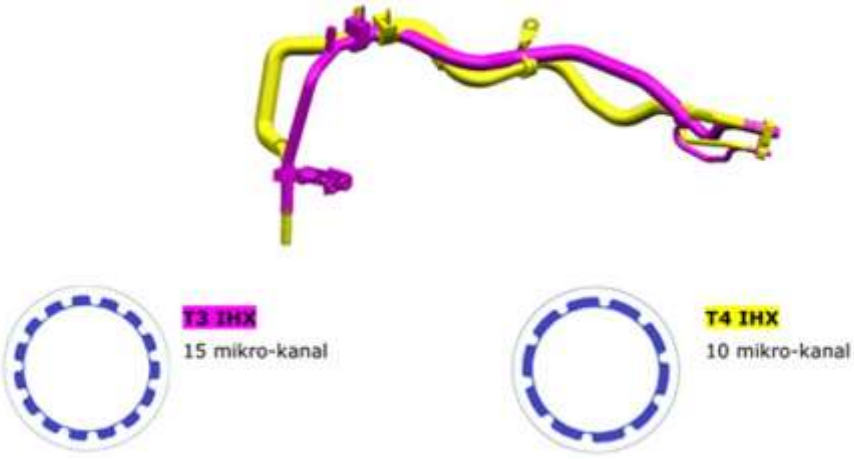
Şekil 8. IHX giriş / çıkış flanşları ile düz boru bağlantıları arasındaki dar kesit arası akış

IHX bölgesinde her bir mikro-kanal ayrı hat olarak modellenmesi gereklidir. Nedeni, Şekil 9'da verildiği gibi, dirsek akış modüllerinde girdi ölçüsü olarak sadece hidrolik çap ve kesitin genişlik/yükseklik oranı girilebilmesidir. Toplam kesit alanına göre tek bir boru olarak modelleme yapıldığında, yüksek Reynolds sayısı nedeni, hatalı sonuçlar alınmaktadır. Çalışmamızda, referans üretim boruları 15 adet mikro-kanal yapılı yeni tedarikçinin boruları da 10 adet mikro-kanal yapısındadır.



Şekil 9. Gaz Karışım modülü dirsek elemanı parametreleri

Çalışmada referans olarak, farklı bir motor seçeneği için farklı bir tedarikçi tarafında devreye alınmış olan iç ısı değiştirişi alınmıştır. Şekil 10'da, T3 IHX referans parça, T4 IHX ise proses optimizasyonu için çalışılan parçanın karşılaştırılması verilmiştir.



Şekil 10. Çalışmada analiz edilen iç ısı değiştirici geometrileri

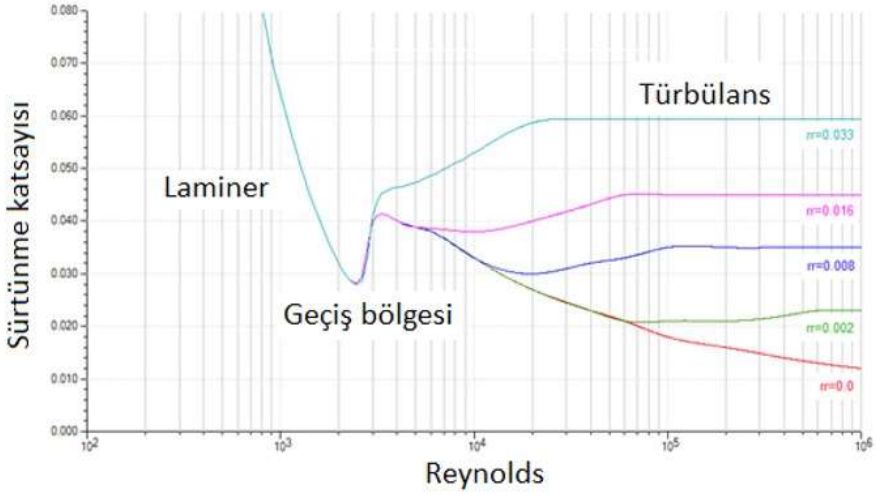
Amesim programı, boru içi akış basınç kayıp hesabında Re < 2500 laminer akış için 2 numaralı denklemi kullanmaktadır.

$$\frac{d(dm1)}{dt} = \frac{A}{L} \cdot \Delta P \pm \frac{32 \cdot \mu \cdot \vartheta \cdot A}{D^2} \quad (2)$$

Re > 2500 türbilanslı akış için 3 numaralı denklemi kullanmaktadır.

$$\frac{d(dm1)}{dt} = \frac{A}{L} \cdot \Delta P \pm \frac{ff \cdot \rho \cdot v^2 \cdot A}{2\,D} \quad (3)$$

Türbülanslı akış için ff sürtünme katsayısı ise Şekil' 11 de ki gibidir. Grafikteki rr katsayısı bağıl yüzey pürüzlülüğü (yüzey pürüzlülüğü / hidrolik çap) ve alüminyum borular için yüzey pürüzlülüğü 6 µm alınabilir.



Şekil 11. 1D model hesaplarında kullanılan sürtünme katsayısının Reynolds sayısına bağlı değişimi

3. SONUÇLAR

Mevcut T3 IHX borusunun deneysel test sonuçların 1D analiz sonuçlarına göre, +%30 sapmalı ölçülmüştür. Sapma nedeni hem 1D model sapması hem de üretim borusunun teknik resimden olan sapması sonucundadır. Genel olarak fiziksel ölçüm sonuçları AMESIM 1D hesaplarına göre yüksek çıkmaktadır. Hem 1D hem de deneysel sonuçlara bakılarak toplam basınç kayıplarının %30'ünün IHX girişinde, %40'ının IHX içinde, %15'inin IHX çıkışında, %15'ininde sıvı hat borusu içerisinde gerçekleşmektedir.

Çalışmamızda analiz ettiğimiz T4 iç ısı değiştiricisi, mevcut üretimdeki referans model T3'e göre, daha kısa olması ve akış kesitinin daha büyük olması nedeni ile Eşitlik 2'ye göre, basınç kayıpları bakımından iyileşme beklenmektedir. Teknik resim ölçülerine göre yapılan 1D analizde T4 IHX borusu basınç kayıplarının T3 IHX'e göre ise %17 düştüğü hesaplanmıştır ve basınç kayıp hedef değerleri olarak alınmıştır.

T4 iç ısı değiştiricisi için, üretimden çıkan ilk parçaların test sonuçları belirlenen teknik hedef değerinden 3 kay yüksek çıkmıştır. Deneysel sonuçlar özellikle çıkış flanşında basınç kayıplarının yüksek olduğunu göstermektedir. 1D analiz sonuçlarında bu bölge için beklenen basınç kayıplarının 10 katı basınç kaybı ölçülmüştür. Parça kesilerek analiz edildiğinde, Şekil'12 deki gibi, akış flanştan düz boruya geçişte, 3 mm'ye kadar düşen bir ani kesit daralması görülmüştür. Proseste iyileşme istenerek 2. Seviye off tool parçada tekrar değerlendirilmiş ve T3 seviyesine ulaştığı doğrulanmıştır.

IHX boru iç akışında ise 10 mikro-kanal yapılı çözümün %30 daha basınç kayıplarını iyileştirici yönde olduğu görülmüştür.

Şekil 12. Flanş kesit daralması

Çalışmamızın çıktısı, erken fazda basınç ölçümü yapabileceğimiz bankonun geliştirilmesi ve bu banko ile yapılan proses iyileştirmeleri ile, soğutucu gaz ile yapılan banko testlerinin olumlu sonuçlanmasıdır. Yeni geliştirdiğimiz test ürün geliştirme sürecine entegre edilmiştir. Çalışmanın bir diğer önemli çıktısı da AMESIM 1D yazılımında hedeflerin belirlenebilmesi için, en uygun kütüphanenin Gaz Karışımı modülü olduğu ve fiziksel sonuçlara göre %20-%30 sapma ile çalıştığı da belirlenmiştir.

ABSTRACT

As a high level of supplier having wide range of OEM customers, Valeo need to find solutions to fullfill customer requirements.
One of OEM customers required addition of high level of misalignment to the existing dynamic test bench of Valeo. This was needed to have the reproduction of failure related to the misalignment.
The Valeo dynamic test bench is a bench that gives torsional movement under rotation simulating the vehicle conditions. Unlike the vehicle, bench crank and GB shafts are operated from the same direction and well aligned on the bench with bearings.
The existing test bench was not fullfill the misalignment requirement and a new test bench was an extremely expensive solution. A smart design was performed to fullfill customer requirement on existing test bench by developing systems preventing the bench damage from radial loads due to misalignment.
This study explains the developed systems on this smart design to prevent the existing bench damage.

Keywords: Misalignment on test bench, adaptation tool, prevent the bench from damage

1. EXISTING ADAPTATION TOOL

1.1. Adaptation tool to assemble the test part to the bench

The torsional movement is given by the angle between inner group (bench internal shaft + FFW extended tool +FFW) and the outer group (bench external shaft + outer house + cover + shaft extended + torsional shaft). All the parts rotate also at vehicle rpm.

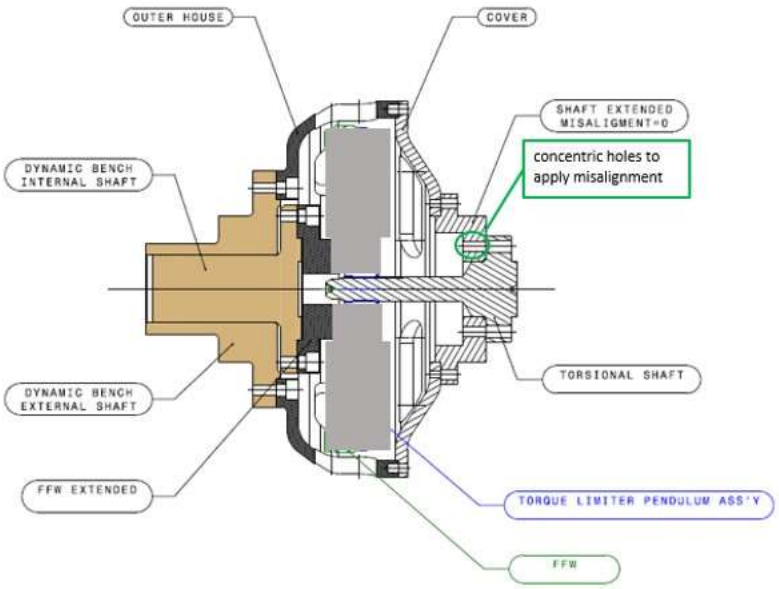

Figure 1. Adaptation tool before the development

1.2. Misalignment addition to the system

The misalignment applied by adding 1.0/1.5/2.0 mm concentricity to the holes on the part 'shaft extended'. In this way, the torsional shaft axis misaligned from the dynamic bench internal shaft.

The radial loads due to misalignment cause damage at bench internal and external shafts and at their bearings.

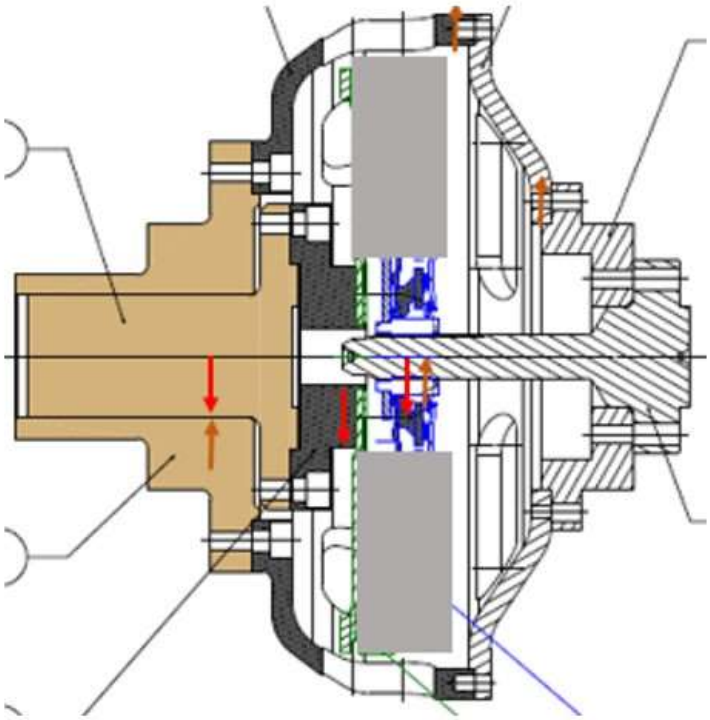

Figure 2. Radial loads due to misalignment

2. IMPROVEMENTS

The full functional system analyzed in terms of loading, weight, COG, balance and burst and developed. Dimensional adjustments done to be able to answer several applications.

2.1. Bearing addition to the adaptation system

The bearing adapted to support inner rotating group and the outer rotating group against bending and the radial loads. Bearing type chosen as XV70 Crossed roller bearing having two inner rings and resistant to both radial and axial loads (part no 14).

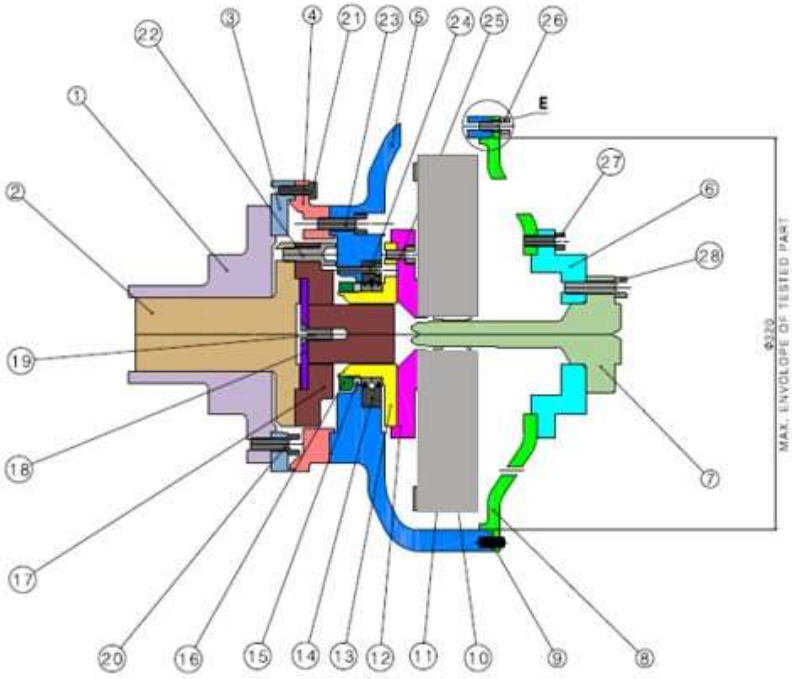

Figure 3. Bearing (part no 14) addition to the system

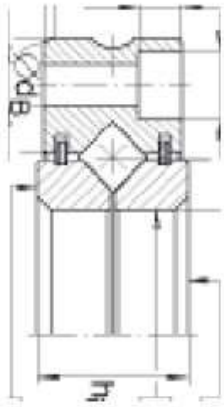

Figure 4. XV70 bearing

2.2. Hub-shaft clearance added between outer rotating group and the inner rotating group

The bearing itself was not sufficient as the bending will be transferred to the bench inner shaft and outer shaft. In addition, the bearing life would be short due to bending caused by misalignment. For that reason, hub-shaft clearance (part no 13 & 17) added between outer rotating group and the inner rotating group to prevent the bending transferred to the bench inner and outer shaft. Hub-shaft clearance designed as T spline to be used for higher torques in the future.

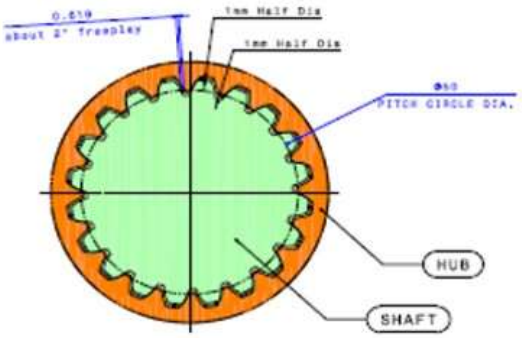

Figure 5. T spline hub-shaft clearance

2.3. Weight reduction and center of gravity adjustment of the system

The components have modified to reduce the weight of the adaptation to the bench supplier permitted value. The more the weight, the more the bending at the bench inner and outer shafts due to moment of inertia.

The components have modified as the Center of Gravity of the system brought closer to the bench. The longer the COG, the more the bending at the bench inner and outer shafts due to moment of inertia.

2.4. Dimensional Adjustments

The outer house dimension is increased to be able to use for higher diameter test parts for other OEM customers (part no 5).

The crank- shaft adaptation spacer (part no 12) is added to allow assembling different products.

Conical edges are added for easy mounting after the system misaligned – Detail E

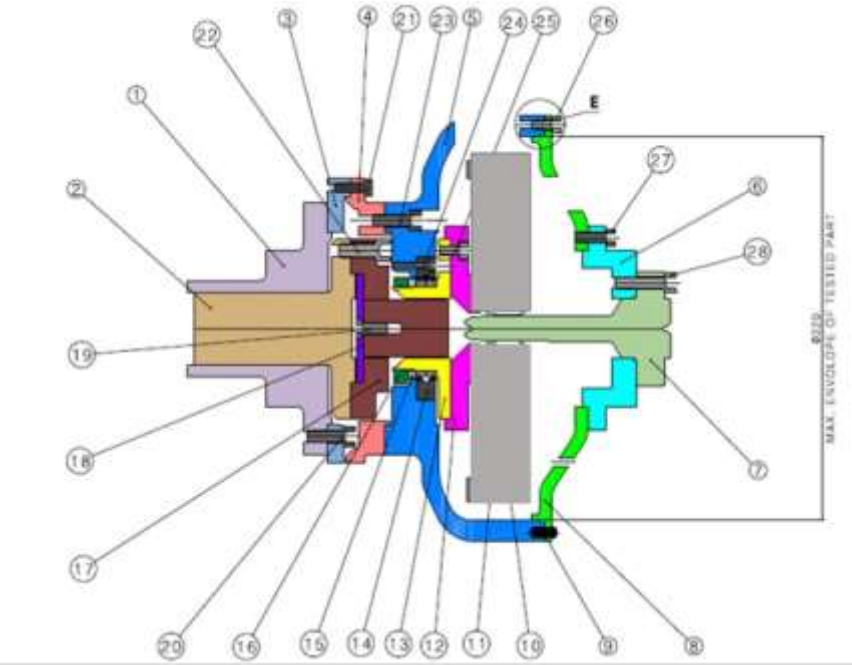

Figure 6. Developed adaptation system with dimensional adjustments

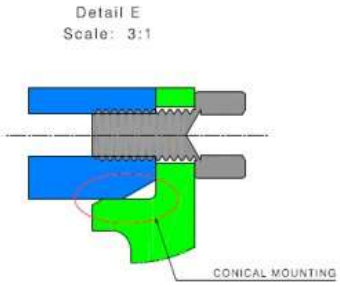

Figure 7. Detail E – Conical edge for easy mounting after the misalignment

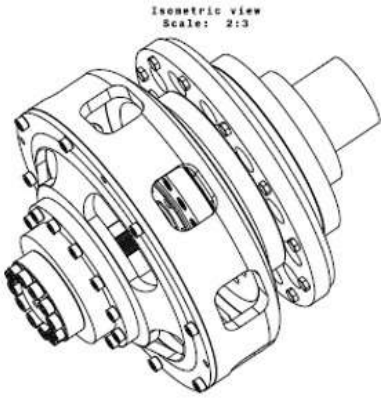

Figure 8. Isometric view of the system

2.5. Easy balance system

The misalignment creates unbalance at the system. As the system rotates at 6000 rpm, the balance is very important. The system designed so that the balance can done at the VALEO balance machine after the system assembled and the balanced assembly can be mount easily to the bench.

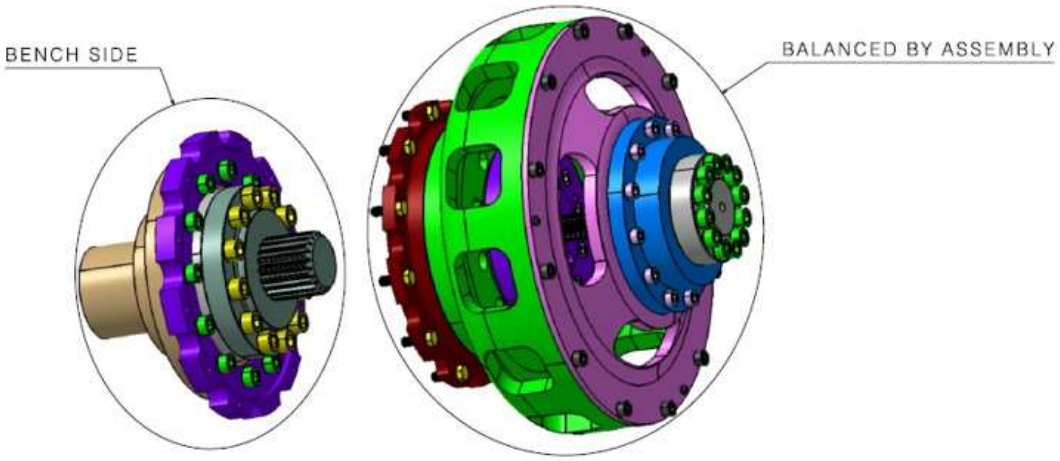

Figure 9. Easy balance system

2.6. FEA to guarantee no burst

The FEA done to guarantee that the system do not burst at 6000 rpm. Outer house (part n°5) holes modified according to FEA team proposal to improve system burst resistance.

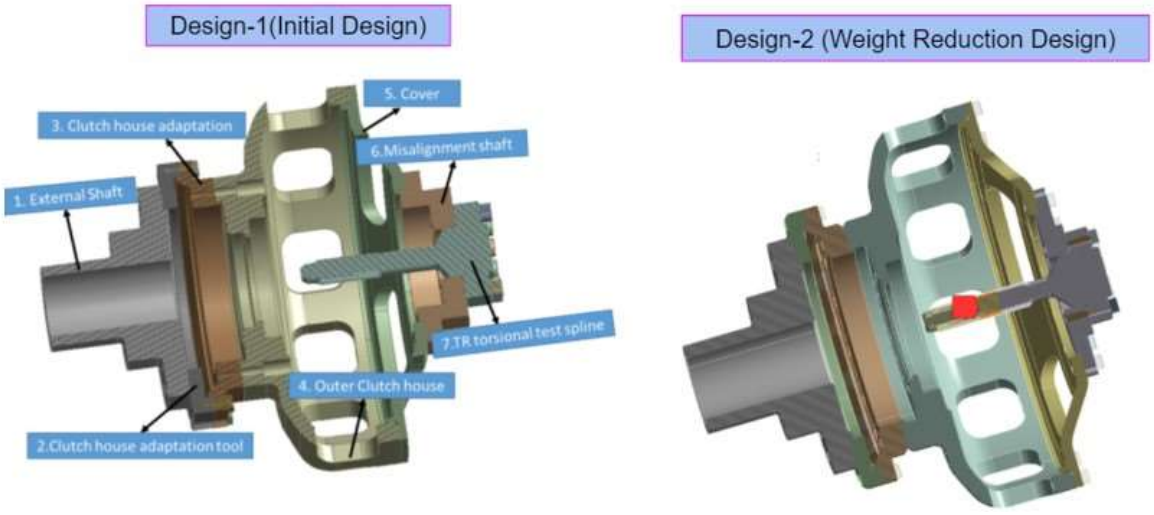

Figure 10. FEA to guarantee no burst

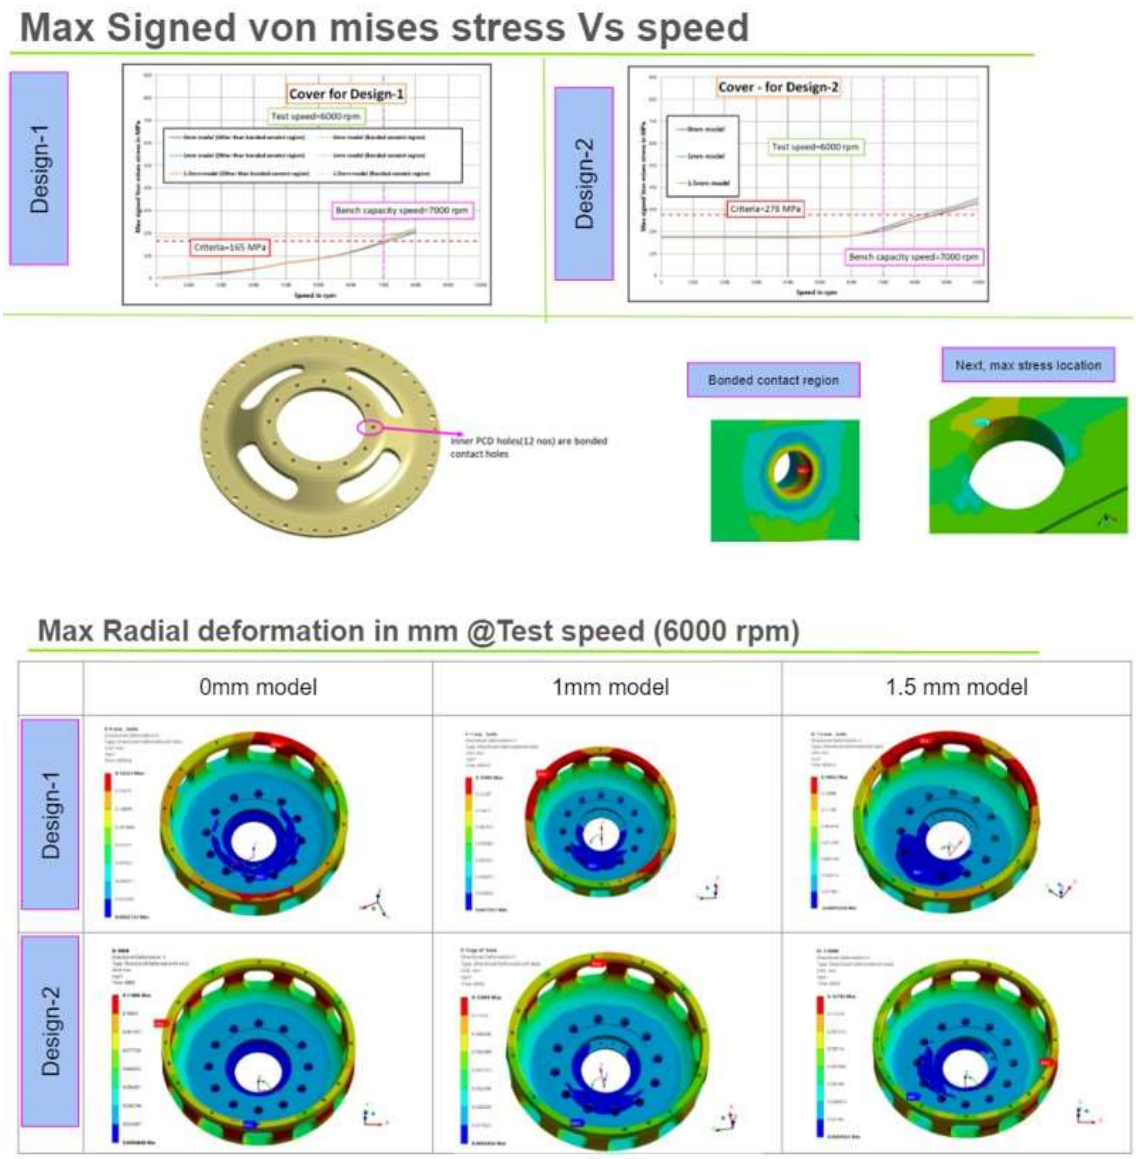

Figure 11. FEA results for components

Components	Mis-alignment value	SSEQV for Design-1 @ 6000 rpm	SSEQV for Design-2 @ 6000 rpm	Criteria in MPa for Design-1	Criteria in MPa for Design-2
Clutch house adaptation	0mm	155	113	621 (40CrNiMo7)	276 (6061-T6-Aluminium)
	1mm	162	114

The below result is presented for 6000rpm.

Component	SSEQV for Design-2	SSEQV for Improved design	Criteria in Mpa
Clutch house adaptation	113	114	276
Outer clutch house	176	153	
Cover	180	179	
Misalignment shaft	151	152	
TR Torsional test soline	98	99	980
Burst speed in rpm	7500	8150	
Note: Early Bursted component is Outer clutch house for both the design.			

Table 2. FEA values in MPa after the design proposal

3. CONCLUSIONS

The customer expectation was met by without launching a new test bench investment. The smart design worked with limited investment. The durability test done successfully at 6000 rpm with high misalignment at vehicle torque without any burst and without any damage to the test bench.

Different size products of other customers can be tested also with this developed adaptation.

ACKNOWLEDGEMENTS

I would like to thank my colleagues and VALEO experts Mr. Patrick Le-Moal and Mr. Elie Geffroy for their expert advices and for their supports in this development.

BENZİNLİ BİR BİNEK ARACIN GERÇEK SÜRÜŞ EMİSYONLARININ VE ŞEHİR MERKEZLERİNDEKİ ETKİSİNİN İNCELENMESİ

Fevzi Buğra Aksop

Tofaş Türk Otomobil Fabrikası A.Ş., ARGE / Güç Sistemleri Müdürlüğü, Bursa, Türkiye

bugra.aksop@tofas.com.tr

ÖZET

Taşıt kaynaklı egzoz gazı emisyonları; hava kirliliğini ve iklim değişikliğini, dolayısıyla insan sağlığını olumsuz etkileyen en önemli faktörlerden biridir. Gün geçtikçe sınırlayıcı hale gelen emisyon kurallarının yanı sıra birçok ülke yüksek emisyonlu taşıtların şehir içlerinde dolaşımını kısıtlamış, şehir merkezlerine girebilecek taşıtlar için çeşitli kurallar koymuştur. Bu gelişmeler sonucunda taşıtların emisyon salınımlarının iyileştirilmesi ve bu emisyonların doğru bir şekilde ölçülmesi de otomotiv sektöründeki önemli konulardan birisidir. Taşıtların gerçek sürüş şartlarındaki emisyonlarının ölçüldüğü ve son yıllarda kullanımı gün geçtikçe artan Gerçek Sürüş Emisyonları (RDE) testi; şehir içi, şehir dışı ve otoban olmak üzere bir taşıtın potansiyel kullanım durumlarının çoğunu temsil eden çevrimlerden oluşur. Bu çalışmada, benzinli binek bir taşıtın gerçek sürüş emisyonlarını ve nüfusun yoğunlukta olduğu şehir merkezlerindeki emisyonlarının etkisini incelemek amacıyla seçilen referans taşıt ile bir dizi RDE testi gerçekleştirilmiş ve egzoz gazı emisyonları gerçek sürüş koşullarında ölçülmüştür. Test sonuçları, şehir içi egzoz gazı emisyonları odağında değerlendirilmiş ve sonuçlar karşılaştırmalı olarak incelenmiştir.

Anahtar kelimeler: Emisyon, gerçek sürüş emisyonları, RDE, şehir içi

STUDY OF REAL DRIVING EMISSIONS OF A GASOLINE PASSENGER VEHICLE AND ITS EFFECT IN CITY CENTERS

ABSTRACT

Exhaust gas emissions originating from road vehicles; one of the most important factors that negatively affect air pollution and climate change, and therefore human health. In addition to the emission rules, which are becoming more and more restrictive day by day, many countries have restricted the circulation of high-emission vehicles in cities and have set various rules for vehicles that can enter city centers. As a result of these developments, improving the emissions of vehicles and measuring these emissions accurately is one of the important issues in the automotive sector. The Real Driving Emissions (RDE) test, in which the emissions of vehicles are measured in real driving conditions and the use of which has increased in recent years; consists of cycles that represent most of the potential use cases of a vehicle: urban, extra-urban and highway. In this study, a series of RDE tests were carried out with the selected reference vehicle in order to examine the actual driving emissions of a gasoline passenger vehicle and the effects of emissions in densely populated city centers and exhaust gas emissions were measured under real driving conditions. The test results were evaluated on the focus of urban exhaust gas emissions and the results were examined comparatively.

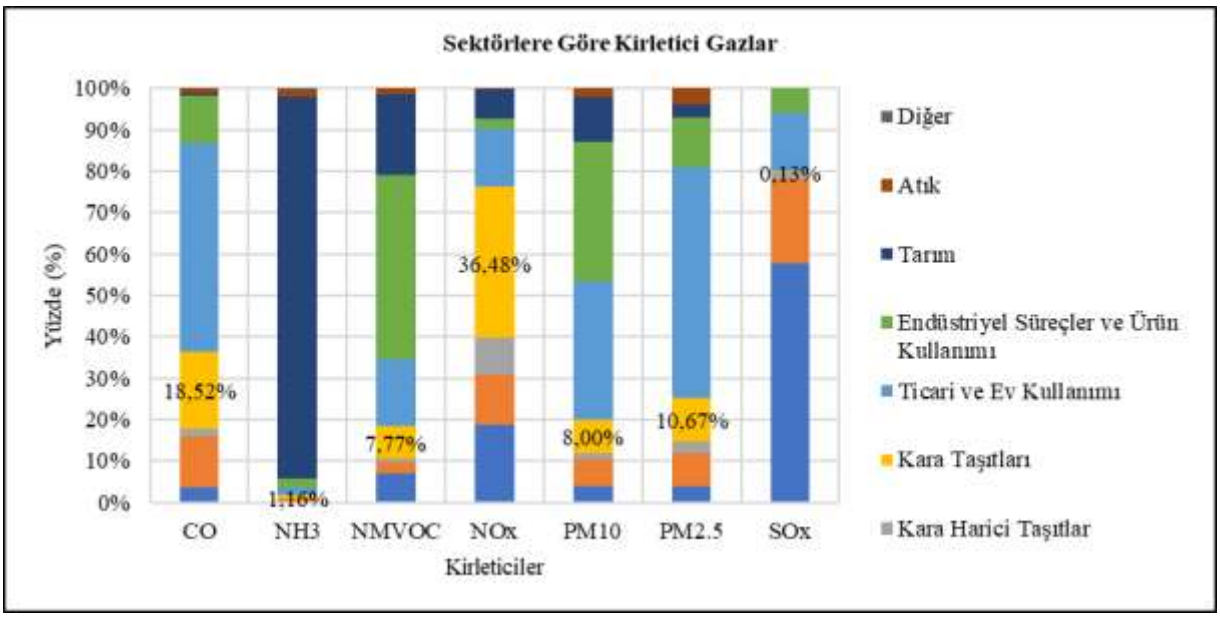
Keywords: Emission, real driving emissions, RDE, urban

1. GİRİŞ

İnsan sağlığı, covid-19 virüsünün hayatımıza girmesiyle bir kez daha önemi anlaşılan ve insanlığın üzerinde durması gereken bir konu olarak karşımıza çıkmıştır. Pandemi süreci ile birlikte devletler, sağlık kuruluşları, sivil toplum örgütleri gibi toplumun bütün kesimleri daha sağlıklı bir yaşam için insan sağlını tehdit eden koşullar karşısında önlemler almaya başlamış, geçmişte aldığı önlemleri de daha agresif bir şekilde uygulamayı sürdürmüştür.

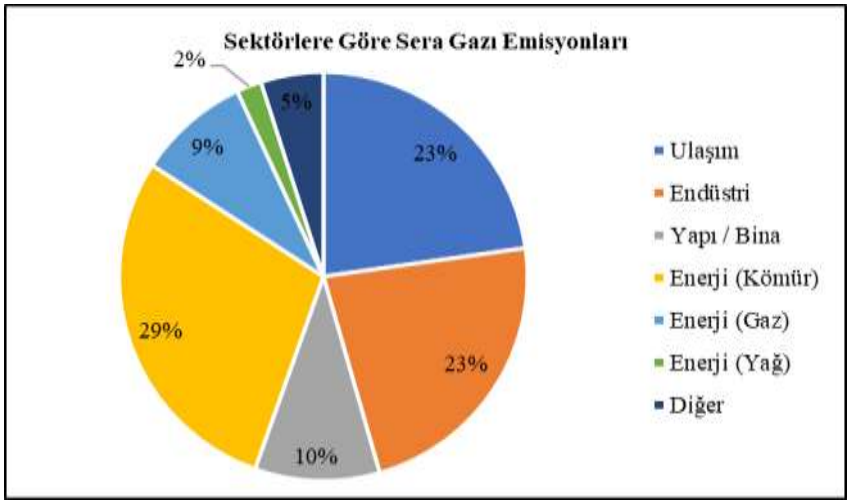
İnsan sağlını etkileyen en önemli konuların başında hava kirliliği gelmektedir. Hava kirliliği doğal nedenlerden meydana gelebileceği gibi sanayileşme, ulaşım, ısınma ve enerji üretimi gibi insan aktivitelerinden de meydana gelebilir. Ayrıca, nüfus artışı, artan şehirleşme ve sanayileşme hava kirliliğini beraberinde getirir. Hava kirliliğini oluşturan kirleticilerin başında; sülfür dioksit (SO_2), nitrojen oksitler (NO_x), ozon (O_3), karbon monoksit (CO) ve

partiküller (PN/PM) gelir. Bu kirleticilerin oluşumunda da fosil yakıtların kullanıldığı ulaşım sektörü başı çekmektedir. Fosil yakıtların yanması ve sonrasında neden oldukları egzoz emisyonları hava kirliliğini arttırarak insan sağlığını tehdit etmektedir. Dünya Sağlık Örgütü (DSÖ) verilerine göre 10 insandan 9'u yüksek seviyede kirletici içeren havayı solumaktadır. İç ortam ve dış ortam hava kirliliği, her yıl yaklaşık 7 milyon erken ölüme neden olmaktadır. Dünya'daki ölümlerin; kalp rahatsızlığından kaynaklıların %24'üne, felç kaynaklıların %25'ine, kronik akciğer kaynaklıların %43'üne ve akciğer kanseri kaynaklıların %29'una hava kirliliği neden olmaktadır (URL1).



Figür 1. Sektörlere göre kirletici gazlar (URL2)

İklim değişikliği de insan sağlığını etkileyen bir diğer önemli konudur. Karbon dioksit (CO_2), metan (CH_4) gibi sera gazı salınımları doğrudan insan sağlığına zarar vermese de sera etkisi ile iklim değişikliğine neden olmaktadır. Salınan sera gazlarının yaklaşık %50'si atmosferde birikerek konsantrasyonun artmasına ve sonucunda Güneş'ten gelen radyasyonun atmosferde birikerek atmosferin sıcaklığının artmasına neden olmaktadır (Soruşbay, b.t.). Sera gazı emisyonları da hava kirliliği ile benzer kaynaklardan ortaya çıkar. Bu nedenle ulaşım sektörü, sera gazı emisyonlarının artmasında da önemli bir kaynaktır.



Figür 2. Sektörlere göre sera gazı emisyonları (International Energy Agency, 2021)

Hava kirliliğinin azaltılmasına yönelik alınan önlemler iklim değişikliğinin önlenmesine belli bir seviyede katkı sağlasa da Avrupa Çevre Ajansı'nın verilerine göre sera gazı emisyonlarını azaltmayı hedefleyen iklim politikaları, hava kirliliğine neden olan emisyonların artmasına neden olmaktadır (European Environment Agency, 2019). Bu noktada, hava kirliliği ve iklim değişikliği gibi insan sağlığını etkileyen konular için uygulanacak entegre çözümler önem kazanmaktadır.

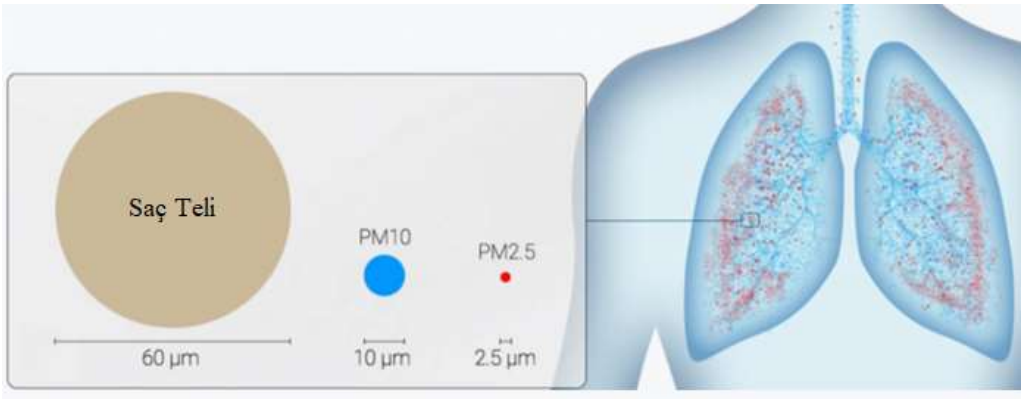
2. TAŞIT KAYNAKLI EMİSYONLAR

Kara taşıtlarındaki emisyonlar 3 alt kategoride incelenebilir. Büyük çoğunluğu oluşturan egzoz emisyonları; yakıtın yanması sonucu ortaya çıkar ve egzoz ile dışarı atılır. Evaporatif emisyonlar taşıtın yakıt sistemindeki buharlaşma sonucu salınan emisyonlardır. Aşınma emisyonları ise başta fren ve lastik olmak üzere taşıttaki mekanik aşınmaların neden olduğu emisyonlardır (European Environment Agency, 2016).

2.1. Taşıt Kaynaklı Egzoz Emisyonları

İçten yanmalı motorda yakıtın yanması sonucu ortaya çıkan zararlı gazların havaya salınması olarak tanımlanan egzoz emisyonları, taşıt kaynaklı emisyonlarının büyük çoğunluğunu oluşturur. Başta CO, CO_2, NO_X, HC ve PM/PN olmak üzere emisyon gazları, taşıtın sahip olduğu motora ve ilgili teknolojiye bağlı olarak farklı oranlarda doğaya salınırlar. Motordaki yanma reaksiyonunun ideal koşullarda açığa çıkan yanma ürünlerinden CO_2 emisyonları güncel emisyon standartları ile araç filoları kapsamında sınırlandırılır. ideal şartların sağlanamaması ve yanmanın tam olmaması sonucunda, yanma işlemi sonrası yan ürün olarak açığa çıkan CO, NO_X, HC ve PN emisyonları ise tekil olarak taşıt özelinde sınırlandırılırlar. Birbirleri ile kıyaslandığında benzinli araçlarda CO, CO_2 ve HC emisyonları, dizel araçlarda ise NO_X ve PN emisyonları daha yüksek oranlarda salınır. Bu emisyonların insan sağlığına ve çevreye çeşitli zararları söz konusudur.

- **Karbon dioksit (CO_2):** Doğrudan insan ve çevre için zararlı etkilere sahip olmasa da atmosferde birikerek sera etkisine neden olur. Sera etkisinin atmosfer sıcaklığı artışı ve iklim değişikliği gibi önemli sonuçları söz konusudur.
- **Karbon monoksit (CO):** Kandaki hemoglobine bağlanması yeteneği oksijenden fazla olduğundan, CO soluyan bir kişinin vücut hücreleri zamanla oksijen alamaz ve zehirlenme ve boğulmaya neden olur.
- **Azot oksitler (NO_X):** CO gibi kandaki hemoglobin ile birleşmesinin yanı sıra en önemli etkisi ciğerde nemle birleşerek nitrik asit (HNO_3) oluşturmalarıdır. Zamanla birikmesiyle solunum hastalıklarına yol açar.
- **Hidrokarbon (HC):** Solunum sistemi hastalıklarına ve kansere neden olmaktadır.
- **Partiküller (PM/PN):** Başta akciğer kanseri olmak üzere 1. derecede kanserojen etkiye sahiptir. PM10 (10 mikrometre çapında ve altındaki partiküller) akciğerlere kadar taşınıp solunum yolları hastalıklarına neden olurken, PM2,5 (2,5 mikrometre çapında ve altındaki partiküller) kan yoluyla bütün vücutta taşınabilir ve kalp hastalıklarına neden olabilirler.



Figür 3. Partikül emisyonlarının insan sağlığına etkileri

2.2. Şehir Merkezlerindeki Egzoz Emisyonları

Kara taşıtları, çalışma koşullarına göre farklı miktarda emisyon salınımlarına neden olurlar. İçten yanmalı motorlar, motora ilk hareketini vermek için gereken silindir içindeki yanma reaksiyonlarını başlatmak amacıyla fazla miktarda yakıt ile çalıştırılırlar. Motorun ideal çalışma rejimine gelene kadar geçen ve soğuk çalıştırma olarak tanımlanan bu periyotta motor normalden fazla miktarda emisyon açığa çıkarır. Benzer şekilde taşıtın trafikte, değişken hızlar ile hatta kimi zaman dur-kalk şeklinde hareket ediyor olması sürekli hareket haline göre daha fazla emisyon açığa çıkaran durumlardan biridir. Bu gibi fazla emisyon salınıma neden olan çalışma koşulları daha çok şehir içi ya da şehir merkezi olarak tanımlanan; insanların taşıtlarını genel olarak kısa mesafelerde kullandığı, trafiğin şehir dışı yerlere göre fazla olduğu, taşıtların park ve hareket hallerinin daha çok değişkenlik gösterdiği durumlarda karşılaşılır (Hooftman, Messagie, Van Mierlo ve Coosemans, 2018).

Tablo 1: Avrupa (EU-28) şehir merkezlerindeki hava kirliliği (Ortiz, 2020)

	PM10	PM2,5	O_3	NO_2	SO_2
Avrupa'daki (EU-28) şehir merkezlerinde AB standartlarının üzerinde hava kirliliğine maruz kalan insan popülasyonu	%15	%4	%34	%4	%<1
Avrupa'daki (EU-28) şehir merkezlerinde DSÖ standartlarının üzerinde hava kirliliğine maruz kalan insan popülasyonu	%48	%74	%99	%4	%19

Sayılar ülkelere göre farklılık gösterse de özellikle büyük şehirlerde yaşayan insan popülasyonu ile kara taşıtı sayısı doğru orantılıdır. Taşıt sayısının artması ile artan taşıt kaynaklı emisyonlar, insanların yaşamlarının büyük çoğunluğunu geçirdiği şehir merkezlerini daha da tehlikeli hale getirmektedir. Bu durum birçok devletin ve kuruluşun bu konuda önlem alması gerekliliğini doğurmuştur. Başta Avrupa ve Amerika'daki bazı büyük şehirler olmak üzere, devletler şehir merkezlerine giren içten yanmalı motora sahip taşıtlara çeşitli sınırlandırmalar getirmiştir. Bu kapsamda Düşük Emisyon Bölgeleri oluşturulmuş, belirli emisyon seviyesinin altındaki taşıtların bu bölgelere girişleri kısıtlanmış, bazılarının ise tamamen yasaklanmıştır. Bu kapsamda, taşıtların gerçek sürüş şartlarındaki emisyon seviyelerinin belirlenmesi ve doğrulanması gün geçtikçe önemli hale gelmiştir (Amundsen ve Sundvor, 2018).

2.3. Emisyon Standartları

Taşıt kaynaklı emisyonlar, zararlı etkileri nedeniyle emisyon standartları ile kontrol altında tutulmaya çalışılmaktadır. Emisyon standartların önemli bir parçası olan emisyon testleri; taşıtların yaşam döngülerinin geliştirme, tip onay, üretim doğrulama ve hizmet içi kullanım gibi farklı aşamalarında uygulanan testlerdir. Geliştirme fazındaki testler taşıt üreticisinin inisiyatifinde olup, güncel emisyon kurallarına uygun araç üretmek amacıyla yapılır. Tip onay aşamasından itibaren yapılan çoğu test regülasyonlar tarafından belirlenen ve onay merciiler tarafından denetlenen testlerdir. Tip onay belgesi alınıp üretimine başlanan taşıt, üretim aşamasında ve hizmet içi kullanıma başladıktan sonra da farklı kontrollere tabiidir. Bu kontrollerde gerçekleştirilen testler emisyon regülasyonları tarafından belirlenir.

Figür 4. Binek bir taşıtın yaşam döngüsündeki emisyon süreç ve testleri

Günümüzde otomotiv sektöründe birden fazla emisyon standardı bulunsa da temel olarak hepsi Avrupa, Amerika gibi belli başlı standartları temel alır. Ülkeler kendi emisyon standartlarını uygulayabilecekleri gibi farklı standartları da kabul edip uygulayabilirler. Türkiye'nin de kabul ettiği Avrupa emisyon standardı, Avrupa Birliği (AB) ve Avrupa Ekonomik Alanı (AEA) üyesi ülkelerde satılan taşıtların emisyon konusundaki kurallarını, "Euro" standartları adı altında tanımlamaktadır. Avrupa standardı emisyon limitleri, hafif yolcu taşıtları için Euro 1 emisyon seviyesi ile birlikte 1992 yılında hayata geçirilmiştir. İlerleyen yıllarda gelişen teknolojiye ve artan hava kirliliğine bağlı olarak limitler giderek azalmış ve taşıtlardan daha az emisyon salınımları hedeflenmiştir.

Güncel Euro 6 emisyon seviyesi, farklı alt seviyeler sahiptir. Bu seviyeler aynı emisyon limitlerine sahip olsa da her birinin uyması gereken farklı prosedürleri vardır. Şasi dinamometresinde gerçekleştirilen Tip 1 Egzoz Emisyonu Testi'nde Euro 6C ile birlikte Yeni Avrupa Sürüş Döngüsü'nden (NEDC) Dünya Genelinde Uyumlaştırılmış Hafif Hizmet Taşıtları Test Döngüsü'ne (WLTC) geçilirken, Euro 6D-Temp ile beraber Gerçek Sürüş Emisyonları (RDE) testi de uygulanmaya başlamıştır. Euro 6D-Final ile beraber ise NO_X gazının Uygunluk Faktörü (CF) 2,10'den 1,43'e düşmüştür (Commission Regulation 2017/1151, 2017).

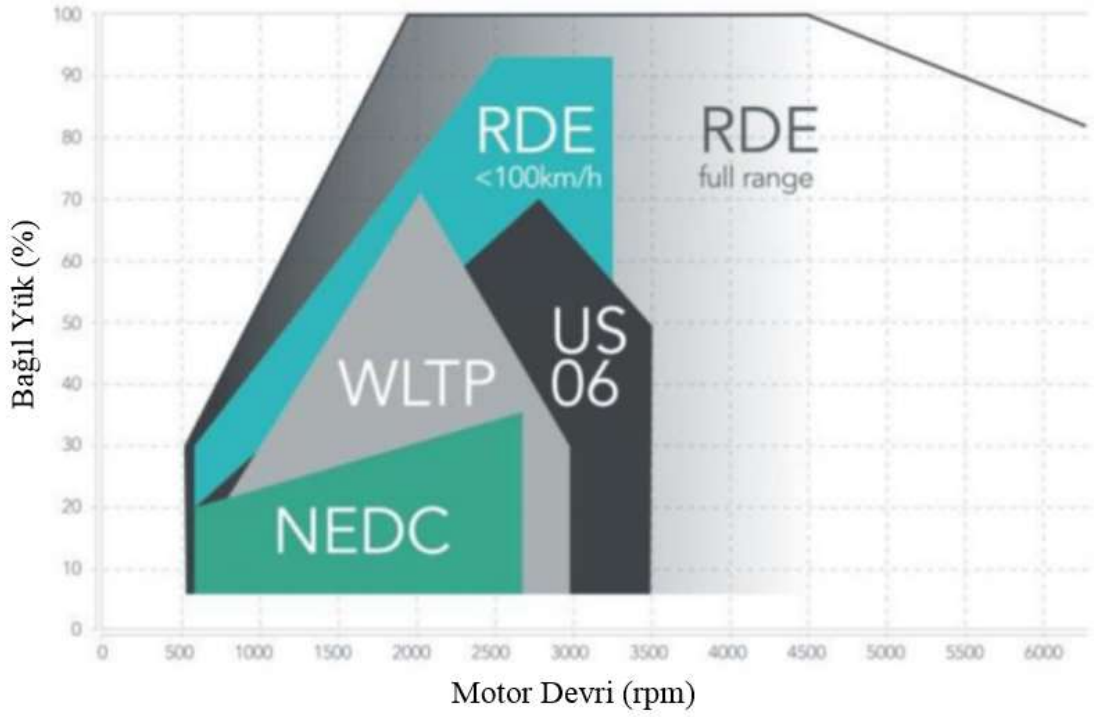
Tablo 2. Euro 6 alt emisyon seviyeleri

	Euro 6B	**Euro 6C**	**Euro 6D-Temp**	**Euro 6D-Final**
Emisyon Limiti	A (1)	A (1)	A (1)	A (1)
Tip 1: Egzoz Emisyon Testi Çevrimi	NEDC	WLTC	WLTC	WLTC

Tip 1A: Gerçek Sürüş Emisyonları (RDE) Testi	Yok	Yok	Var	Var
CF NO_X (2)	-	-	2,10	1,43
CF PN (3)	-	-	1,50	1,50
(1): Bütün emisyon seviyelerinin aynı limitlere tabi olduğunu ifade etmek amacıyla kullanılmıştır. *(2): RDE testindeki NO_X emisyonu uygunluk faktörü* *(3): RDE testindeki PN emisyonu uygunluk faktörü*				

2.4. Gerçek Sürüş Emisyonları (RDE) Testi

Euro 6D-Temp emisyon seviyesi ile hayatımıza giren RDE testi, diğer emisyon testlerinden farklı olarak yolda, gerçek sürüş şartlarında, taşıtın gerçekte saldığı emisyonları ölçtüğü için gün geçtikçe önemi artan bir testtir. Başta şasi dinamometresinde gerçekleştirilen Tip 1 Egzoz Emisyonu Testi olmak üzere laboratuvardaki emisyon testleri, standart kapalı bir ortamda gerçekleştirilir ve sabit hız-zaman profilleri kullanılarak taşıtların emisyonları ölçülür. RDE testinde ise, gerçek yol şartlarında sabit hız-zaman profilleri tekrar edilemeyeceği için teste etki eden süre, hız, sıcaklık, rakım, ivmelenme gibi parametreler için tanımlanan farklı sınırlar dahilinde test gerçekleştirilir. Ayrıca, emisyonlara etki eden fakat laboratuvarda uygulanması mümkün olmayan trafik, sıcaklık, rakım ve yol eğim ve kuvvetleri gibi değişikliklerin etkileri de dikkate alınarak emisyon ölçümü daha geniş ve gerçekçi bir aralıkta gerçekleştirilir.



Figür 5. Farklı emisyon testi çevrimlerinin yük-devir haritası

Şehir içi, şehir dışı ve otoban olmak üzere 3 ayrı fazdan oluşan RDE testinin başlıca sınır koşulları Tablo 3'te verilmiştir. Bu sınırlar içerisinde gerçekleştirilen her test geçerli sayılır.

Tablo 3. RDE testi limitleri (Commission Regulation 2017/1151, 2017)

	Şehir İçi	**Şehir Dışı**	**Otoban**
Süre	Toplam: 90 – 120 dak		
Mesafe	> 16 km	> 16 km	> 16 km
Dağılım	% 29 - 44	% 23 - 43	% 23 - 43
Hız	≤ 60 km/s	> 60 km/s ve ≤ 90 km/s	> 90 km/s
Ortalama Hız	15 – 40 km/s	-	-
Sıcaklık	≥ 0°C ve ≤ 30°C		
Rakım	0 – 700 m		

3. DENEYSEL ÇALIŞMALAR

Çalışma kapsamında seçilen referans taşıt ile bir dizi RDE testi gerçekleştirilmiştir. Taşıtın gerçek sürüş emisyonları şehir içi, şehir dışı ve otoban fazlarında test edilmiştir.

3.1. Referans Taşıt

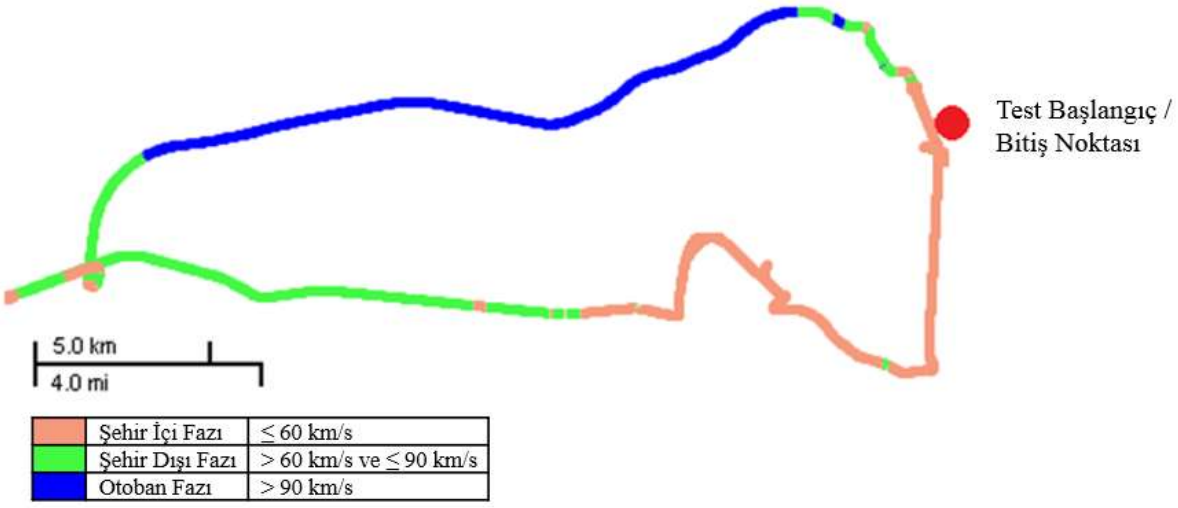
Testlerde referans taşıt olarak benzinli bir içten yanmalı motora sahip sedan bir binek taşıt kullanılmıştır ve tekrarlanabilirlik açısından bütün testler aynı taşıt, ekipman ve test personeli kullanılarak gerçekleştirilmiştir. Gerçek kullanım koşullarını daha gerçekçi temsil etmesi açısından yaklaşık 15.000 kilometrelik bir taşıt seçilmiştir. Referans taşıtın özellikleri Tablo 4'teki gibidir.

Tablo 4. Referans taşıtın özellikleri

Yakıt Tipi	Benzin
Silindir Sayısı	4
Valf Sayısı	16
Silindir Hacmi	1,368 cc
Azami Güç	95 BG (70 kW) / 6.000 d/dak
Azami Tork	127 Nm / 4.500 d/dak
Yakıt Besleme	Çok Noktalı Püskürtme (MPI)
Emisyon Sınıfı	Euro 6D-Temp
Çekiş	Önden
Vites Tipi	Manuel
Vites Sayısı	6 İleri

3.2. RDE Test Rotası

Çalışma kapsamınki RDE testleri Bursa'da, önceden belirlenmiş bir test rotasında gerçekleştirilmiştir. Rota, regülasyona uygun olarak; sırasıyla şehir içi, şehir dışı ve otoban fazlarında oluşmakta ve aynı noktada başlayıp, sonlanmaktadır.



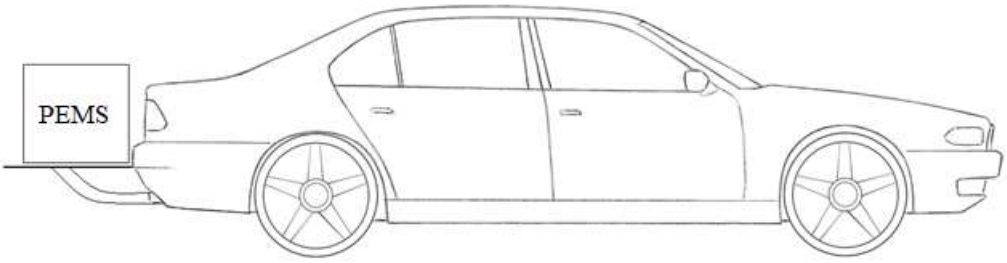
Figür 6. RDE test rotası faz gösterimi

3.3. RDE Test İçeriği

Gerçekleştirilen RDE testleri, ilgili Avrupa Komisyonu (EC) emisyon standardına uygun olarak;

- Testlere soğuk başlangıç şartında; taşıtlar 23°C ortam sıcaklığında şartlandırıldıktan sonra başlanmıştır
- Testler 90 ila 100 dakika arasında sürmüştür
- Testler 73 ila 75 kilometrelik mesafelerde gerçekleşmiştir
- Testler her bir faz 20 ila 25 kilometre arası ve %30 ila %40 arası faz dağılımı olacak şekilde gerçekleşmiştir
- Testler 10 ila 25°C ortam sıcaklığında ve 40 ila 160 metre rakım arasında gerçekleştirilmiştir

RDE testlerinde emisyon ölçümü, portatif emisyon ölçüm cihazı (PEMS) ile gerçekleştirilmiştir. Cihaz, taşıt arkasına takılan bir aparat yardımı ile taşıta monte edilmiştir. Egzoz çıkışına bağlanan bağlantı ile egzoz gazı, dışarı salınmadan önce cihazın ölçüm yapabileceği şekilde yönlendirilmiştir.

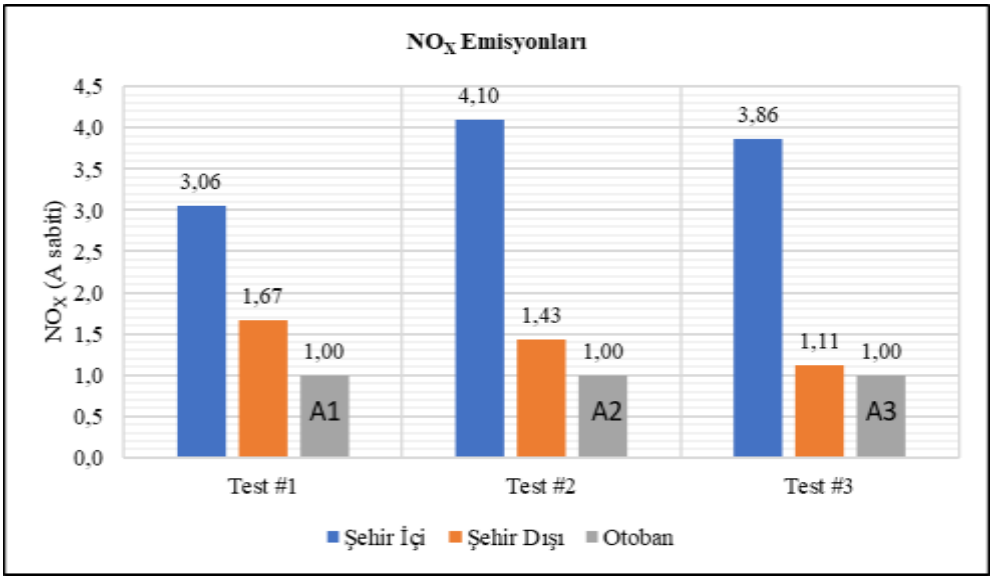


Figür 7. PEMS takılı RDE test taşıtı

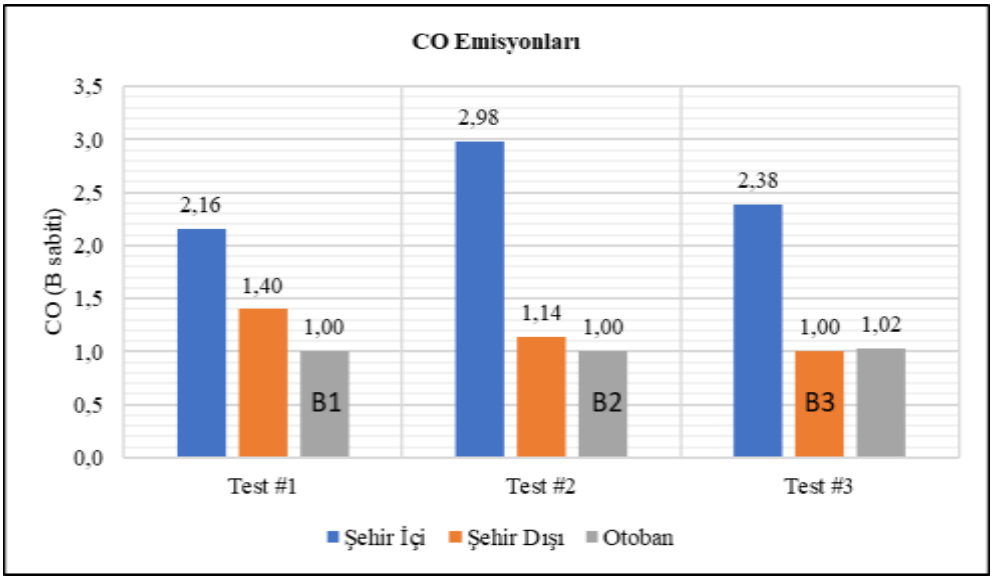
Güncel Euro 6 emisyon standartları gereği binek taşıtların RDE testlerinde ölçülen emisyon gazları NO_X, CO, CO_2 ve PN'dir. Manifolda püskürtmeli benzinli motorlu binek taşıtlarda PN ölçümü yapılmadığı için çalışma kapsamındaki testlerde NO_X, CO ve CO_2 gazları ölçümü gerçekleşmiştir.

4. SONUÇ VE ÖNERİLER

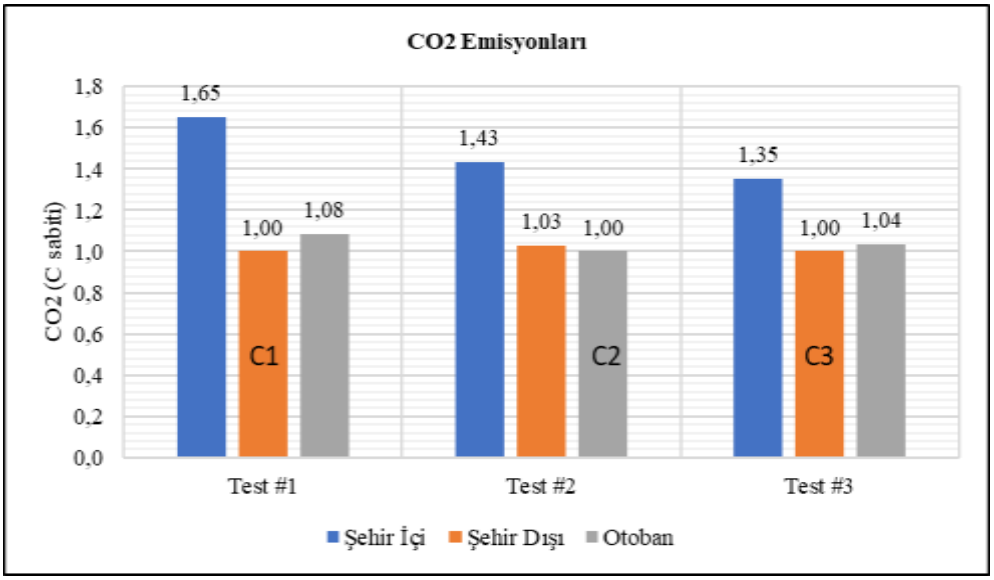
Çalışma kapsamında üç ayrı RDE testi gerçekleştirilmiştir. Test sonuçlarında elde edilen NO_X, CO ve CO_2 emisyonları değerleri, her biri için kendine özgü limite sahip olması ve test sonuçlarının tamamının bu limitlerin altında sonuçlanmasından dolayı okuyucuya kolaylık sağlaması açısından, Figür 8, 9 ve 10'da şehir için, şehir dışı ve otoban fazları ayrı ayrı olacak şekilde, karşılaştırmalı olarak gösterilmiştir. NO_X emisyonları A, CO emisyonları B, CO_2 emisyonları ise C katsayısı kullanılarak verilmiştir. Her bir testteki en düşük faz emisyon sonucuna ilgili katsayı tanımlanmış, diğer fazlar bu katsayıya göre oranları şeklinde verilmiştir. Örneğin; Test #1'in en düşük NO_X emisyonuna sahip olan otoban fazı sonucu A1 ile ifade edilmiş, şehir dışı NO_X emisyonu 1,67 A1, şehir için NO_X emisyon sonucu 3,06 A1 olarak gösterilmiştir. Sonuçlar bu şekilde incelendiğinde her bir zararlı gaz için şehir içi emisyonları, diğer faz emisyonlarına göre seviyeleri kolaylıkla görülebilir.



Figür 8. NO_X emisyonları



Figür 9. CO emisyonları



Figür 10. CO_2 emisyonları

Sadece Test #2 CO emisyonları ile Test #1 CO_2 emisyonlarının en düşük değerleri şehir dışı fazlarında görülürken, diğer bütün emisyonlarının en düşük değerleri otoban fazında görülmüştür. Bir taşıtın en düşük faz sonuçlarına göre şehir için emisyonları incelendiğinde ise;

- NO_X emisyonları şehir içlerinde ortalama 3,67 kat
- CO emisyonları şehir içlerinde ortalama 2,51 kat
- CO2 emisyonları şehir içlerinde ortalama 1,48 kat

fazla çıktığı görülmüştür.

CO_2 emisyonlarının sera etkisi ile dolaylı olarak insan sağlığına zarar vermesi, CO_2'in şehir içi/dışı fark etmeksizin zararlı etkisini sürdürebileceği anlamına gelir. Bu açıdan bakıldığında test sonuçlarında CO_2 emisyonlarının en düşük şehir içi etkisine sahip oluyor olması, CO_2'in avantajlı durumunu bir anlamda önemsiz hale getirir. Fakat NO_X ve CO gibi salındığı ortamda direkt olarak solunum yolu ile insan sağlığına etki eden emisyonların, insan popülasyonunun fazla olduğu şehir içlerinde yüksek oranlarda salınması, taşıt kaynaklı egzoz emisyonlarının şehir içlerindeki durumunun kritikliğini bir kez daha gözler önüne serer.

Emisyon salınımları güncel emisyon standartlarına uygun olsa da taşıt kaynaklı egzoz emisyonlarının şehir içlerindeki fazla salınımları insan sağlını tehdit etmeye devam etmektedir. Karayollarında seyahat eden ve günümüz emisyon

kontrol teknolojilerine çok uzak hatta hiçbir emisyon kontrolüne sahip olmayan eski taşıtların insan sağlığını daha çok tehdit eden bölgelerde kullanımının kontrol edilmesi, bu gibi emisyon salınımı fazla olan taşıtların şehir merkezlerindeki düşük emisyon bölgelerine girişlerinin kısıtlanması, şehirlerdeki düşük emisyon bölgelerinin sayılarının arttırılması gibi mevcut durumu kontrol altına almak adına çeşitli önlemler alınabilir. Gelecekteki taşıt kaynaklı emisyonlarının şehir merkezlerindeki insan sağlığına zararlarını önlemek için ise hibrit ve elektrikli taşıtların yaygınlaştırılması ve kullanımı teşvik edilmesi bir çözüm olarak gözükebilir. Elektrikli taşıtların hiçbir durumda egzoz emisyonu salmamaları, hibrit taşıtların ise özellikle ilk çalıştırma, trafik, düşük hız gibi içten yanmalı taşıtlar için fazla emisyon salınan durumlarda elektrik motoru ile çalışması şehir içlerindeki taşıt kaynaklı egzoz emisyonlarını düşürebilecek ve insan sağlığına olumlu olarak etki edebilecek çözümler olarak gözükmektedir.

TEŞEKKÜR

Çalışma kapsamındaki testlerin gerçekleştirilmesindeki emeklerinden dolayı Tofaş Emisyon Laboratuvarı personeline teşekkürlerimi iletirim.

TASARIMI GERÇEKLEŞTİRİLEN MEKANİK KONTROLLÜ VE FİŞEK REZİSTANS KONTROLLÜ TERMOELEMANLARIN PERFORMANS ANALİZİ

Hasan GÜNGÖR, Selin EFE KAYABAŞI, Ömer OKUMUŞ

Kırpart Otomotiv Parçaları Sanayi ve Tic. A.Ş, Ar-Ge Merkezi, Bursa, Türkiye
Correponding Author: Selin EFE KAYABAŞI, selin.efe@kirpart.com.tr

ÖZET

Binek araçlarda motorun belli bir çalışma sıcaklığında optimum performans göstermesi istenir. Bu sıcaklığın sağlanması için motor soğutma sisteminin tasarımı önemlidir. Motor soğutma sisteminde yer alan termostat bu sıcaklığa göre soğutma sıvısının geçiş güzergahını belirlemektedir. Sistemin olması gerektiği sıcaklık koşullarının hızlı bir şekilde sağlanamaması yakıt tüketimini ve emisyon değerlerini artırmaktadır. Günümüzde yapılan yasal düzenlemeler ile yüksek emisyon oranları istenmemektedir. Bu nedenle içten yanmalı motorlardan çevreye salınan zararlı gazların emisyon değerlerinin azaltılmasına yönelik çözümler üzerinde çalışılmaktadır. Bu çalışmada sistemde termostatın hızlı bir şekilde soğutma sıvısı sıcaklığını algılayarak soğutma sıvısının yönünü doğru ve uygun zamanda yönetebilecek 4 farklı termoeleman tasarımı gerçekleştirilmiştir. Gerçekleştirilen tasarımların tepki süresi testleri ve CFD analizleri yapılarak performansları karşılaştırılmıştır. 4 farklı tasarımdan çanak yapısının iki kısmında diş formlarının olduğu ve fişek rezistansın kullanıldığı tasarımın ısı iletiminin en iyisi olduğu ve aynı zamanda geleneksel silindirik termoeleman yapısına göre yüksek ısı iletimi sağladığı görülmüştür. Termoeleman üzerine yapılan çalışmalar, sonrasında çanak yapısının iki kısmında diş formlarının olduğu ve fişek rezistansın kullanıldığı tasarım seçilerek, binek araçlarda kullanılan termostat çalışmaları şeklinde genişletilecektir.

Anahtar Kelime: Termostatlarda tepki süresi, ısı iletimi, map kontrollü termostat, termoeleman

PERFORMANCE ANALYSIS OF THE DESIGNED MECHANICALLY CONTROLLED AND CARTRIDGE RESISTANCE CONTROLLED THERMOELEMENTS

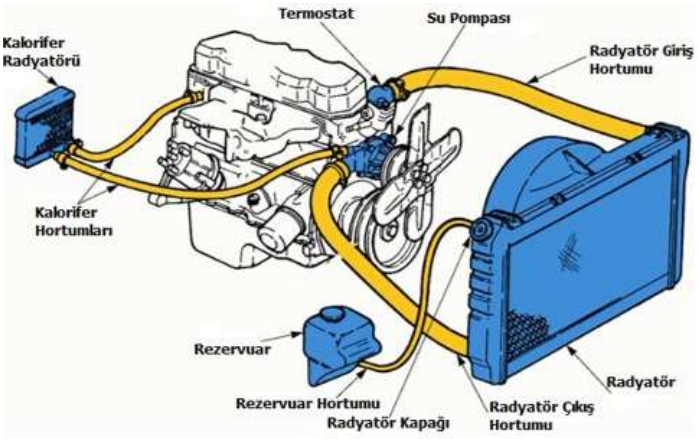
ABSTRACT

In passenger cars, the engine is required to show optimum performance at a certain working temperature. The design of the engine cooling system is important to maintain this temperature. The thermostat in the engine cooling system determines the passage route of the coolant according to this temperature. Failure to provide the system temperature conditions quickly increases fuel consumption and emission values. With today's legal regulations, high emission rates are not desired. For this reason, solutions are being studied to reduce the emission values of harmful gases emitted to the environment from internal combustion engines. In this study, 4 different thermoelement designs have been carried out in the system, allowing the thermostat to detect the temperature of the coolant quickly and manage the direction of the coolant at the right time. The performance of the designs has been compared by performing reaction time tests and CFD analysis. It has been observed that there are tooth forms in two parts of the bowl structure from 4 different designs and the design using the cartridge resistor is the best heat conduction and at the same time provides high heat conduction compared to the traditional cylindrical thermoelement structure. The work on the thermoelement will then be expanded into the thermostat studies used in passenger vehicles, by selecting the design with tooth forms in two parts of the bowl structure and using the cartridge resistor.

Keyword: Response time on thermostat, heat transfer, map controller thermostat, thermoelement

1. GİRİŞ

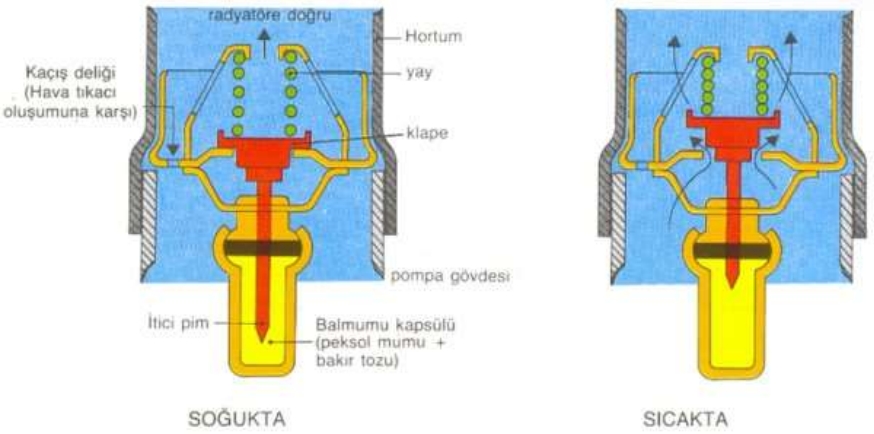
Sıvı soğutmalı içten yanmalı motorlarda çalışma sırasında yüksek sıcaklık oluşabilmektedir. Motor soğutma sistemi, motor bloğundaki geçitlerden soğutucu sıvı göndererek çalışır. Soğutma suyu bu geçitlerden geçerken ısıyı absorbe eder. Motor soğutma sisteminde yer alan radyatör, termostat ve su pompasının görevi motorun çalışması için gerekli olan soğutma sıvısı sıcaklığını sağlamak ve kontrol altında tutmaktır. Isınarak rayatöre gelen soğutma sıvısı radyatör kısmına gelen hava akışı ile soğutulur. Sistemde, araç çalışır vaziyette iken bu döngü sırasıyla radyatör, su pompası ve termostat bileşenlerinin soğutma sıvısına etkimesi ile devam eder. Şekil 1' de örnek bir motor soğutma sistemi verilmiştir. Sistemde su pompası soğutma sıvısının kanallarda dolaşımını sağlarken soğutma sıvısını uygun sıcaklığın üzerinde kaldığını kontrol edilmesi için termostat bulunmaktadır.



Şekil 1. Motor soğutma sistemi [1]

Bir binek otomobilde 80˚C-120˚C çalışma sıcaklığı aralığında ideal motor performansı beklenmektedir. Günümüz soğutma sistemleri çevre sıcaklığının -25˚C 45˚C arasında olması koşuluyla motoru sabit bir sıcaklıkta tutar. Motor sıcaklığının sabit tutulamaması yakıt ekonomosine zarar verir ve emisyon değerleri artar [3,4].

Bu çalışmada motor soğutma sisteminde yer alan motor sıcaklığını düzenleyen termostat ve termoeleman üzerinde durulmuştur. Geleneksel termostatta, termoelemana gelen soğutma sıvısı sıcaklığı yükseldikçe termoeleman içinde vaks genleşmeye başlar ve termoeleman pistonu hareket eder; bu sayede termostat gövdesinden geçen sıvı debisi artar. Sıcaklık düştüğünde termostat gövdesinde hareket eden iç gruptaki yay, pistonu başlangıç konumuna geri iter ve termostat gövdesinden geçen soğutucu sıvı debisini düşürerek soğutma devresini kapatır (Şekil 2).



Şekil 2. Termostat çalışma prensibi [1]

Soğutucu sıvı akışının termoeleman ile temas etmediği durumlarda ısı transferinin gecikmesinden dolayı termostatın sistemde devreye girmesi zaman alabilmektedir. Bu durum termostat tepki süresini uzatmaktadır. Mekanik kontrolün kullanıldığı geleneksel termostat teknolojisinde termostatın açık olduğu durumda soğutma sıvısı olması gereken

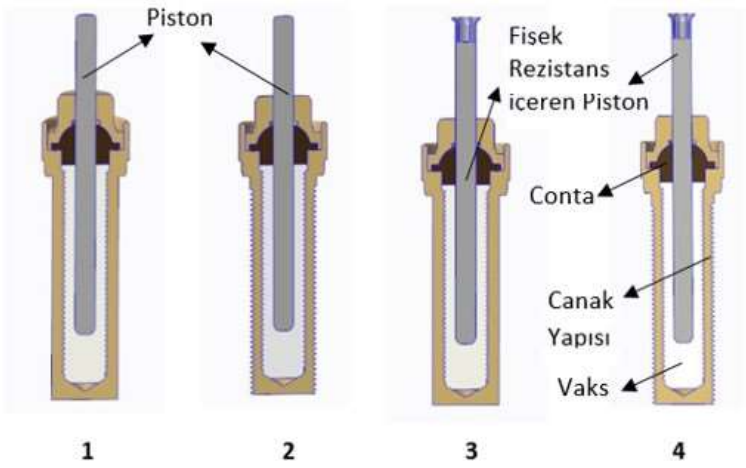
sıcaklığın altında ise soğutma sıvısı sirkülasyonunun motor sisteminde dönmesi ve temoelemanın içindeki vaksa etkimesi uzun zaman alabilmektedir. Bu durum günümüz motor teknolojilerinde istenmeyen bir özelliktir. Motorun sıcaklık değerine göre soğutma sistemini yönlendiren termostat mekanizmasının bilgiyi kısa sürede alıp uygulaması motor performansına ve ömrüne pozitif etki yaratacaktır.

Literatürde yapılan çalışmalara bakıldığında motor teknolojilerinin bu yönde iyileşme kaydedilerek ilerleyeceğine yönelik ve bu çalışmaların sağlayacağı avantajlara yönelik yayınlar yer almaktadır [2-4].

Kırpart binek araçların çalışma sıcaklığını güvenli bir şekilde yüksek seviyeye çıkarmak ve böylece yanmaya eşlik eden dış faktörleri optimize etmek için fişek rezistansın ve diş formlarının kullanıldığı yeni bir termoeleman teknolojisi geliştirilmiştir. Isı transferini kısa sürede yüksek oranda gerçekleştirmesi üzerine yapılan bu çalışma ile zor bir proses olan metal üzerinde diş formu oluşturma işlemi gerçekleştirilmiştir. Bu yapı ve kullanılan fişek rezistans ısı iletimine geleneksel silindirik termoelemana göre oldukça avantaj sağlamıştır. Bu teknolojinin farklı tasarımlar ile karşılaştırmalı test ve CFD analizi sonuçları ele alınmıştır. Bu aşamadan sonra tasarlanan termoelemanın binek araçlarda kullanılan termostat ve ECU ile haberleşmesi üzerine çalışmalar sürdürülecektir.

2. GEOMETRİK MODEL

2 adet mekanik kontrollü ve 2 adet fişek rezistans kontrollü termoeleman tasarımı gerçekleştirilmiştir. Gerçekleştirilen termoeleman tasarımlarının kesit görüntüleri Şekil 3' te verilmiştir. Aynı kontrol tipine sahip termoelemanların birbirine göre geometrik model farklılıkları mevcuttur. Tablo 1' de tasarlanan termoelemanların birbirinden farklılıkları ile birlikte geometrik modellerinin açıklamaları yer almaktadır. Bu tasarımlarda aynı tip ve miktarda vaks karışımı kullanılmıştır. Tasarımların, iç hacmi aynı olmakla birlikte çanak yapısına eklenen diş formları vaks yapısının duvar kalınlığını etkilemektedir ve çanak yapısının geometrisine göre farklılık göstermektedir.



Şekil 3. Gerçekleştirilen termoeleman tasarımlarının kesit görüntüleri

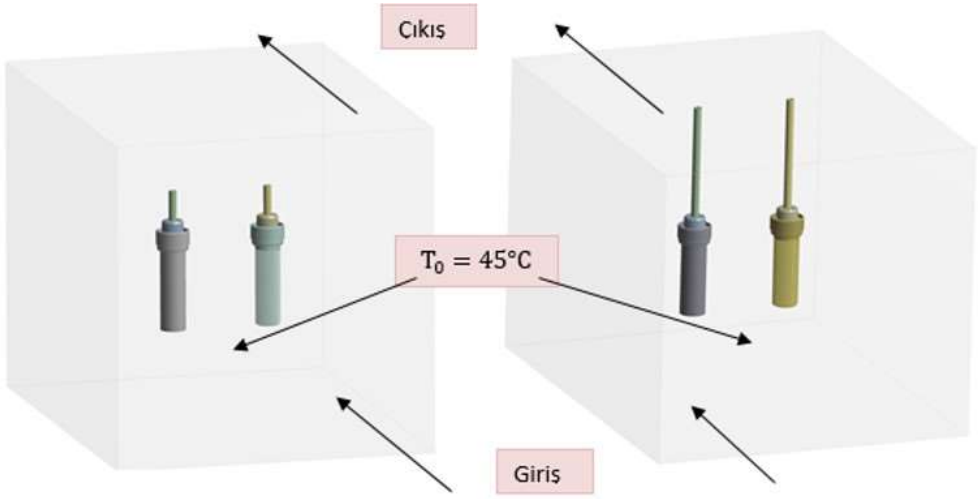
Tablo 1. Oluşturulan tasarımlar

Tasarım Numarası (Şekil 1)	Açıklama
1	Çanak yapısının iç kısmına diş açılmış mekanik kontrollü termoeleman
2	Çanak yapısının iç ve dış kısmına diş açılmış mekanik kontrollü termoeleman
3	Çanak yapısının iç kısmına diş açılmış fişek rezistans kontrollü termoeleman
4	Çanak yapısının iç ve dış kısmına diş açılmış fişek rezistans kontrollü termoeleman

3. ANSYS CFX MODÜLÜNDE OLUŞTURULAN FİZİKSEL MODEL

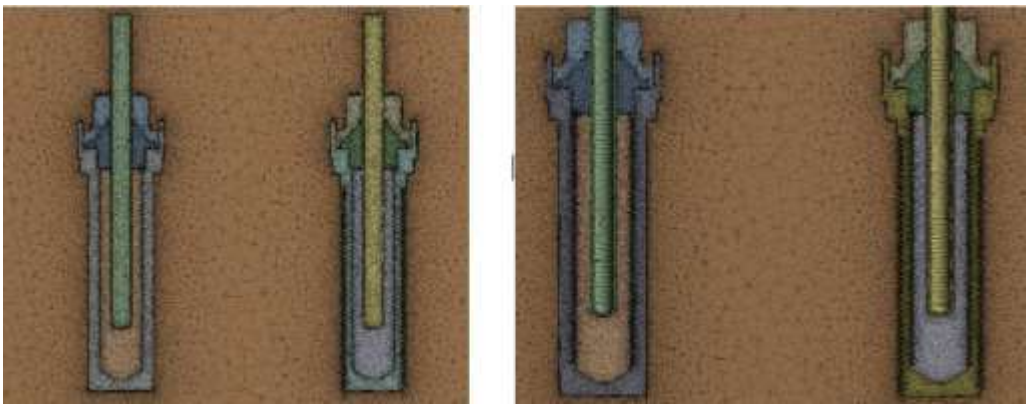
Gerçekleştirilen tasarımların prototiplerinin oluşturulup deneysel yöntemlerle doğrulanması gerekir fakat günümüzde tek başına yeterli bir yöntem değildir. Bu çalışmada, oluşturulan termoelemanların tasarımının yanında termoelemanların çalışacağı ortamı ve test şartlarını simüle edebileceğimiz fiziksel modeller üzerine Ansys' in CFX modulünde sistem tasarımı gerçekleştirilmiştir.

Şekil 4' te mekanik kontrollü termoelemanlar ve fişek rezistans kontrollü termoelemanlar için oluşturulmuş fiziksel modeller yer almaktadır. 4 farklı termoeleman tasarımının 3 boyutlu modelleri ile CFD analizleri gerçekleştirilmiştir. Giriş ve çıkış sınırları şekilde belirtildiği gibi tanımlanmıştır. Termoelemanın çalıştığı ortamı simüle edebilmek için dikdörtgen prizma şeklinde bir alan oluşturularak giriş ve çıkış şartları tüm yan duvarlara simetrik olarak tanımlanmıştır. Analiz zamana bağlı olarak çözümlenmiştir. Toplam süre 70 sn ve zaman adımı olarakta 0,1 sn tanımlanmıştır. Başlangıç durumunda ilk sıcaklık 45 ˚C (T_0) seçilmiştir ve akışkan 1 m/s hızda (V_g) su tanımlanmıştır.



a. Mekanik kontrollü termoeleman modeli **b.** Fişek rezistanslı termoeleman modeli

Şekil 4. Fiziksel model



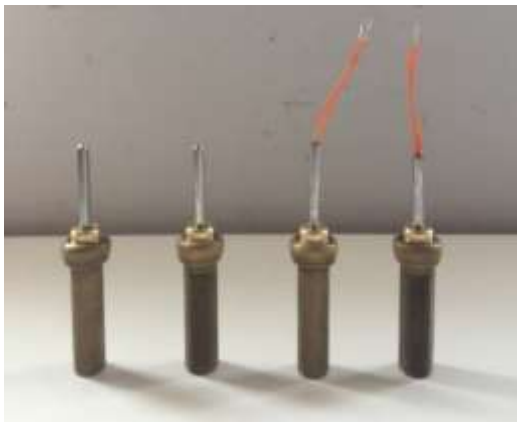
a. Mekanik kontrollü termoeleman modeli ağ yapısı **b.** Fişek rezistanslı termoeleman modeli ağ yapısı

Şekil 5. Fiziksel modelin ağ yapısı

Tanımlanan şartlara ek olarak fişek rezistanslı termoeleman modellerinin fişek rezistans kısmına 9,6 Watt' lık elektrik gücü tanımlanmıştır. Fiziksel modelin malzeme özellikleri ve çalışma koşulları tanımlanmasının ardından ağ yapısının oluşturulması için mesh atama işlemi gerçekleştirilmiştir (Şekil 5). Analizde tüm modellerin merkezlerindeki noktaların sıcaklık değişimleri incelenerek 70 sn' ye kadar analizleri gerçekleştirilmiştir [5-6].

4. TASARIM DOĞRULAMA ÇALIŞMALARI

3 boyutlu tasarımı ve Ansys CFD analizleri gerçekleştirilen 4 farklı termoeleman tasarımının numune üretimleri gerçekleştirilmiştir (Şekil 6). Gerçekleştirilen tasarımların herbirinin test edilebileceği ve fişek rezistans kullanılan termoeleman numunelerinde bulunan elektrik kablolarının su ile temasını önleyen bir fikstür tasarımı yapılarak termoelemanların tepki süresi testi gerçekleştirilmiştir (Şekil 7). Termoelemanlar sırası ile test fikstürüne yerleştirilerek önce 45 ℃ sıcaklıkta soğutma sıvısı ile doldurulmuş termal banyoya daldırılarak 10 dk beklenir. Daha sonra 75 ℃' ye ayarlanmış, içerisi soğutma sıvısı ile havuza daldırılarak termoelemanın maksimum açma değerine karşılık gelen zaman hesaplanır ve kaydedilir. Mekanik kontrollü termoelemanların test prosedürüne ilave olarak fişek rezistans kontrollü termoelemanlarda sisteme DC güç kaynağı ilave edilerek termoelemanın fişek rezistansına 12 V' luk bir gerilim uygulanmaktadır (Şekil 8).



Şekil 6. 4 farklı termoeleman tasarımının numuneleri

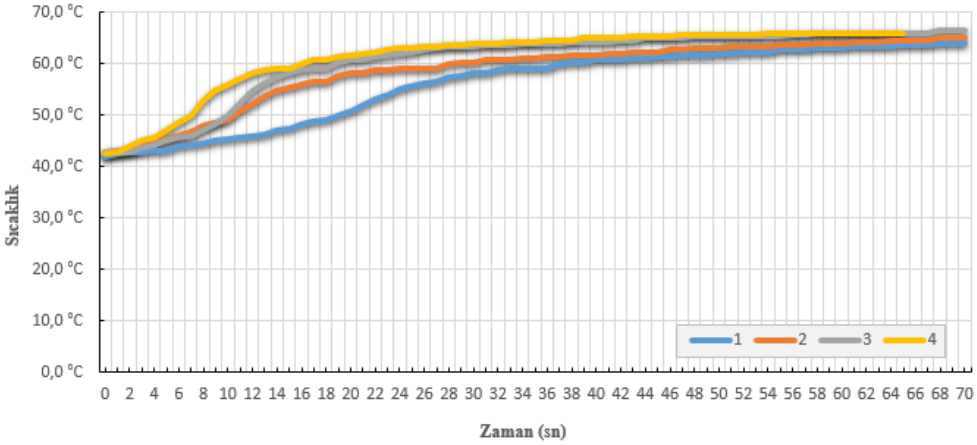
Şekil 8. Test banyosu ve DC güç kaynağı

5. SONUÇ VE TARTIŞMA

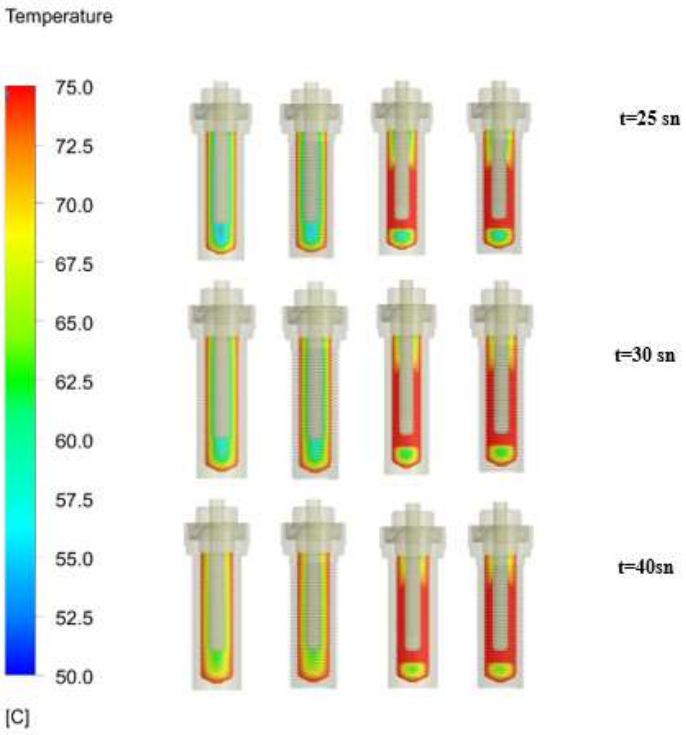
Tasarım 1 olarak oluşturulan termoeleman piyasada yaygın olarak kullanılan silindirik bir çanaktan ziyade proses zorluğu olan, iç yapısına diş formu oluşturulmuş çanak tasarımı ile gerçekleştirilmiştir. Bu tasarım referans tasarım

olarak seçilmiştir. 2, 3 ve 4 numaralı tasarımlarda bu tasarım üzerinden değişikliklere giderek oluşturulmuştur. Tasarım 1 ve 2 pistonun kullanıldığı ve mekanik kontrollü tasarımlar iken aralarındaki geometrik fark tasarım 2'nin çanak yapısının dışında da diş formunun bulunmasıdır. Tasarım 3 ve 4 'te benzer geometrik formlar seçilerek kontrol tipinin farklı olduğu, piston yerine fişek rezistansın kullanıldığı tasarımlar gerçekleştirilmiştir.

Bu çalışmada tasarlanan termoelemanların tasarım doğrulama çalışmaları, test çalışmaları ve Ansys CFX modülünde CFD analizleri ile yapılmıştır. Şekil 9' da test esnasında kaydedilen zaman, sıcaklık ve termoeleman açma verilerinden; 4 farklı tasarım için 0-70 sn aralığındaki verilerden yararlanılarak oluşturulan zaman –sıcaklık grafiği verilmiştir. Şekil 10' da Ansys CFD analizinde 70 sn kadar gerçekleştirilen analiz sonuçlarının 25 sn, 30 sn ve 40 sn için termoelemanın içindeki vaksın sıcaklık dağılımını veren kesit görüntüleri verilmiştir. Test sonuçları ve CFD analiz sonuçları karşılaştırılmalı olarak Tablo 2' de verilmiştir.



Şekil 9. Test sonuçları ile oluşturulmuş sıcaklık-zaman grafiği



Şekil 10. 4 farklı termoeleman tasarımının farklı zamanlardaki Ansys analizi ile sıcaklık dağılımı

Tablo 2. Oluşturulan tasarımların vaks sıcaklık değerlerinin karşılaştırılması

Tasarım Numarası	Test Sonucu (25 sn)	CFD Analiz Sonucu (25 sn)	Test Sonucu (30 sn)	CFD Analiz Sonucu (30 sn)	Test Sonucu (40 sn)	CFD Analiz Sonucu (40 sn)
1	55,6 ˚C	55,90˚C	58,1˚C	57,89˚C	60,7˚C	63,12˚C
2	59˚C	55,98˚C	60,3˚C	58,2˚C	61,6˚C	63,76˚C
3	62,3˚C	62,63˚C	63,3˚C	64,67˚C	64,3˚C	65,28˚C
4	63˚C	63,50˚C	64˚C	65,46˚C	65˚C	65,96˚C

Elde edilen verilere bakıldığında termoelemanın çanak yapısında kanatçık formuna benzetebileceğimiz diş formlarının eklenmesi, mekanik ve fişek rezistans kontrollü termoelemanlarda ısı iletimini artırdığı görülmüştür. Diş formlarının ısı iletimini artırmasının yanı sıra termoeleman içerisinde yer alan vaks kapsülünün çanağın iç duvar yapısına konumlanan kalınlığın azalmasına etki etmektedir. Bu durum ısı iletimini artıran bir etkidir (Tablo 2).

Kontrol tipinin değiştiği durumlar incelendiğinde fişek rezistansın kullanıldığı termoeleman tasarımlarında ısı iletiminin daha fazla olduğu görülmektedir. Termoelemanın içerisinde yer alan vaks elemanına ek olarak 12 V ‘luk bir gerilim ile ısıtılması vaks yapısının ergimesine katkı sağlayarak ısı iletimini artırdığı görülmektedir (Tablo 2).

Bu çalışma ile geleneksel silindirik çanak yapısına diş formlarının ve fişek rezistansın eklenmesinin ısı iletimini artırdığı ve bu durumda termoelemandan beklenen çalışma sıcaklığı derecesine daha kısa sürede ulaşabileceği görülmektedir (Şekil 9). Gerçekleştirilen tasarımlar ile Kırpart zor bir proses olan termoeleman çanak yapısına diş formunu uygulama yeteneği kazanmıştır. Yeni motor teknolojilerine adapte olabilecek termoeleman tasarımı geliştirmiştir.

ÖZET

Metalik tüpler yüksek enerji absorbe etme kabiliyetleri nedeniyle birçok sanayi dalında sıklıkla kullanılmaktadır. Eksenel yük altında katlanarak deforme olan tüpler ortaya çıkan çarpışma enerjisini absorbe ederek, kullanıldıkları ana yapıda oluşacak hasarı engellemekte veya azaltmaktadır. Bu çalışmada 6063 serisi alüminyum alaşımı kare kesitli tüplerin enerji absorbe etme kabiliyetleri incelenmiştir. Bu kapsamda, T4 ve T6 olmak üzere iki farklı ısıl işlem durumundaki tüpler kullanılmıştır. Ayrıca ön deformasyon ve köpük takviyesinin enerji üzerindeki etkilerinin görülebilmesi için tüplere içeriden cidar ezme işlemi uygulanmış ve köpük olarak ta PVC köpük kullanılmıştır. Boş ve işlemsiz tüpe oranla; cidar ezme işleminin yüksek dayanıma sahip T6 ısıl işlemli tüplerde %10 daha yüksek enerji sağladığı görülmüştür. Bu değerin T4 ısıl işlemli tüplere nazaran daha yüksek oranda olması ayrıca dikkat çeken bir husus olmuştur. Ayrıca köpük takviyeli numunelerde, boş tüp ve PVC köpüğün absorbe ettikleri enerjilerin toplamının köpük takviyeli numuneden daha düşük olduğu görülmüştür. Tüp cidarı ile köpük arasında deformasyon esnasında ortaya çıkan bu etkileşimin T4 ısıl işlemli numunelerde T6 ısıl işlemli tüplere oranla %38 daha yüksek olduğu anlaşılmıştır. Son olarak, özgül enerjinin en yüksek değerini cidar ezme işlemi uygulanmış T6 ısıl işlemli tüpün PVC köpük takviye edilmesi durumunda 14,8 J/g olarak elde edilmiştir.

Anahtar kelimeler: metalik tüp, özgül enerji, PVC köpük, alüminyum

EXPERIMENTAL INVESTIGATION OF THE ENERGY ABSORBING CAPABILITY OF REINFORCED ALUMINUM SQUARE TUBES

ABSTRACT

Metallic tubes are frequently used in many industries due to their high energy absorbing ability. Tubes that deform by folding under axial load absorb the collision energy and prevent or reduce damage to the main structure they are used in. In this study, the energy absorption capabilities of 6063 aluminum alloy square tubes were investigated. In this context, tubes with two different heat treatment conditions, T4 and T6, were used. In addition, the effects of pre-deformation and foam reinforcement on the absorbed energy were investigated by applying internal wall crushing to the tubes and reinforcing PVC foam. Compared to the base tube; It has been observed that the wall crushing process provides 10% higher energy in T6 heat treated tubes. It is also noteworthy that this value is higher than T4 heat treated tubes. In addition, it was observed that the sum of the energies absorbed by the empty tube and PVC foam was lower than the foam reinforced sample. It was understood that this interaction between the tube wall and the foam during deformation was 38% higher in T4 samples than in T6 tubes. Finally, the highest value of the specific energy was obtained as 14.8 J/g in the case of PVC foam reinforcement of the T6 heat-treated tube with the wall crushing process.

Keywords: metallic tube, specific energy, PVC foam, aluminum

1. GİRİŞ

Tüp yapıların eksenel ve açılı yükler altında sergilediği deformasyon davranışı oldukça ilgi çekicidir. Kendi cidarı üzerinde katlanarak akordeon benzeri şekilde deforme olan tüpler, oldukça yüksek enerji absorbe kabiliyeti sunmaktadır. Bu kapsamda yapılmış çalışmaların büyük bir kısmının son yıllara ait olması, konunun önemini

göstermesi açısından önemlidir. Tüp yapılarla ilgili çalışmalarda ağırlıklı olarak metalik tüpler tercih edilmekle birlikte kompozit (Palanivelu ve ark, 2010) ve hibrid (Cheol ve ark, 2002) yapılarda kullanılmaktadır. Tüplerin enerji absorbe etme kabiliyetlerinin tüp geometrisi (Bambach ve ark, 2009; Guillow ve ark, 2001; Marzbanrad ve ark, 2009) ve yükün türü ve uygulanma açısına (Gao ve ark, 2016; Li ve ark, 2015; Mete ve ark, 2018; Yalçın ve ark, 2019) ait parametrelerle doğrudan ilişkilidir. Kare kesitli ve çok köşeli ince cidarlı yapıların eksenel zorlanma altında enerji ve kuvvet değerlerindeki değişim ve deformasyon davranışları detaylı olarak incelemiştir (Abramowicz ve Wierzbicki, 1989). Deformasyon davranışının detaylıca incelendiği bir çalışmada (Singace ve ark, 1995) kuvvet altındaki deformasyon sırasında tüp cidarının ortalama eksenin içine ve dışına doğru yönlendiği rapor edilmiştir. Metalik tüplerin deformasyon davranışlarının deneysel ve sayısal olarak incelendiği çalışmalar da bulunmaktadır. Bu çalışmalarda sadece takviyesiz tüplerdeki gibi çap ve cidar kalınlığı oranları (D/t) değil, ayrıca içeriden farklı yoğunluktaki metalik köpük (Ahmad ve Thambiratnam, 2009; Zarei ve Kröger, 2008) ve polimer esaslı köpük (Alia ve ark, 2015; Mozafari ve ark, 2015) türlerinin kullanıldığı kompozit yapılar da incelenmiştir. Bu çalışmalarda, takviye olarak kullanılan köpük malzemelerin mekanik özelliklerinden faydalanılmıştır. Enerji verimliliği açısından önemli bir değerlendirme parametresi de tüp yapıların özgül enerji absorbe etme kabiliyetleridir. Bu kapsamda en düşük ağırlıkla en yüksek enerjinin absorbe edilmesi temel hedef olarak zikredilebilir. Dolayısıyla tüp yapının absorbe edeceği enerji değerini artıracak her türlü takviyenin, yapının toplam ağırlığına oranının takviyesiz duruma göre daha yüksek olması gerekmektedir. Bu nedenle de genellikle nispeten çok daha düşük yoğunluğa sahip polimer esaslı köpükler birçok çalışmada tercih edilmiştir (Chen ve ark, 2002; Ouellet ve ark, 2006; Yalçın ve Genel, 2019). Bu çalışmalarda takviyeli tüplerin ortalama ezilme kuvvetlerinde artış olduğu, bu artışa paralel olarak özgül enerji absorbe etme kabiliyetinin de iyileştiği gözlenmiştir.

Bu çalışmada, farklı ısıl işlem durumlarındaki 6000 serisi kare kesitli alüminyum tüplerin enerji absorbe etme kabiliyetleri deneysel olarak incelenmiştir. Bu kapsamda tüp cidarları iç yüzeylerinden bölgesel olarak ezilerek bölgesel dayanım artışları sağlanmış ve bunun enerji ve deformasyon üzerindeki etkileri incelenmiştir. Ayrıca takviye elemanı olarak PVC köpük kullanılarak tüp cidarı ile köpük arasındaki etkileşime bağlı enerji artışları da irdelenmiştir.

2. DENEYSEL ÇALIŞMA

2.1. Malzeme Özellikleri ve Numune Hazırlama

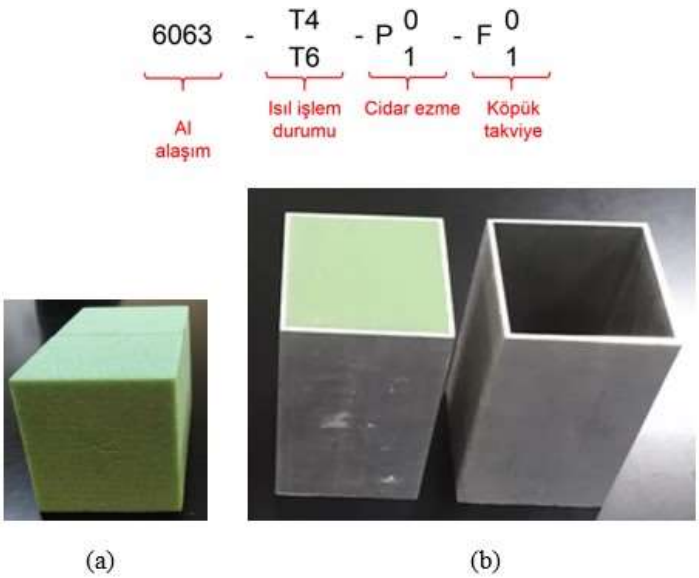
Deneysel çalışmada, T4 ve T6 ısıl işlem durumundaki 6063 alüminyum alaşımı kare kesitli tüpler kullanılmıştır. Her iki ısıl işlem durumundaki tüp yapıların mekanik özelliklerinin belirlenebilmesi amacıyla numunelerden standartlara uygun olarak çıkarılan çekme numuneleri, Instron marka çekme cihazı kullanılarak test edilmiştir. Yapılan çekme deneyi sonucunda elde edilen mekanik özellikler Tablo 1'de verilmiştir.

Tablo 1. Alüminyum malzemelere ait mekanik özellikler

	Elastiklik Modülü (GPa)	Akma Dayanımı (MPa)	Çekme Dayanımı (MPa)	Uzama (%)	Sertlik (HB)
T4	69	90	160	21	50
T6	69	172	212	12	75

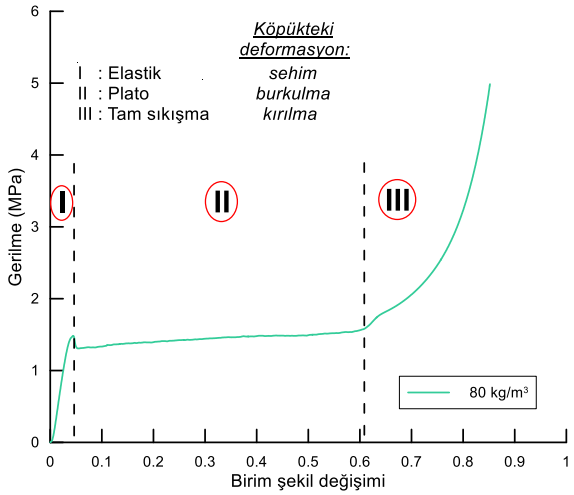
Deneysel çalışmada kullanılan kare kesitli alüminyum tüpler sırasıyla 2 mm cidar kalınlığına, 106 mm uzunluğa ve 60 mm kenar ölçüsüne sahiptir. Deney esnasında presin plakalarının tüpün tüm kesitine aynı anda temas etmesi numunelerde oluşacak deformasyonun düzgünlüğünün sağlanması açısından önemlidir. Bu nedenle tüplerin alt ve üst yüzeyleri CNC freze yardımıyla işlenerek geometrik düzgünsüzlüklerden kaynaklanabilecek problemlerin önüne geçilmiştir.

Kare kesitli tüplerin içeriden takviyesinde yüksek enerji sönümleme kabiliyetine sahip C70 ticari kodlu 80 kg/m3 yoğunluğa sahip PVC köpük kullanılmıştır. PVC köpük takviyeler, 56 mm kenar uzunluğunda kare kesitli ve 106 mm uzunluğunda (tüp içine boşluksuz geçecek şekilde ve tüp uzunluğunda) olacak şekilde plakadan işlenmiştir. Şekil 1a'da tüplere yerleştirilmek üzere hazırlanan PVC köpüğe ait görüntü verilmiştir. Numuneler isimlendirilirken aşağıdaki sistem kullanılmıştır. Numunelerin ısıl işlem durumları isimlerindeki T4 ve T6 parametreleri ile gösterilmişken cidar ezme işlemi ve köpük takviyesi sırasıyla P ve F harfleriyle simgelenmiştir. Bu iki parametreden herhangi birinin tüp yapıda bulunmaması "0" bulunması durumu ise "1" değeriyle gösterilmiştir. Şekil 1b'de takviyesiz ve takviyeli alüminyum tüplere ait numune görüntüleri verilmiştir.



Şekil 1. (a) Takviye elemanı PVC köpük, (b) takviyesiz ve takviyeli tüp numuneler

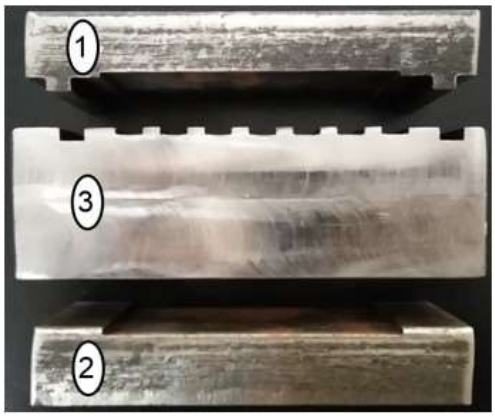
PVC köpüğün mekanik özelliklerinin belirlenebilmesi amacıyla basma deneyleri yapılmış ve elde edilen gerilme-birim şekil değişimi eğrisi Şekil 2'de verilmiştir. Eğrinin farklı karakteristikteki üç farklı bölgeden oluştuğu görülmektedir. Gerilmenin hızla arttığı ilk bölge, uygulanan kuvvet etkisiyle köpükte meydana gelen elastik şekil değişimine karşılık gelmektedir. Bu aşamada köpüğün hücre duvarlarında yük kaldırıldığında eski haline dönen çok küçük deformasyonlar meydana gelmektedir. Plato bölgesi olarak ta isimlendirilen ikinci bölgede, gerilmenin yaklaşık sabit bir değerde kaldığı görülmektedir. Bu aşamada hücre duvarlarında burkulma ve eğilme gibi büyük oranda kalıcı deformasyonlar meydana gelmektedir. Ayrıca plato bölgesi köpüğün yük taşıma kabiliyetini de göstermesi açısından önemlidir. Devam eden süreçte, hücre duvarlarındaki kırılmalarla meydana gelen tam sıkışma durumuna bağlı olarak gerilmenin hızla arttığı üçüncü bölge ortaya çıkmaktadır.



Şekil 2. PVC köpüğe ait gerilme-birim şekil değişimi eğrisi

2.2. Cidar Ezme İşlemi

Kare tüpün iç yüzeylerinin bölgesel olarak ezilmesinde Şekil 3'te görülen aparat kullanılmıştır. Bu işlem için özel olarak tasarlanan ezme aparatı şekilden de görülebileceği üzere üç parçadan meydana gelmektedir. 1 ve 2 numaralı parçalar sırasıyla üst ve alt destek plakalarını, 3 numaralı parça ise ana gövdeyi göstermektedir. Çok sayıda cidar ezme işlemi uygulanması aparatta aşınmaya ve hasara (tekrarlı yüklemeden dolayı) sebep olabileceğinden, aparatın imalatında ısıl işlem sonrasında yüksek tokluk ve aşınma direnci (yaklaşık 54 HRC sertlik) sunan DIN 1.2767 soğuk iş takım çeliği kullanılmıştır.



Şekil 3. Kare tüp cidarlarının içeriden ezilmesinde kullanılan aparat

Alüminyum kare tüplerin iç yüzeylerindeki ezme işlemi, Şekil 3'te 3 numara ile gösterilen ana gövdeye 10 mm aralıklarla işlenmiş 6 mm genişlikteki 6 adet diş yardımıyla gerçekleştirilmektedir. Alüminyum tüp, cidar ezme işlemi için üç adımda hazırlanmaktadır:

1- tüp 3 numaralı ana gövde üzerine yerleştirilir,
2- ana gövde 2 numaralı alt parçanın üzerine konulur,
3- 1 numaralı üst parça ana gövdenin üzerine oturtulur,

Bu işlemlerin ardından hidrolik prese yerleştirilen aparat cidar ezme işlemine hazır hale gelmektedir. Cidar ezme işleminin tüpün tüm yüzeylerinde özdeş olması (aynı konumda ve derinlikte) deney sonuçlarının güvenilirliği için oldukça önemlidir. Ezme bölgelerinin tüm yüzeylerde aynı konumda olması, üst parçada bulunan iki adet merkezleme tırnağı ile sağlanmaktadır. Bu sayede tüpün sağa/sola hareket etmesi, aparata yerleştirildikten sonra ve cidar ezme işlemi sırasında da engellenmiş olmaktadır. Dolayısıyla tüpün hareketiyle farklı yüzeylerdeki ezme bölgeleri arasında oluşabilecek bir kaçıklığın da önüne geçilmektedir. Eşit ezme derinliğinin sağlanması için ise aparat imal edilirken üst parça ile ana gövdedeki dişlerin üst yüzeyleri arasında önceden belirlenen 1,7 mm boşluk bırakılmıştır. Bu sayede, her bir yüzeydeki ezme bölgelerinin derinliği cidar kalınlığının %15'ine karşılık gelen 0,3 mm derinlikte olmaktadır. Bu değerin belirlenmesinde yazarların önceki çalışmalarından faydalanılmıştır (Yalcin ve Genel, 2019). Hidrolik presle sıkıştırma işlemi başladığında tüpün alt kısmına herhangi bir kuvvet iletilmemesi gerektiğinden ana gövde ile alt parça arasında 3 mm boşluk işlenmiştir. Bu sayede de ezme işlemi sırasında kare tüp alt parçaya temas etmeden askıda kalmakta ve işlem sırasında tüpün alt kısmına herhangi bir kuvvet etki etmemektedir. Şekil 4'te kare kesitli tüpün cidar ezme işlemi uygulandıktan sonraki görüntüsü verilmiştir.

Şekil 4. Cidar ezme işlemi uygulanmış kare kesitli tüp numune

Takviyesiz ve farklı şekillerde takviye edilmiş tüp yapıların eksenel ezilme deneyleri 250 kN kapasiteli hidrolik pres kullanılarak gerçekleştirilmiştir. Kuvvet-deplasman çiftine ait veriler deneylerle eş zamanlı olarak kaydedilmektedir. Deneylerde ilerleme hızı 1 mm/s olarak belirlenmiş ve tüm deneyler kamera yardımıyla kaydedilmiştir.

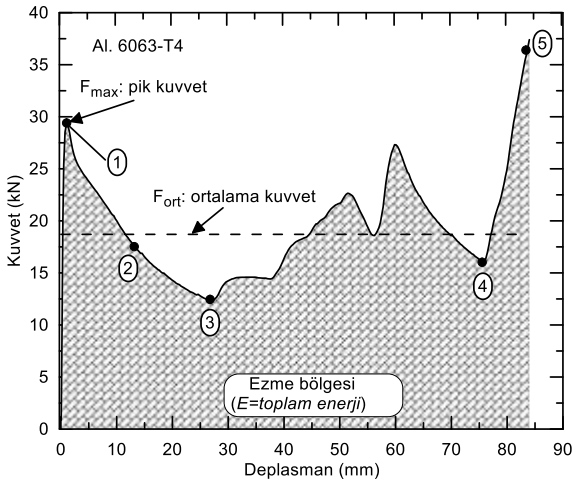
3. SONUÇLAR ve TARTIŞMA

Çalışmada her bir numune kombinasyonu için deneyler en az üçer kez tekrarlanmıştır. Deneylere ait kuvvet-deplasman eğrilerinde veri karmaşıklığına yol açmaması amacıyla yapılan deneylerden ortalama değere sahip olanlar verilmiştir. Tüm deneylerde deplasman değeri tüp uzunluğunun %65'i olarak belirlenmiştir. Bu değerin belirlenmesinde amaç,

numunenin fazla ezilmesiyle oluşacak numune hasarlarının ve bu durumda ortaya çıkan aşırı yüklerin deney cihazlarına verebileceği zararın önlenmesidir.

3.2. Kare Kesitli Tüplerin Deformasyonu

Eksenel yük altındaki kare kesitli tüplerin deformasyon davranışının detaylı bir şekilde incelenebilmesi amacıyla yapılan deneye ait kuvvet-deplasman eğrisi Şekil 5'te verilmiştir. Şekil 5'te görülen kuvvet eğrisinin, deneyin başlangıcında tüpte herhangi bir deformasyon olmamasına bağlı olarak, çok hızlı bir şekilde artarak 1 noktasına (F_{max}) ulaştığı görülmektedir. Bu kuvvet değeri, deneyin sonundaki sıkışmadan kaynaklanan aşırı kuvvet artışı göz ardı edilirse, katlanma sürecindeki en yüksek değer olarak karşımıza çıkmaktadır. Deneyin devamında, tüpün alt ucuna yakın bir bölgede ön-arka yüzeylerin dışa, sağ-sol yüzeylerin ise içe yönlenmesiyle başlayan deformasyonla birlikte kuvvetin hızla azalarak ilk katın tamamlandığı bir minimum değere ulaştığı görülmektedir. İlk kat oluşurken tüpün ön ve arka yüzeylerinin dışa doğru yönlendiği, sağ ve sol yüzeylerinin ise tam tersine içe doğru yönlendiği gözlenmiştir Bu minimum değer aynı zamanda ikinci katın da başlangıç safhası olduğundan, kuvvet değerlerinin arttığı ve eğrinin yukarı yönlü bir trende girdiği görülmektedir. Ancak eğrinin eğiminin bu aşamada ilk kat oluşumuna göre çok daha düşük olduğu dikkat çekmektedir. Bu durum, ikinci katlanmada tüp cidarının, ilk katlanmanın aksine, hali hazırda deforme olmuş olmasından kaynaklanmaktadır. Katlanma aşamasının tamamlandığı 4 noktasından sonra deneyin devam ettirilmesi durumunda kuvvetin, tüpün sıkışmasından dolayı başlangıç durumuna benzer şekilde, çok hızlı bir şekilde arttığı görülmektedir.



Şekil 5. Kare kesitli tüpe ait karakteristik bir deformasyon eğri

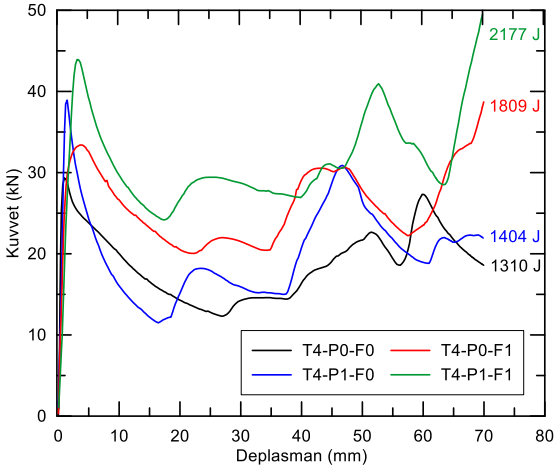
Kare kesitli tüpün eksenel yük altında absorbe ettiği toplam enerji, Şekil 5'te verilen eğrinin altındaki taralı alana karşılık gelmektedir. Enerji değerinin ezilme deplasmanına bölünmesiyle de ortalama kuvvet değeri hesaplanmaktadır.

3.2. T4 Tüplerin Deney Sonuçları

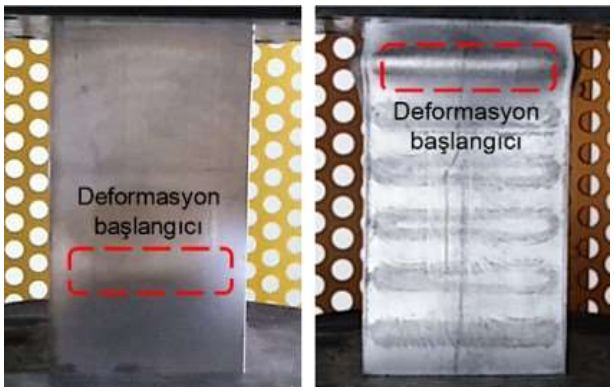
Bu kısımda 6063-T4 alüminyum alaşım tüplerin eksenel ezilme deneylerine ait sonuçlar verilmiştir. Bu kapsamda öncelikle boş kare tüpler ve bu tüplerin köpükle takviye edilme durumlarına ait deneyler gerçekleştirilmiştir. Sonrasında ise cidar ezme işlemi uygulanmış boş tüplerin ve bu tüplerin köpük takviyeli durumlarının eksenel ezilme deneyleri gerçekleştirilmiştir.

Şekil 6'da numunelerin eksenel ezilme deneylerine ait kuvvet-deplasman eğrileri verilmiştir. Eğriler incelendiğinde, numunelerin pik kuvvet ve minimum kuvvet değerlerinin birbirlerinden farklı olduğu dikkat çekmektedir. T4-P0-F0 numunesinde 30 kN olan pik kuvvet değerinin cidar ezme işlemi uygulanmış T4-P1-F0 numunesinde %32 artışla yaklaşık 40 kN değerine ulaştığı, minimum kuvvet deplasman değerinin de 27 mm değerinden 16 mm değerine gerilediği görülmektedir. Pik kuvvetteki ve minimum kuvvet deplasmanındaki bu farklılığın daha detaylı bir şekilde irdelenebilmesi için bu iki numunenin deformasyon aşamalarına ait görüntüler Şekil 7'de birlikte verilmiştir. Şekil 7'dan deformasyon başlangıç bölgesinin cidar ezme işlemi uygulanmış tüpte T4-P0-F0 numunesine göre uç kısma daha yakın gerçekleştiği görülmektedir. Deformasyonu nispeten daha kısa bir alanda oluşturmanın daha yüksek kuvvet gerektirmesi ve cidar ezme işlemiyle tüp cidarının artan dayanımı cidar ezme işlemi uygulanmış T4-P1-F0 ve T4-P1-F1 numunelerinde meydana gelen pik kuvvet artışını açıklamaktadır. Ayrıca pik kuvvetten sonra ulaşılan minimum kuvvete ait deplasman değerinin boş tüpe oranla daha düşük olması da, yine deformasyon başlangıç bölgesinin cidar

ezme işlemi uygulanmış numunedeki konumuyla doğrudan ilintilidir. Buna ek olarak, köpük takviye edilmiş T4-P0-F1 numunesinde pik kuvvetin yaklaşık 34 kN değerinde kaldığı görülmektedir. Dolayısıyla cidar ezme işleminin ilk pik kuvvet değeri üzerindeki etkisinin köpük takviyesinden daha baskın olduğu barizdir. Ayrıca köpük takviyesinde pik kuvvetin diğer numunelere nazaran daha yumuşak bir geçiş gösterdiği görülmektedir.



Şekil 6. T4 ısıl işlem durumundaki takviyeli ve takviyesiz tüplerin kuvvet-deplasman eğrileri



(a) (b)

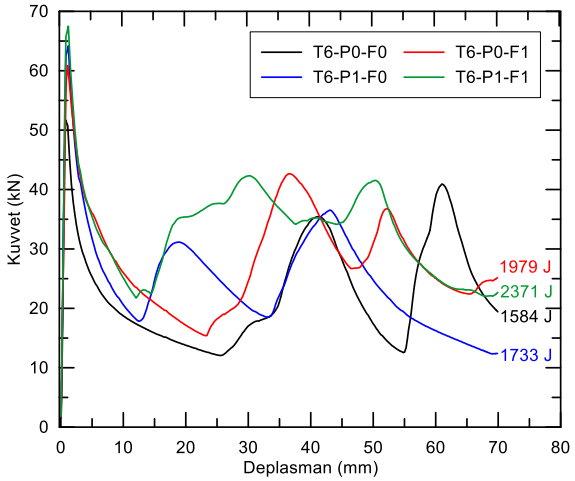
Şekil 7. Cidar ezme işlemi (a) uygulanmamış, (b) uygulanmış tüplerde deformasyon başlangıcı

Şekil 6'da verilen numunelerin absorbe ettikleri enerji değerleri incelendiğinde, 1310 J enerji absorbe etmiş olan T4-P0-F0 numunesi ile 1404 J enerji absorbe etmiş olan T4-P1-F0 numunesinin eğimlerinin birbirine oldukça yakın olduğu görülmektedir. Cidar ezme işlemiyle absorbe edilen enerjide 94 J değerinde bir artış (yaklaşık %7) sağlandığı anlaşılmaktadır. Ancak köpük takviye edilmiş T4-P0-F1 numunesi T4-P0-F0 numunesine oranla %38 daha yüksek enerji absorbe etmiştir. Köpük takviyesiyle elde edilen 499 J enerji değerinin, cidar ezme işlemiyle elde edilen 99 J'den yaklaşık 5 kat daha fazla olması dikkat çekici bir durumdur. Bu durum takviye elamanı olan köpüğün eksenel yüke karşı gösterdiği direnç ve deformasyon esnasında tüp cidarı ile girdiği etkileşimin toplam etkisi olarak tanımlanabilir (Reddy, Yalçın). Köpük takviyesinin cidar ezme işlemiyle ilişkisi T4-P1-F0 ve T4-P1-F1 numunelerin enerji değerleri karşılaştırıldığında açıkça görülmektedir. Bu numunelerdeki 773 J değerindeki enerji farkının, boş tüpün köpük takviye edilme durumuna (T4-P0-F1) oranla çok daha yüksek olması cidar ezme işlemiyle birlikte tüp-köpük etkileşiminin çok daha etkin bir hale geldiği anlaşılmaktadır. Ayrıca T4-P1-F1 numunesinin absorbe ettiği enerjinin, T4-P0-F0 numunesinin absorbe ettiği enerji (1310 J) ile cidar ezme işlemindeki (94 J) ve köpük takviyesindeki (499 J) kazançların toplamı olan 1903 J değerinden %14,4 daha yüksek bir değerde (2177 J) olması dikkat çekici bir durumdur.

3.2. T6 Tüplerin Deney Sonuçları

Bu bölümde, T4 ısıl işlem durumundan daha yüksek dayanıma sahip 6063-T6 tüplerin eksenel ezilme deney sonuçları verilmiştir. Numunelerin deney sıralamasında 6063-T4 tüplerdeki sıralama takip edilmiştir. Bu numunelere ait kuvvet-deplasman eğrileri Şekil 8'de verilmiştir. Kuvvet eğrileri incelendiğinde, numunelerin pik kuvvet değerlerinde önceki grup numunelere (6063-T4) benzer bir değişimin olduğu görülmüştür. T6 ısıl işlem durumundaki base tüpün (T6-P0-F0) pik kuvvet değeri, daha yüksek dayanımlı olmasına bağlı olarak, T4 ısıl işlem durumuna göre yaklaşık %70 daha

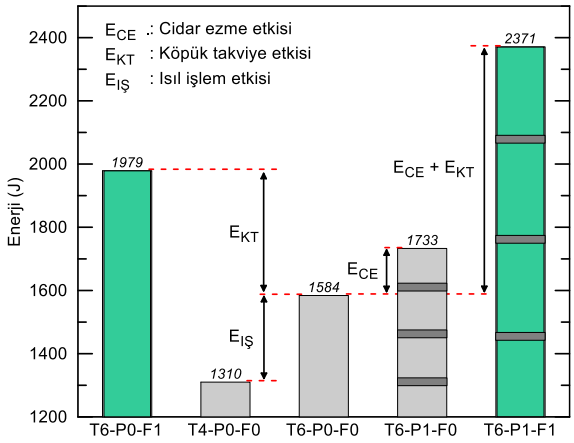
yüksek olmuştur. İlk katın tamamlandığı minimum kuvvet değerlerinin cidar ezme işlemi uygulanmış numunelerde işlem uygulanmamış tüplerden yaklaşık %50 daha küçük bir deplasmanda gerçekleştiği görülmektedir. Bu durum Şekil 7'de verilen deformasyon başlangıç konumlarıyla alakalı olarak açıklanabilir.



Şekil 8. T6 ısıl işlem durumundaki takviyeli ve takviyesiz tüplerin kuvvet-deplasman eğrileri

Şekil 8'de verilen enerji değerleri incelendiğinde cidar ezme işlemi uygulanmış T6-P1-F0 numunesinin T6-P0-F0 numunesine oranla yaklaşık %9,5 daha yüksek enerji absorbe ettiği anlaşılmaktadır. Bu farkın T4 ısıl işlem durumundaki aynı numune kombinasyonlarında daha düşük olması cidar ezme işleminin, T6 ısıl işlem durumunda T4 ısıl işlem durumuna oranla daha etkin olduğunu göstermesi açısından oldukça önemlidir. Nitekim ısıl işlem durumlarındaki farklılık enerji eğrilerine ait grafiklerden de açıkça görülebilmektedir. T4 ısıl işlem durumundaki numunelerin eğrilerinin verildiği Şekil 6'da bu numune kombinasyonlarına ait eğriler neredeyse çakışıkken, Şekil 10'da verilen eğrilerde bariz bir farklılık göze çarpmaktadır. Buna mukabil, köpük takviye edilmiş T6-P0-F1 numunesinde base tüpe oranla %25 daha yüksek enerji absorbe edildiği görülmektedir. Bu oranın T4 ısıl işlem durumunda %38 mertebesinde olması, tüp-köpük etkileşimin T6 ısıl işlem durumunda çok daha az etkin olduğunu göstermektedir. Bunun T6 ısıl işlem durumundaki tüplerde (daha yüksek dayanıma sahip) tüpün deformasyonu esnasındaki yönlenmelerine, köpüğün yoğunluğu itibariyle, yeteri kadar direnç gösterememesinden kaynaklandığı düşünülmektedir. Dolayısıyla yüksek dayanıma sahip tüplerin takviye edilmesinde daha yüksek yoğunluğa sahip polimerik veya metal köpüklerin kullanılması köpüğün absorbe edilen enerjiye olan katkısını artırabilir. Nitekim literatürde bu duruma uygun olarak, daha yüksek dayanıma sahip çelik tüplerin takviye edilmesinde polimerik köpüklerin yerine daha yüksek yoğunluklu metalik köpüklerin (alüminyum köpük gibi) tercih edildiği görülmektedir (Reid ve ark, 1986).

Şekil 9'da verilen bar grafikte T6 ısıl işlem durumundaki numuneler ile T4 ısıl işlem durumundaki boş tüpe ait absorbe edilen enerji değerleri ve enerji değerleri arasındaki farklılıklar ve bar grafikler yardımıyla gösterilmiştir. Grafikte ısıl işlem durumunun tüplerin absorbe ettiği enerji değerine etkisi EHT ile gösterilmiştir. Bu kapsamda karşılaştırılan T6-P0-F0 numunesinin T4-P0-F0 numunesine nazaran 21% oranında daha yüksek enerji absorbe ettiği görülmektedir. Bu farklılığın sebebini ısıl işlemle dayanımı artmış olan tüpün deformasyonu için daha yüksek kuvvetlere gereksinim duyulması şeklinde açıklamak mümkündür. Yine grafikte, köpük takviyesinin enerji değeri üzerindeki etkisi EFF ile gösterilmiştir. Bu etkinin, T4 ısıl işlem durumuna nispetle daha düşük kaldığı görülse de, EWC ile gösterilen cidar ezme işlemine göre enerji değerine daha yüksek oranda katkı sunduğu anlaşılmaktadır. T6-P1-F1 numunesinde elde edilen enerji değerinin T6-P1-F0 numunesinden 638 J (%35) daha fazla olduğu görülmektedir. Bu farklılığın T4 ısıl işlem durumunda %55 mertebesinde olduğu göz önünde bulundurulursa, cidar ezme işlemiyle enerjide sağlanan artışın tüp-köpük etkileşiminden kaynaklanan düşüşü telafi etmediği anlaşılmaktadır. Ayrıca T4 ısıl işlem durumundaki numunelere benzer şekilde, T6-P0-F0 numunesinin absorbe ettiği enerjinin cidar ezme işlemiyle ve köpük takviyesiyle sağlanan sırasıyla 149 J ve 395 J değerlerindeki enerji kazançlarıyla toplanması durumunda 2128 J değerinin elde edildiği görülmektedir. Bu değerin T6-P1-F1 numunesinin absorbe ettiği 2371 J değerinden %11,4 daha düşük olduğu, dolaysıyla bu numenlerde de iki bileşenin birlikte kullanılması durumunda, her ne kadar T4 ısıl işlem durumundaki kadar yüksek olmasa da, ekstra bir etkileşimin oluştuğunu göstermesi açısından önemlidir.



Şekil 9. T4 ve T6 ısıl işlem durumundaki tüplere ait enerji değerlerinin karşılaştırılması

3.3 Tüp-Köpük Etkileşimi

Metalik veya polimer esaslı farklı malzemelerden imal edilmiş köpükler, gözenekli yapıları nedeniyle imal edildikleri ham maddeye oranla çok daha düşük yoğunluktadırlar. Ayrıca oldukça düşük ve neredeyse sabit kuvvette uzun deformasyon deplasman değerleri sunmaktadırlar. Bu iki önemli fayda, köpüklerin tüp yapılarda takviye elemanı olarak sıklıkla tercih edilmelerine yol açmıştır. Bu kapsamda yapılmış birçok çalışmada köpüklerin, yapının toplam ağırlığını fazla artırmadan absorbe edilen enerjiye ciddi katkı sundukları rapor edilmiştir. Yazarların bu kapsamda yaptığı önceki çalışmalarda (Yalçın ve Genel, 2019), özellikle polimer esaslı köpüklerin absorbe edilen enerjiye aşağıda belirtilen iki mekanizma ile katkı sundukları anlaşılmaktadır:

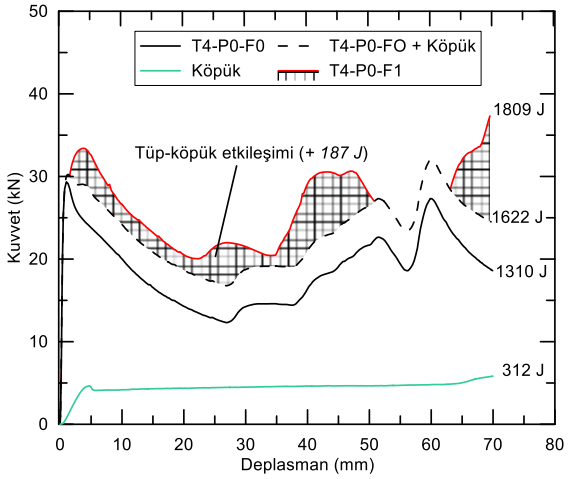
i- yapının maruz kaldığı eksenel yüke karşı göstermiş olduğu direnç,

ii- eksenel yük altında içeri ve dışarı yönlenerek deforme olan tüp cidarı ile girdiği etkileşim

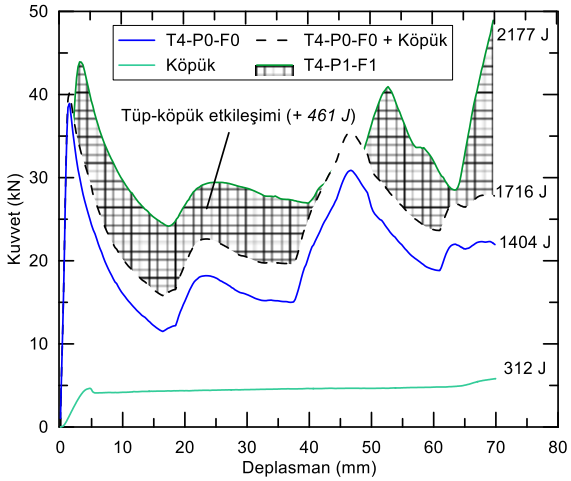
İlk madde de eksenel yüke karşı gösterilen direncin köpüğün yük taşıma kabiliyetini de gösteren plato bölgesiyle ilintili olduğu, bir başka deyişle köpüğün yoğunluğuyla orantılı olarak arttığı ifade edilebilir. Dolaysıyla artan yoğunluğun bu madde için olumlu etkisi olacağı söylenebilir.

İkinci madde ise kendi içerisinde, köpüğün deformasyon esnasında tüp cidarının içeri doğru yönlenme hareketini (köpüğe penetre olmaya çalışmasını) kısıtlaması ve içe yönlenen katlar arasında sıkışması şeklinde iki kısma ayrılabilir. Buna göre artan köpük yoğunluğuyla tüp cidarının içe yönlenme oranı daha fazla kısıtlanacağından azalacak, yönlenme oranının azalmasıyla da içe yönlenen katlar arasında sıkışan köpük miktarı düşecektir. Dolayısıyla artan köpük yoğunluğuyla, bu iki hususun ilkinin tüp yapının absorbe edeceği enerjiye katkısı pozitif, ikincinin katkısı ise negatif yönde etkilenecektir. Sonuç olarak, yukarıda zikredilen ilk madde artan köpük yoğunluğuyla artarken, ikinci maddenin optimum bir köpük yoğunluğunda maksimum katkıyı sunacağı anlaşılmaktadır. Bu durum yazarların bu kapsamda yaptığı önceki çalışmada çok daha detaylı olarak ele alınmıştır (Yalçın ve Genel, 2019).

Köpük takviye edilmiş tüp yapıların enerji değerleri incelendiğinde absorbe edilen enerjinin, boş tüp ve köpüğün absorbe ettiği enerji değerlerinin toplamından daha yüksek olduğu dikkat çeken bir husus olarak karşımıza çıkmaktadır. Bu özel durum, tüple köpük arasında deformasyon esnasında literatürde "interaciton effect" olarak tanımlanan bir etkileşimin ortaya çıktığını göstermektedir. Bu etkileşimin daha açık bir şekilde görülebilmesi için T4-P0-F0 ve T4-P0-F1 numuneleri ile T4-P1-F0 ve T4-P1-F1 numunelerinin kuvvet-deplasman eğrileri Şekil Y'de birlikte verilmiştir. Şekil 10a'da verilen köpük takviyeli T4-P0-F1 numunesinin absorbe ettiği 1809 J enerji değeri, T4-P0-F1 numunesinin ve köpüğün ayrı ayrı absorbe ettikleri enerji değerlerinin toplamı olan 1622 J değerinden %11,5 daha yüksektir. Bu durum, tüp içerisine yerleştirilen köpüğün tüp cidarıyla deformasyon esansında girmiş olduğu etkileşimin yapıya 187 J ekstra enerji kazandırdığını göstermektedir. Benzer şekilde Şekil 10b'deki T4-P1-F0 numunesi ve köpüğün eksenel yük altında absorbe ettiği enerjilerin toplamı 1716 J iken, bu değerin T4-P1-F1 numunesinde 2177 J olduğu görülmektedir. Enerji değerleri arasındaki %27 oranındaki bu farkın (461 J) cidar ezme işlemi uygulanarak bölgesel olarak dayanımı artırılmış tüp cidarıyla köpüğün, deformasyon esnasında girdiği etkileşimden kaynaklandığı sonucuna ulaşılmaktadır.



(a)



(a)

Şekil 10. Tüp cidarı ile köpük arasında deformasyon sırasında meydana gelen etkileşim

Yukarıda belirtilen tüp-köpük etkileşimlerinin iki farklı numune grubunda farklı olduğu, cidar ezme işlemiyle bu etkileşimden sağlanan enerji artışının yaklaşık 2 kata ulaştığı görülmektedir. Numunelerde kullanılan PVC köpüğün özdeş olması, köpüğün eksenel yüke karşı gösterdiği direncin bütün numunelerde eşit olduğunu göstermektedir. Dolayısıyla numuneler arasındaki bu farkın, yapının deformasyonu esnasında tüp cidarının hareketiyle alakalı olarak ortaya çıkan tüp-köpük etkileşimiyle ilgili olduğu açıktır. Bahsedilen bu etkileşimdeki farklılık ise tüplerin deformasyon davranışlarındaki farklılıklarından kaynaklanmaktadır. Bu kapsamda cidar ezme işlemi uygulanmamış ve uygulanmış tüplere köpük takviye edilmesiyle elde edilen numunelerin (T4-P0-F1 ve T4-P1-F1) eksenel yük altındaki deformasyon görüntüleri Şekil 11'de birlikte verilmiştir. Şekil incelendiğinde, deformasyon esnasında köpük takviyeli her iki tüpün yüzeylerinin de içe ve dışa doğru yönlendiği görülmektedir. Kat oluşumu esnasında cidar ezme uygulanmamış tüpteki yönlenmenin, ön ve arka karşılıklı yüzeylerde dışa, sağ ve sol yüzeylerde ise içe doğru olduğu görülmektedir (Şekil 11a). Tüp içerisindeki köpük, içeri yönlenen yüzeylerle etkileşim içerisine girdiğinden (cidar hareketini kısıtlama, araya sıkışma) bu numunede her bir kat oluşumunda sadece iki yüzeyle etkileşim ortaya çıkmaktadır. Cidar ezme işlemiyle birlikte numunenin deformasyon davranışında bir değişim olduğu, bu numunede tüpün her yüzeyinin içeriye doğru yönlendiği görülmektedir (Şekil 11b). Dolayısıyla bu numunedeki takviye elemanı olan köpük, her bir kat oluşumunda tüpün dört yüzeyin tarafından da sıkıştırılmakta ve buna bağlı olarak ta bu yüzeylerle etkileşime girmektedir. Tüp geometrisinde ve kuvvetin uygulanmasında herhangi bir değişiklik yapılmadan, sadece cidar ezme işlemiyle sağlanan deformasyon davranışındaki bu değişim ayrıca önemli bir husustur.

Şekil 11. Cidar ezme işlemi (a) uygulanmamış, (b) uygulanmış tüplerde devam eden deformasyon davranışı

Tablo 2'de tüm numune kombinasyonlarına ait absorbe edilen enerji, ağırlık ve bu iki değerin oranlanmasıyla elde edilen özgül enerji absorbe (ÖEA) değerleri birlikte verilmiştir. Absorbe edilen enerji verimliliği için önemli bir gösterge olan ÖEA değerinin her bir ısıl işlem durumunda ki en düşük değeri boş tüplerde elde edilmiştir. Buna mukabil en yüksek değerlerin ise cidar ezme uygulanmış tüplerin köpük takviye edilmeleri durumunda elde edilmiştir. Her ne kadar en yüksek en yüksek ÖEA değeri T6 ısıl işlem durumunda elde edilmiş olsa da (%24), boş tüplere nazaran sağlanana artış açısından T4 ısıl işlem durumundaki tüpün daha verimli bir artış sunduğu dikkat çekmektedir (%37).

Tablo 2. Özgül enerji absorbe değerleri

Numuneler	Ağırlık, (g)	Enerji, (J)	Özgül Enerji, (J/g)
T4-P0-F0	133	1310	9.9
T4-P0-F1	133	1404	10.6
T4-P1-F0	160	1809	11.3
T4-P1-F1	160	2177	13.6
T6-P0-F0	133	1584	11.9
T6-P0-F1	133	1733	13.1
T6-P1-F0	160	1979	12.4
T6-P1-F1	160	2371	14.8

4. GENEL SONUÇLAR ve ÖNERİLER

Farklı ısıl işlem durumlarındaki kare kesitli alüminyum tüplerin eksenel yük altında sergiledikleri deformasyon davranışı ve absorbe ettikleri enerji değerinin deneysel olarak incelendiği çalışmada düşük dayanıma sahip ısıl işlem durumunda takviye elemanı olarak kullanılan köpüğün absorbe edilen enerji üzerinde daha etkili olduğu görülmüştür. Ön deformasyon işlemi olan cidar ezme işleminin ise yüksek dayanıma sahip T6 ısıl işlem durumunda daha verimli olmuştur. Tüp-köpük etkileşiminin absorbe edilen enerji değeri üzerinde önemli bir etkisinin olduğu görülmüştür. Elde edilen sonuçlara göre, daha yüksek enerji verimliliğinin elde edilebilmesi için yüksek dayanıma sahip tüplerde daha yüksek yoğunluğa sahip köpükler kullanılabilir. Ayrıca pekleşme davranışının daha yüksek olduğu metalik tüpler kullanılması durumunda da cidar ezme işlemiyle daha yüksek ÖEA değerleri elde edilebilir.

ABSTRACT

This paper proposes a novel approach to increase the reliability of the lane detection and extend the driving horizon of a vehicle that is already equipped with a front camera, by improving the lane centering capabilities for the use cases where the front camera performance is not sufficient. A standard definition digital map software with GPS sensor is used as the input source. The geometrical route information from the digital map is transformed to ego vehicle coordinate frame and a lane construction method with weighted least squares polynomial regression is developed to generate map-based lane boundaries. An optimization approach is introduced to fuse the available camera-based lane boundaries with the obtained map-based lane boundaries. The resultant fused lane information is utilized to increase the system availability and the horizon length. The validation is performed on a simulated environment using real-life test data per pre-defined use case scenarios. The validation results confirmed that the lane centering functionality can be improved up to 20 meters.

Keywords: ADAS, Lane Centering, Digital Map, Camera

1. INTRODUCTION

A major portion of the road accidents is caused by unintentional lane change, emphasizing the significance of the lane keeping action in terms of safety [1]. Accordingly, lane keeping action has been one of the main focus for ADAS applications bringing a significant potential in preventing single-vehicle lane departure crashes [2]. Lateral assist functions like lane departure warning/prevention and lane keeping/centering assist systems are already commercialized with a high consumer acceptance by most of the vehicle manufacturers [3].

Autonomous lane centering aims to correct the deviation from the lane center by continuously monitoring the relevant vehicle states and generating the steering angle according to the lane information derived from sensor data. A brief layout of the system is given in Figure 1(a). The states of interest are the offset ε and the heading angle Ψ_h of the ego vehicle with respect the lane center curvature which are evaluated at characteristic parameters x_{bumper} and x_{lah}, namely the bumper and look ahead longitudinal distances. The ego vehicle states speed v_x and yaw rate w_z are also input to the lateral controller. An illustration of these states and parameters are presented in Figure 1(b).

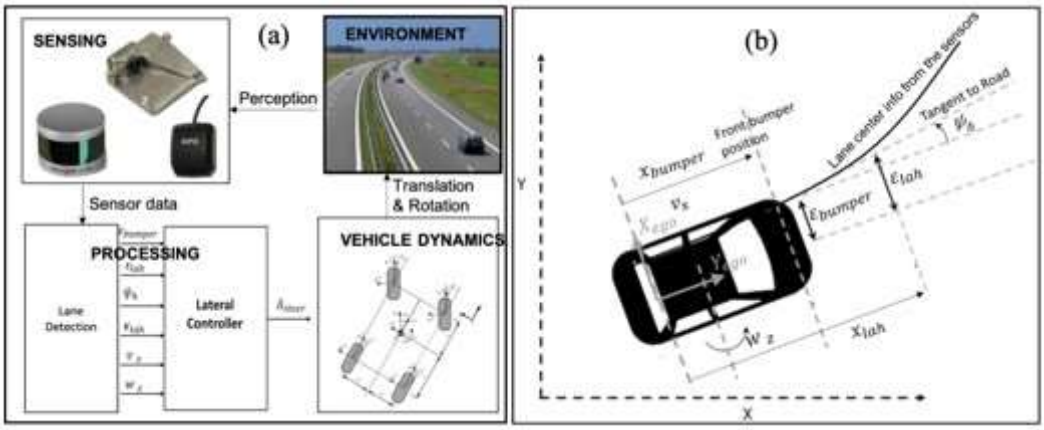

Figure 1. (a) Brief illustration of a lane centering system, and (b) ego vehicle states and parameters for lateral vehicle control.

In lane centering systems, it is assumed that sensory information that represents the lane center up to a certain distance, i.e. the "horizon", is provided and sufficient for the system to control the ego vehicle. In today's commercialized technology, the horizon can be generated by various sensor types such as a front camera, LIDAR or RADAR, where fusion of these sensor types is also applied in order to increase the availability and the reliability [4,5]. Amongst the various sensor types, front camera one of is the common type for the commercial lane centering systems by its low-cost with a sufficient horizon length and an acceptable reliability for most of the use cases [6,7]. For instance, the front camera has a high close to mid-range (<50m) lane positioning accuracy with an error margin smaller than 4 cm [8]. One of the main issues though, is that camera data is not always available. For example, when the view is blocked.

Recently, digital map-based techniques are also being implemented on advanced driving assistance systems, by constructing an electronic horizon consisting of various road features along the ego vehicle's driving path. In literature, there exist numerous studies and applications that utilize digital maps for lateral assist. Curvature estimation and traffic sign detection for speed adjustments is common among map based ADAS applications [9,10]. By the utilization of the high definition maps, identification of the lanes which is hard to detect especially at intersections becomes possible [4]. There are studies that show that the lane model geometry and high-level semantic information, such as lane connectivity, supports the automated driving actions with the path planning and decision making [5]. The road features obtained from the map can correct the camera detection, such as when the guardrails misguide the camera and cause a wrong lane estimation [11]. There are readily commercialized solutions that guide the vehicle in the correct lane to avoid last minute lane changes by detection of the junctions upfront [10].

The strategies mentioned above can be further extended by introducing new methods on the existing literature. One of the main issues is that either high resolution maps are required, or an accurate GPS system for accurate localization has to be used. This paper presents an innovative approach by creating a mathematical lane boundary representation from the map data, followed by fusion with the camera data. The aim is to improve the lane keeping functionality by utilization of the map's long and continuous horizon, while poor accuracy and refresh rate of the GPS is mitigated by the camera's close range in-lane localization accuracy. The target scenarios in which the camera lane detection can be degraded when the lane markers are missing or blocked due the road, whether or traffic conditions [3,12] are illustrated in Figure 2. The study also aims to achieve a feasible solution that can be implemented on entry level commercial ADAS packages, thus the sensor domain is configured to involve only a single front camera and SD (standard definition) map software with GPS localization. In vehicle odometer sensor information is also utilized during the study for ego vehicle state estimation and localization improvements by using conventional Kalman filtering methods, however details of this process are not mentioned in this paper. Under these objectives, the research question can be captured as: "How can SD map data be integrated to a camera-based lane centering system in order to extend the driving horizon and manage the scenarios that cannot be achieved with the front camera only?"

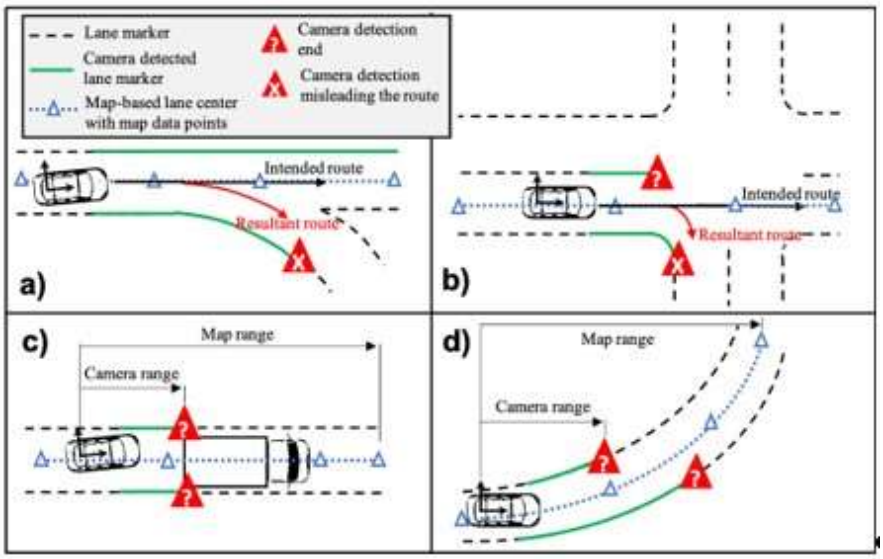

Figure 2. Common scenarios when the camera-based lane centering might fail to generate the lane center reference while the map-based system is capable of providing it: a) Right lane marker causing to deviate from the intended straight driving route due to a highway exit. b) A junction where the lane markers disappear in the center, misleading the ego vehicle by leading it along the right-hand marker curvature instead of guiding through the intended straight route. c) A large vehicle blocking the camera view, diminishing the driving horizon. d) A road segment with a high curvature causing the left and right lane markers to overlap and shift out of the camera view.

The outline of this paper is as follows; First the mathematical representation of camera-based lane data is introduced in section 2. Then the conversion of map data's World Geodetic System (WGS) localization to Cartesian coordinates is described in section 3.1. In section 3.2 this is followed by a map-based lane center construction process by using weighted polynomial curve fitting methods. The fusion of camera-based lane information with the constructed map-based lane center is given in section 3.3. Finally, the results on real-life driving data is presented in section 4 and the paper is finalized with a discussion part.

2. FRONT CAMERA BASED LANE CENTERING

A front camera is capable of generating ego lane information by detecting the lane markers with image processing. Resultant lane boundary information from the camera can be transformed to ego-vehicle based Cartesian coordinate frame, where the left and right lane boundaries can be represented as points lying on polynomial equations. Figure 3 illustrates the detection of the lane boundaries from the lane markers and transformation of the lane boundary information to the Cartesian coordinates. 3rd degree polynomials are commonly used [13] to express lane boundary coordinates since they provide sufficient accuracy for lateral control purposes.

The principal coordinate system is defined as the ego vehicle coordinate frame with an origin at the middle of the rear axle, and is shown in Figure 3. The axis $\mathbf{X}$ is the longitudinal direction heading straight from the origin, i.e. the middle of the rear axle, to the middle of the front axle [14]. The axis $\mathbf{Y}$ is perpendicular to $\mathbf{X}$, having the positive direction to the left of the ego vehicle.

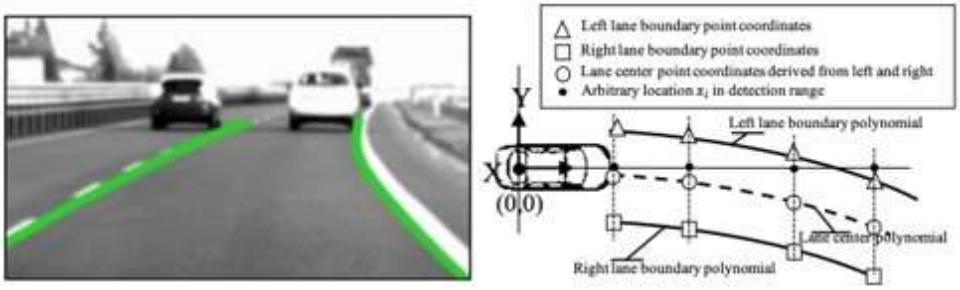

Figure 3. For ADAS purposed, the vehicle front camera can identify the lane markers to generate ego lane boundary data (left). For arbitrary longitudinal distances along the driving path, the lane boundary and lane center points can be located on the polynomial curves with respect to the ego vehicle coordinates (right).

The front camera provides separate polynomial coefficients for the left and right lane boundaries. The lane center line information can be virtually constructed by averaging the left and right lane boundary information. This way, lane boundary information is reduced to four polynomial coefficients provided by the camera (*cam*), where lateral position $y(x)$ of a lane boundary point can be estimated for any longitudinal distance x from the ego vehicle. Notice that at origin ($x = 0$), the lateral offset reduces to d.

$$y(x) = a_{cam}x^3 + b_{cam}x^2 + c_{cam}x + d_{cam} \tag{1}$$

Some important road features can also be derived from the 3rd degree polynomial equations. For instance, the 1st derivative of (1) results in the slope of the lane center line. This can be interpreted as the heading angle difference of the road with respect to the ego vehicle Ψ_h at any longitudinal distance x.

$$\Psi_h(x) = \frac{dy(x)}{dx} = 3a_{cam}x^2 + 2b_{cam}x + c_{cam} \tag{2}$$

The curvature of the road κ can be estimated by the 2nd derivative of (1) for small curvatures, which is the case for targeted driving scenarios since even for the sharpest turns at highway entry and exits with a turning radius as low as 50 meters[15]:

$$\kappa(x) \simeq \frac{d^2y(x)}{dx^2} = 6a_{cam}x + 2b_{cam}b \tag{3}$$

Finally, the last information about the road that can be extracted from the polynomial representation is the rate of curvature change:

$$\kappa'(x) \approx \frac{dy}{dx}\left(\frac{d^2y(x)}{dx^2}\right) = 6a_{cam} \tag{4}$$

3. MAP-BASED HORIZON CONSTRUCTION IN FUSION WITH CAMERA DATA

3.1. Transformation of the Map Data Points to Cartesian Coordinates

A standard definition digital map software can provide information about the ego-vehicle's horizon route which consists of World Geodetic System (WGS) based longitude and latitude information of the data points along the driving route. In the map software, these features are parametrized with a scalar distance (l with respect to the ego vehicle. Using a WGS to Universal Transverse Mercator (UTM) conversion technique, the longitude and latitude information can be transformed into Cartesian coordinate frame, which is crucial for lateral control purposes. The data transformed points are located in $X-Y$ coordinates according to UTM easting-northing reference frame [16]. Figure 4 illustrates the WGS data transformation to UTM data for an exemplary map-based route consisting of 5 data points.

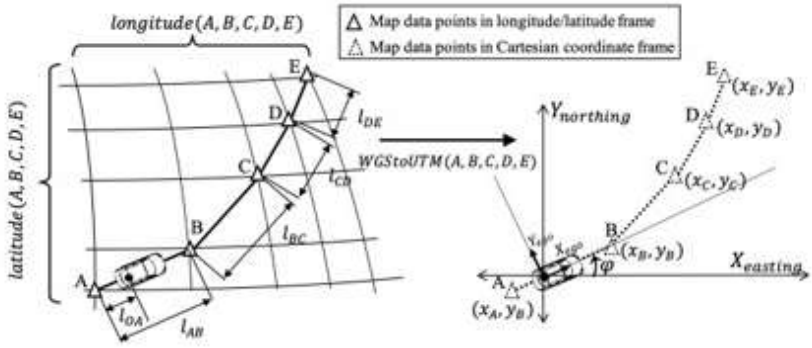

Figure 4. An exemplary digital map driving route where the longitude and latitude features of the data points are provided with respect to scalar distance l from the ego vehicle in a segmented structure are transformed to Cartesian coordinates

The SD map route lacks the information of the ego vehicle's lateral offset and heading angle difference to the lane center, since the vehicle is abstracted as a point moving along the 1D route segments without a width feature. As an initial approximation, a transformation can be performed by using the angle φ between the $X_{easting}$ and the segment the vehicle is on, as shown in Figure 4. For each UTM based map data point coordinate $(x_{i,UTM}, y_{i,UTM})$, the rotation matrix in (5) can be applied to obtain data point coordinate set $(x_A, y_A, x_B, y_B, \dots, x_E, y_E)$ in ego vehicle coordinate frame.

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} \cos(-\varphi) & -\sin(-\varphi) \\ \sin(-\varphi) & \cos(-\varphi) \end{bmatrix} \begin{bmatrix} x_{i,UTM} \\ y_{i,UTM} \end{bmatrix} \tag{5}$$

3.2. Lane Center Construction with Weighted Polynomial Curve Fitting

The transformed map data points shown in Figure 4 provide a segmented route information where the curves of the actual driving path cannot be observed. To achieve a true physical representation of the driving path, the data points need to be connected in a continuous and splined manner. 3rd degree polynomial lines can again be used in order to have the same mathematical representation as with the front camera.

The least square regression finds the optimum coefficient set (a, b, c, d) for n data points with the residual R^2:

$$R^2 = \underset{a,b,c,d}{\operatorname{argmin}}\left(\sum_i^n [y_i - (ax_i^3 + bx_i^2 + cx_i + d)]^2\right) \tag{6}$$

Since the polynomial represents a reference driving path for a lane keeping system, it is important that the error is controlled in way that it is minimized within the range of interest of the lateral controller, in trade off with the increased fitting error for the data points further away from the ego vehicle. Introducing weighting factors w_i would serve this purpose, since the magnitude of the weight factors will determine the influence of its corresponding data point in the regression. The resultant residual term R^2 becomes [17]:

$$R^2 = \sum_i^n w_i [y_i - (ax_i^3 + bx_i^2 + cx_i + d)]^2 \tag{7}$$

In order to find the optimum polynomial coefficient set (a, b, c, d) that minimizes R^2, the partial derivatives of the residual term with respect to each polynomial coefficient is set to zero, i.e. $\frac{\partial R^2}{\partial a} = \frac{\partial R^2}{\partial b} = \frac{\partial R^2}{\partial c} = \frac{\partial R^2}{\partial d} = 0$. This results in the following system of linear equations:

$$\begin{bmatrix} w_i n & \sum_{i=1}^{n} w_i x_i & \sum_{i=1}^{n} w_i x_i^2 & \sum_{i=1}^{n} w_i x_i^3 \\ \sum_{i=1}^{n} w_i x_i & \sum_{i=1}^{n} w_i x_i^2 & \sum_{i=1}^{n} w_i x_i^3 & \sum_{i=1}^{n} w_i x_i^4 \\ \sum_{i=1}^{n} w_i x_i^2 & \sum_{i=1}^{n} w_i x_i^3 & \sum_{i=1}^{n} w_i x_i^4 & \sum_{i=1}^{n} w_i x_i^5 \\ \sum_{i=1}^{n} w_i x_i^3 & \sum_{i=1}^{n} w_i x_i^4 & \sum_{i=1}^{n} w_i x_i^5 & \sum_{i=1}^{n} w_i x_i^6 \end{bmatrix} \begin{bmatrix} d \\ c \\ b \\ a \end{bmatrix} = \begin{bmatrix} \sum_{i=1}^{n} w_i y_i \\ \sum_{i=1}^{n} w_i x_i y_i \\ \sum_{i=1}^{n} w_i x_i^2 y_i \\ \sum_{i=1}^{n} w_i x_i^3 y_i \end{bmatrix} \tag{8}$$

One can define the matrices X, Y, W and P as in (9) in order to solve the linear system of (8). Notice that X is the Vandermonde matrix of x_n^3 where x is the map data points' longitudinal distance, W is the diagonal weight coefficient matrix, Y is the set of the map points' lateral distance y and P is the solution matrix for the map-based lane center polynomial coefficients:

$$X = \begin{bmatrix} 1 & x_1 & x_1^2 & x_1^3 \\ 1 & x_2 & x_2^2 & x_2^3 \\ \vdots & \vdots & \vdots & \vdots \\ 1 & x_n & x_n^2 & x_n^3 \end{bmatrix}, \quad W = \begin{bmatrix} w_1 & \cdots & \cdots & 0 \\ \vdots & w_2 & \cdots & \vdots \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & \cdots & w_n \end{bmatrix}, \quad Y = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}, \quad P = \begin{bmatrix} d_{map} \\ c_{map} \\ b_{map} \\ a_{map} \end{bmatrix} \tag{9}$$

The system of equations in (8) can accordingly be solved by (10) using the matrices defined in (9) [18]:

$$P = (X^T W X)^{-1} X^T W Y \tag{10}$$

Finally, the map-based lane center can be represented in a 3rd degree polynomial form like the front camera:

$$y_{map}(x) = a_{map} x^3 + b_{map} x^2 + c_{map} x + d_{map} \tag{11}$$

Determination of the weight coefficient matrix W can be set by relating every weighing coefficient w_i to its corresponding data point's longitudinal offset x_i obtained in (5). It is desired to have less fitting error for the closer distances, hence the weighing factors are assigned in a way that their magnitudes increase while their distance to ego vehicle decreases. The proposed equation satisfying this condition is presented in (12). The weighing factor's dependency on the distance can further be tuned by applying a power factor k_w. To prevent w_i from approaching infinity and become overly dominant, a limiting value of 20 is set, considering a ratio of a maximum total horizon of 60 meters (180 km/h speed with a typical look ahead time of 1.2 s) and a minimum data point distance at the front bumper level, being typically around 3 meters.

$$w_i = \left(\frac{x_{total\ horizon}}{abs(x_i)} \right)^{k_w} \tag{12}$$

The curve fitting strategy is practiced on some real-life map data point set from a typical highway entry and exit with different weight power factors k_w=0 (no weighting), $k_w = 2$ and $k_w = 5$. The estimated lane center lines and the fitting error magnitudes are illustrated in Figure 5. It can be observed that weighting allows lower error in close range (< 20 m), however as the distance increases, the error can dramatically rise with higher power factors such as 5.

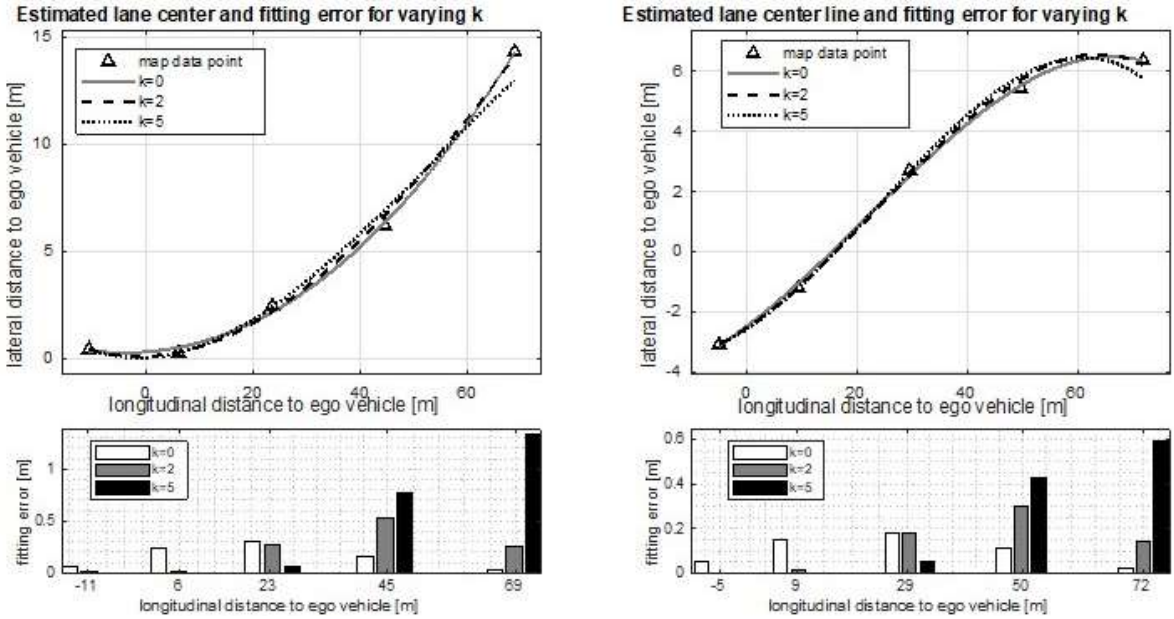

Figure 5. Illustration of lane construction with 3rd degree polynomial fitting with fitting errors of different weighting power factor for highway exit (left) and merge (right) cases.

3.3. Correction of Lane Center Offset and Orientation by Utilization of the Front Camera

As previously explained in Section 3.1, the SD map assumes the vehicle as a point entity traveling along the lane center constructed from the map data points. Obviously, the map-based lane center is a line and it does not have any knowledge of the width of the road nor the orientation of the vehicle with respect to the lane. It was also shown in (1) and (2) that the c and d coefficients of the lane center polynomial represent the lateral offset and heading angle of the ego vehicle with respect to lane center respectively. Therefore, polynomial coefficients c and d derived from map-based lane construction cannot be reliable. Accordingly, it can be concluded that the SD map can provide an accurate estimation of the curvature of the driving horizon within the map detection range which is designated by the furthest data point, while failing to provide the offset and orientation of the ego vehicle with respect to the lane center. This phenomenon is illustrated in Figure 6(a), showing that the actual heading angle (polynomial coefficient c) and lateral offset (polynomial coefficient d) are failed to be estimated by only using the map data. Furthermore, 1 to 5 Hz update rate and low accuracy of the standard in-vehicle GPS receivers is not sufficient in terms of autonomous vehicle lateral control which requires at least 10 Hz in order to capture the vehicle dynamics states [19], thus making the parallel utilization of other vehicle sensors essential in order to make use of the map data for lane keeping purposes.

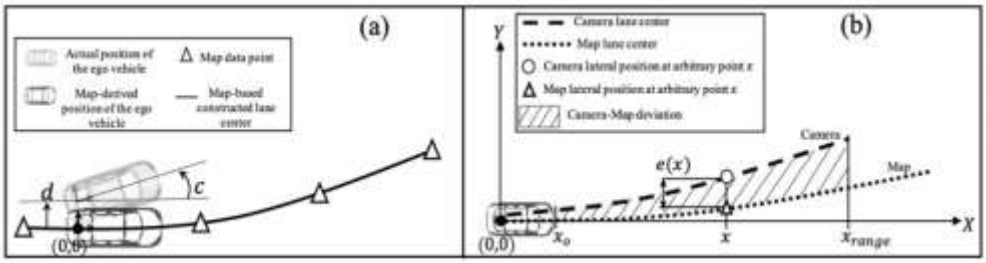

Figure 6. (a) A generic illustration showing the SD digital map failing to estimate the orientation (polynomial coefficient "c") and lateral offset (polynomial coefficient "d"), (b) Lateral deviation of camera and map-based lane centers to be used as the cost function.

On the other hand, unlike the front camera, the map is capable of providing continuous lane center information and maintain the correct driving route in the presence of lane marker discontinuities such as junctions, highway exits and entries, as previously illustrated in Figure 2. An optimization approach is proposed at this step, where it is aimed to minimize the quadratic cost function J in (13), which is defined as the integral of the lateral deviation of the map lane center with respect to camera lane center through the range where the camera lane information is assumed to be reliable. This deviation is illustrated in Figure 5(b).

$$J = \int_{x_o}^{x_{range}} e^2(x)\,dx \tag{13}$$

For an arbitrary longitudinal point x within the reliable camera detection range, the lateral deviation term e is the difference between the lateral distance presented in (1) and (11) and becomes

$$e = (a_{cam} - a_{map})x^3 + (b_{cam} - b_{map})x^2 + (c_{cam} - c_{map})x + (d_{cam} - d_{map}) \tag{14}$$

Since lane the center polynomial from the camera is assumed to be valid between x_o and x_{range}, the camera polynomial coefficients ($a_{cam}, b_{cam}, c_{cam}, d_{cam}$) are constant parameters in (14) at a specific detection instance. Additionally, the curvature estimation from the map data is assumed to be reliable, thus the curvature related polynomial coefficients from the map data (a_{map}, b_{map}) can be taken as constants as well. Consequently, constant terms can be defined as in (15) and the minimization for the quadratic cost function J in (16) becomes finding the optimum $[c_{map}, d_{map}]$ set that re-arranges the offset and orientation of the map-based lane center, reducing to combed area in Figure 6(b) to its possible minimum.

$$A = a_{cam} - a_{map}\,, \quad B = b_{cam} - b_{map}\,, \quad C = c_{cam}\,, \quad D = d_{cam} \tag{15}$$

$$J = \underset{c_{map}, d_{map}}{\operatorname{argmin}} \left(\int_0^{x_{range}} \left(Ax^3 + B^2 + (C - c_{map})x + (D - d_{map}) \right)^2 dx \right) \tag{16}$$

Finding optimum (c_{map}, d_{map}) requires that the partial derivatives of J for optimization variables are equal to zero:

$$\frac{\partial J}{\partial c_{map}} = 0\,, \quad \frac{\partial J}{\partial d_{map}} = 0 \tag{17}$$

At a specific detection instance, the integration limits x_o and x_{range} can be treated as constants. Thus, one can define the below equation set (18) of x for each power term:

$$X_7 = x_{range}^7 - x_o^7,\ \ X_6 = x_{range}^6 - x_o^6,\ \ \ldots,\ \ X_2 = x_{range}^2 - x_o^2,\ \ X_1 = x_{range} - x_o \tag{18}$$

Inserting (18), the integration in (16) is evaluated as:

$$J = \left[-\left(\frac{2AX_5}{5}\right) - \left(\frac{BX_4}{2}\right) - \left(\frac{2X_3C}{2}\right) - (X_2D) \right] c_{map} + \left[\frac{X_3}{3}\right] c_{map}^2 + \left[-\left(\frac{AX_4}{2}\right) - \left(\frac{2BX_3}{3}\right) - (2X_1D) - (X_2C) \right] d_{map} + [X_1] d_{map}^2 + [X_2] c_{map} d_{map} + K;\ \ with\ the\ constant\ K = \frac{A^2X_7}{7} + \frac{ABX_6}{3} + \frac{2AX_5C}{5} + \frac{B^2X_5}{5} + \frac{AX_4D}{2} + \frac{BX_4C}{2} + \frac{2BX_3D}{3} + \frac{X_3C^2}{3} + X_2CD + X_1D^2 \tag{19}$$

Solving (19) for (17), the linear system giving the heading and angle lateral offset related polynomial coefficients of the map-based lane center, c_{map} and d_{map} respectively, can be obtained as in (20), as long as the camera-based polynomial coefficients exist within $[x_o\ x_{range}]$. Note that the system has to be solved and the parameters are updated at each detection sample received from the camera and map that are in synchronization. A typical camera-base lane centering system has 15 Hz detection and processing frequency requirement [20] while a SD map-based system GPS can go as low as 1 to 2.5 Hz [19], thus the map coefficients shall be modified between its updates by the faster camera rate.

$$\begin{bmatrix} \frac{2X_3}{3} & X_2 \\ X_2 & 2X_1 \end{bmatrix} \begin{bmatrix} c_{map} \\ d_{map} \end{bmatrix} = \begin{bmatrix} \frac{2AX_5}{5} + \frac{BX_4}{2} + \frac{2X_3C}{2} + X_2D \\ \frac{AX_4}{2} + \frac{2BX_3}{3} + X_2C + 2X_1D \end{bmatrix} \tag{20}$$

The camera and map lane center matching requirements were set for lateral control parameters lane center offset and heading angle difference +/-40 cm and +/-2 degrees respectively [21]. The output of the optimization is tested for a typical highway exit shown Figure 7. It can be observed in the left side figures that although the map is capable of providing a longer horizon and good curvature estimation, the inaccuracy in heading angle and lateral offset lead to a lateral lane center deviation from the reference (camera), growing over 2 meters in 50 meters driving horizon. After the correction of the coefficients c_{map} and d_{map}, the deviation is minimized and a close match between the map-based and camera-based (reference) lane center is achieved as given in the right, where the lateral difference is reduced below 20 cm.

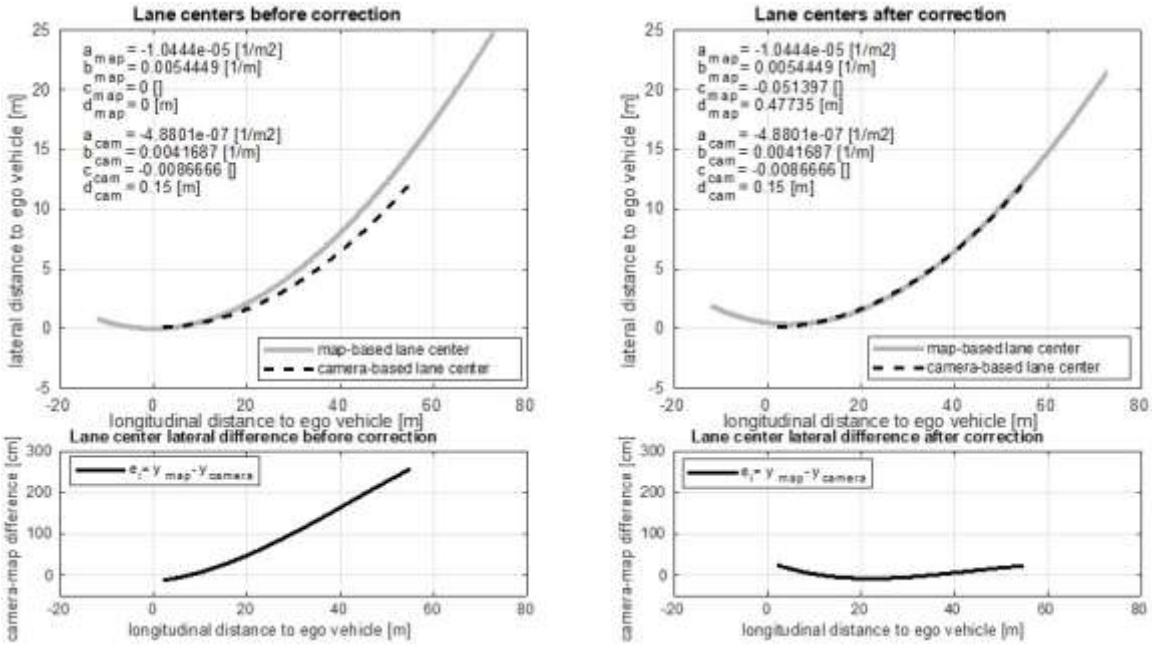

Figure 7. The map-based lane center polynomial coefficient correction results with the camera-based lane center reference.

Prior to the implementation of the method, a flow diagram of the system designed under described methods is given in Figure 8 for clarity, where the sensory information from the GPS, camera and odometry are processed to generate and for evaluation purposes, record the map-based horizon.

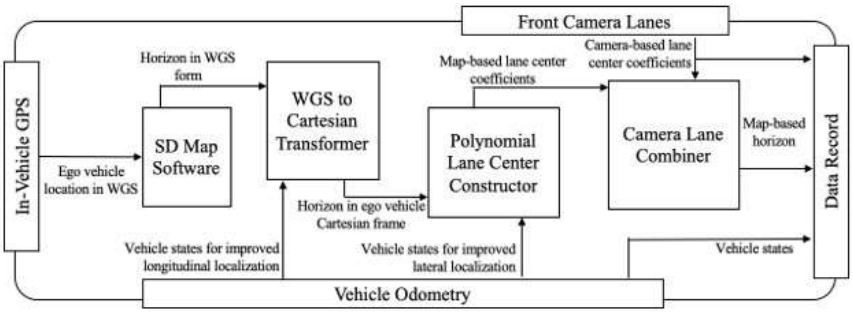

Figure 8. Flow diagram of the map-based horizon construction

4. RESULTS

The validation of the proposed system was performed on German roads for highway merge and intersection scenarios as illustrated in Figure 9(a_2) and (b_2) respectively. The synchronous data recorded from camera, odometry and digital map during these sessions was replayed and processed with the system summarized in Figure 8 in a simulation environment. Sample results are given in Figure 9(a_1) and (b_1) for specific instances in their respective scenarios. In both cases, map-based lane center construction was observed to be successful; (a_1) shows that the camera horizon (framed blue) was extended by the map by 24 meters (framed red) for high curvature highway merge case, while (b_1) shows that the almost expired camera horizon close to the intersection (framed blue) is sustained up to 64 meters by the map (framed red).

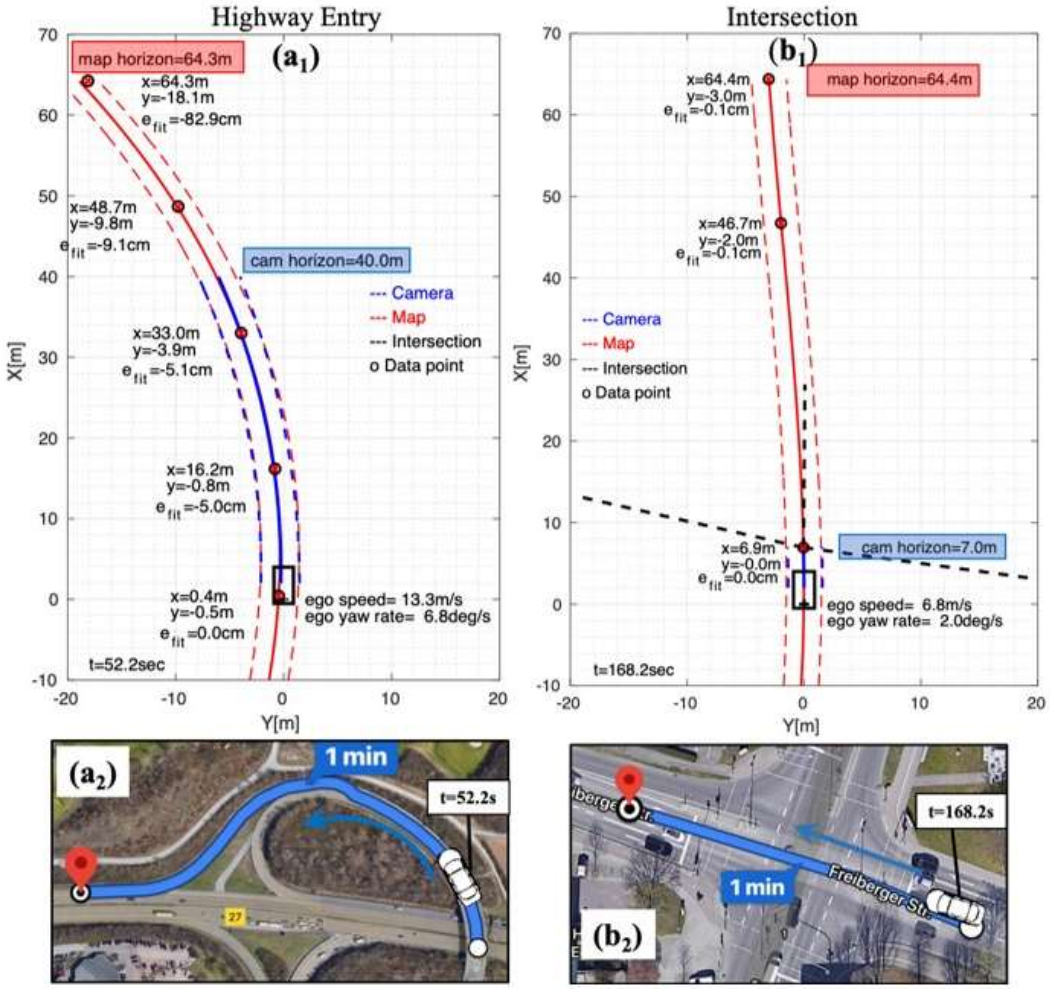

Figure 9. The highway merge (a_1) and the intersection scenarios (b_1) driven for data record. (a_2) and (b_2) show instances from the simulation outputs of the system.

To evaluate the performance for both scenarios, the horizon length of the map is compared against the camera. In Figure 10 it can be seen (left) that during the 35 seconds driving highway merge case, 19.4 meters of average horizon extension is achieved while the extension can go up 65 meters. To evaluate lane accuracy of the map, the camera data at look ahead distance is utilized due to its close-range reliability. It is observed that the lateral control parameters lane center offset (middle) and heading angle difference (right) are closely matching, staying within camera matching requirements by staying error ranges of +/-40 cm and +/-2 degrees. The average deviation from the camera was calculated as 17 cm for the lane center offset and 0.7 degrees for the heading angle difference.

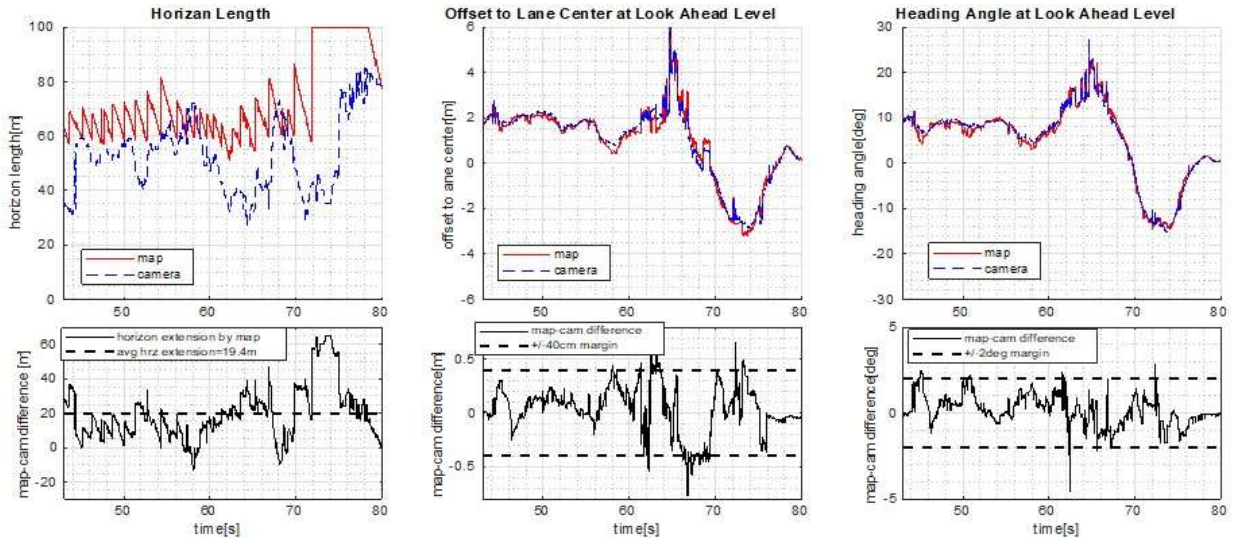

Figure 10. Highway merge results comparing the horizon length(left), lane center offset (middle) and heading angle (right)

The intersection results in Figure 11 show that when the camera horizon is limited by an intersection, the map can assist in extending the horizon until the end of the intersection (60 to 100 meters) even when the camera detection is lost inside the junction (left, 168s<t<175s). Since the map data is still available inside the junction, the essential lateral control parameters lane center offset (middle) and the heading angle difference (right) can be provided for steering assist. During this short phase, the less reliable vehicle odometry can be utilized in the absence of camera for in lane localization. When the camera detection is recovered in Figure 10 (t=175s), the control parameters show a close match, indicating a good lane construction accuracy performance from the map during the intersection crossing.

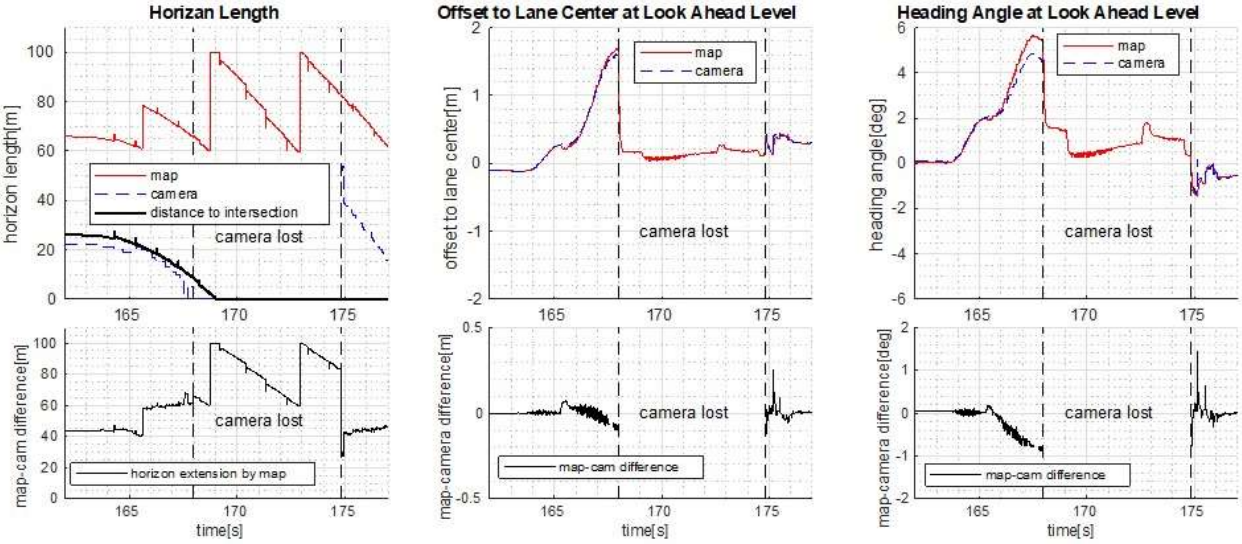

Figure 11. Intersection results comparing the horizon length(left), lane center offset (middle) and heading angle (right)

5. CONCLUSION AND RECOMMENDATIONS

In this paper, a map-based lane construction method for lane centering is presented. The proposed system aims to improve the front camera-based lateral assist during the scenarios where the lane markers are hard to detect. As a baseline, a front camera system is taken and standard definition map software is utilized for introducing a novel and feasible solution on the existing commercial technology. The map coordinates are transformed to vehicle coordinates to calculate a polynomial lane center representation, similar to that provided by the camera. To align the map and camera polynomials, a fitting error is calculated between the map and camera polynomial.

To show the performance, a test vehicle equipped with a front camera lane detection system and GPS-sourced standard definition map software is driven at highway merge and intersection routes. The real time simulation on synchronously recorded camera and map data show that the proposed method is successful at constructing accurate lane center

information, which can extend the camera horizon 20 meters average and up to 60 meters maximum for a highway entry case. The intersection results show that the map can support the lane centering system until the junction is crossed since the lane marker discontinuity did not affect the map's horizon. The accuracy of the map-based lane center is evaluated with the close-range camera data, where 17cm and 0.7 degrees of average deviations are observed for lateral offset and heading angle differences respectively. In conclusion, results show that the study proposes a promising step towards enhancing the camera-based lane centering without introducing high cost and complexity.

As a future work, it can be advised to evaluate the performance with a more reliable ground truth instead of the camera. Adaptive power factors (k_w) for weighting during lane construction could be a mathematical improvement and their influence can also be analyzed for a wider range. The effect of the polynomial degree on lane construction accuracy can be studied for higher degrees. A technique for more robust odometry utilization can be added to the work for tracking the ego vehicle position from the detection history when camera detection is lost. Finally, when brought to a certain maturity level, the method can be used in close loop lateral control for the ultimate verification.

ACKNOWLEDGEMENTS

This study was performed under an Eindhoven University of Technology PDEng Project in collaboration with Valeo Schalter und Sensoren GmbH, where Valeo was the financial sponsor and facilitator of the development and testing equipment.

ABSTRACT

In last decade, paint performance test were became more important due to world climate changing. Natural atmospheric aging is main performance test for understanding paint performance with customer usage and vehicle warranty life. Aging test is generally takes 2 to 5 years in hot and wet climates. In vehicle product development phase 2 to 5 years takes longer than vehicle development phase. Therefore Original Equipment Manufacturers generally perform accelerated aging simulation test on paints. SAE J2527 aging test is one of many aging simulation test and designed to simulate aggressive US Florida-Arizona climate. Due to nature of simulation, it is inevitable to not comprehend performance measuring of natural aging test with a simulation. There are some critical research have done to understand difference between simulation and natural test difference. With every paint formulation change, it would be difficult to change understand test performance difference. Because cosmetic demands of market is forcing all paint manufacturers to developing more resistance paint formulations.

In this study white and red solid colors were chosen to understand performance difference of 3 years natural outdoor atmospheric aging and SAE J2527 2500 kj accelerated aging test. There is a life estimation of body paint with the test result comparison in aspect of gloss and color evaluation.

Keywords: Outdoor Natural Aging Test, Accelerated aging test, Florida-Arizona weathering, High Bake Paint Application

1.INTRODUCTION

Automotive vehicle marketplaces become more competitive every day. Always cosmetic visuals is one of main tool for advancing the competition. Generally vehicles body paint color is heading cosmetics. Because body color of vehicles are making first expression on customers.

On the other hand, durability of body paint is a very critical indicator for brand perception. In addition to perception, world climatic variation is forcing weathering durability requirements everyday. Weathering conditions is important to understand aging behaviour of paint. There are 3 main factor to age a inorganic layers, These are;

- Temperature,
- Humidity,
- Light (Radiation)

Paint developers and specialists generally prefer Arizona-Florida climate for understanding weathering effect on paint formulations. Reason of defining Arizona-Florida areas as are aggressive climate in aspect of humidity, temperature and radiation climates. Main aging related research companies has laboratories and natural aging facilities in this areas as in figure 1 [1-2-3].

Figure 1: Natural Aging Visual

The most convenient way for understanding lifetime behaviour of paint /organic coating is performing natural /outdoor aging test for 2-5 years. But this duration is too long and precious for total vehicle development process in terms of competition and related model's production life. This time limits are directing paint developers to perform accelerating aging simulation tests. Mostly preferred accelerating aging simulation test is SAE J2527 test. Reasons of preferation of SAE J257 test are high humidity (Moisture and Rain simulation), temperature, radiation (0,**55 w/m2 and 340 w**) and day/night simulation in test cycle. SAE J257 test has 4 different cycle that have presented in Table 1. Paint developers and manufacturer's material engineers generally choose Boro/boro light filtering option to filter beams 275 nm above. Also total energy to qualify material is around 2500 kj to 6250 kj due to different climate like EMEA, NAFTA [4].

Table 1. SAE J2527 Test Cycle

Step	**1**	**2**	**3**	**4**
Temperature of Cabinet (oC)	38	47	47	47
Temperature of Black Panel (oC)	38	70	70	70
Irradiance (W/m2)	0 (Dark)	0,55	0,55	0,55
Humidity (% rh)	95	50	50	50
Water Spray	Front and Back	None	Front	None
Duration(Min)	60	40	20	60

For accelerated aging test performance has one un-clear point when compared with outdoor natural aging. Accelerated test is a simulation of outdoor natural aging test and does not match one hundred percent of climate changing in aspect of test stability. Also basis of the outdoor natural aging test is Florida – Arizona areas. In terms of less aggressive climates vehicle usage, Test could have more expectations than area requirements [4].

In order to understand difference, there are 2 different paint colour is used and aged with SAE J2527 and Bursa City Climate Between 2018 April and 2021 April for this study. These are 2 colours were selected for this study. White solid colour due to most convenient choice in aspect of easily cleaning and repairing and red solid colour due to charming of red colours. Atlas CI 4000 (Figure 2.) Weatherometer Device has used for accelerated aging test and 2500 kj has chosen for total aging energy. Outdoor natural aging area has been contsructed in Bursa for outdoor aging test.

Figure 2. Atlas CI 4000 Weatherometer Device

2. EXPERIMENTAL

In this study, it is aimed compare result of outdoor natural aging and accelerated aging simulation of white and red color in aspect of color and gloss change. Therefore all samples are prepared in same process condition with three layers conversional high bake paint system.

2.1. Experimental Procedure

For accelerated aging test SAE J2527 test were applied. As duration and filter of this test total 0, 500, 1000, 1500, 2000, 2500 kj exposures at 340 nm wavelength and B/B filters were chosen. For Outdoor exposures 1, 2, 3 year results have been chosen in Bursa City. During exposures, gloss values are measured in 20° measurement angle. gloss measurement angles had shown in Figure 5 [5-6].

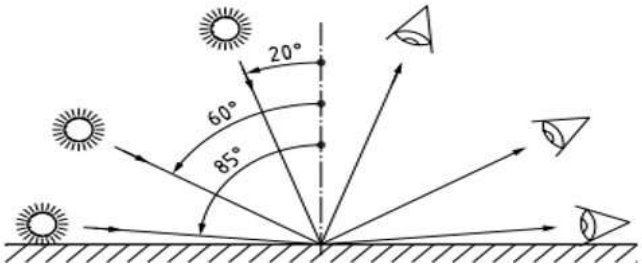

Figure 3. Gloss Measurement Angles

45° color measurement angle has chosen due to solid color and measured in same period of gloss measures. X-Rite MA 98 X device used for color measurements. Color measurements were performed on CIELAB L.a.b. color space that presented in Figure 3 [5-6].

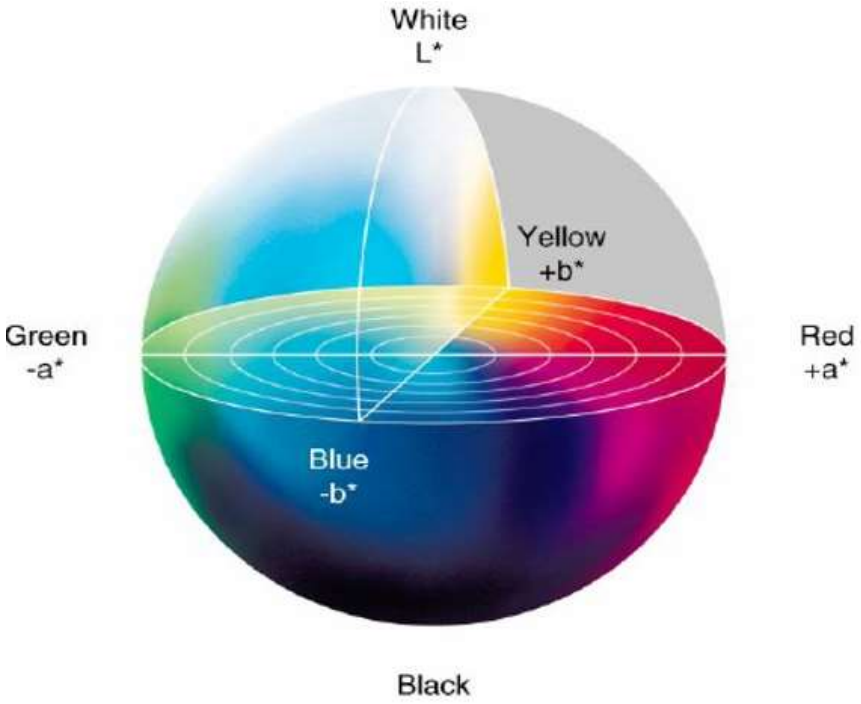

Figure 4. CIELAB L. a. b. color space

Control periods of samples were shown in Table 2

Table 2. Control Periods of Test

Test	Control 1	Control 2	Control 3	Control 4	Control 5	Control 6	Control 7	Control 8	Control 9
SAE J 2527 (kj)	0 (Natural)	500	1000	1500	2000	2500	-	-	-
Outdoor Aging (Year)	0 (Natural)	-	-	-	-	-	1	2	3

3. RESULTS

After aging periods that defined in Table 2, panels are conditioned in laboratory condition for six hours. As first step, 20º gloss controls were performed. Figure 5 shows gloss change values of SAE J2527 at 45º test and Figure 6 shows gloss change values of outdoor natural aging test.

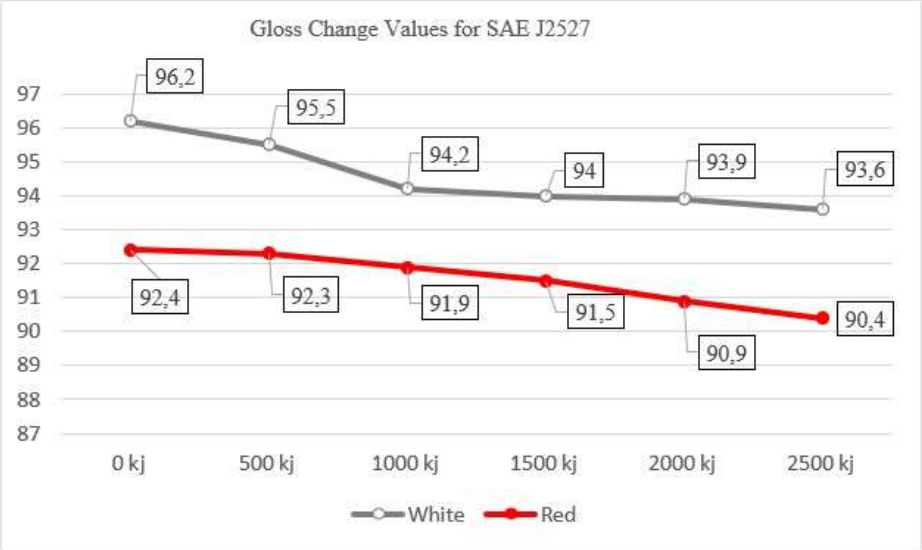

Figure 5. Gloss Change Values for SAE J2527 Test Results (upper side ; more glossy)

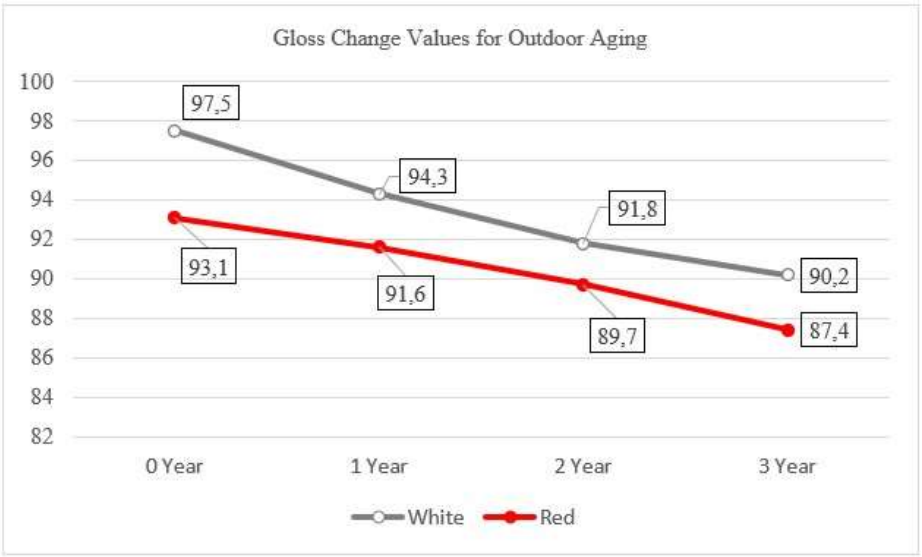

Figure 6. Gloss Change Values for Outdoor Aging Test Results (upper side ; more glossy)

It can be observed from Fig. 5 & 6 that gloss changing values are not so different for both test method. Outdoor natural aging test has slightly more effects on gloss changing level for both colours.

Figure 7 and 8 are showing L (Lightness/ Whiteness) values of both paints. Figure 7 shows L value changes of SAE J2527 test and Figure 8 shows L value changes of outdoor natural aging test

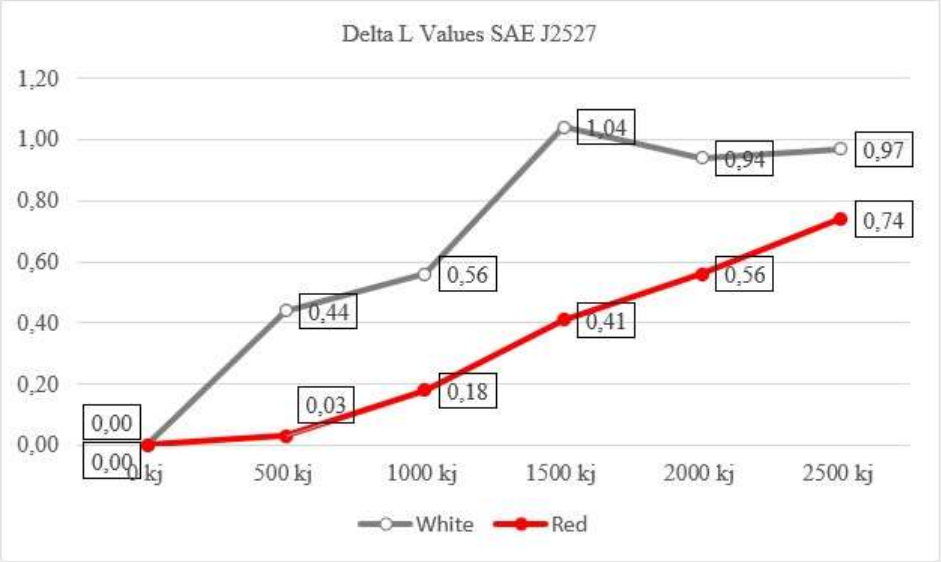

Figure 7. L value changes for SAE J2527 Test Results (upper Side ; darker)

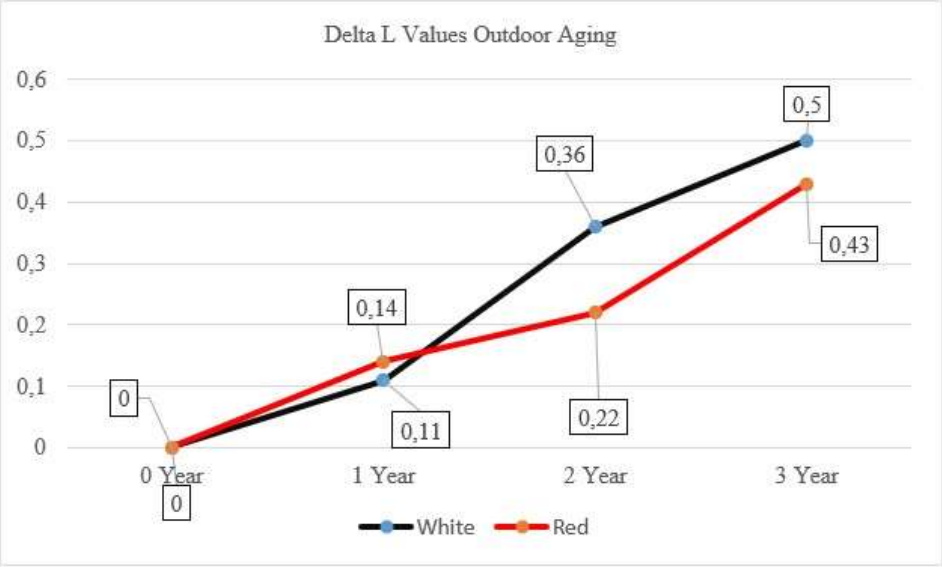

Figure 8. L value changes for Outdoor Aging Test Results (upper side ; darker)

It can be observed from Fig. 7 & 8 that L values changes were not critical for both test methodology and materials. Both materials were shows darkening effect from natural condition. SAE J2527 test result were showing slightly higher difference.

Figure 9 and 10 are showing ‘a’ (a ; + red, a ; - green) values of both paints. Figure 9 shows ‘a’ value changes of SAE J2527 test and Figure 10 shows ‘a’ value changes of outdoor natural aging test.

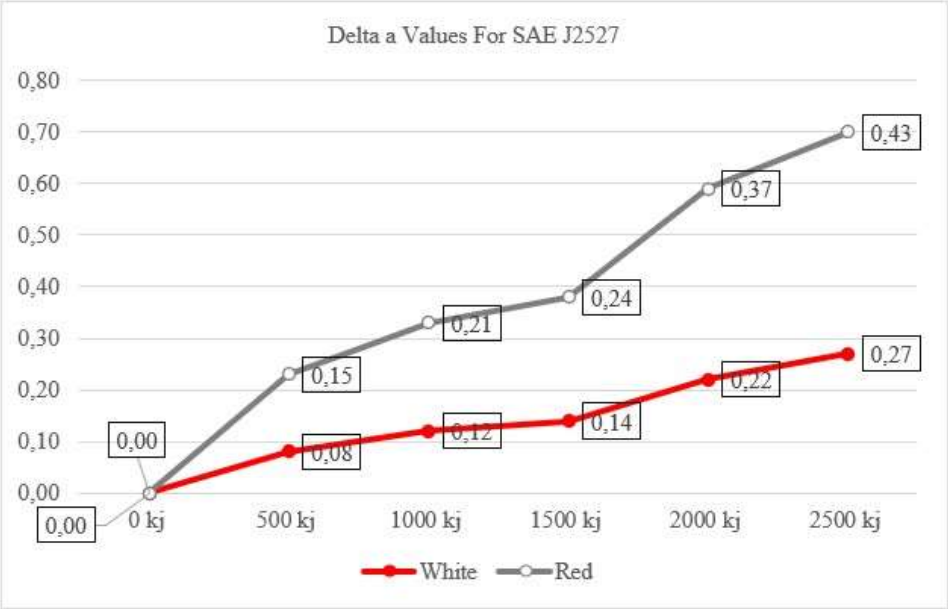

Figure 9. 'a' value changes for SAE J2527 Test Results (upper side; more green)

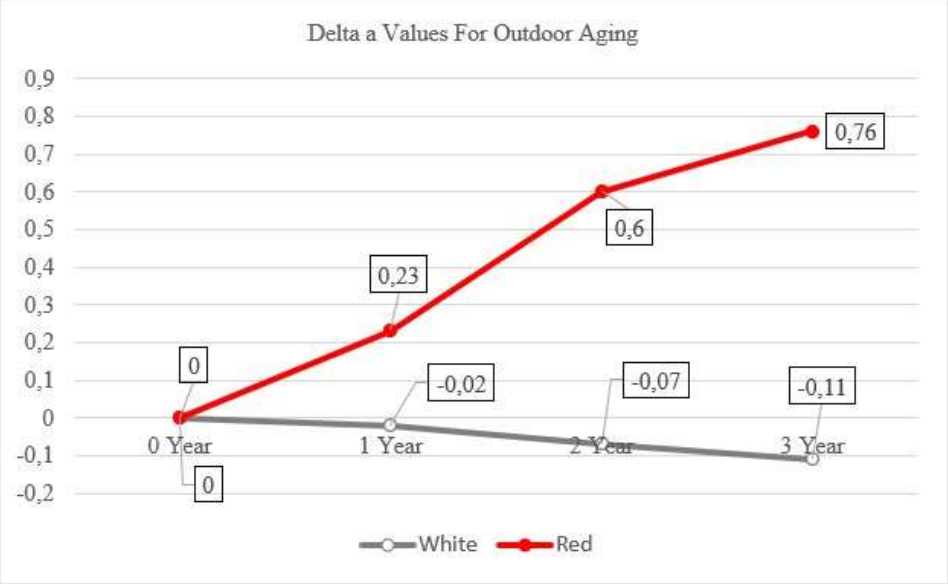

Figure 10. 'a' value changes for Outdoor Aging Test Results (lower side; more red)

It can be observed from Fig. 9 & 10 that 'a' values changes were not critical for red colour. Outdoor natural aging test has more effect on red colour. Both materials were directing the green area (a-)

On the other hand, white colour has no same situation with red colour. 'a' values are not critical and slightly different from both test but curves of 'a' values were not in same direction. That shows us SAE J2527 test effected 'a' values to slightly green side and outdoor natural aging test effected 'a' values to slightly red side.

Figure 11 and 12 are showing 'b' (b ; + yellow, b ; - blue) values of both paints. Figure 7 shows 'b' value changes of SAE J2527 test and Figure 8 shows 'b' value changes of outdoor natural aging test

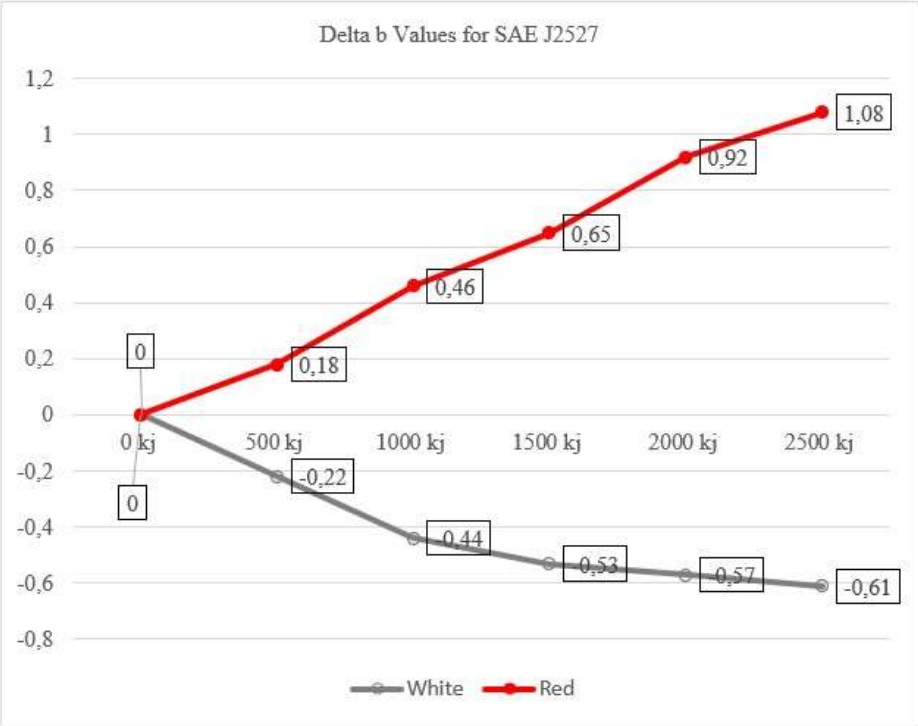

Figure 11. 'b' value changes for SAE J2527 Test Results (upper side; more blue)

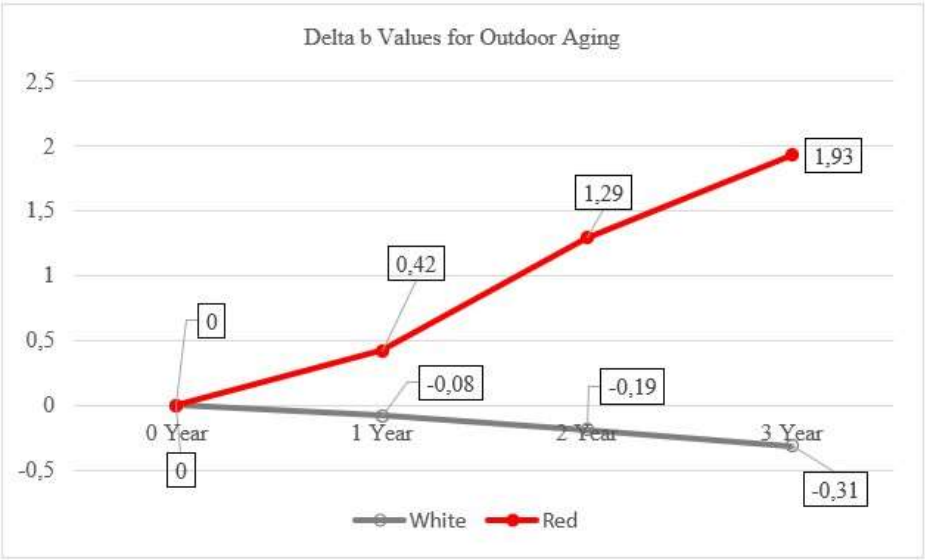

Figure 12. 'b' value changes for Outdoor Aging Test Results (lower side; more yellow)

It can be observed from Fig. 11 & 12 that 'b' values changes were not critical for white color. Both materials directed to yellowish (b+) side with slight difference.

Same situation was not valid for red color. There are different color changes for both test methods. It is clear that both test methods effecting red colour to 'b' values. Because both curves were directed to blue side. from fig. 12, change of 'b' values shows, colour would be more bluish in terms of more outdoor exposure. Also

4.CONCLUSIONS & RECOMMENDATIONS

In this study, accelerated aging and Bursa City Outdoor Natural aging condition were investigated for solid white and solid red color. SAE J2527 samples were controlled in every 500 kj, Outdoor aging test were controlled in every year to understand curve of changings. In order to understand changings, 20º gloss and 45º Color with CIELAB L.a.b. color system were measured.

Gloss changings and comparison of both methods indicated that there are no big and critical difference for both materials and methodology. We could clearly assume that both test methodologies and durations are same effect and very correlated with each other.

Color changing and comparison of both methods indicated that there are difference for both materials and methodology is aspect of 'L' values. White color has been effected in different way for both test methodology in aspect of 'a' values. Because curves of changes directing different axis. Outdoor aging given very slight red effect to color opposite to SAE J2527 test.

On the other hand, most critical changes were observed on red color's 'b' values. Because both tests show more than one delta values could be critical in aspect of bluish. Also outdoor aging test showed more effect on 'b' values than SAE J2527 test. In case of long outdoor exposure this value could be critical in aspect of visual change.

ÖZET

Araçlarda yakıt dolum borusu ile başlayan ve enjektörlere kadar uzanan hat, yakıt hattı olarak tanımlamaktadır. Yakıt hatları üzerinde basıncı ayarlayıcı bazı elemanlar bulunmaktadır. Bu elemanlarla birlikte yakıt hatları düşük basınç ve yüksek basınç olarak ayrılmaktadır. Basınç değiştirici elemanlar vasıtasıyla yapılan değişiklerle hattaki basınçta bir dalgalanma meydana gelmektedir. Bu dalgalanma değerleri belirli bir yükseklik altında sistemin elemanları tarafından sönümlendiği için sorun oluşturmazken bu dalgalanma değerlerinin yüksekliği arttıkça özellikle araç gövdesi gibi sabit bağlantı bölgelerinde yüksek iletim yapıp vibrasyona ve bazı durumlarda araç içinden bile duyulabilecek bir sese sebebiyet vermektedir. Bu makalede yakıt hatlarındaki basınç dalgalanmasının sebepleri ve oluşturduğu sonuçların önlenmesi için yapılabilecek alternatif çözümlerin karşılaştırmalı olarak incelenmesi için yapılan fiziksel denemelerin sonuçları sunulmuştur.

EXPERIMENTAL STUDIES ABOUT DAMPING OF THE VIBRATION ON FUEL LINES

ABSTRACT

There are some pressure adjusting elements on the fuel lines from the fuel tank to the injectors of the vehicles. With these elements, the fuel lines are divided into low pressure and high pressure. A fluctuation occurs on the pressure in the line with the changes made by the pressure changing elements. These fluctuation values do not cause a problem as they are damped by the elements of the system under a certain height, but as this height increases, it causes high transmission and vibration, especially in fixed connection areas such as the vehicle body. In this article, the results of physical trials conducted to comparatively examine the causes of pressure fluctuations in fuel lines and alternative solutions that can be made to prevent their consequences are presented.

Keywords: Fuel, Fuel line, Vibration, Pressure

1. GİRİŞ

İçten yanmalı motora sahip araçlarda motorun çalışması için gerekli olan yakıtı yakıt deposundan alıp motora iletilmesi için yakıt boruları kullanılmaktadır. Buna ek olarak bazı motor tiplerinde, motora kadar iletilen ancak motorda kullanılmayan yakıtın depoya geri dönmesi içinde yakıt boruları kullanılmaktadır.

Yakıt depodan düşük basınçlı yakıt pompası ile alınan yakıt, araç taban altından ilerleyen borular vasıtasıyla sırasıyla yakıt filtresi (eğer dizel versiyon ise), motor üstünde bulunan yüksek basınç pompası, sabit yakıt basıncı ayarlama yolu ve enjektörlere iletilir. Bu iletim hattı basınç bakımından iki kısma ayrılmaktadır. Bunlar düşük basınç hattı ile yüksek basınç hattı olarak adlandırılmaktadır.

Yakıt depodan başlayarak motor girişindeki yüksek basınç pompasına kadar olan hat ‘düşük basınç hattı’ (Şekil 1) olarak adlandırılmaktadır. Bu hatta bulunan düşük basınç pompası, basınç değişkenliğini sağlamaktadır. Bazı araçlarda düşük basınç pompası motor üstünde de bulunabilir. Bu pompa sabit debili olabildiği gibi motorun anlık isteklerine

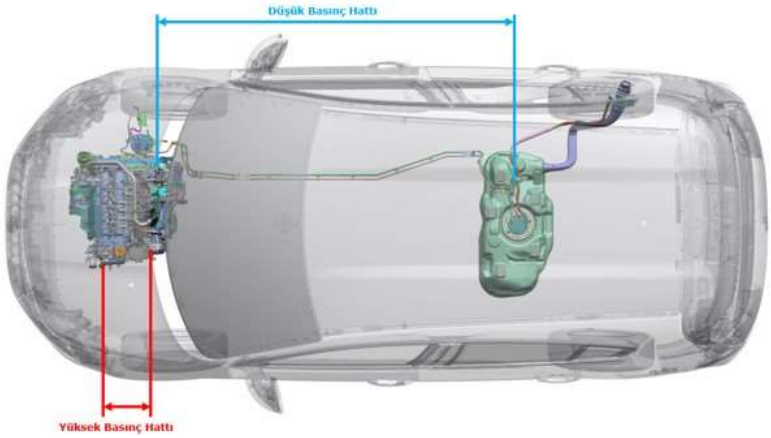
cevap verebilen darbe genişlik modülasyonu (PWM) kontrolü ile sürülebilen değişken debili bir pompa da olabilir. Örnek olarak, araç düz yolda sabit devirde ve ortalama hızla giderken düşük yakıt tüketimi yapacağı için PWM kontrollü pompa tarafından motora daha az yakıt gönderilir. Ancak motor yüksek hızlarda, devirlerde ve dikey eğimli yollarda ilerlerken yüksek yakıt tüketeceği için PWM kontrollü pompa tarafından motora daha fazla yakıt gönderilir.

Yüksek basınç pompası ile enjektörler arasında kalan hat 'yüksek basınç hattı' olarak adlandırılmaktadır. Bu hatta yüksek basınç pompasına giren yakıt basınçlandırılarak enjektörlere iletilir. Bu basınçlandırma esnasında çok yüksek basınç değerlerine ulaşılır.

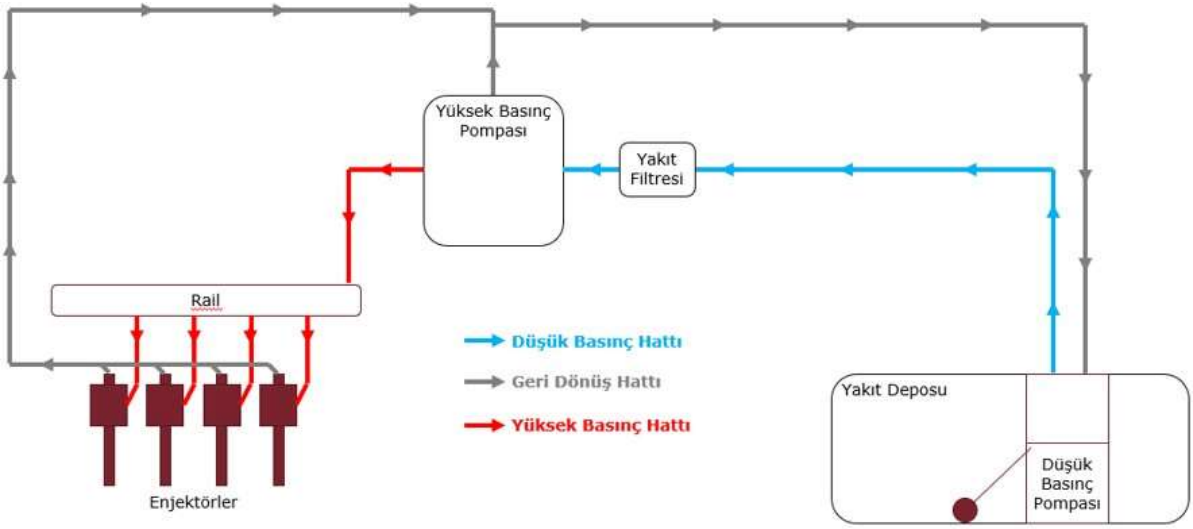
Yüksek basınç pompası tarafından basınçlandırılmayan yakıt, geri dönüş hattı vasıtası ile yakıt depoya geri gönderilmektedir. Bu yakıta ek olarak geri dönüş hattı ile enjektörlerde kullanılmayan yakıt da tekrar kullanım için yakıt depoya geri gönderilmektedir.

Yakıt deposundan enjektörlere uzanan yakıt hatları üzerinde basıncı ayarlayıcı elemanların varlığı sebebiyle yapılan basınç değişiklikleri hattaki basınçta bir dalgalanma meydana getirmektedir. Bu dalgalanma basınç değiştirici elemanların hassasiyetleri ile ilgilidir. Basınçlandırma yaparken tek seferde yapılan yüksek hacimli basınçlandırma işlemi dalgalanma boyutunu artırmaktadır. Bunun yerine çok seferde düşük hacimli basınçlandırma tercih edilmelidir. [3], [2]

Bu dalgalanma değerleri belirli bir yükseklik altında sistemin elemanları tarafından sönümlendiği için sorun oluşturmazken bu yükseklik arttıkça motor çalışma koşulları ile çakışma olan frekanslarda özellikle araç gövdesi gibi sabit bağlantı bölgelerinde yüksek iletim yapıp vibrasyona sebebiyet vermektedir. [4]



Şekil 1. Araç üstü yakıt hatları gösterimi



Şekil 2. Araç üstü yakıt hatları şematik gösterimi

2. DENEYSEL TASARIM VE TEST KOŞULLARI

Bu çalışmada yakıt hattındaki basınç değiştirici elemanların çalışma sırasındaki yakıt basıncına etkisi ve meydana getirdikleri basınç değişkenliğinin nasıl düşürülebileceği aşağıda belirtilen şartlar ve ekipmanlarla birlikte araç üstü fiziksel denemeler yaparak incelenmiştir.

Denemeler sırasında kullandığımız ekipmanların detaylı özellikleri aşağıda belirtilmiştir.

- Bir araç
- Dizel bir motor
- Düşük basınç pompası
- Yüksek basınç pompası
- Yakıt iletim hatları
- Basınç sönümleyici eleman
    - Kauçuk yakıt borusu: Plastik veya metal olan yakıt boru hattının bir kısmını kauçuk malzeme ile değiştirerek sönümlemeyi borunun kendisinin yapması sağlanabilir. [1]
    - Sönümleyici eleman içeren bağlantı noktaları: Yakıt borusunun araç üstüne bağlandığı noktalarda bulunan bağlantı elemanlarının boruyu tutan kısmına kauçuk eklentiler yaparak borunun içindeki basınç değişimi sönümlenebilir.
    - Sönümleyici boş hacim: Yakıt boru hattına seri olarak bağlanan ve rezonatör görevi gören boş bir hacimdir. Bu hacim içine giren yakıt basınç değişkenliğini kaydedip sabit basınçla devam edebilir. Bu şekilde basınç değişimi sönümlenebilir. [4]
    - Sönümleyici boş hacim + 3,5 bar yaylı sistem: Yakıt boru hattına seri olarak bağlanan ve rezonatör görevi gören boş bir hacimdir. Bu hacim aynı zamanda içinde bir yay barındırır. Bu yayla birlikte yakıt geçen bölge arasında yayın hareketi sönümlemesine izin veren esnek yapıda bir membran bulunur. Bu hacim içine giren yakıt basınç değişkenliğini kaydedip sabit basınçla devam edebilir. Yay 3,5 bar kuvvete sahiptir. Bu şekilde basınç değişimi sönümlenebilir.
    - Sönümleyici boş hacim + 4,5 bar yaylı sistem: Yakıt boru hattına seri olarak bağlanan ve rezonatör görevi gören boş bir hacimdir. Bu hacim aynı zamanda içinde bir yay barındırır. Bu yayla birlikte yakıt geçen bölge arasında yayın hareketi sönümlemesine izin veren esnek yapıda bir membran bulunur. Bu hacim içine giren yakıt basınç değişkenliğini kaydedip sabit basınçla devam edebilir. Yay 4,5 bar kuvvete sahiptir. Bu şekilde basınç değişimi sönümlenebilir.
    - Sönümleyici boş hacim + 5,5 bar yaylı sistem: Yakıt boru hattına seri olarak bağlanan ve rezonatör görevi gören boş bir hacimdir. Bu hacim aynı zamanda içinde bir yay barındırır. Bu yayla birlikte yakıt geçen bölge arasında yayın hareketi sönümlemesine izin veren esnek yapıda bir membran bulunur. Bu hacim içine giren yakıt basınç değişkenliğini kaydedip sabit basınçla devam edebilir. Yay 5,5 bar kuvvete sahiptir. Bu şekilde basınç değişimi sönümlenebilir.
    - PWM kontrollü düşük basınç pompası iptali: PWM kontrollü pompalar motorun isteğine göre yakıt iletimi yaptıkları için yakıt hattı içinde bir dalgalanmaya sebebiyet verirler. Bu dalgalanmanın olmaması için sabit debili bir pompa kullanılabilir.

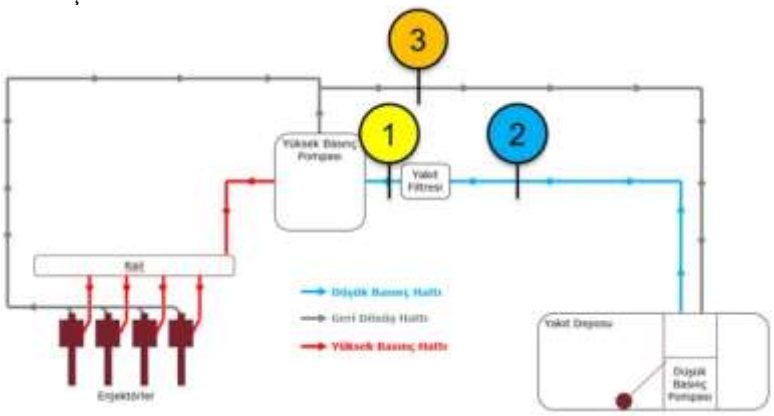
Yakıt hatlarındaki basınç değişkenliğini düşürmek için yukarıda belirtilen alternatifler sırası ile denenmelidir. Bu denemeler esnasında yakıt boru üstüne uygulanacak basınç sönümleyici elemanların önüne ve arkasına etkisini görebilmek için basınç ölçer eklemek gereklidir. Bu şekilde alınacak verilerde basıncın kabul edilebilir limitler içinde salınıp salınmadığı görülebilir.

Alternatif sönümleyicileri çözümlerinin basınç değişimine etkisini incelemek için ilk olarak normal şartlar altında +24°C sıcaklıkta sürüş koşulları (rüzgâr, hız vb.) gerekmeden test yapılmalıdır. Buradaki etki incelendikten sonra araç için daha zorlayıcı olan düşük hava sıcaklıklarındaki(-20°C) davranışları incelenmelidir. Bunun sebebi malzemelerin düşük sıcaklık şartlarında daha sert ve kırılgan bir yapıda olması sebebiyle sönümleme elemanı etkisinin azalmasıdır. Düşük sıcaklık testine başlamadan önce araç üstündeki bütün parçaların ortam sıcaklığı olan sıfırın altında -20°C'ye şartlanabilmesi için araç emisyon laboratuvarında bulunan klimatik kabinde 8 saat boyunca motor kaputu açık olarak, serbest koşullarda bekletilmelidir. Bu koşullarda araç boş vites durumunda, bütün devir aralıklarını tarayacak şekilde ses ve basınç değişimi ölçümüne tabi tutulmalıdır.

Son olarak bu ölçümleri numerik olarak yapmanın yanı sıra, müşteri gözüyle değerlendirme için sübjektif değerlendirme de yapılmalıdır.

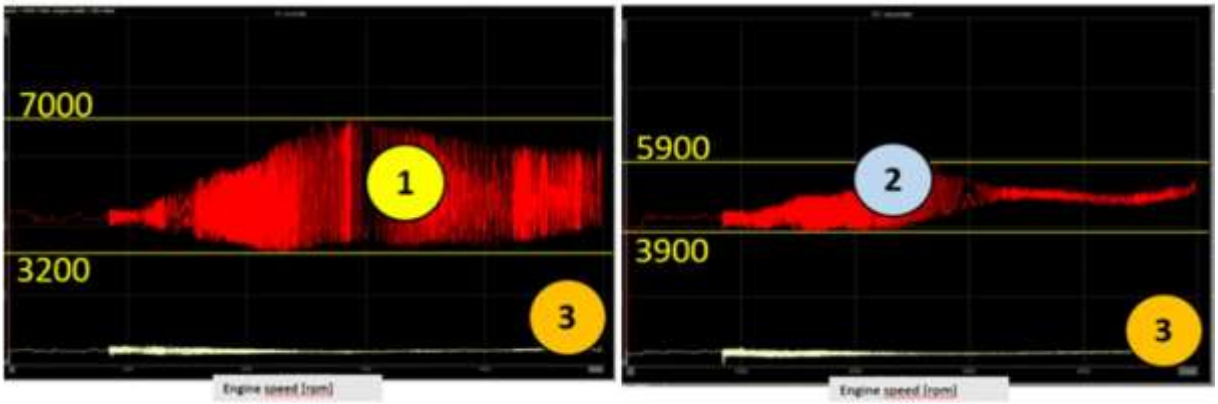
3. SONUÇ VE TARTIŞMALAR

Yapılan çalışmada ilk olarak mevcut durumun analizi gerçekleştirilmiştir. Bunun için araç üstünde aşağıdaki şekilde şematik olarak gösterilen sistemimizin belirlediğimiz 3 noktasından basınç ölçüm değerleri alınmıştır. Buna göre bütün devir aralığını tarayarak basınç dalgalanmasını gözlemlenmiştir. Bu şekilde basınç sönümleyici elemanların nereye eklenmesi gerektiği belirlenmiştir.



Şekil 3. Araç üstü sensör yerleşimi şematik gösterimi

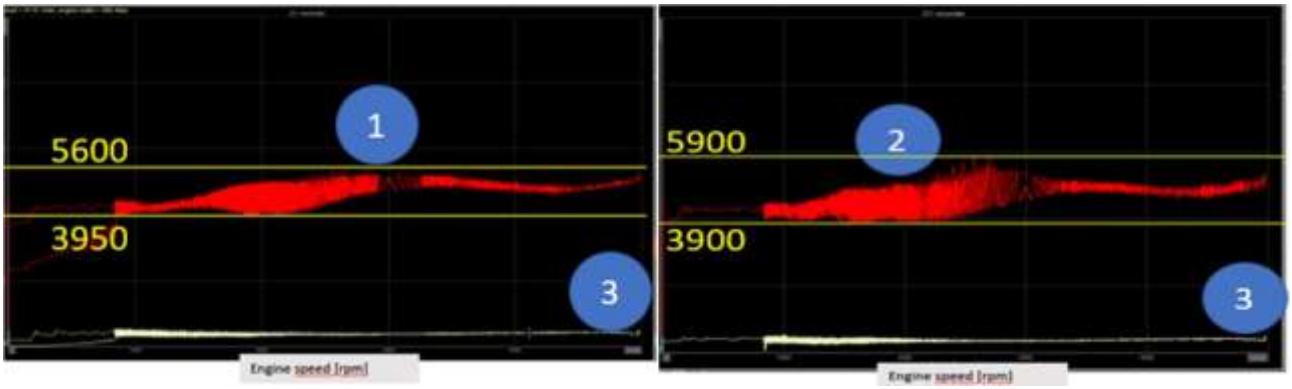
Aşağıda grafiklerle belirtilen analiz sonuçlarına göre 1 numara ile gösterilen yakıt filtresi ile yüksek basınç pompası arasında bulunan basınç sensörü 3200xbar ile 7000xbar arasında salınım yapmaktadır. 3 numara ile belirtilen geri dönüş hattında ise herhangi bir basınç dalgalanması bulunmamaktadır. 2 numara ile belirtilen yakıt filtresi öncesinde ise 3900xbar ile 5900xbar arasında bir salınım vardır. Bu veriler ışığında en yüksek dalgalanmanın 1 numara ile gösterilen yakıt filtresi ile yüksek basınç pompası arasında olduğu belirlenmiştir. Dolayısıyla buraya ekleyeceğimiz bir basınç sönümleyici bu basınç dalgalanma problemini ortadan kaldırabilir. Aşağıdaki ölçümden çıkarılacak bir diğer sonuç ise yakıt filtre elemanının bir basınç sönümleyici olarak çalışmasıdır. Filtre hem basınç alt limitini hemde üst limitini sınırlandırabilmiştir. Ancak yine de çok büyük bir iyileştirme yapamamıştır. Burada asıl dikkat edilmesi gereken nokta yüksek basınç pompası çalışmasından dolayı oluşan basınç dalgalanmasının hattın akış yönünün tersi yönde olmasıdır.



Şekil 4. 1 ,2 ve 3 numaralı noktalara ait basınç ölçümü

İlk alternatif basınç sönümleme elemanımız olan kauçuk yakıt borusu yüksek basınç pompası ile yakıt filtresi arasına eklenerek aynı ölçüm tekrarlanmıştır. Boy miktarı artırılarak denemeler yapılmış olup en son 1 metre uzunluğunda bir kauçuk boru ile istenilen basınç düşüşü sağlanabilmiştir. Bu çözüm ile basınç üst noktası 7000xbar seviyesinden 5600xbar seviyesine düşmüştür. Yine alt noktası ise 3200xbar seviyesinden 3950xbar seviyesine çıkmıştır. Basınç dalgalanma aralığı düşürülmüştür. Ancak bu kadar uzun bir borunun araç üstünde değerlendirilmesi mümkün değildir.

Şekil 5. Birinci alternatif basınç düşürücü eleman görseli



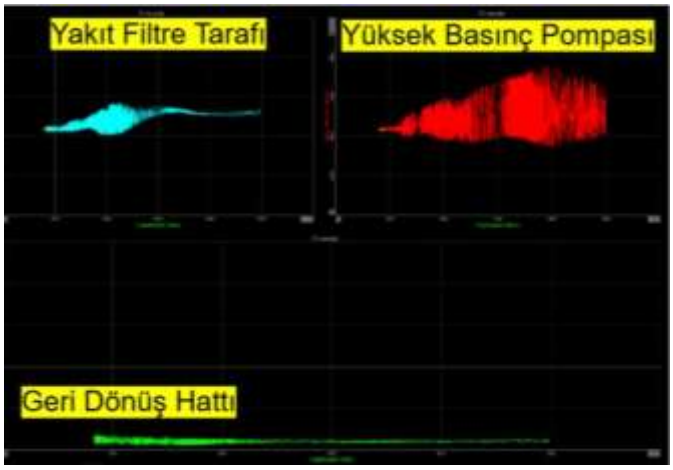
Şekil 6. 1 ,2 ve 3 numaralı noktalara ait basınç ölçümü

İkinci alternatif basınç sönümleme elemanımız olan sönümleyici eleman içeren bağlantı noktaları yakıt borusunun araç üstüne bağlandığı noktalarda borunun hareketini sönümleyebilir. Bu parçalar yakıt borunun araç bağlantı noktalarının hepsinde kullanılabileceği gibi basınç dalgalanma oluşumuna en yakın bağlantı noktalarında da kullanılabilir. Bu parçalar bütün bağlantı noktalarına eklenerek aynı ölçüm tekrarlanmıştır. Bu çözüm ile basınç değerlerinde bir değişim görülmemiştir. Ancak ses ölçümlerinde az da olsa bir iyileşme olmuştur.

Şekil 7. İkinci alternatif basınç düşürücü eleman görseli

Üçüncü alternatif basınç sönümleme elemanımız olan sönümleyici boş hacim yüksek basınç pompası ile yakıt filtresi arasına eklenerek öncesinde ve sonrasında basınç ölçümü yapılmıştır. Bu çözüm ile basınç üst noktası düşmüştür ve alt noktası yükselmiştir. Basınç dalgalanma aralığı düşürülmüştür. Ancak bu çözüm ses ölçümlerinde bir iyileştirme sağlayamamıştır.

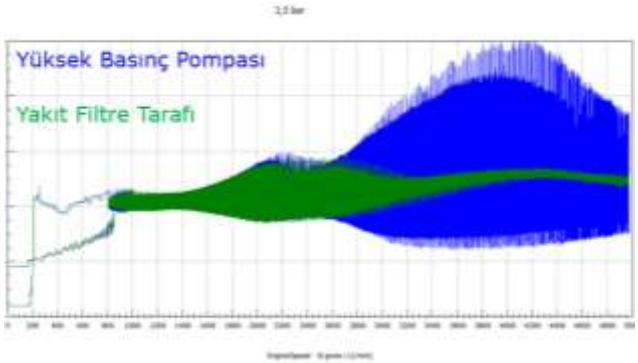
Şekil 8. Üçüncü alternatif basınç düşürücü eleman görseli



Şekil 9. Üçüncü alternatif basınç düşürücü eleman araç üstü basınç ölçümü

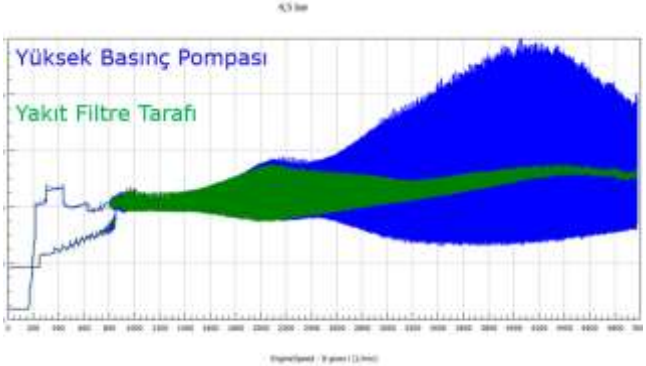
Dördüncü alternatif basınç sönümleme elemanımız olan sönümleyici boş hacim + 3,5 bar yaylı sistem yüksek basınç pompası ile yakıt filtresi arasına eklenerek öncesinde ve sonrasında basınç ölçümü yapılmıştır. Bu eleman özellikle yüksek devirlerde çok iyi bir basınç sönümleme etkisi göstermiştir. Ancak ses ölçümlerinde az bir iyileşme sağlayabilmiştir. Yine müşteri gözüyle değerlendirme de ise kabul edilebilir limitin altında kalmaktadır.

Şekil 10. Dördüncü, beşinci ve altıncı alternatif basınç düşürücü eleman görseli



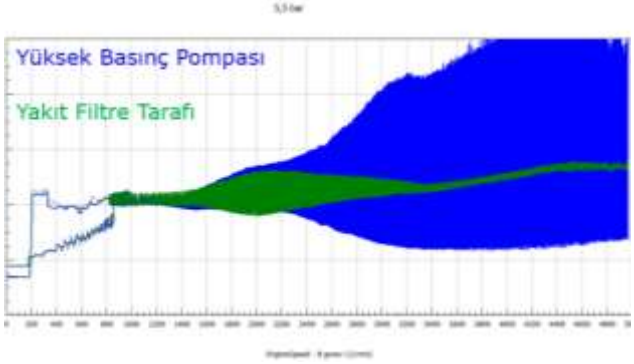
Şekil 11. Dördüncü alternatif basınç düşürücü eleman araç üstü basınç ölçümü

Beşinci alternatif basınç sönümleme elemanımız olan sönümleyici boş hacim + 4,5 bar yaylı sistem yüksek basınç pompası ile yakıt filtresi arasına eklenerek öncesinde ve sonrasında basınç ölçümü yapılmıştır. Bu eleman özellikle yüksek devirlerde çok iyi bir basınç sönümleme etkisi göstermiştir. Ses ölçümlerinde de bir iyileşme sağlayabilmiştir. Müşteri gözüyle değerlendirme de ise kabul edilebilir limitin üstündedir.



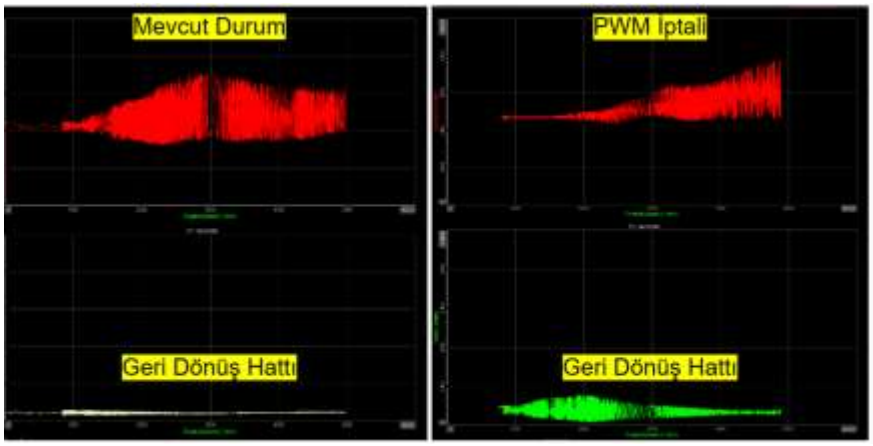
Şekil 12. Beşinci alternatif basınç düşürücü eleman araç üstü basınç ölçümü

Altıncı alternatif basınç sönümleme elemanımız olan sönümleyici boş hacim + 5,5 bar yaylı sistem yüksek basınç pompası ile yakıt filtresi arasına eklenerek öncesinde ve sonrasında basınç ölçümü yapılmıştır. Bu eleman özellikle yüksek devirlerde çok iyi bir basınç sönümleme etkisi göstermiştir. Ses ölçümlerinde de bir iyileşme sağlayabilmiştir. Müşteri gözüyle değerlendirme de ise kabul edilebilir limitin üstündedir ve diğer alternatiflere göre en iyi durumda olan çözümdür.



Şekil 13. Altıncı alternatif basınç düşürücü eleman araç üstü basınç ölçümü

Yedinci alternatif olarak PWM kontrollü düşük basınç pompası iptal edilerek yerine sabit debili düşük basınç pompası eklemiştir ve aynı ölçüm tekrarlanmıştır. Aşağıdaki şekilde görüleceği üzere PWM iptali düşük devirlerde yakıt besleme hattında bir basınç düşüşü sağlasa da geri dönüş hattında basınç dalgalanmasında artış gözlemlenmiştir.



Şekil 14. Yedinci alternatif basınç düşürücü eleman araç üstü basınç ölçümü

Bütün alternatifleri denedikten sonra basınç sönümlemesinde iyi olan alternatifler için araç üstü ses ölçümü ve müşteri gözüyle değerlendirme yapılmıştır. Buna göre sonuçların karşılaştırmalarını aşağıdaki tabloda sunulmuştur.

Tablo 1: Yedi alternatif basınç düşürücü eleman karşılaştırması

Alternatif No	Basınç	Ses	Müşteri Gözüyle Değerlendirme
1	+	0	0
2	X	0	X
3	+	X	X
4	+	0	0
5	+	+	+
6	+	+	0
7	X	X	X

+: İyileşme var
X: İyileşme yok
0: Az iyileşme var

Bu çalışmada depodan enjektörlere kadar olan yakıt iletim sisteminde bulunan yakıt basıncı ayarlayıcı pompaları kaynaklı olan yakıt basınç dalgalanmasını önlemek için kullanılan basınç sönümleyici alternatiflerin birbirine göre deneysel olarak karşılaştırması yapılmıştır.

Yakıt basınç dalgalanması için yaptığımız ölçümlerde normal şartlar altında (+24°C) herhangi bir problem görülmeyen çalışma koşulları olmuştur. Ancak araç çalışma şartlarının daha zor olduğu -20°C sıcaklıklarda problemler görülmüştür. Bu sebeple bundan sonra yapılacak çalışmalarda sıcaklık olarak en kötü durumu düşünerek analizler yapılması gerekmektedir.

Bu çalışmanın devamında farklı yüksek basınç pompa tipleri ve benzinli motor tipleri dahil olmak üzere motor kombinasyonları ile bu çalışma genişletilip genel bir basınç sönümleyici eleman kullanımı matrisi oluşturulabilir. Bu şekilde oluşturulacak bir matris ile gelecek projelerde tasarım sırasında seçilecek motor ve yüksek basınç pompası kombinasyonlarında sönümleyici elaman gerekli olup olmadığını araç üretip fiziksel test yapmadan belirleyebiliriz.

4. TEŞEKKÜRLER

Yaptığımız çalışmalarda laboratuvar imkanlarını bize sunan Tofaş Emisyon Laboratuvarı ve çalışanlarına teşekkürler.

ÖZET

Bu çalışmada kardan mili seçiminde etkili başlıca parametrelerden biri olan kritik hız faktörü araştırılmıştır. Çalışmanın amacı, şanzıman ve diferansiyel arasında ön ve arka kardan milinin birlikte kullanımı olan bir ağır ticari araç uygulamasında, aynı yerde tek bir kardan mili kullanımına olanak sağlamaktır. Bu konuda yapılan çalışmalar, mevcut bir ağır ticari araç uygulaması üzerinde yapılmıştır. Öncelikle mevcut araç uygulamasındaki durum kritik hız teorisi açısından değerlendirilerek aynı araçta tek parçalı kardan mili kullanımına olanak sağlayacak boru boyutu belirlenmiştir. Giriş maliyetini minimize etmek amacıyla ilk etapta yeni boru ile mevcut parçaların montajını sağlayacak adaptör parça tasarlanarak numune kardan mili üretilmiştir. Numune kardan mili araç üzerinde NVH testine tabii tutulmuştur. Test sonucunun olumlu sonuçlanması ile birlikte yeni boru boyutuna uygun birim parçalar tasarlanmıştır. Böylece adaptör kullanımı elimine edilerek tasarım seri üretime uygun hale getirilmiştir. Yeni birim parçaların tasarımı sürecinde Altair HyperWorks programı ile sonlu elemanlar metodu uygulanarak model analizleri gerçekleştirilmiştir. Yeni birim parçalar ile numune kardan mili üretilerek Tirsan Kardan bünyesinde statik burulma ve yorulma testlerine tabii tutulmuştur. Testlerin olumlu sonuçlanması ile birlikte ürün doğrulama süreci tamamlanmıştır. Yeni ürün ile birlikte çalışma yapılan ağır ticari araçta tek bir kardan mili kullanımına geçilmiş, hem ağırlık azalması hem de maliyet iyileşmesi sağlanmıştır.

Anahtar kelimeler: Kardan mili, kritik hız, sonlu elemanlar metodu, yeni ürün tasarımı

DESIGN AND PRODUCTION OF A CARDAN SHAFT BASED ON CRITICAL SPEED LIMIT INCREASE AND WEIGHT REDUCTION

ABSTRACT

In this study, the critical speed factor, which is one of the main factors during cardan shaft selection process, has been investigated. The purpose of the study is to enable the use of a single cardan shaft in an existing heavy commercial vehicle application which has combined use of the front and rear cardan shafts. Studies on this subject have been carried out on an existing heavy commercial vehicle application. The situation in the current vehicle application was evaluated in terms of the critical speed theory and the pipe size that would allow the use of single cardan shaft in the same vehicle was determined. In order to minimize the cost, an adapter part which is suitable for the new pipe and existing parts was designed and the sample cardan shaft was produced. The sample cardan shaft was subjected to NVH test on the vehicle. The usage of single cardan shaft is approved with the positive result of the NVH test, and new parts suitable for the new pipe are designed to eliminate adepter part. During new part design, the finite element method was carried out with Altair HyperWorks application. The sample cardan shaft was produced with new parts and was subjected to static torsion and fatigue tests at Tirsan Kardan. With the positive results of the tests, the product verification process has been completed. As result of the study, a single cardan shaft is now being used on the selected heavy commercial vehicle, and both weight reduction and cost improvement was achieved.

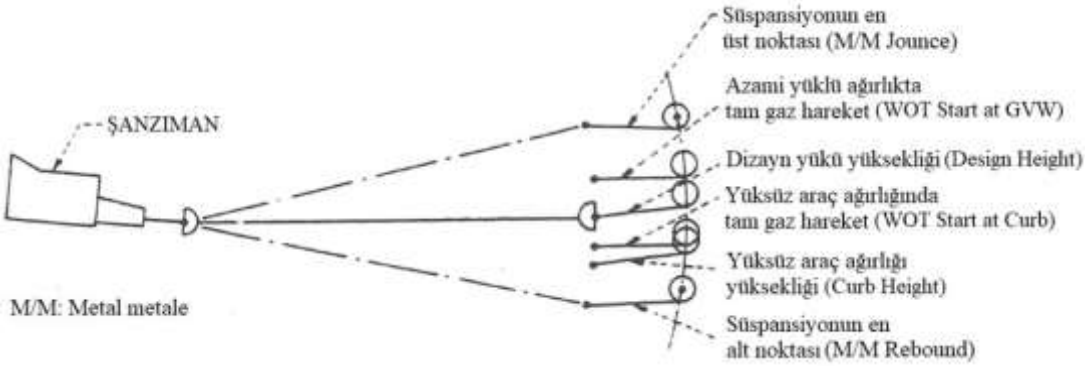
Keywords: Cardan shaft, critical speed, finite element method, new product designation

1. GİRİŞ

Kardan milleri motorda üretilen ve şanzıman aracılığı ile seviyelendirilen tork ve dönme hareketinin diferansiyele veya bir başka üniteye (transfer kutusu gibi) iletilmesinden sorumlu araç güç aktarma organıdır. Yaptığı işin doğası gereği burulma ve kesme kuvvetlerine maruz kalmaktadır. Üretiminde kullanılan malzeme çoğunlukla çeliktir ve az da olsa alüminyum ve kompozit malzeme kullanımı mevcuttur.

Klasik bir araç yerleşiminde motor aracın ön tarafına, tahrik ise arka tarafına konuşlandırılır. Kardan mili kendine oranla daha büyük kütle atalet momentine sahip olan şanzıman ve diferansiyel arasında burulma yayı gibi davranır (SAE, 1991). Böyle yerleşimdeki araçlarda şanzıman ile diferansiyel arası uzun olduğu için kullanılan kardan milleri konfigürasyonu da etkilenmektedir.

Kardan milinin birincil görevi tork ve devir iletimi olmak ile birlikte, açı değişimi ve boy değişimini de kompanse edebilmelidir. Yol düzgünsüzlükleri, araç yük durumu ve sürüş dinamiklerinden dolayı diferensiyel, konstrüksiyonel olarak izin verilen en üst nokta (M/M Jounce) ve en alt nokta (M/M Rebound) pozisyonları arasında gezer ve bu da kardan milinin açı ve boy değişimine uğramasına neden olur (Şekil 1).



Şekil 1. Arka aks hareketleri

1.1. Kardan Mili Bileşenleri ve Türleri

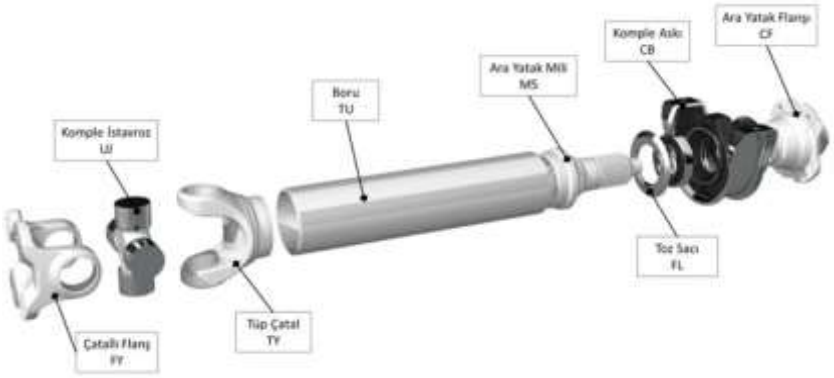
Kardan milleri, temel olarak istavroz ve istavroza bağlanan kulaklı parçaların oluşturduğu iki adet kardan mafsalı ve bu mafsalların genelde boru ile birleştirilmesiyle oluşur. Bu bağlantı literatürde üniversal mafsal veya Hooke mafsalı olarak geçmektedir. Oldukça eski bir mekanizmadır. İngiliz bilim adamı Robert Hooke, kardan mafsalının düzgün olmayan hareket karakteristiğini ve bu durumun doğru faz açıları ile giderilebileceğini keşfetmiştir (SAE, 1991).

Kardan milleri tek parçalı, 2-parçalı, 3-parçalı ve çok parçalı olarak kullanılır. İki ve daha fazla parçalılarda özel durumlar dışında eksenel hareketi sağlayan bir adet kayıcı mafsal bulunur, diğer mafsallar ise sabit mafsaldır. Tek parçalı kardan milleri ise ön kardan mili, arka kardan mili ve kısa kardan mili olmak üzere üçe ayrılabilir. Bu çalışmaya konu olan araçta ön kardan mili ve arka kardan mili olduğu için bu iki tipe değinilecektir.

Şekil 2'de görüldüğü üzere arka kardan milleri, üzerinde eksenel harekete izin veren kayıcı takım bulunan iki mafsallı ürünlerdir. Eksenel hareket, erkek parça üzerine azdırma veya grob (cold forming) ile ve dişi parça üzerine broş çekme (spline broaching) ile spline açılması ve bu parçaların birbiri üzerinde hareketi ile sağlanır. Spline profili evolvent veya kare profil olabilir.

Şekil 2. Arka kardan mili

Ön kardan milleri ise, şanzıman ile diferansiyel arasının uzun olduğu ve tek parçalı kardan mili kullanımının bu uzunluktan dolayı mümkün olmadığı durumlarda, bu uzunluğu bölmek amacıyla kullanılmaktadır. Belli uzunluktan sonra tek parçalı kardan mili kullanamamanın sebebi ileride kritik hız altında detaylı olarak açıklanacaktır. Şekil 3'te görüleceği üzere ön kardan milleri bir adet sabit mafsal, boru ve yataklama için rulman ve kauçuk takozdan oluşan askı komplesini ihtiva ederler.



Şekil 3. Ön kardan mili

Kardan mili seçiminde etkili başlıca parametreler;

- Kardan mili üzerine gelebilecek en fazla tork değeri
- Kritik hız durumu
- Yorulma ömrü
- İşletme şartları

olarak sıralanabilir. Bu maddeler, kardan milinin görevini sorunsuz şekilde yerine getirebilmesi için kontrol edilmesi gereken şartlardır. Aksi takdirde ani kırılmalar, titreşim problemleri veya kardan mili alt parçalarında (istavroz rulmanı, istavroz, askı takozu gibi) kısa sürede hasarlanmalar görülebilir.

1.2. Kritik Hız

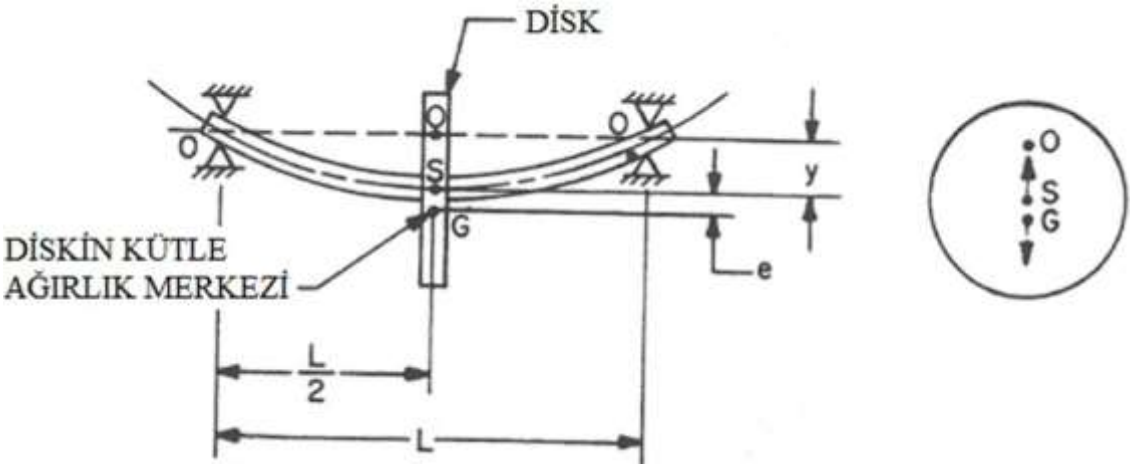
Dönen makine elemanlarının güvenli bir şekilde çalışması için hız limitini ortaya çıkaran ve whirling (dönen milin dönme ekseninden dışarıya zorlanması) terimini dönme dinamiğine katan Rankine'dir. Bu alanda araştırmalar devam etmiş ve bir çok kritik hız modunun olduğu farkedilmiştir (Crâştiu ve ark., 2018).

Dönen makine elemanlarında artan titreşim problemini çözmek için en önemli görev, bu parçaların dengesizlik derecesini minimize etmektir. Kardan milinin dengesizliği, titreşim oluşturması ile sonuçlanan en önemli nedenlerden biridir (Savaliev, 2018).

Dönen bir şaft, atlama ipi gibi eğilir ve dönme ekseninden uzaklaşır. Şaftın devri arttıkça sehim artar. Şaftı dönme ekseninden uzaklaştıran bu kuvvet, dengesizliğinden gelir. Ne kadar iyi dengelenirse dengelensin tüm şaftlar bir miktar dengesizliğe sahiptir ve bu durum kritik hız arızasına neden olacaktır. Klasik kritik hız hata modu, Şekil 4'teki örnekte görüldüğü gibi şaft burkulmasıdır (Robert, 2017).

Şekil 4. Şaft burkulması ile sonuçlanmış kritik hız hatası (Robert, 2017)

1887 yılında Carl Gustav de Laval; dönen bir şaftın hızı arttıkça her zaman sehiminin artmadığını, kritik hızından sonra devrinin arttıkça daha düzgün bir şekilde döndüğünü bulmuştur. Sistemde bir hasar meydana gelmemesi için kritik hızın hızlıca aşılması gerekmektedir (Thoss, Schmelz, Aucktor, 2006).
Literatür araştırmasından da anlaşılacağı üzere, titreşim problemleri ile karşılaşılmaması için kardan millerinin iyi bir şekilde dengelenmesi gerekmektedir. Bu nedenle üretimde kardan milleri özel istekler haricinde ISO 1940 G16 standardı doğrultusunda dengelenir; ancak üzerinde her zaman dengesizlik kalır. Bu dengesizlikten kaynaklanan santrifuj kuvvetinin, mil iç dengeleme kuvvetine eşit olduğu noktada iş parçası rezonansa girer.



Şekil 5. Merkezinde dengesiz disk bulunan mil (SAE, 1991)

Şekil 5'te iki ucundan mesnetli ve ortasında dengesiz bir yük bulunan mil yer almaktadır. G=Ağırlık merkezi, e=Eksentriklik, y=Dönme ekseninden oluşan sehim, ω= açısal hız, m=diskin kütlesi olarak adlandırılmıştır.

1894 yılında Dunkerley santrifuj kuvveti denklemini aşağıdaki gibi hesaplamıştır;

$$F_c = m \times (y + e) \times \omega^2 \tag{1}$$

Milin iç dengeleme kuvveti ise aşağıdaki gibidir;

$$F_d = k \times y \tag{2}$$

Bu iki kuvvetin birbirine eşit olması durumunda;

$$k \times y = m \times (y + e) \times \omega^2$$

$$k \times y = (m \times y \times \omega^2) + (m \times e \times \omega^2)$$

$$k \times y - (m \times y \times \omega^2) = (m \times e \times \omega^2)$$

$$y \times (k - m \times \omega^2) = (m \times e \times \omega^2)$$

$$y = \frac{m \times e \times \omega^2}{k - m \times \omega^2} = \frac{e \times \omega^2}{\frac{k}{m} - \omega^2}$$

$$\omega_n = \sqrt{\frac{k}{m}}\,; \qquad y = \pm \frac{e \times \omega^2}{{\omega_n}^2 - \omega^2}$$

Yukarıdaki eşitlikten görüleceği üzere $\omega = \omega_n$ olduğunda sehim miktarı sonsuza gider ve rezonans meydana gelir.

Buna benzer bir sonuç, belli bir noktada disk olmaksızın homojen dağılmış kendi kütlelerine sahip şaftlar için de elde edilir (Thoss, Schmelz, Aucktor, 2006):

$$\omega_1 = \frac{\pi^2}{l^2} \times \sqrt{\frac{E \times J}{\rho \times A}} \qquad (3)$$

Çelik bir mil için E (Elastisite modulü) = 2.08 x 10^{11} [N/m^2], J (Atalet momenti) = $\pi d^4/4$ [m^4], ρ (yoğunluk) = 7.8 x 10^3 [kg/m^3], A (kesit alanı) = $\pi d^2/4$ [m^2], *l* dönen parçanın uzunluğu [m] bilgileri eşitlikte yerine yazılır ise;

$$\omega_1 = \frac{\pi^2}{l^2} \sqrt{\frac{2.08 \cdot 10^{11} \cdot \pi\, d^4 \cdot 4}{7.8 \cdot 10^3 \cdot 64 \cdot \pi\, d^2}}$$

$$\omega_1 = \frac{d}{l^2} \cdot \pi^2 \cdot 0.129 \cdot 10^4 \; [rad/s]$$

Yukarıda elde edilen açısal hız değeri dev/dak'ya çevirmek için 30/π ile çarpılır;

$$n_1 = \frac{30}{\pi}\omega_1 = \frac{30}{\pi}\frac{d}{l^2} \cdot \pi^2 \cdot 0.129 \cdot 10^4 \; [dev/dak] \qquad (4)$$

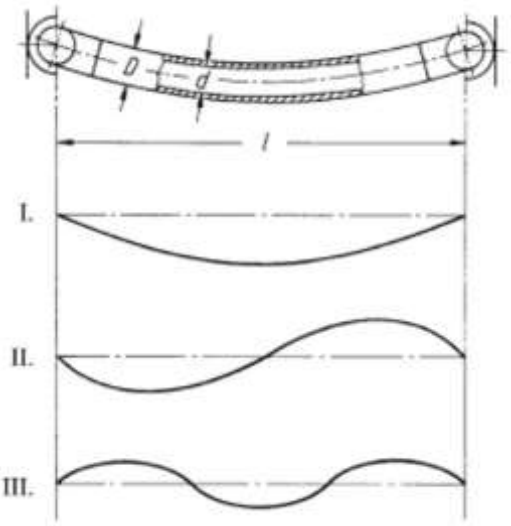
Eşitliği [mm]'ye çevirmek için 10^4 yerine 10^7 yazılır ve sonuç olarak

$$n_{k1} = 1.22 \cdot 10^8 \cdot \frac{d}{l^2} \; [dev/dak] \qquad \text{içi dolu mil için} \qquad (5)$$

$$n_{k1} = 1.22 \cdot 10^8 \cdot \frac{\sqrt{D^2+d^2}}{l^2} \; [dev/dak] \qquad \text{sabitlenmiş boru için} \qquad (6)$$

Bu eşitlik ile elde edilen hız en düşük kritik hız değerini verir. Diğer kritik hız modları harmonikleridir ve 4, 9, 16, … katlarında meydana gelir. Genel uygulamada kardan mili için birincil kritik eğilme modu çok önemlidir (Thoss, Schmelz, Aucktor, 2006).

Kritik hız değerini belirlemek için eşitlikteki uzunluk (*l*) yerine, kardan milinin rijit bir boru gibi davranacağı iki mafsal arası mesafe girilmelidir. İki mafsal arası mesafe ve kritik hız mod şekilleri Şekil 6'da görülmektedir.



Şekil 6. Kritik hız 1., 2. ve 3. mod şekilleri (SAE, 1991)

Aktarma organlarının gerçekteki kritik hızı, teorik olarak hesaplanandan biraz daha düşük olacağından, izin verilebilir maksimum operasyon hızını belirlemek için emniyet katsayısı kullanılabilir. Genel olarak binek araçlar ve hafif ticari araçlar için emniyet katsayısı olarak 0,85 kullanılırken, orta ve ağır ticari araç uygulamaları için 0,75 kabul edilmektedir (SAE, 1991).

2. MATERYAL VE YÖNTEM

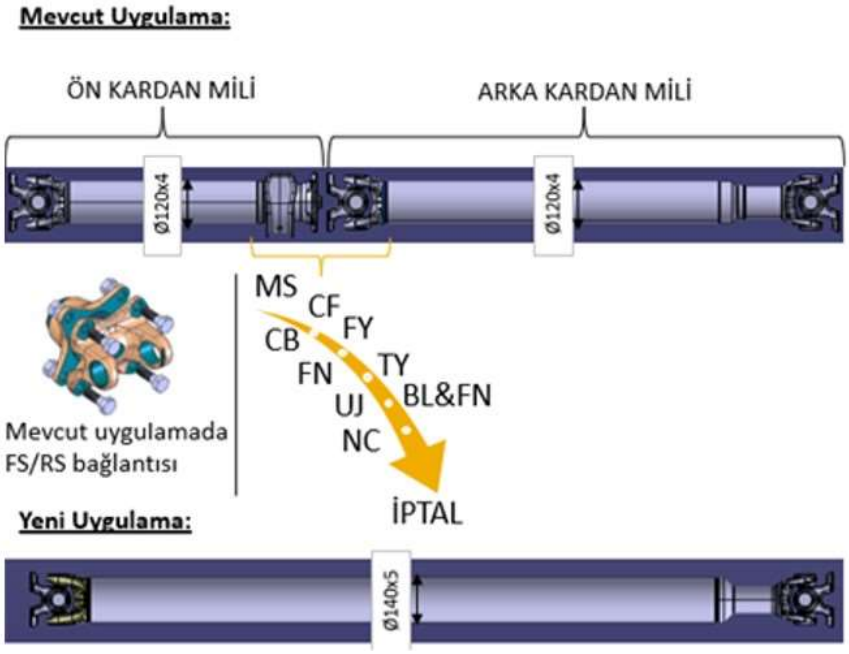
Bu çalışmada ön kardan mili ve arka kardan milinin birlikte kullanıldığı 18 tonluk 4×2 bir yol kamyonu belirlenmiştir. Bu araçta 68745 seri 935 mm boyunda ön kardan mili ve 68745 seri 1560 mm boyunda arka kardan mili kullanılmaktadır. 68745 seri kardan mili boyutunu ifade etmektedir ve bu serinin standart boru boyutu Ø120×4 mm'dir. Bu iki kardan mili yerine tek bir kardan mili kullanılması durumunda boy ihtiyacı 2495 mm olmaktadır.

0,75 katsayısı kullanılarak kritik hız hesabı yapıldığında mevcut durumda ön kardan mili kritik hız değeri 27614 dev/dak, arka kardan mili kritik hız değeri 7233 dev/dak'dır. 2495 mm boyundaki arka kardan milinin kritik hız değeri ise standart Ø120x4 boru ile 2660 dev/dak olmaktadır. Belirlenen araçta kardan milinin çalışacağı en yüksek hız 3000 dev/dak olarak belirlenmiştir. Görüleceği üzere bu araçta 2495 mm boya sahip kardan mili kullanımı kritik hız açısından uygun değildir. Uygun hale getirmek için kritik hız değerinin arttırılması gerekmektedir.

Kritik hız limiti formülasyonuna bakılırsa boru boyutları değiştirilerek kritik hız değerinin arttırılabildiği görülebilir. 2495 mm boyundaki arka kardan milinin kritik hız hesabı Ø140x5 boru ile yapıldığında kritik hız değeri 3097 dev/dak olmakta ve böylece aynı araçta tek parçalı kardan mili kullanımı uygun hale gelmektedir.

Teorik olarak kritik hız açısından bir problem olmadığı hesaplansa da gerçek durum bundan farklı olabilir. Bu neden ile tasarımın doğrulanması için yapılabilecek en iyi yöntem sahada test etmek olacaktır. Yapılacak testler için numune üretilmesi gerekmektedir; ancak mevcut 68745 seri birim parçaları tüp çatal (TY) ve kayıcı kovan (TS), Ø120x4 boru ile monte edilmeye uygundur. Numune üretilebilmesi için bu parçaların yeniden tasarlanıp Ø140x5 boruya uygun hale getirilmesi gerekmektedir. Bunun için yeni model tasarımı, analiz çalışmaları, yeni dövme kalıplarının üretimi, yeni aparat/fikstür üretimleri gerekecek ve çok yüksek maliyetler ile karşılaşılacaktır. Araç üstü NVH testinin olumsuz sonuçlanması durumunda ise bu harcamalar boşa gitmiş olacaktır. Bu nedenle mevcut birim parçalar ile yeni boru arasında köprü görevi görecek adaptör parça üretilmesine karar verilmiştir. Böylece ara bir çözüm ile hem yüksek giriş maliyetinden kaçınılmış hem de daha hızlı numune üretimi sağlanmış olacaktır.

Test safhası ikiye bölünmüştür. İlk olarak üretilecek adaptörlü numune ile araç üstünde NVH testi yapılarak ürün NVH açısından doğrulanacaktır. Devamında ise Ø140x5 boruya uygun yeni tüp çatal ve kayıcı kovan modellenip üretilecek ve Tirsan Kardan'da yapılacak yapısal testler ile ürün doğrulaması tamamlanacaktır. Şekil 7'de mevcut ve yeni uygulama arasındaki farklılık görülmektedir.

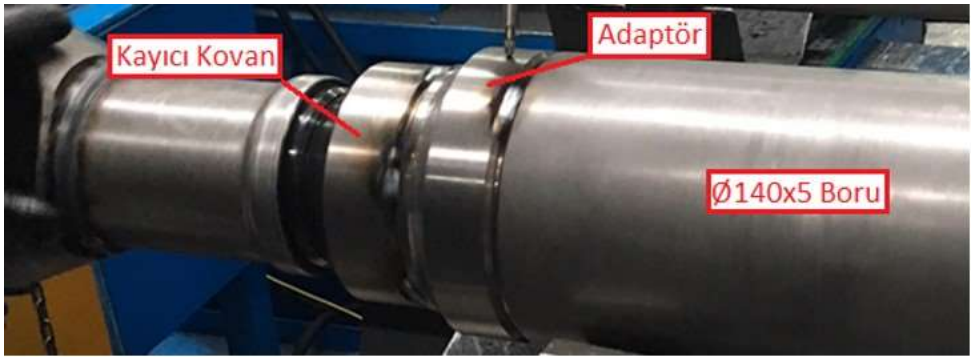


Şekil 7. Mevcut uygulama & yeni uygulamanın karşılaştırması

3. ÜRÜN TASARIMI VE NUMUNE ÜRETİMİ

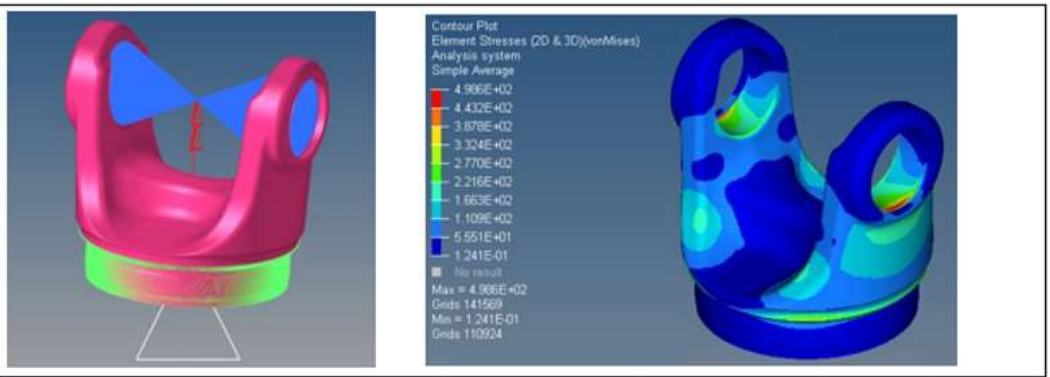
Mevcut birim parçalar ile Ø140x5 borunun montajını sağlayacak adaptör parça tasarlanmış ve dolu malzemeden işlenerek üretilmiştir. Bununla 2495 mm boyunda adaptörlü numune arka kardan mili üretilmiş ve araç testine gönderilmiştir. İleride testler bölümünde daha detaylı bahsedilecek olan araç testi olumlu sonuçlanmıştır. Bu sonuç ile

birlikte seri üretim için yeni boruya uygun tüp çatal ve kayıcı kovan tasarımına geçilmiştir. Seri üretimde adaptör kullanılmamasının nedenini açıklamak gerekirse; Şekil 8'den de görüleceği üzere adaptör parça, birim parça ve boru arasındadır ve her iki parçaya çakma operasyonu ile birleştirildikten sonra salgı alınması çok zor olmaktadır, bu durum balans kalitesini olumsuz etkilemektedir ve titreşim problemleri ile karşılaşma riski taşımaktadır. Aynı zamanda birbirine çok yakın iki kaynak dikişi olmaktadır. Bu hem kaynak kalitesini bozarak sahada kırılma riski oluşturmakta hem de operasyon süresini uzatmaktadır.



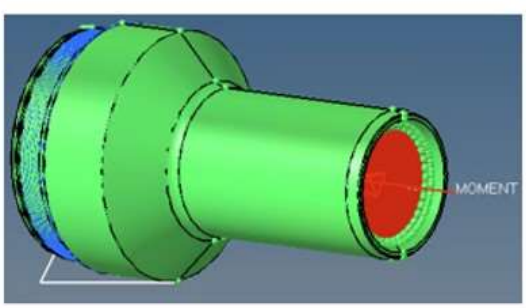
Şekil 8. Adaptörlü numune arka kardan mili üretiminden görsel

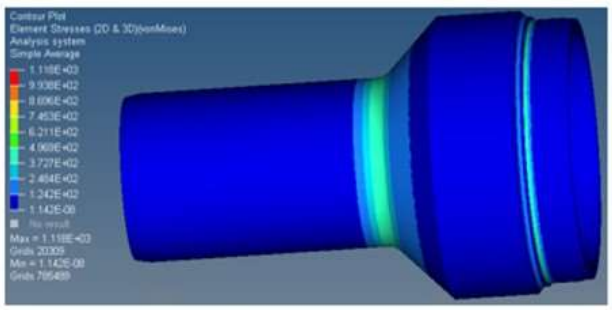
Yeni boruya uygun tüp çatal ve kayıcı kovanın katı modelleri Catia programı ile oluşturulmuştur. Yeni modellerin HyperWorks yazılımı ile doğrusal statik analizleri gerçekleştirilmiştir. Modellerin boru ile etkileşimde olduğu bölgesi sabitlenmiş, tüp çatal için kulak bölgesinden kayıcı kovan için ise spline bölgesinden 68745 serinin fonsiyonel limit torku olan 17000 Nm tork uygulanmıştır. Analiz sonuçları ve yeni modele ait ham parça ve işlenmiş parça ağırlık bilgileri mevcut parça ile karşılaştırılmıştır. Analiz modeli sınır şartları ve von Mises gerilme dağılımları Şekil 9 ve Şekil 10'da görülmektedir.



PARÇA Numarası	Ağırlık (Ham)	Ağırlık (Mamül)	Gerilme Değerleri
TY_68745_11_02 (mevcut)	7,84 kg	4,88 kg	OK
TY_68745_XX_02_R5 (yeni)	6,60 kg	5,35 kg	OK

Şekil 9. Tüp çatal ağırlık bilgisi ve von Mises gerilme dağılımları





PARÇA Numarası	Ağırlık (Ham)	Ağırlık (Mamül)	Gerilme Değerleri
TS_68745_01_02 (mevcut)	6,60 kg	4,40 kg	OK
TS_68745_XX_02_R2	7,98 kg	4,93 kg	OK

Şekil 10. Kayıcı kovan ağırlık bilgisi ve von Mises gerilme dağılımları

4. TESTLER

Yeni ürün tasarımında analiz çalışmaları ilk doğrulama için çok önemli bir aşamadır. Bu çalışmalarda elde edilen gerilme değerleri; kullanılan malzeme, ürün çalışma şartları, maruz kaldığı yükleme türleri ve şirket teknik hafızası kapsamında değerlendirilerek üretim aşamasına geçmeden önce en uygun tasarımının belirlenmesine yardımcı olur. Ancak nihai ürün doğrulaması ve tasarımın geçerli kılınması testlerle mümkün olmaktadır.

Kardan millerini ve alt bileşenlerini test etmenin amacı; ürünün fonksiyonunun, dayanımının ve güvenilirliğinin kapsamlı bir değerlendirmesini yapmaktır. Ürünün laboratuvar ortamında veya araç testi ile değerlendirilmesi, tasarımın gerçek uygulamada tatmin edici bir performans gösterip gösteremeyeceğini doğrulamak için en önemli işlemdir. Genel olarak test prosedürleri, gerçek saha koşullarını yansıtmak için hızlandırılmış bir simülasyondur (SAE, 1991).

Gerçek saha koşullarında çok fazla uygulama tipi ve çevresel etki vardır ve bunların hepsinin laboratuvar ortamında simule edilmesi ve bu durumun yönetilmesi ekonomik olarak mümkün değildir. Laboratuvarda uygulanan test prosedürleri; gerçek saha kullanımından ya da kontrollü test koşullarından elde edilse de gerçek araç deneyiminin yerini tutmaz. Ürünün en kapsamlı değerlendirmesi, gerçek saha koşullarını yansıtan araç testleri ile yapılabilir (SAE, 1991).

4.1. NVH Testi

NVH; ses (noise), titreşim (vibration) ve gürültünün (harshness) kısaltılmasıdır. Ses ve titreşim ölçülebilir ve elde edilen veriler ile objektif olarak değerlendirilebilir; ancak gürültü her ikisinin toplanmış halidir ve ölçülemez; bu nedenle sadece subjektif olarak değerlendirilebilir. Gürültü, düzensiz ve ahenksiz olarak karakterize edilir. NVH mühendisleri üzerinde çalışılan sistemde ses ve titreşim ile ilgili ölçümler yaparak NVH iyileştirmesi için çalışmalarda bulunur. Bunun için üç temel prensip kullanılır; ses ve titreşim kaynağının gücü azaltılabilir, bariyer veya izolatörler ile ses ve titreşim transferi bozulabilir veya ses ve titreşim enerjisi absorbe edilebilir (Korkut, 2008).

Çalışma kapsamındaki 4×2 yol kamyonu üzerindeki mevcut ön ve arka kardan milleri sökülerek yerine numune arka kardan mili takılmış ve araç NVH testi için hazır hale getirilmiştir. NVH mühendisi ile birlikte 15 km süren bir sürüş testine çıkılmıştır. Test sürüşünde farklı viteslerde hızlanma, yavaşlama, farklı devirlerde sürüş, viteş geçişleri gibi sürüş modlarında denemeler yapılmıştır. Subjektif olarak; gazı bırakıp yavaşlama sırasında aks uğultusu (axle whine) olarak adlandırılan ses ve 50 km/h'de hızlanma sırasında aks tarafında kazıntı sesi tespit edilmiştir. Yapılan test neticesinde kabinde hissedilir seviyede olmasa da kötüleşme olduğu raporlanmıştır. Ancak yapılan test, araç üzerinde damper ve yük yok iken yapılmıştır ve bu durumun NVH karakteristiğine etki edecek olması nedeni ile testin tekrarlanmasına karar verilmiştir. İkinci test ivmeölçer (Şekil 11) ve mikrofon gibi enstrümanlar kullanılarak yapılmıştır. Araç yüklü iken yapılan testte 4 saatlik data toplama sonrası yapılan değerlendirmede minör kötüleşme olsa da değişikliğin kabul edilebilir ve uygun olduğu raporlanmış böylece tasarım NVH açısından doğrulanmıştır.

Şekil 11. Araç üstü NVH testi görseli

4.2. Yapısal Testler

NVH testinin olumlu sonuçlanması ile birlikte, tasarlanıp doğrusal statik sonlu elemanlar analizleri gerçekleştirilen yeni birim parçaların testler ile doğrulanması aşamasına geçilmiştir. Yeni birim parçaların doğrulanması için üretilecek numune kardan milleri ile üçer adet statik burulma ve yorulma testi yapılmasına karar verilmiştir.

4.2.1. Statik Burulma (Akma) Testi

Statik burulma testinde, doğrusal ve kontrollü olarak artacak şekilde bir tork yüklemesi, kardan mili bileşenlerinde kırılma gerçekleşinceye kadar uygulanır (Şekil 12). Statik burulma testi süresince test makinalarında uygulanan tork ve buna bağlı açısal değişimi grafik olarak elde edilir. Bu grafik kullanılarak %0,1 öteleme methodu ya da Johnson Apparent Elastic Limit (JAEL) methodu gibi teknikler uygulanarak akma noktası tespit edilir (SAE, 1991).

Her kardan mili serisi, fonksiyonelliğini kaybetmeden dayanabileceği tork değerine sahiptir. Bu değer fonksiyonel limit torku olarak adlandırılır. Statik burulma testinde elde edilen akma torkunun, kardan mili fonsiyonel limit torku üzerinde olması gerekir.

68745 serinin fonksiyonel limit torku 17.000 N·m'dir. Tasarımın statik olarak doğrulanması için üç adet numune kardan mili statik burulma testine tabii tutulmuş ve testler olumlu sonuçlanmıştır. Test edilen kardan millerine ait görseller Şekil 13'te yer almaktadır.

Şekil 12. Statik burulma test cihazı (Işık, 2009)

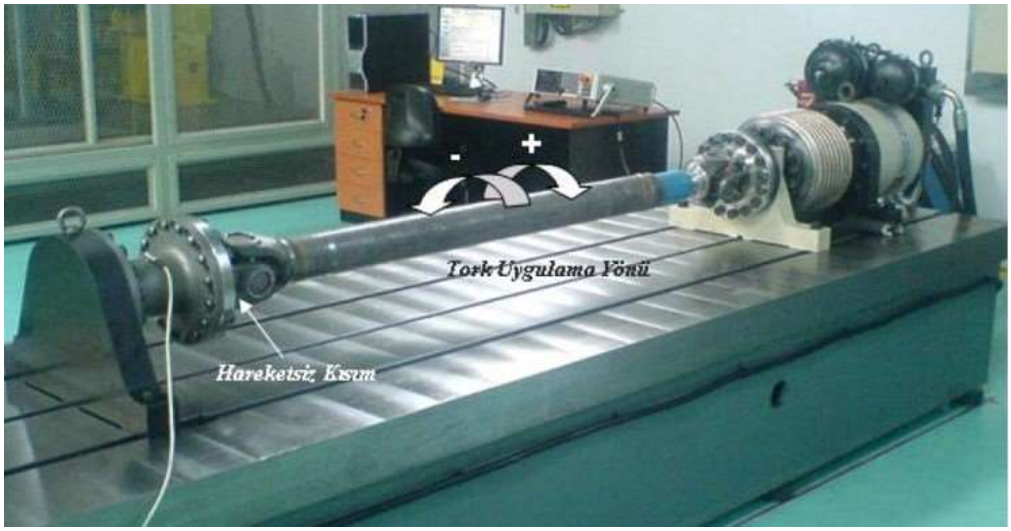
Şekil 13. Yapılan statik burulma testine ait görüntüler (Tirsan Kardan A.Ş., 2020)

4.2.2. Burulma Yorulma Testi

Kardan mili ve bileşenleri araç üzerinde değişken büyüklükte ve yönde tekrarlı burulma yüklerine maruz kalmaktadır. Uygulamaya bağlı olarak bu yükleme koşulları; sıfırdan maksimum değere kadar tek yönlü yüklerden, tamamen tersine çevrilmiş yüklerden veya ortalama seviyede yüke ilave değişken yüklerden oluşmaktadır (SAE, 1991).

Karşılaşılan yükleme koşullarınının benzetimi için yorulma testi yapılabilir. Yorulma testinde, araç üzerinde gelişen yükleri ve gerilmeleri kopyalamak tercih edilir; ancak yükleme datası ulaşılabilir değilse yorulma testi sonuçlarından elde edilecek S-N eğrisi kullanılarak ürünün yorulma ömrü tahmin edilebilir. Yorulma testi verilerinin analiz edilerek S-N eğrisi oluşturmaya destek olması için Weibull analizi ve Goodman diagramları gibi analitik ve grafiksel yöntemler kullanılabilir (SAE, 1991).

Kardan mili test düzeneğine bağlanarak bir ucu sabitlenir ve diğer ucundan uygulamaya bağlı olarak belirlenen tork ile iki yönlü ve belli bir frekansta yüklemeye maruz bırakılarak test edilir (Şekil 14). Test bir bileşen kırılıncaya kadar veya belli bir çevrim sayısına ulaşılıncaya kadar devam ettirilir.
Üretilen üç adet numune kardan mili burulma yorulma testine tabii tutulmuştur. Testlerden ikisi 300.000 çevrim sayısına kadar biri 1.000.000 çevrim sayısına kadar sürdürülmüş, herhangi bir kardan mili bileşeninde kırılma görülmemiş ve sonuç olarak testler olumlu sonuçlanmıştır.



Şekil 14. Burulma yorulma test cihazı (Işık, 2009)

5. SONUÇ

Çalışma sonucunda belirlenen ağır ticari araçta ön ve arka kardan mili kullanılımından tek bir arka kardan mili kullanımına geçilmiştir. Bunun neticesinde;

- Ön kardan milinin iptal edilmesi ile 5 adet birim parça ve 4 adet satın alma parçası olmak üzere 9 adet parçanın kullanımı elimine edilmiştir.

- Ön kardan milinin iptal edilmesi ile kardan mili üretim süresinde 19 dk'lık azalma sağlanmıştır.
- Ön kardan milinin iptal edilmesi ile araç montaj hattında 2 dk'lık iyileşme sağlanmıştır.
- Hem Tirsan Kardan A.Ş. hem de araç üreticisi için maliyet iyileştirmesi sağlanmıştır.
- 84 kg'lık toplam kardan mili kütlesi 70 kg'a düşmüştür; böylece yaklaşık %17 kütlesel azalma sağlanmıştır.
- Kritik hız limitinde %16'lık iyileşme sağlanmıştır.

ABSTRACT

Yield criteria can directly predict anisotropy parameters based on the r value and the yield stress ratio directionalities with analytical approach. When, yield criteria related to the computed anisotropy parameters are implemented into the finite element software, it is uncertain that the finite element software could reflect the anisotropic behavior of the material and capture the analytical input values completely. In this study, the differences between the analytical and numerical predictions of angular variations of r values and the yield stress ratios were evaluated. For this purpose, a single finite element test was performed based on uniaxial tensile tests by three directions using Hill-48 yield criteria. A material widely used in the automotive industry, namely DP800 is used. Lankford parameters and the yield stress ratios were determined for different material orientations using finite element analyses and analytical calculations. It is seen r-based Hill-48 model have a good agreement with the experiments using analytical method, however there is a quite difference at predicted yield stress ratios by finite element analyses.

Keywords: Plasticity modeling, Anisotropy, Dual Phase Steel, Finite Element Analyses

1. INTRODUCTION

Determining the material behavior accurately and precisely during the forming processes of materials has a great importance for engineering. During the forming process, a material first undergoes an elastic and then a plastic deformation. Since the elastic behavior of a material is represented by a linear curve, it is easy to describe and model this behavior mathematically. This linear relationship between the stress and strain values can be expressed by Hooke's law (Çetin, 2007). Since the plastic behavior of the material is non-linear and the evolution of yield stress is represented by hardening, it is more difficult to model the plastic behavior in comparison to the elastic behavior (Gürsoy, 2019). Mathematical expressions of modeling the plastic behavior of materials are called as plasticity models. In order to model the plastic behavior of a material under the general stress state, a yield criterion, a flow rule and a hardening rule are required (Esener, 2020). The yield criterion describes the onset of the plastic deformation for different stress states, the flow rule establishes the relationship between the stress increment and the strain rate increment, and the hardening rule defines the change in shape or the displacement of the yield surface which separates the elastic and plastic regions in stress space (Ziegler, 1958) (Firat, 2008). In this context, it is possible to examine plasticity models in three groups as isotropic material-isotropic hardening, anisotropic material-isotropic hardening and anisotropic material-kinematic hardening (Gürsoy and Esener, 2019). In this sense, there are many advanced plasticity models in the literature (Feng continued, 2019; Javanmardi and Maheri, 2019; Meng continued, 2019; Zhou continued, 2019). Tresca, von Mises, Hershey, Hosford criteria can be given as examples for the plasticity models assuming isotropic material-isotropic hardening. For the second group, anisotropic material-isotropic hardening plasticity models can be exampled as Hill-48, Barlat-89, Hill-93, Hu-2003 criteria. Yoshida- Uemori model can be considered for the last group regarding the anisotropic material – kinematic hardening assumption (Banabic, 2010). Among the components of plasticity models, definition of the yield criterion requires higher number of input values when compared to the hardening rule and mostly, in forming processes hardening rule was assumed as isotropic for simplicity (Yoon continued, 2010) (Singh continued, 2018). The input parameters required by the yield criterion are obtained from the mechanical tests and characterization of the advanced yield criteria require more input values. Correspondingly, definition of an advanced yield criterion requires more mechanical tests and optimization processes. For this reason, due to the lack of the conducted mechanical tests and complicated optimization processes, generally, yield criteria containing few numbers of parameters are preferred. Hill48 criterion, which can perform precise and accurate operation with few parameters, is still among the most widely used models. Through the constitutive equations of plasticity models, directionalities of anisotropy coefficient and yield stress ratio can be obtained analytically. As a result, the need for plasticity models to describe the

plastic behavior of materials has increased. With the development of today's computer technology, plasticity models have been incorporated into finite element software. Thus, plasticity model-based numerical applications have started to take place in many engineering applications, especially in the automotive industry, where computer-aided design is widely used. However, it is predicted that differences may arise during the implementation of plasticity models into finite element software.

In this study, analytical calculation was presented using both the r-based and stress-based versions of the Hill48 criterion, which is one of the commonly used yield criteria today. In addition, the single finite element test analyses were performed for both shell and solid elements and numerical prediction results were obtained. For the sake of simplicity, isotropic hardening rule was assumed. Dual phase DP800 steel, which is widely used in the automotive industry, has been investigated as material.

2. MATERIAL AND METHOD

With today's developing material technology, in many sectors, especially in the automotive sector, mild steels and traditional steels have been replaced by advanced high strength steels (AHSS). The situation is result from the fact that AHSS have higher tensile strength and show significant formability limit compared to the mild and high strength steels (Quadfasel continued, 2017). Dual phase steel class (DP-Dual Phase) from the AHSS family stands out with its high strength, high formability, good weldability features (Karaçalı, 2015; Pavlina continued, 2008). DP steels contain ferrite and martensite phases and the martensite phase in its internal structure is located in the form of islands surrounded by soft ferrite matrix. In this way, a steel group with high strength and improved deformation capability has been obtained (Aghaei and Rad, 2020). DP steels are used in many automobile parts such as wheel rim, crashbox, seat frame, bumper, door panels, chassis, wheel covers, belt pulleys and some fasteners etc. (Karaçalı, 2015; URL 1, 2021). In this study, DP800 steel grade was used. Mechanical properties of DP800 are given in Table 1.

Table 1. Mechanical Properties of DP800 Steel

		Elasticity Modulus (GPa)	Yield Stress (MPa)	K (MPa)	n	r
DP800	RD	210	457,83	1150,27	0,12	0,71
	DD	200	428,96	1096,98	0,11	0,88
	TD	212	460,59	1175,44	0,13	0,83

2.1. Hill-48 Yield Criterion

Hill presented an anisotropic yield criterion in 1948. In this criterion, the material has anisotropy in three orthogonal symmetry planes (Hill, 1948). The most general form of Hill48 criterion can be written as in Equation (1).

$$2f(\sigma_{ij}) = F(\sigma_{22} - \sigma_{33})^2 + G(\sigma_{33} - \sigma_{11})^2 + H(\sigma_{11} - \sigma_{22})^2 + 2L\sigma_{23}^2 + 2M\sigma_{31}^2 + 2N\sigma_{12}^2 = 1 \quad (1)$$

Hill48 yield criterion can be calculated both as r-based and stress-based. The constants F, G, H, L, M and N given in Equation (1) are the values depending on the anisotropy coefficients and yield stresses. Again, for the plane stress case, Hill-48 criterion can be written as in Equation (2).

$$2f(\sigma_{ij}) = (G + H)\sigma_{11}^2 - 2H\sigma_{11}\sigma_{22} + (H + F)\sigma_{22}^2 + 2N\sigma_{12}^2 = 1 \quad (2)$$

In Hill48's r-based calculation; The relations of F, G, H and N constants with the anisotropy coefficients are given in Equation (3).

$$F = \frac{r_0}{(1 + r_0)(r_{90})}$$

$$G = \frac{1}{(1 + r_0)} \quad (3)$$

$$H = \frac{r_0}{(1 + r_0)}$$

$$N = \frac{(r_0 + r_{90})(2r_{45} + 1)}{(2(1 + r_0))r_{90})}$$

Here, r_0, r_{45} and r_{90} represent the anisotropy coefficients at the rolling, diagonal, and transverse directions, respectively. It offers a great advantage to users due to the simple r-based approach of the Hill48 criterion in defining the anisotropy of metals, and this advantage makes this criterion one of the most frequently used criterion today.

In the stress (σ) based calculation of Hill48; The relations of F, G, H and N constants with yield stress are given in Equation (4).

$$F = \frac{1}{2}\left(\left(\frac{\sigma_0}{\sigma_{90}}\right)^2 - 1 + \left(\frac{\sigma_0}{\sigma_b}\right)^2\right)$$

$$G = \frac{1}{2}\left(1 - \left(\frac{\sigma_0}{\sigma_{90}}\right)^2 + \left(\frac{\sigma_0}{\sigma_b}\right)^2\right)$$

$$H = \frac{1}{2}\left(1 + \left(\frac{\sigma_0}{\sigma_{90}}\right)^2 - \left(\frac{\sigma_0}{\sigma_b}\right)^2\right) \quad (4)$$

$$N = \frac{1}{2}\left(\left(\frac{2\sigma_0}{\sigma_{45}}\right)^2 - \left(\frac{\sigma_0}{\sigma_b}\right)^2\right)$$

Here σ_0, σ_{45} and σ_{90} represent yield stresses in the rolling, diagonal, and transverse directions, respectively.

3. APPLICATION STUDY

In this study, two different versions of Hill48 yield criterion (r-based and stress-based) were used for predicting angular variations of yield stress ratios and anisotropy coefficients as analytically and numerically. In the first part of the study, yield locus and directionalities of r values and yield stress ratios for DP800 material were obtained from the analytical approaches (Fig.1).

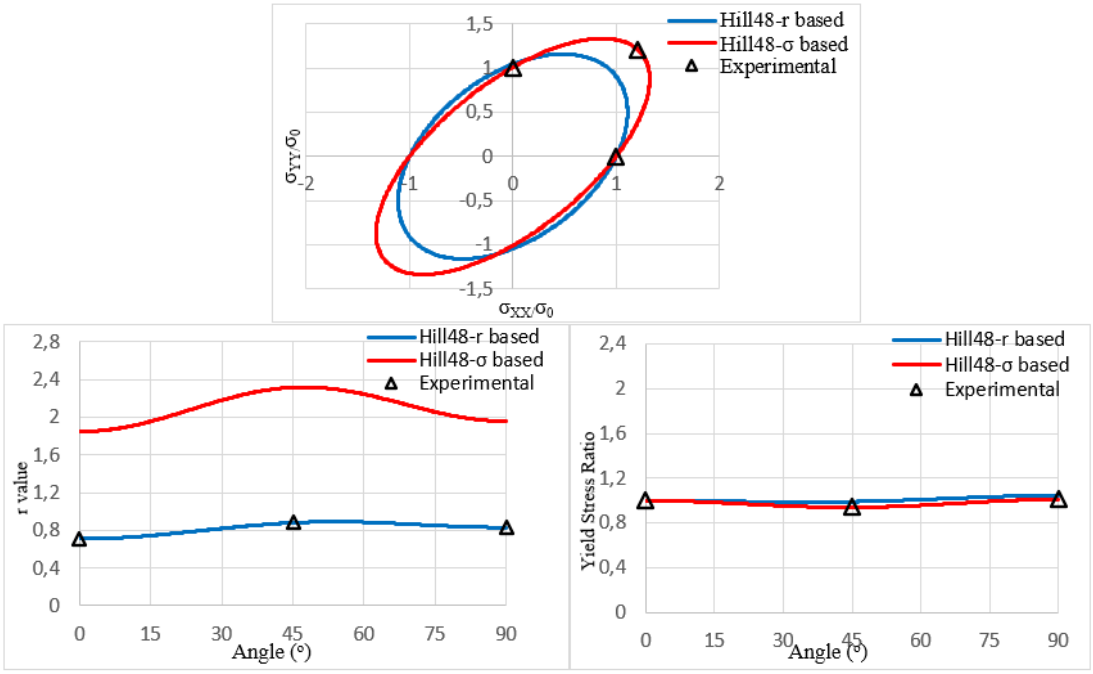

Figure 1. Yield locus and directionalities of r values and yield stress ratios for DP800 material predicted by analytical approach

Then, in the numerical modeling part of the study, single finite element simulations for uniaxial tensile test conditions were performed to determine the prediction accuracy of plasticity models in finite element anayses. For this purpose, fully integrated thick shell element formulation with 7 integration points, and a fully integrated hexahedral solid

elements were considered, seperately. Boundary conditions of the single finite element tests can be seen in Fig. 2. Msc Marc commercial software was used for finite element analyses. In order to obtain the yield stress ratios and anisotropy coefficients, uniaxial tensile tests in 3 directions were performed.

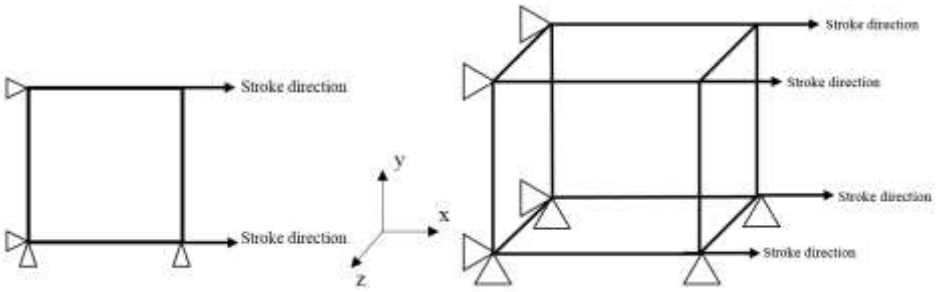

Figure 2. Boundary conditions of the single finite element tests

Firstly, stress and strain curves of uniaxial tensile tests simulations were obtained for DP800 steel according to the r-based and stress-based definition of Hill48 criterion for solid and shell element formulations, seperately. The results are given in Figure 3 and Figure 4 for solid elements and shell elements, respectively. The comparison of the stress-strain curves obtained from the single finite element tests are summarized in Figure 5. In the next step of the study, the angular variations of yield stress ratios and anisotropy coefficients were determined numerically. Comparison of the results is summarized in Fig. 6.

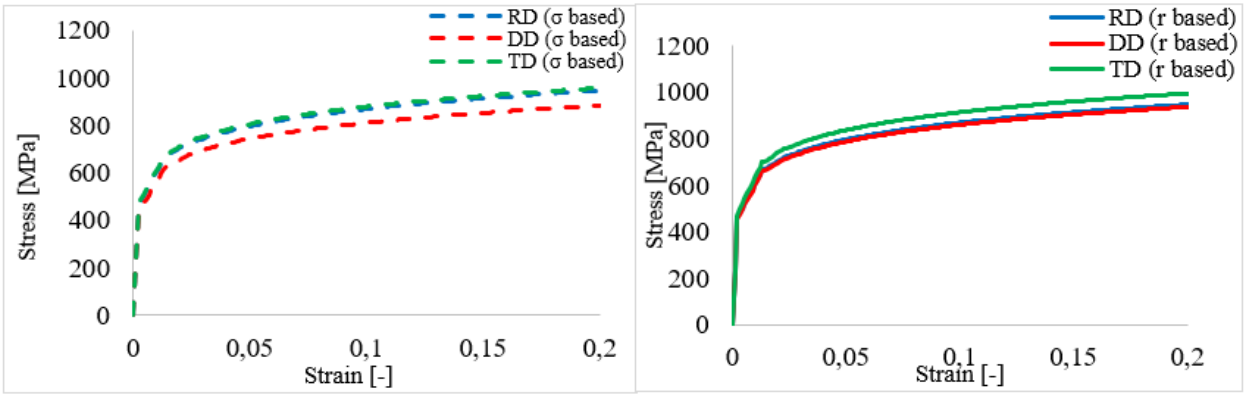

Figure 3. Stress-Strain curves obtained by solid elements

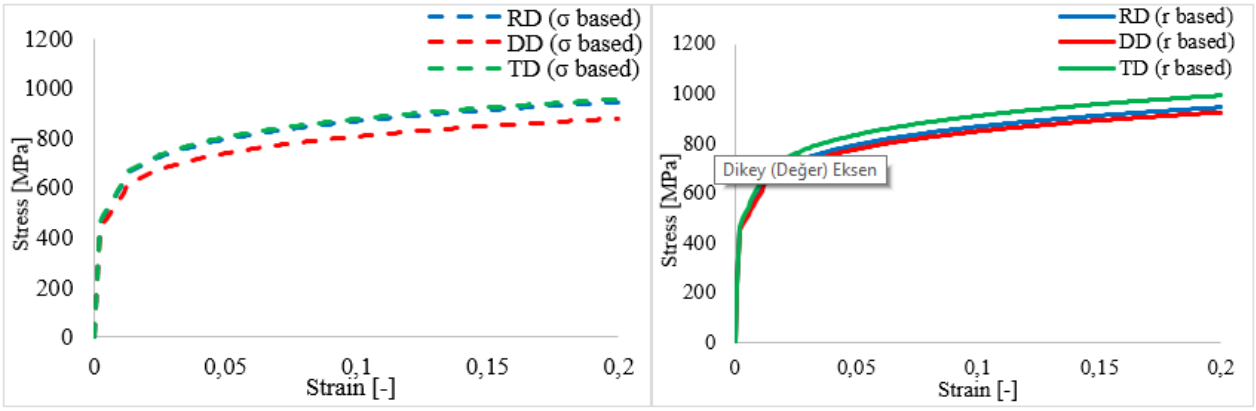

Fig 4. Stress-Strain curves obtained by shell elements

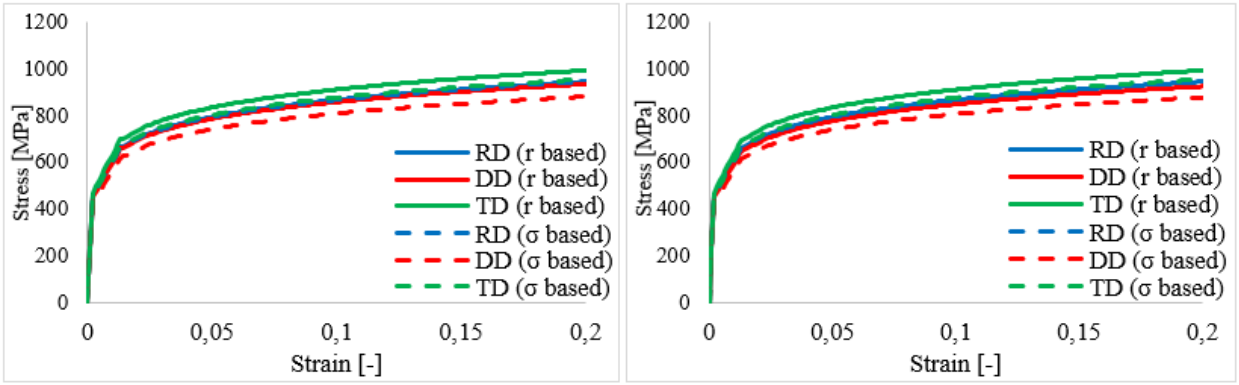

Figure 5. Comparison of the stress-strain curves obtained with the single element tests (Left: Solid elements, Right: Shell elements)

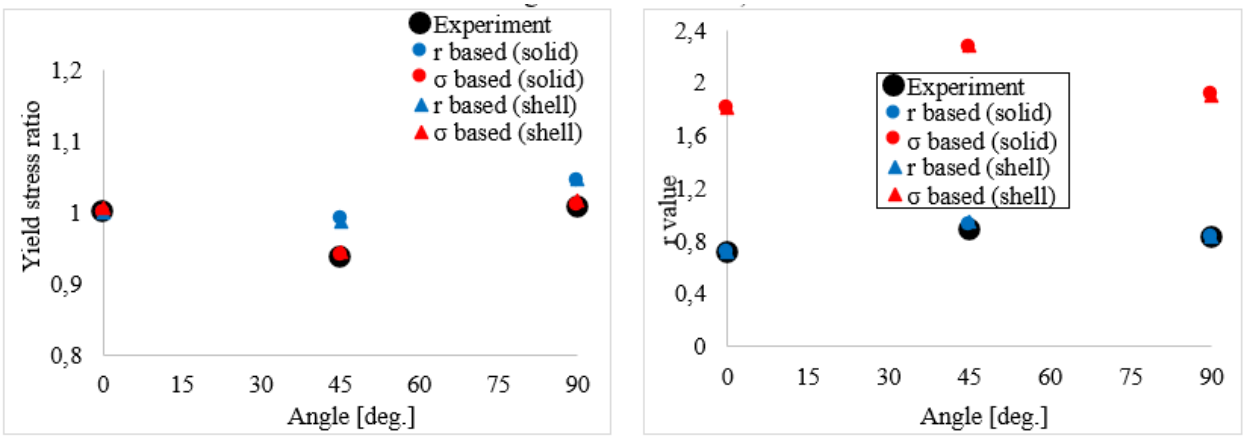

Figure 6. Angular varitions of both yield stress ratios and r-values for DP800 obtanied with finite element analyses

4. CONCLUSION

Within the scope of this study, the difference in r value and yield stress ratio predictions between the analytical and numerical approaches were investigated for DP800 steel, which is widely used in the automotive industry. The r-based and stress-based identification procedures of the Hill48 yield criterion were used. Initially, the angular variations of the yield stress ratio and anisotropy coefficients were obtained analytically. Later, numerical calculations were carried out for both solid and shell elements by using the Msc Marc software. Uniaxial tensile test conditions were applied on a single element. Results obtained from both analytical and numerical methods were compared with each other and experimental results.

When the results are examined, it was seen that the solid and shell elements gave similar results for the stress-strain curves obtained from the uniaxial tensile test simulation of the single element test. When the stress-strain curves of Hill48's r-based and stress-based models were compared, it was observed that there was no significant difference. In finite element analyses, r-based Hill48 model predicted the Lankford coefficients compatible with experiments, while stress-based model predicted directionality of the yield stress ratio accurately. No significant difference was observed between the solid and shell element predictions. In the analytical method, it was determined that the r-based model predicts both the anisotropy coefficients and yield stress ratios compatible with the experimental results.

TRIZ 'İN OLASI UYGULAMASININ OTOMOTİV ENDÜSTRİSİNE SAĞLAYACAĞI AVANTAJLARIN OYAK-RENAULT BAĞLAMINDA İNCELENMESİ

Kayhan SIRDAR
Oyak-Renault Otomobil Fabrikaları A.Ş. Bursa/Türkiye

Özet

Makalenin amacı, TRIZ'in potansiyel otomotiv uygulamaları için bir örnek oluşturmaktır. Makale TRIZ' uygulamasının şirkete sağlayacağı potansiyel finansal ve finansal olmayan kazançları tanımlar ve inceler. Buna ek olarak çalışma, ileride olası uygulamalar için paydaş katılımı ve gerekli yönetim stratejileri değişimleri için alternatif yaklaşımlar sunar. Mevcut uygulamalar incelenerek ve röportajlar yapılarak TRIZ uygulamaları ile verimliliği iyileştirilebilecek alanlar belirlenmiş ve bunlar analiz edilmiştir. Son olarak, makale olası TRIZ uygulamalarının yenilik, tasarım ve teknolojik gelişmeler yoluyla şirket stratejisini nasıl etkileyebileceğini inceler.

Anahtar Kelimeler

TRIZ, değişim yönetimi, uygulama stratejisi, inovasyon

EXAMINING THE ADVANTAGES OF TRIZ'S POSSIBLE APPLICATION TO THE AUTOMOTIVE INDUSTRY IN THE CONTEXT OF OYAK-RENAULT

Abstract

The purpose of the paper is to provide examples of TRIZ's potential application to automotive industry. The article identifies and examines possible financial and non-financial benefits that TRIZ application will bring to the company. Furthermore, the article provides alternative approach for the context of management strategy and stakeholder engagement for potential applications. By conducting interviews and examining current applications, the areas could improve efficiency with TRIZ applications were analysed and identified. Finally, the article concludes how potential application of TRIZ can influence company strategy through innovation, design and technological advances.

Key Words

TRIZ, change management, application strategy, innovation

1.Giriş

Yaratıcı problem çözme metodu (devamında TRIZ) yenilikçi çıktılarla birlikte sistematik bir problem çözme yaklaşımıdır [1]. Yöntembilim e çözümlerin üretilmesine olanak sağlayan işleyişlerin kavramsal olarak ayırt edilmesi üzerine kurulmuştur. TRIZ kullanıcılarına, tercihlerine uygun, benzersiz ve hızlandırılmış problem çözme araç seti oluşturma olanağı sağlar. Ancak TRIZ bazı kullanıcılar tarafından karşılaşılan sorunlara yalnızca kavramsal olarak teknik bir çözüm sağlayan ve bu çözümlerin yalnızca karşılaşılan sorunlara özgül yöntembilim olduğu şeklinde yorumlanmaktadır. Bu kapsamda bazı kullanıcılar TRIZ uygulamalarının 6 sigma, kaizen vb. devamlı gelişme yöntembilimleri ile desteklenmediği müddetçe etkin bir çözüm yaratma olasılığını düşük olacağını savundular [2]. Makale TRIZ'in otomotiv sektöründeki olası kullanımları için bir uygulama stratejisi oluşturmak ve şirket stratejisine olan etkisini incelemek amacı ile kaleme alınmıştır.

Oyak-Renault (makalenin devamında OR olarak anılacaktır) Oyak ile Renault Grubu'nun katılımları ile 1969 yılında Bursa'da kurulmuştur. Kuruluşundan bu yana ilklere imza atmaya devam eden ve otomotiv sektöründe önemli bir yere sahip olan şirket, Renault marka araçların üretimi ve ihracatını gerçekleştirmektedir. 1971 yılında üretime başlamasından bu yana OR Renault 12 SW modeli ile Türkiye'nin ilk station wagonlu, Renault 12 GTS modeli ile ilk klimalı, Renault 9 modeli ile ilk otomatik vitesli, Renault 21 Concorde modeli ile ilk yol bilgisayarlı otomobilini ve ilk dizel otomobil motorunu üreterek Türkiye için birçok ilke imza attı. 1998 yılında Megane Wagon sadece OR'de üretilmeye başlayarak bugün de devam etmekte olan Türk Otomotiv Sanayisinin yüksek miktarda ihracata başlamasına öncülük etti. Buna ek olarak elektrik motorlu Fluence üretimi ile Türk Otomotiv Sanayi'sinde çağın ötesinde yeni bir çığır açtı. OR aynı zamanda araştırma geliştirme ve mühendislik alanlarında önemli yatırımlar yapmıştır. Şirketin

mühendislik departmanlarına ek olarak, Bursa fabrikasında AR-GE birimi bulunmaktadır. OR şirket kültürü yenilik ve araştırma geliştirme çalışmalarına büyük bir önem vermektedir [3].

1.1Araştırma Methodu

Araştırma kapsamında retro perspektif araştırma metodu ile literatür ve endüstriden inceleme için gerekli bilgiler toplanmıştır. Bu kapsamda birim analizi için geçmiş veriler incelenip uygulamanın olası etkileri hakkında çıkarımlar yapılmıştır. Temel olgu TRIZ'in ticari uygulamaları ve uygulamadan en çok etkilenmesi olası paydaşlar (ürün geliştirme, insan kaynakları ve ARGE) arasındaki etkileşim olarak tanımlanmıştır. Potansiyel etki alanları ise değişim yönetimi, verimlilik üzerine etki, proje yönetimi ve şirket stratejisi olarak belirlenmiştir. Çalışma kapsamında farklı departmanlarda görevli toplamda 10 adet OR çalışanı ile röportaj yapılmıştır. Röportaj verileri ve şirket dökümanları birincil veri kaynağı olarak kullanılmıştır. İkincil kaynak olarak, TRIZ ve ticari uygulamaları ile ilgili literatür taramasında tespit edilen akademik yayınlar kullanılmıştır. Potansiyel uygulamalar verilerin karşılıklı analizi yoluyla incelenmiştir. Bu kapsamda inceleme ve değerlendirme çalışmaları, olası uygulama hakkında tatmin edici sonuçlar elde edilene kadar devam etmiştir.

Yöntembilimi stratejisi olarak tümevarımsal yaklaşım gözlemlerinin araştırmasında ve değerlendirilmesinde kullanılmıştır. Bu kapsamda olgu şablonu, gözlemler ve gelişme açıklamaları ile oluşturulmaya çalışılmıştır. Veri kümeleri temel alınarak, modeller ve kullanılan ilişkiler sonuçlandırılmaya çalışılarak olgu açıklanmak istenilmiştir [4]. Keşfedilen ilişkiler, makalenin araştırma hedefine olan "TRIZ'in olası otomotiv uygulaması için strateji gelişimi" ne karşılık sağlanması amacı ile kullanılmıştır. Bu kapsamda süreç odaklı soruların analizinde tümevarımsal yöntem tercih edilmiştir. Potansiyel uygulamanın şirket üzerinde olan etkileri hakkında bilgi sahibi olunması amacı ile literatür tarama çalışması; TRIZ, sürekli iyileştirme, değişim yönetimi, problem çözme, proje planlaması, teknolojik gelişim ve şirket stratejisi üzerine olan etkisi alanlarında yoğunlaşmıştır.

1.2 Literatür Taraması

TRIZ Genrich Altshuller ve ekibi tarafından 40.000 patent incelenmesi ve bu patenler ile yaratılan yeni fikirleri ve bulanan çözümlerin temel işleyişleri arasında benzerliklerin incelenmesi ile oluşturulmuştur. Bu yöntembilim, yeni sistemlerin tasarlanması ve temel alınan teknolojinin işleyişinin ve gelişiminin tahmini açısından faydalı bulunmuştur [5]. TRIZ uygulamalarının amaçları, ürün/süreç iyileştirmeleri, üretim maliyetinin düşürülmesi, yeni teknolojilerin geliştirilmesi, mevcut patentlere alternatif çözüm bulma ve konsept tasarımı olarak belirlenmiştir. Bu amaçlarla örtüşür şekilde, TRIZ'in gelişim doğrultuları mevcut ürün iyileştirmesi, yeni ürün geliştirilmesi, üretim teknolojilerinin iyileştirilmesi, patent 'e alternatif bulma ve patent geliştirilmesi, uzun/kısa vadede öngörüde bulunma ve teknolojinin gelişim tahmini olarak belirlenmiştir [6].

Mevcut problem çözme ve sürekli iyileştirme yöntembilimlerinden farklı olarak TRIZ sorunun temel nedenlerini analiz ederek ve sınıflandırarak sorunları belirlemeye ve soruna doğrudan çözümler önermeye yardımcı olur. Akademi dışı bir tabirle TRIZ yöntembilimi, "*Mevcut probleme benzer bir problem mutlaka başka birisi tarafından çözülmüştür*." şeklinde özetlenebilir. Önerilen çözümler yaratıcı ilkeler, teknolojinin gelişim eğilimleri ve temel çözümler kullanılarak oluşturulur. İhtiyaç duyulan iyileştirmelerin tanımlanabilmesi için TRIZ yöntembilimi problemin temellerine indirgenmesi gerektiğin ve sorunun kavramsal bir şekilde incelenmesi gerektiğini savunur. Sonrasında tanımlanan kavramsal çözümlerin yaşanılan sorunu gidermek için kullanılabileceğini belirtir. Ancak ve ancak kavramsal çözümler, orijinal sorunu ele alan gerçeklere dayalı ve özel çözüme dönüştürülebilir [7].

TRIZ araçları katı bir uygulama sıralaması belirtmemesine rağmen, bu araçlar mevcut durum, kaynaklar, hedefler, istenilen durum ve değişim başlıkları altında özetlenebilir. Mevcut durum araçları mevcut durum hakkında bilgi sağlamayı amaçlar, kaynak araçları mevcutta kullanılmakta olan ve kullanıma uygun olan kaynakların tespitine olanak sağlar, Hedef araçları kullanıcının hedeflerine ulaşmasını ve sonuçlandırmasına yardımcı olur, istenilen durum araçları gelecekteki çözümün nasıl görüneceği ve işleyeceği hakkında bilgi sağlar. Değişim araçları mevcut durumla istenilen durum arasındaki geçiş basamaklarının tanımlanmasına olanak sağlar [8].

Sürekli iyileştirme süreci mevcut işleyişin aşamalı olarak ve sürekli bir biçimde iyileştirilmesini amaçlar. Birbirinden farklı sürekli iyileştirme araçları arasında gözlenen bazı birleşik hedefler müşteri ihtiyaçlarını karşılamak, şirket performansını arttırmak ve kalite hatalarını azaltmak olarak belirtilmiştir [9]. Sürekli iyileştirme metotlarının sağladığı avantajlara ek olarak, TRIZ mühendislik parametreleri, yaratıcı ilkeler ve çelişki matrisi araçları ile etkili ve hızlı çözümler sunar [10]. Mevcut problemleri çözmeye ek olarak TRIZ, şirketlerin yeni ürün geliştirmesine, pazar akımlarının tahmin edilmesine ve teknoloji gelişiminin öngörülmesine olanak sağlar. Buna ek olarak TIRZ, farklı sektörler ve şirketlerden edinilen deneyimlere dayalı olarak oluşturulmuş neden/sonuç veri tabanına erişim olanağı sağlayabilir [11]. Teknolojinin gelişiminin tahmini ve pazar eğilimlerinin öngörülmesi şirketlerin stratejik gelişimine ciddi bir üstünlük sağlar.

Genel olarak TRIZ, tasarımcılara tasarım ve geliştirme alanlarında deneme ve yanılma sürecini azaltan bir araçlar bütünü olarak düşünülür [12]. Buna ek olarak Sperafico ve Russo TRIZ'i kalite iyileştirmelerinde kullanılacak veya süreç / ürün yeniliklerinde kullanılabilecek bir yöntembilim olarak tanımlar [13]. Ancak TRIZ yöntembilimi ve uygulamaları TRIZ literatürünün yetersiz özgüllüğü ve fikir sunma yöntemlerinin eksikliği sebebi ile eksik bir yöntembilim olarak tanımlanmıştır [14]. Kelime merkezli yapısı ve görsel düşünme tarzlarına uyumsuzluğu, temel ilkelerini zor kavranılması, aşina olamama, standartların ve kurumsal sponsorların eksiliği TRIZ uygulamalarını zorlaştıran bariyerler olarak tanımlanabilir [15,16,17]. Teorik olguların hayata geçirilmesi ile TRIZ'e olan yabancılık ortadan kaldırılabilir. Buna benzer şekilde Jirásek ve Kulhavý, gerçek hayatta yenilikler yaratmaya yönelik uygulamalı eğitimlerin somut sonuçlar sağlayarak popülariteyi artırabileceğini belirtmektedir [18].

Samsung Group TRIZ'i öncü olarak uygulayan şirketlere bir örnek olarak gösterilebilir. 1998-2004 yılları arasında, şirket TRIZ uygulamaları ile finansal karşılığı 250 Milyon Amerikan doları olan 150 adet patent sağlamıştır. TRIZ genel olarak teknoloji gelişimi öngörüsü ve ürün geliştirme amacı ile kullanılmıştır. Şirket TRIZ'i ürün ve süreç geliştirmeleri, üretim maliyeti düşürme ve geleceğin teknolojileri tahmin etme ve tasarlama amacı ile TRIZ'i kullanmıştır. TRIZ'e olan aşinalık sorunu TRIZ'in şirket içi başarılı uygulamaları ile ortadan kaldırılmıştır. Başarılı uygulamanın temel gereksinimleri yönetim desteği, şirket içi tanınırlık, inovasyon ağı ve inovasyon tecrübesine sahip insanların sürece dahil edilmesi olarak tanımlanmıştır. Başlangıç aşamasında en önemli etken olarak kabul edilen yönetim desteği, TRIZ'in şirkete Genel müdür seviyesinde tanıtılması ile sağlanmıştır. İnovasyon tecrübesine sahip insanları sürece dahil edilmesi, terfi süreçlerinde TRIZ tecrübesinin aranması TRIZ'in şirket içi hızlı ve etkin bir şekilde uygulanmasına olanak sağlamıştır. Gerçek projelerde sağlanan başarılı sonuçlar etkin uygulanması ve TRIZ'in şirket içinde benimsenmesine ciddi oranda katkı sağlamıştır. Şirket TRIZ ile sağlanan başarılar hakkında farkındalık yaratmak adına başarılı TRIZ projelerinin sergilendiği şirket içi TRIZ festivali düzenlemiştir. Son olarak, çalışanlara danışmanlık ve destek sağlaması adına şirket tam zamanlı TRIZ uzmanları istihdam etmiştir [19].

Şirketlerin inovasyon yetenekleri, endüstrinin zorlayıcı ve düzenli olarak değişen taleplerinin karşılaşmasında en önemli araçların başında gelmektedir. Teknolojik çeşitlendirme farklı alternatif çözümler sunulabilmesi sayesinde patent portföyünün genişletilmesi ve şirket içi süreçlerin iyileştirilebilmesine olanak sağlar. Başarılı ve etkin inovasyon yeteneği şirkete karşılaşılan problemler karşısında farklı çözümler sunarak ve önceliklendirilmesine destek olarak şirketin rekabetçiliğine katkıda bulunabilir [20,21]. Teknolojik çeşitlilik farklı alternatifler sunarak, geliştirilen yeniliği satılabilir mal ve hizmetlere dönüştürmek için teknolojik stratejinin planlama ve üretim ile detaylandırılması gereken şirketin stratejik düşüncesi ile bütünsel ilişkiyi destekler [22].

Sorunsuz ve etkin bir uygulama için, ilgili paydaşların kendilerini sürecin bir parçası olarak hissetmesi gerekmektedir. Çalışan görüşüne danışılması, çalışanların kendilerini değişimin bir parçası olarak düşünmelerine ve paydaşların sürece daha güçlü bir aidiyet hissetmelerine olanak sağlar. Bu süreçte gereklilikler, istenilen sonuçlar ve değişimin nedeni paydaşlara detaylı olarak açıklanmalıdır. Daha etkin bir değişim yönetimi için farklı seviyelerdeki kişisel ihtiyaçlar ve başlangıç planları uygun bir şekilde düzenli olarak güncellenmelidir. Süreç boyunca uygulanacak uygulamaların ve araçların birbirini tamamlayıcı şekilde seçilmesi ve bu araç ve uygulamaların güncel uygulamalarla bütünleştirilmesi gerekmektedir [23].

Bu kapsamda yönetim, dikkat edilmesi, ölçülmesi ve kontrol edilmesi gereken etkenleri düzenleyerek değişimin uygulanmasında büyük role sahiptir. Ayrıca yönetim rol modelliği yapmak ve çalışanları yönlendirmek sureti ile gereksinimlerin içselleştirilmesini sağlar [24]. Yöntemin içselleştirilmesi için, yöneticiler sorunları kendileri çözmek yerine çalışanların karşılaşılan problemleri kendilerinin çözmelerine koçluk yapmalıdır [25]. Üst yönetim davranışı, uygulama sürecini ve hedeflerini paydaşların söz konusu dilin karmaşık veya teorik perspektiften nerelerde kaçınılması gerektiğini anlayabilecekleri şekilde tercüme etmek olmalıdır [26]. Bu kapsamda şirket kültürü yöneticilere farklı fikirlere açık olmayı ve değerleri paylaşmayı vurgularsa, yöneticilerin önyargıların üstesinden gelmelerine yardımcı olabilir [27].

2 Analiz ve Uygulama Stratejisi

Analiz ve sonuçlar bölümü, literatür araştırmasında elde edilen bilgilerle, röportajlardan elde edilen birincil verileri karşılaştırılması ile yazılmıştır. Farklı kaynaklardan elde edilen veriler olası TRIZ uygulamasının şirkete sağlayacağı maddi ve maddi olmayan faydaların incelenmesinde, değişim yönetimi stratejisinin oluşturulmasında, şirkete yaratacağı olası etkilerin değerlendirilmesinde ve uygulama stratejisinin geliştirilmesine kullanılmıştır.

2.1 Analiz

Sürekli iyileştirme yöntembilimleri üretim endüstrilerinde süreç izleme, üretim kontrolü, önleyici bakım ve ürün/süreç iyileştirilmelerinde kullanılmaktadır. Ancak sürekli iyileştirme yöntembilimleri, yenilik olmadan sorunları çözmeye odaklanmak ve katılık oluşturması sebebi ile eleştirilmektedir. Röportaj yapılan kişiler, bu araçların yeniliğe katkıda bulunmak için yeterli olmadığını, karmaşık problemler için etkisiz olduğunu ve üretime aşırı odaklanarak bu eksikliklere katkıda bulunmaktadırlar. Görüşülen bir kişi, yeniliğe uygun olmayan araçların esnek ve yenilikçi çözümler üretmek konusunda başarısız olduğunu belirtmektedir. Görüşülen kişilerin çoğunluğu günlük hayatlarında karşılaşılan problemlerin sürekli tekrar ettiğini ve bu problemlere benzer çözümler geliştirdiklerini belirtmektedirler.

OR şirket içi inovasyon aktivitelerinde Alliance Production Way (buradan itibaren APW) yöntembilimini kullanmaktadır. APW tüm paydaşları ve tedarik zinciri parçalarını organizasyonel yeteneklerin iyileştirilmesi ve etkililiğini uygulamak için ortak paydada buluşma fırsatı sağlar. OR şirket içi karşılaşılan teknik problemleri gidermek ve şirket içi inovasyonu güçlendirmek için Kaizen, Lean, Six-Sigma, FMEA, ANPQP, QRQC, Lessons Learned gibi çok çeşitli problem çözme ve sürekli iyileştirme araçlarını kullanmaktadır. Ancak bu araçlar, süreç iyileştirmeleri ve günlük sorunlar için faydalı sonuçlar sağlasa da yenilikçi çözümler getirememektedir. TRIZ, şirketin yenilikçi çözümler geliştirmesine ve şirketin gelecekteki ürünleri geliştirmesine yardımcı olabilecek teknoloji evrimini tahmin edilmesine yardımcı olabilir. Görüşme yapılan kişiler arasında yalnızca 4 kişi önceden yaşanılan problemlerin detaylarının ve çözümlerini anlatıldığı "Lessons Learnt Cards" ları tekrar eden problemlerin çözümünde kullanmaktadır.

Sürekli iyileştirme metodolojilerinin yaratıcı çözümler sağlayamadığı durumlarda bu eksikliklerin üstesinden gelmek için TRIZ faydalı olabilir. Mevcut sürekli iyileştirme yöntembilimlerinin eksik kaldığı ve TRIZ'in katkı sağlayabileceği alanlar aşağıdaki gibi tanımlanmıştır.

- Mevcut yöntembilimler, teknolojinin gelişebileceği alanlar açısından bir öngörü sunamamaktadır.
- Mevcut araçlar karşılaşılan sorunları ana sebebini tanımlayabilmektedir ancak direkt çözümler öneremememektedir.
- Mevcut araçlar sorunları yenilik yaratmadan çözmektedir.
- Öğrenilen dersler kartları (Lessons Learnt Cards) etkin bir şekilde kullanılmamaktadır.

OR yenilikçi olmayı şirket değerleri arasında en önemli maddelerden biri olarak tanımlamaktadır. Mevcut sürekli iyileştirme yöntembilimleri şirketin yenilikçi olma hedefine önemli bir katkı sağlamaktadır. Buna ek olarak yenilikçi olmak şirketin müşteri öngörülerine ve yenilikçi çözümler geliştirmede öncülük etmesini sağlar. Otomotiv endüstrisini etkileyen akımlar ürünlerin dijitalleşmesi için artan talep, aracın çevreye olan etkisinin azaltılması, artan güvenlik standartları, teknoloji devleri ile rekabet olarak tanımlanmaktadır. OR'nin bu akımlarla gereksinimlerini sağlamak için yeniliği gerekli olarak görmektedir. Görüşülen kişilerin nerdeyse tamamı inovasyonun OR için çok önemli olduğunu belirtmektedir. Buna ek olarak görüşülen kişiler inovasyonun verimliliği arttırdığını, mevcut yeteneklerin geliştirilmesine katkı sağladığını, rekabetin sürdürülmesine olacak sağladığını belirtmektedirler.

Sürekli iyileştirme yöntembilimlerinin en önemli amacı üretim maliyetinin düşürülmesi olarak belirtilmiştir. TRIZ diğer mevcut sürekli iyileştirme yöntembilimlerinden üretim maliyetlerinin düşürülmesine yönelik çözümler sunmasına ek olarak, yenilikçi olması ile ayrılır. Sürekli iyileştirme yöntembilimleri genellikle süreç iyileştirmelerine odaklanmaları sebebi ile ürün gelişmeye katkıda bulunmazlar. Röportaj yapılan bir kişinin belirttiği üzere katı uygulama yöntemleri ve mevcut sorun analizi odağı sebebi ile sürekli iyileştirme yöntembilimleri genel olarak yeniliğe katkıda bulunamamaktadırlar. TRIZ'in üretim teknolojisi ve ürün eksenleri sürekli iyileştirme yöntembilimleri ile paralel olarak süreç iyileştirmelerine olanak sağlar. Buna ek olarak TRIZ'in yeni teknoloji geliştirme, yeni kavramların öngörülmesi, patentin etrafında dolaşma ve yeni patentlerin keşfedilmesi eksenleri TRIZ'in yeniliğe katkıda bulunmasını sağlar. Buna ek olarak bilimsel araştırmalar, patentin etrafında dolaşma ve geliştirme, teknolojik gelişmeler hakkında öngörüde bulunma özellikleri TRIZ'in olası bir uygulamasının OR 'ye sağlayacağı katkılar arasındadır. Son olarak teknolojik gelişme eğilimleri hakkında öngörüde bulunma ilgili kişilere değer yaratımı hakkında keşifler yapma ve tasarımın evirilebileceği sınırların belirlenmesine katkıda bulunabilir.

TRIZ, diğer metodolojilere kıyasla nispeten esnek bir yapı sağlayarak, farklı kullanıcıların farklı araçların kombinasyonu ile farklı sorunlar için belirlenmiş benzersiz araç setlerini geliştirebilecekleri mevcut inovasyon yeteneklerini geliştirmeye yardımcı olabilir. OR 40 yenilik prensibi ve çelişki matrisini kullanarak ayrıntılı tasarımına ve ürün stratejisindeki evrimsel eğilimlere hakkında detaylı bilgi edinebilir. Ancak, röportaj yapılan bir kişinin belirttiği gibi OR'de bu konunun detaylı incelendiği detaylı bir TRIZ eğitimi mevcut değildir. Buna ek olarak TRIZ şirkete rekabetin daha az olduğu ve teknolojik eğilimlerin tahmininin etkin olarak kullanılabileceği iş potansiyellerinde ciddi bir fayda sağlayabilir. Bu olanaklar sayesinde OR yenilikte öncü olma geleneğini güçlendirebilir. Öncü olmanın sağlayacağı piyasaya ilk giren olma faydası müşteriye ilk ulaşan olma ve teknoloji standartlarını belirleme açısından globalde azımsanamayacak faydalar sağlayabilir.

2.2 Uygulama Stratejisi

Sürekli iyileştirme yöntembilimleri ağırlıklı olarak süreç iyileştirmeleri ve üretim operasyonlarının verimliliğini arttırmak üzere kullanılmaktadır. TRIZ'ın yenilik becerilerinin öne çıkarılması ve şirket içinde yenilikçi bir yöntembilim olarak açıklanması TRIZ'e olan ilgiyi arttırıp, tanıtımına önemli bir katkı sağlayabilir. Röportaj yapılan kişilerin çoğunluğu, sürekli iyileştirme yöntembilimleri üzerine yaptıkları çalışmaları için ana motivasyon kaynağının bu çalışmaların sunduğu kişisel gelişim fırsatları olarak belirtmişlerdir. Bu kapsamda TRIZ'in sunduğu kişisel gelişim fırsatları olası bir uygulama durumunda çalışan motivasyonu için kaynak oluşturabilir. Röportaj yapılan kişilerden biri, sürekli iyileştirme yöntembilimlerinin günlük işleri açısından faydalı olduğunu belirtmektedir. Sürekli iyileştirme yöntembilimlerinin sunduğu kalite ve üretim verimliliği iyileştirme fırsatları bu departmanlarda çalışan kişilerin ilgisini çekmekte ve yaygın olarak kullanılmaktadır. Ancak bu yöntembilimler tasarım, ürün geliştirme ve patent bulma fırsatları ile ilgili yeterli yenilik fırsatı sağlayamadıkları için bu ekiplerdeki çalışanlar tarafından kullanılamamaktadır. TRIZ'in sunmakta olduğu ürün geliştirme ve patent bulma fırsatları ile mühendislik ve ARGE departmanlarındaki çalışanların ilgisini çekebilir. TRIZ bünyesinde bulunan teknolojik gelişmelerin tahmini aracı ise tasarımcıların geliştiricilerin çalışmalarını bir adım ileriye götürmelerine yardımcı olabilir. Buna ek olarak, teknoloji gelişim tahmini aracı tasarımın gelişim sınırlarının ve değer yaratım analizini geliştirilmesine olanak sağlar. Ürünün gelecekte durumunu belirleme aracı ve evrimsel sınırlar araçları farklı alternatifler arasında seçim yapılmasında kullanılabilir. Sürekli iyileştirme yöntembilimlerinin katı uygulama süreçleri uygulamalarda yeniliği sınırlamaktadır. Bunun aksine, TRIZ yöntembiliminin esnek yapısı ve yeniliği teşvik eden araçları, şirket içinde etkin kullanımına zemin hazırlayabilir.

TRIZ'in sağladığı gelişmiş yenilik becerileri dış kaynaklı teknolojilerin azalmasında ve şirketin sahip olduğu patent portföyünün geliştirmesinde kullanılabilir. Röportaj yapılan bir kişinin belirttiği üzere teknolojinin evrimsel eğilim aracı ürün stratejisine ve yol haritasına rehberlik etmek için faydalı olabilir. Yenilik aktivitelerinin başarıya ulaşması ve uygulanabilmesi için şirketin planlama ve üretim faaliyetleri ile uyumlu olmalıdır. TRIZ'in bünyesinde bulunduğu araçlar yeniliğin etkin bir şekilde uygulanması ve şirket stratejisi ile uyumlu olmasını sağlar. TRIZ OR diğer sürekli iyileştirme yöntembilimleri ile ortak uygulamalar sayesinde tanıtılabilir. Bu iş birlikleri kullanımın verimliliğini arttırmaya ek olarak, şirketin kendi araçlarını geliştirmesine olanak sağlar. Kaizen mevcut tasarımın analiz ve değerlendirmesine yardımcı olurken TRIZ yenilikçi tasarım çözümleri ile sistemin gelişimine katkıda bulunabilir. Yalın üretim ve 6 sigma sağlanan fayda karşılığında, oluşturulacak zarar konusunda yaşanan çelişkide ideal çözümü bulmayı hedeflerken TRIZ, bu çelişkilerin ortadan kaldırılmasını sağlar. FMEA ve QRQC uygulamalarında ise kavramsal analiz kısmında güçlü yenilik araçları ile çözüm sağlanmasına yardımcı olur. Bu kullanımlar TRIZ uygulamalarını sınırlamak olarak değerlendirebilir ancak şirket içinde farkındalık yaratmak ve ilk uygulamayı pekiştirmek açısından yararlı olacağı düşünülmektedir.

Şirket içi yenilik ağının oluşturulması uygulama için vazgeçilmez bir öneme sahiptir. Yenilik ağı TRIZ projeleri için kullanıcılara eğitim, danışmanlık ve yönlendirme alanlarında destek sağlayabilir. Ayrıca, tam zamanlı uzman, deneyim ve becerilerinin daha sorunsuz ve etkili bir uygulama sağladığı uygulamalarda çalışana danışmanlık, eğitim ve problem çözme konularında yardımcı olarak başlangıç aşamasında faydalı olabilir. Departman içi uygulamaları kolaylaştırmak için genel takımlara ek olarak departman içi takımlar oluşturulabilir. Ekipler, projelerin uygulanmasında eğitim, danışmanlık ve problem çözme alanlarında TRIZ uzmanları tarafından desteklenebilir. TRIZ uzmanlarına ek olarak, TRIZ ekipleri de çalışanlara destek sağlayabilir. TRIZ ekiplerinin daha önce inovasyon deneyimi olan üyelerle oluşturulması halihazırda uygulanan yenilik aktivitelerinin verimliliğini arttırabilir ve projeler hakkında daha gerçekçi analizler tahminler sunulmasına olanak sağlar. TRIZ ekibi üyeleri yalın ve 6 sigmadaki şampiyonlara benzer şekilde TRIZ ekiplerine rehberlik ve yardım sağlayan yöntembilim hakkında teknik uzmanlar olarak değerlendirebilir.

Eğitim içeriği ve yoğunluğu etkin uygulama için önemli etkenlerden biridir. Temel ve ileri seviyeler olmak üzere iki eğitim programı oluşturulmalıdır. Temel eğitim kapsamında içerik olarak ana araçların kullanımı planlanarak TRIZ hakkında temel bir farkındalık yaratılabilir. Temel seviye eğitim kullanıcıya karşılaştığı günlük problemlere çözüm sağlayan temel teknikler hakkında eğitim ve tecrübe sağlar. Bu programda başarılı olan kullanıcılar ileri seviye eğitime aday olarak gösterilebilir. İleri seviye eğitim kapsamında kullanıcılara detaylı TRIZ eğitimi sağlanarak şirket dışı eğitimci desteğini ortadan kaldırmak amacı ile şirket içi TRIZ uzmanları yetiştirmeyi hedefler. Katılımcılar detaylı eğitimlerini tamamladıktan ve TRIZ kullanarak çözüm sağladıkları güncelik problemlerinden oluşturdukları projelerini bitirdikten sonra olabilirler. Daha kuvvetli bir motivasyon ve farkındalık sağlamak amacı ile temel ve ileri eğitim programlarının odağı karşılaşılan gündelik problemler olmalıdır. TRIZ yöntem farklılığı, kelime odaklı yapısı sebebi ile önyargılı bir şekilde karmaşık bir yöntembilim olarak tanımlanmıştır ancak güncel problemler üzerinden örneklendirilerek ve görsel odaklı eğitim metotları tercih edilerek bu problemler giderilebilir. TRIZ'in bir kişisel gelişim fırsatı olarak tanıtılması çalışanın TRIZ'e olan ilgisini ciddi oranda arttırabilir.

3. Sonuç

Makale kapsamında mevcut akademik kaynaklar incelenerek ve OR çalışanları ile röportajlar yapılarak, TRIZ'in şirkete sağlayacağı etkiler incelenip olası bir uygulama stratejisi oluşturulmaya çalışılmıştır. Röportajlar OR'nin farklı departmanlarında görev yapmakta olan çalışanlar ile yapılmıştır. Röportaj içerikleri şirkette kullanılmakta olan sürekli iyileştirme yöntembilimleri, bu yöntembilimlerin sağladığı fayda ve zararlar, çalışanların bu yöntembilimler hakkındaki düşünceleri, mevcut yöntembilimlerin uygulanma şekilleri ve çalışanların TRIZ'e karşı düşünceleri olarak özetlenebilir. Literatür taraması değişim yönetimi, yenilik ve bilgi yönetimi, çalışan motivasyonu, şirket stratejisi ve TRIZ alanlarına odaklanmıştır. Oluşturulan uygulama metodu şirketin inovasyon hedeflerine olumlu bir yönde katkı sağlayacağı ve mevcutta kullanılan sürekli iyileştirme yöntembilimlerine katkı sağlayacağı sonucuna ulaşılmıştır. Çalışmanın sonuçları çalışan profili, şirket yapısı ve kültürü, yenilik ve bilgi yönetimi stratejisi, mevcut iyileştirme yöntembilimleri ve olası etkileri değerlendirilerek otomotiv endüstrisi için genellendirilebilir.

ABSTRACT

Acoustic comfort in the vehicle is a priority in NVH studies, which is one of the important topics in the automotive industry. Acoustic insulation materials are used to increase the NVH performance of cars. These materials are constantly measured and developed by NVH engineers following automotive manufacturers' specifications. Small-scale changes made in these insulation materials, which will affect the overall performance of the vehicle, can lead to significant differences in the entire vehicle. There are some measurement methods in the literature to determine the acoustic properties of insulation materials. In this study, the impedance tube with one-dimensional sound waves and the reverberation cabin in the multidimensional diffuse sound field that performs the sound absorption coefficient measurements will be given comparatively. Thus, by transferring the obtained data to the literature, it will be ensured that the information for the on-vehicle test is included in the literature. The study will be instructive in terms of reverberation cabin and impedance tube correlations.

Keywords: Sound absorption coefficient, reverberation cabin, impedance tube, porous

1. INTRODUCTION

Trim materials, which are generally used for sound absorption in the automotive industry, should be determined by NVH (noise, vibration, and harshness) engineers (Olivier continued, 2010). The acoustic performances of the materials in terms of thickness and weight, usually are compared. Impedance tube and reverberation cabin systems are frequently used to perform these comparison processes (Kierzkowski continued, 2017). According to the results obtained by examining the acoustic properties of these materials as a database, an idea about their use on the vehicle is obtained (Liu continued, 2015). Also, this sound absorption coefficient (SAC) and other physical properties are used to predict NVH performance of such as vehicle trimmed simulation NVH analysis (Caillet continued, 2014).

Acoustic textiles are frequently used for the interior design section of the vehicle (Fung and Hardcastle, 2001) (Ghosh, 2014). The basic component in products to be created with these materials are fibrous materials or polyurethane foams (Arenas and Croker, 2010). In addition to these, heavy layer materials are also used (Dogru, 2020). There are studies in the literature about obtaining the acoustic properties of these materials (Shoshani, 1993) (Ballagh, 1996) (Lee and Joo,2003). In this study, the correlation of reverberation cabin and impedance tube will be examined. Because these test methods provide quick solutions in short project times. During compact project times, many validation tests are required to decide the use of a part on the vehicle. As a result of these tests, the parts decided to be included in the vehicle must be evaluated with the proofing to be carried out on the vehicle. Prototype parts are produced, trials and on-vehicle tests are carried out. Before the prototype stage, acoustic values can be obtained from the samples thanks to the reverberation cabin and impedance tube. In this way, some approaches are developed to enhance work efficiency considering project time and cost. (Batmaz and Aydın, 2012).

This study aims to obtain the acoustic properties of trim materials with different weight areas by impedance tube and reverberation cabin measurements. The results obtained in the study will be shown comparatively. In this way, it will be examined whether there is a correlation between two test methods. Impedance tubes are preferred due to the ease of production of small samples. In the reverberation cabin, the sample dimensions must be large enough to fill the frame inside. If close results can be obtained with impedance tube measurements, the usability of the impedance tube will be questioned for approximation purposes.

2. MATERIAL and METHOD

In this study, primarily trim materials with different weight areas were produced. The samples of appropriate size for each test were obtained by cutting with a press. Instruments used in this study shown in Table 1.

Table 1. Instruments used in the study

Instrument Name	Brand	Model	Measurement Range
Impedance Tube	Brüel&Kjær	4206 type	100-6400 Hz
Reverberation Cabin	Autoneum	Alpha Cabin	400-10000 Hz
Microphone	GRAS	46BL-S1	10-10000 kHz
Data Acquisition	NI Instruments	USB-4431	0.8 Hz AC/DC 24 bit
Amphi	SMSL	S 36-A PRO	20 Hz-20 kHz / 8Ω

In order to make convenient comparison of the results; five samples from each material were used. Acoustic tests with using impedance tube were carried out according to ISO 10534-2 standard. Moreover ISO 354 standard was used in reverberation cabin measurements.

2.1. Impedance Tube Measurement

In impedance tube measurements, one-dimensional measurements are performed with the normal incident wave. This method gives similar approximation results to measurements made with the random incident wave. The standing wave ratio is used for the standing waves created inside the impedance tube. The sound absorption coefficient is calculated through the difference between the minimum and maximum values of the sound pressure level. With this method, only 1 frequency is obtained. The rest time pressure in the tube is given in Equation 1 (Cox and D'Antonio, 2009).

$$p = A(e^{ikz} + R_r e^{-ikz}) \tag{1}$$

Here R_r is the reflection factor. K is the wavenumber and A is the complex constant. Here, the first term refers to the incident wave and the second term to the reflected wave. Here, the reflection coefficient is determined from the steady-state wave ratio and this ratio is shown in Equation 3.

$$S = P_{max}/P_{min} \tag{2}$$

$$R = (s-1)/(s+1) \tag{3}$$

The transfer function method uses 2 microphones with distances z_1 and z_2 according to the measurement sample. The sound absorption coefficient is determined by the data from the signals of these microphones. The complex pressurized reflection coefficient is given in Equation 4.

$$R_r = \frac{H_{12}e^{ikz_1} - e^{ikz_2}}{e^{-ikz_2} - H_{12}e^{-ikz_1}} \tag{4}$$

Here, $H_{12} = p(z_2)/p(z_1)$ is used in transfer function calculations. As a result, the sound absorption coefficient is calculated by Equation 5 (Allard and Atalla, 2009).

$$\alpha = 1 - |R_r^2| \tag{5}$$

Measurement of sound absorption coefficient is shown in Fig 1.

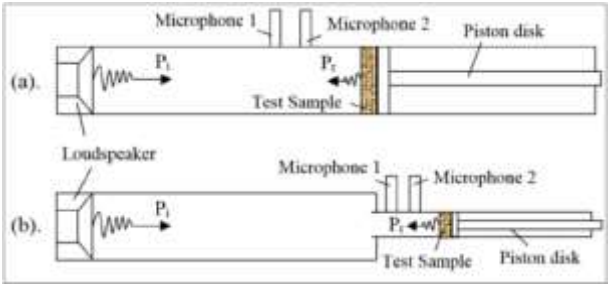

Fig 1. Sound absorption coefficient measurement with impedance tubes (Liu continued, 2015)

In this test method, plane waves are produced in a tube by a noise source. Microphones mounted on the wall of the tube allow the measurement of acoustic pressures in two fixed positions. Then, the calculation of the complex acoustic transfer function is provided by the software of the device (Dogru, 2020).
The advantages of this method are it allows rapid testing with using quite simple equipment and the small size of the samples required for testing. On the other hand, the method has some disadvantages such as the accurate results can be obtained only for sound waves impinging perpendicular to the surface of the sample. Furthermore, impedance tube test is not convenient for measurement on formed parts.

2.2. Reverberation Cabin Measurement

The Alpha cabin is a small reverberation room that are commonly used in automotive industry for the measuring the sound absorption coefficient of a wide range of materials. This test method is suitable for formed parts without a need for cutting as well as flat samples of standard dimensions. The measurement frequencies are between 400 Hz and 10 kHz which corresponds to the needs of automotive industry. The reverberation cabin used in sound absorption coefficient calculations is shown in Fig 2.

Fig 2. Sound absorption coefficient measurement with reverberation cabin (URL1, 2021)

The absorption coefficient by the Alpha cabin is calculated from the measurement of the reverberation time. Here V is the volume of the cabin, S_0 is the area of the closed cabin, S_1 is the area of the sample to be characterized, T_0 is the reverberation time when there is no sample in the cabin, T_1 is the reverberation time with the sample in the cabin. The first hypothesis consists of the omission of the term 1/(S_0 T_0), which can be justified here by the influence of a strong reverberation time T_0 and a large field S_0. After this simplification, the new Sabine equation takes the following form in Equation 6.

$$a_S \cong 0.163V \left[\frac{1}{S_1T_1} - \frac{1}{S_1T_0}\right] \quad (6)$$

In this test method, random incidence waves are produced in a cabin by a noise source. Microphones mounted on the top of the cabin in five fixed positions. First, when the cabin is empty, the reverberation time is measured. Then the sample is placed inside the frame of 1-1.2m in the cabin. In case there is a sample in the cabin, the reverberation time is measured again. Thus, the absolute sound absorption coefficient is obtained by making use of the difference in the reverberation time. Since the Alpha cabin consists of walls that are not parallel to each other due to its structure, mutual sound waves do not damp each other, and accurate measurement is obtained.

2.3. Materials Used in Study

In this study, as seen in Figure 3 below, an epoxy and phenolic resin felt made of recycled fibers, and a felt containing polyester fibers were used. These materials are in the porous material class. Porous materials are generally preferred because of their high sound absorption capacity. For this reason, only sound absorption coefficient values were measured to make a meaningful comparison in the study. These porous materials are used as an absorption layer in addition to the barrier layer. In the automotive sector, they are frequently preferred as engine firewall insulators, inner dash insulators, carpet underlay insulators.

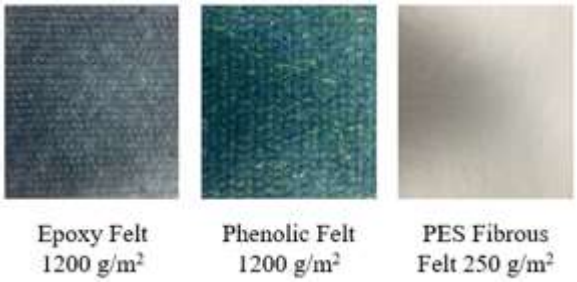

Fig 3. Materials used in the study

3. RESULTS

The measurement results will be shared firstly for the impedance tube and then separately for the reverberation cabin. Later, the differences that will be formed by superimposing them will be observed.

3.1. SAC Measurements with Impedance Tube

In Figure 4, the sound absorption coefficients of the materials used in the study are shown in the range of 200-6300 Hz. As can be seen in the figure, similar results were repeated for fibrous materials. The impedance tube measurement samples are easy to obtain, so they can be preferred in terms of such comparisons.

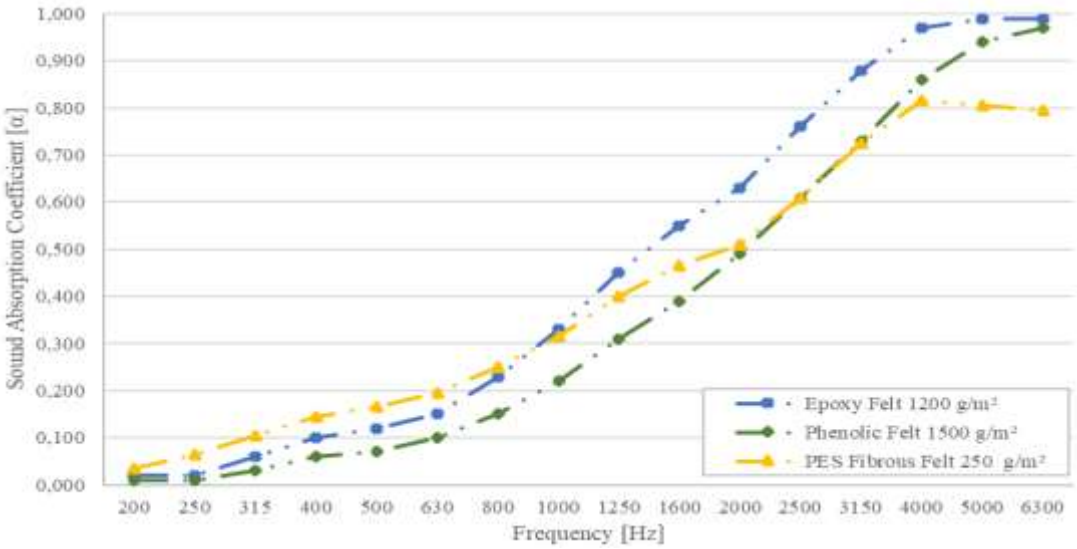

Fig 4. Measurement results with an impedance tube

For the samples to fit into the tube, waterjet cut samples should be preferred. Because, in impedance tube measurements, since the measurements are made by analyzing the transfer function based on the pressure differences between two microphones, all changes that may occur in the boundary conditions affect the measurement results.

3.2. SAC Measurements with Reverberation Cabin

The sound absorption coefficients of the materials used in the study in the range of 400-10000 Hz are shown in Figure 5.

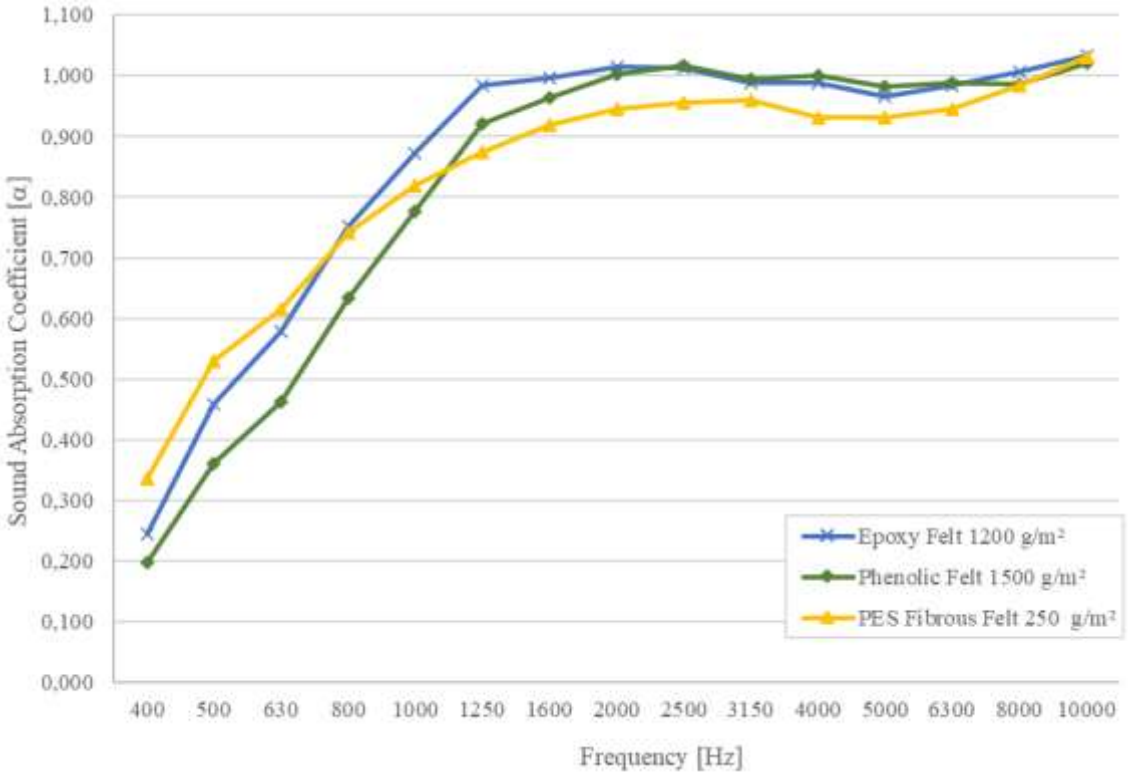

Fig 5. Measurement results with reverberation cabin

Since the reverberation cabin measurements are obtained from the reverberation time that occurred in the cabin, the effect of the leakage does not occur as in the impedance tube. For this reason, more accurate measurement results are obtained. The important feature of the reverberation cabin, that makes it stand out compared to the impedance tube is that measurements can be carried out on formed parts. Formed insulators used on the vehicle are placed in the cabin and measurement is provided utilizing the reverberation time. In this way, the sound absorption coefficients of insulators formed with different weights or different materials can be measured. Before the prototyping period, it can be decided which material to use by comparing the measurements taken from flat samples. The impedance tube also provides these measurements for low-frequency ranges. However, it is seen that the measurement results differ as higher frequencies are reached. For this reason, the superimposed graphic should be examined.

3.3. Comparison of Measurements

In Figure 6, impedance tube and reverberation chamber measurements are shown comparatively. It is clear from the figure that the sound absorption coefficient was higher in the measurements performed with the reverberation cabinet. The sound absorption coefficient is lower than the reverberation cabin due to leaks in the impedance tube measurements.

Figure 6 is examined carefully; it is seen that the proportional sound absorption coefficient curves continue similarly throughout the frequency band. This proportional similarity disappears as moves towards higher frequencies. Measuring up to a maximum of 6400 Hz is provided with the impedance tube designed following the standards used in this study. At high frequencies, the measurement results lose their accuracy. There are some standardized methods in the literature to obtain more accurate measurements and a smaller diameter impedance tube is used in these measurements. High-frequency audible noise has a large effect on perceived quality (Kimura continued, 2014). For this reason, high

frequencies should also be reviewed. However, this time, low frequencies become unable to be evaluated with the impedance tube. With the reverberation cabin, a large range, 400-10000 Hz, is measured. For this reason, the reverberation cabin becomes advantageous based on the frequency.

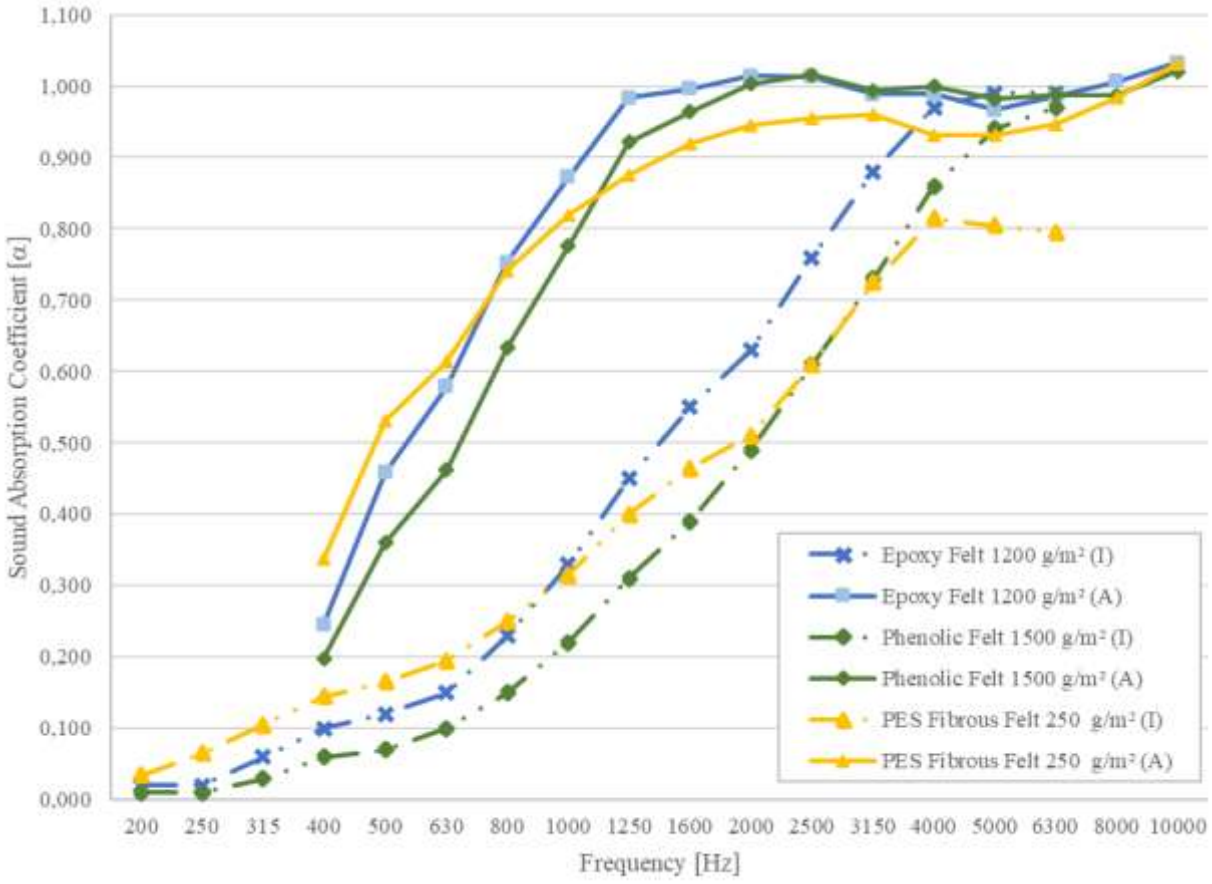

Fig 6. Comparison of measurements made with impedance tube and reverberation cabin

The studies in the literature were examined in detail, it was seen that higher levels of sound absorption coefficients were obtained in the measurements performed for different materials with the reverberation cabin (Egab continued, 2014). One of the reasons for this is that the 1-dimensional normal sound wave pressures of the impedance tube are measured on both sides of the sample (Chappuis, 1993). Possible leaks in the measurements carried out in this way cause the sound absorption coefficient to be lower. To eliminate these effects, there are applications such as adapters or sealants placed around the sample in the literature (Allan continued, 2014). Since the reverberation cabin provides measurement with 3-dimensional sound waves under the random diffuse sound field, more accurate measurement results are obtained.

Impedance tube is preferred as suggestive with its ease of sample production and fast measurement results. The measurement results performed with the impedance tube reveal useful results to determine which material gives better results. In addition, impedance tube measurements are preferred to obtain the acoustic characterization properties of the samples. As one of the results of this study, it is seen that impedance tube measurements may be preferred when a comparison with the rapid measurement result is requested. However, as can be seen in this study, it has been revealed that measurements of the reverberation cabin should be selected to obtain precise results in sound absorption coefficient measurements.

4. CONCLUSIONS

This paper discusses acoustical measurements of interior trim materials. It gives an overview of the comparison of impedance tube and reverberation cabin measurements. The results obtained from the measurements made with the impedance tube in the low-frequency band have been shared. However, as a result of the comparison of the

measurement results to be carried out in this way with the reverberation cabin, it was seen that low SAC values were obtained depending on the frequency. It was mentioned that the measurements made with the reverberation cabin are more accurate because they take place in the random diffuse sound field. It has many advantages such as measuring over reverberation cabin, formed materials, and having a wide frequency band. Also, impedance tube measurements should be performed precisely due to sealing and vibration problems. Also, the convenience of impedance tubes in sample production should be taken into account when comparing materials. Impedance tube measurements come to the fore in terms of acoustic characterization. Comparisons that can be made with fast measurement results, especially in tight project times that may occur in the automotive sector, can speed up the process.

ÖZET

Bu çalışmada otomobil kabininde ön camda oluşan buzun giderilmesi amacıyla iklimlendirme elemanından çıkan havanın hız ve sıcaklık dağılımına bağlı olarak buz çözme süresinin belirlendiği üç boyutlu sayısal analizi, Hesaplamalı Akışkanlar Dinamiği (HAD) yöntemi kullanılarak gerçekleştirilmiştir. Test verilerinde kullanılan otomobil kabini modelinin matematiksel modelinden ölçüm alınarak yeni bir model tasarlanmıştır. Modelde, iklimlendirme elemanlarının standart ısıtma süreci için sürekli ve geçici rejimde yapılan sayısal analizler sonucunda, hava akışı, ön cam bölgesindeki ve buz tabakasındaki sıcaklık dağılımları elde edilmiştir. Sınır ve başlangıç koşulları uygun doğrulama sağlanması açısından deney verisi ile aynı olacak şekilde seçilmiştir. Sayısal analizler iki aşamalı olarak sürekli ve geçici rejimde gerçekleştirilmiş, sürekli rejimde momentum denklemleri çözdürülüp akışkan hareketi incelenmiş, geçici rejimde ise enerji çözdürülerek ön cam bölgesinde zamana bağlı sıcaklık dağılımı ve buz çözme süresi analiz edilmiştir. Sonuçlar deney verileri ile karşılaştırılarak doğrulama sağlanmıştır. Yapılan çalışmalar sonucunda otomobillerde görüş kısıtlaması nedeniyle sürüş güvenliği açısından hayati öneme sahip olan ön cam buz çözme süresinin, sayısal analizler ile çözümlenerek optimizasyon sağlanabileceği anlaşılmıştır.

NUMERICAL AND EXPERIMENTAL INVESTIGATION OF THE WINDSHIELD DEFROSTING PROCESS IN AUTOMOBILES

ABSTRACT

In this study, the three-dimensional numerical analysis of the defrosting time based on the speed and temperature distribution of the air exiting the air conditioning element in order to remove the ice formed on the windshield in the automobile cabin was performed using the Computational Fluid Dynamics (HAD) method. New model was designed by taking measurements from the mathematical model of the automobile cabin model used in the experimental data obtained for the real car cabin. In the model, as a result of the numerical analysis of the standard heating process air flow, temperature distributions in the windshield area and the ice layer are obtained. The boundary and initial conditions were chosen to be identical to the experimental data to provide proper verification. The numerical analyzes performed using CFD method were carried out in two stages in continuous and transient regime, momentum equations were solved in continuous regime and fluid motion was examined, and in transient regime, the percentage of time-dependent defrosting in the windshield region was analyzed by dissolving energy. Validation is provided by comparing the results with experimental data. As a result of the analysis, it was understood that the windshield defrosting time, which is vital for driving safety due to bad visibility conditions, can be solved with numerical analysis and optimization can be achieved.

Key words: CFD, Heat Transfer, Deicing/Defrosting, Climate Control

1. Giriş

Otomobil iklimlendirme sistemlerinin en önemli görevleri arasında sürüş güvenliği ve yolcuların ısıl konforunu sağlamak gelmektedir. Yılın kış aylarında hava sıcaklıkları 0 ° C'nin altına düştüğünde otomobillerin ön camındaki buz tabakası sürücünün görüşünü engelleyerek sürüş güvenliği açısından tehdit oluşturabilmektedir. Aracın iklimlendirme Heating, Ventilating and Air Conditioning (HVAC) ünitesi, sıcak havanın en az dirençle otomobil kabinine alınmasından sorumludur ve bu işlem, soğuk hava koşullarında ön / yan camlardan buz ve buğuyu gidererek sürüş güvenliği sağlar. İklimlendirme ünitesinin verimi de buz buğu çözme prosesleri açısından son derece önemlidir. Otomotiv endüstrisinde iklimlendirme sistemlerinin gelişimi için Hesaplamalı Akışkanlar Dinamiği (HAD) yöntemi sıklıkla kullanılmaktadır.

Son yıllarda HAD alanındaki gelişmeler ile otomotiv endüstrisi, bu yöntemi aktif olarak kullanarak uygun test koşullarını sağlamakta, prototip maliyetlerine harcanan zamandan ve paradan da tasarruf etmektedir. HVAC sistemlerinin gelişimi için literatürde birçok çalışma yapılmıştır. Araştırmacılar, menfezlerden çıkan havanın hareketini inceleyerek, ön camın iç yüzeyine çarpan hava jeti üzerinde HAD analizleri ve deneyler yapmışlardır. Bu çalışmaların temel amacı, ön cam üzerindeki buz ve buğuyu temizleyerek, kabin içindeki havanın hareketini gözlemlemek ve ön camdaki sıcaklık dağılımını belirlemektir. Bu bilgiler ışığında, tasarlanan sistemlerin buz çözme olgusu, iklimlendirme elemanları ve performans kriterleri belirlenmeye çalışılmıştır. Nasr ve Abdoul, Nour ve ark. ön camda sıcaklık dağılımı ve hava akışı için ölçüm yöntemlerini belirleyerek deneysel ve sayısal analizleri içeren kapsamlı çalışmalar yapmıştır [1, 2]. Abdoulnour sıcak telli bir anomometre kullanarak, havalandırma çıkışında ve ön camın yakınında hava hızı ölçümleri gerçekleştirmiştir [3]. HAD yöntemini kullanarak buz çözme sisteminin akış alanının sayısal simülasyonunu gerçekleştirerek test sonuçlarını doğrulamayı amaçlamıştır. Willenborg ve arkadaşları, sıcak tel hızı ölçümünü kullanarak havalandırma menfezlerinden çıkan ve ön camın iç yüzeyine etki eden hava jeti akışını gözlemlemiştir [4]. Mutlu ve ark. otomobilin ön cam buğu çözme işlemi için deneysel ve sayısal bir çalışma gerçekleştirmişlerdir. Geçici rejim koşulları altında gerçekleştirilen HAD analizlerinde üç boyutlu araç modeli kullanılmıştır. Sayısal hesaplamalarda ön camdaki buğulanmış alanın karşılaştırılması için hem damlacık hem de duvar filmi modellerini kullanmışlardır [5]. Subrata Roy ve ark. eğimli bir yüzey üzerine çarpan bir hava jetinin termal akış özelliklerini tanımlayan bir çalışma oluşturmuşlardır [6]. Yüzey ile çarpan hava jeti arasındaki ısı transfer katsayılarının haritası gösterilmiş, sayısal sonuçlar deneysel verilerle karşılaştırılarak ve sonuçlar doğrulanmıştır. Kumar ve ark. HAD yöntemiyle tam bir araç kabini geometrisi kullanarak ön camda hava akışı optimizasyonu üzerinde çalışmalar gerçekleştirmişler ve iklimlendirme elemanlarının buz çözme performansını daha az zaman ve maliyetle değerlendirebilmişlerdir [7]. Aroussi ve ark. araç ön ve yan camlarının buğu giderme işleminin etkilerini ve yolcu konforunu değerlendirme ve karşılaştırmalı buz çözme performansı için HVAC sistemleri hakkında çalışma yapmışlardır [8]. Swales ve ark. optimum buz çözme ve buğu giderme performansı için bilgisayar destekli mühendislik hesapları ve deneysel yöntemlerini birleştirerek bir çalışma yapmışlardır [9]. Juan ve ark. elektrikli araç için buğu giderme performansının değerlendirmesini araştırmışlardır [10]. Kang ve ark. araç buz çözme sistemini tam ölçekli bir model aracılığıyla analiz etmişlerdir [11]. Gerçekleştirilen bu çalışmada ise otomobil kabini ön cam buz çözme analizi gerçekleştirilerek elde edilen sonuçlar deneysel verilerle karşılaştırılmış ve sonuçların doğruluğunun belirlenmesi amaçlanmıştır. Ayrıca bu analizde, ön cam buzunun çözülmesinin sadece taşıt HVAC sisteminin sağladığı sıcak havadan kaynaklanması koşulu göz önünde bulundurulmuştur.

2. METODOLOJİ

Bu çalışmada, ön cam buz çözme işleminin sayısal analizi için ANSYS Fluent yazılımı kullanılmıştır. Gerçekleştirilen sayısal analizlerde sonlu hacim yöntemi kullanılarak ticari araç kabini için süreklilik, momentum ve enerji denklemleri çözülmüştür. Sonlu hacim yöntemi, hesaplama alanında sıvı akışını çözmek için daha fazla esnekliğe sahiptir [12]. Türbülanslı akışın karmaşık geometri üzerinde modellenmesi amacıyla SIMPLE algoritması ve standart k-epsilon türbülans modeli tercih edilmiştir. HAD analizleri sürekli ve geçici rejim koşulları altında gerçekleştirilmiştir. Buz çözme analizlerinde, sürekli rejim koşullarında akış ve türbülans, geçici rejim koşullarında ise sadece enerji denklemleri çözdürülmüştür.

Sayısal analizlerde kullanılan süreklilik, momentum ve enerji için korunum denklemleri Denklem 1-5 arasında görülebilmektedir [5].

$$\frac{\partial \rho}{\partial t} + \nabla . (\rho \vec{v}) = S_m \qquad (1)$$

Denklem 1 kütle korunumu için genel denklemdir ve bu denklemde yer alan S_m kaynak terimdir. Momentum korunum denklemi ise Denklem 2' de verilmiştir.

$$\frac{\partial}{\partial t}(\rho\vec{v}) + \nabla.(\rho\vec{v}\vec{v}) = -\nabla p + \nabla.(\bar{\bar{\tau}}) + \rho\vec{g} + \vec{F} \quad (2)$$

Burada p statik basınç, $\bar{\bar{\tau}}$ gerilme tensorü, $\vec{F}$ ve $\rho\vec{g}$ sırasıyla yerçekimi ve dış gövde kuvvetlerini ifade etmektedir. $\bar{\bar{\tau}}$ gerilme tensorü ise Denklem 3'te verilmiştir.

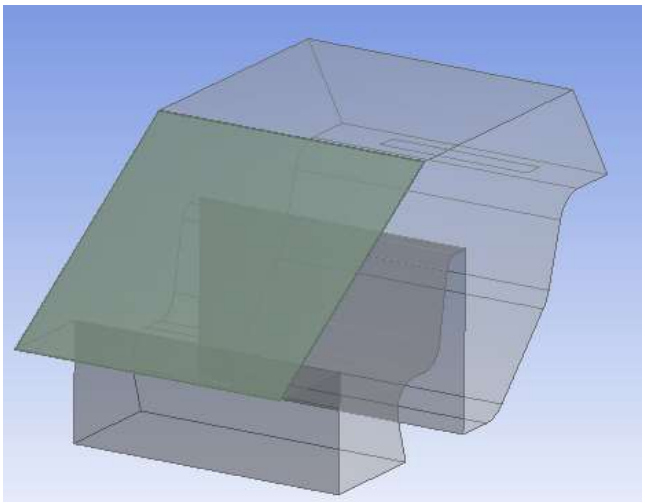
$$\bar{\bar{\tau}} = \mu\left[(\nabla\vec{v} + \nabla\vec{v}^T) - \frac{2}{3}\nabla.\vec{v}I\right] \quad (3)$$

Burada μ moleküler viskoziteyi, I birim tensörü ifade etmektedir. Enerji korunum denklemi aşağıda verilmiştir.

$$\frac{\partial}{\partial t}(\rho E) + \nabla.(\vec{v}(\rho E + p)) = \nabla.\left(k_{eff}\nabla T - \sum_j h_j\vec{J}_j + (\bar{\bar{\tau}}_{eff}.\vec{v})\right) + S_h \quad (4)$$

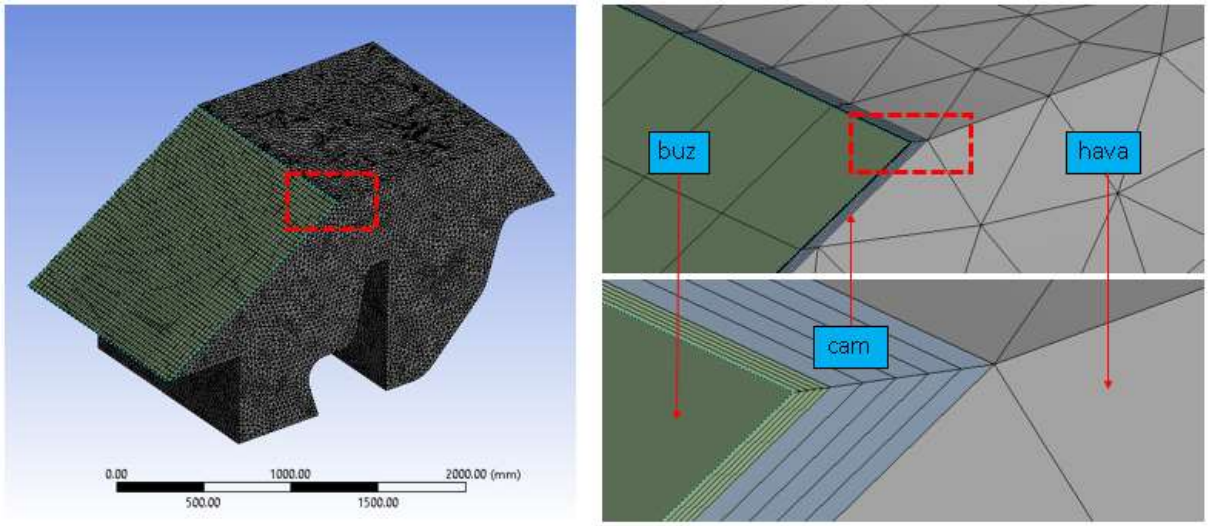
$$E = h - \frac{p}{\rho} + \frac{v^2}{2} \quad (5)$$

Ticari aracın kabin içi geometrisi, SIEMENS NX 9.0 tasarım yazılımında aracın 1: 1 ebatları kullanılarak yaklaşık olarak modellenmiştir. Model Şekil 1'de gösterilmiştir.



Şekil 1. 3 Boyutlu yaklaşık kabin geometrisi

Şekil 2'de buz ve cam modellerin buz çözme analizi için kabin geometrisine eklendiği ve matematiksel modelin tamamlandığı görülmektedir. Hesaplama alanı iki sıvı ve bir katı bölgeden oluşmaktadır. Kabin ve buz alanları akışkan bölgeler olarak modellenirken, cam alan katı bölge olarak modellenmiştir. Buz ve cam bölgelerinin ağ yapısı hexahedral elemanı tipinden oluşmaktadır. Kabin modeli için ise üçgensel eleman tipi kullanılmıştır. Hesaplama alanının toplam öğe sayısı yaklaşık 1 milyondur. Her bir hesaplama alanının termofiziksel özellikleri simülasyonlar sırasında sabit tutulmuş ve Tablo-1'de listelenmiştir. [13]

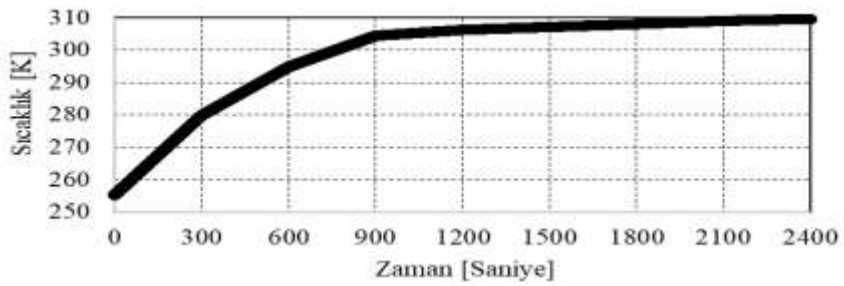


Şekil 2. Hava, cam ve buz bölgeleri ve ağ yapısı

Tablo 1. Sayısal çalışmada kullanılan malzemelerin termofiziksel özellikleri

	Air	Ice	Glass	
Yoğunluk	1,225	920	2500	$kg.m^{-3}$
Özgül ısı	1006,43	2040	750	$j.kg^{-1}.K^{-1}$
Termal iletkenlik	0,0242	1,88	1,4	$W.m^{-1}.K^{-1}$
Viskozite	1,7894e-05	0,00553	-	$kg.m^{-1}.s^{-1}$
Ergime ısısı	0	334960	-	$j.kg^{-1}$
Katı haldeki sıcaklık	0	271	-	K
Sıvı haldeki Sıcaklık	0	273	-	K

Giriş hızı için deneysel test çalışmasında akışkan akış hızı hava hızı ile aynı değerde tanımlanmıştır. Çıkış için ölçülen basınç 0 Pa'dır. Sürekli rejim momentum hesaplamaları için hava sıcaklığı 355,2 K'dir. Geçici rejim olan ikinci aşamada hız girişi için zamana bağlı sıcaklık değişim grafik değerleri tanımlanmıştır. Zamana bağlı sıcaklık grafiği Şekil 3'te gösterilmiştir. Bu grafik için deneysel çalışma sıcaklık değerleri baz alınmıştır.



Şekil 3. Giriş havası için zamana bağlı sıcaklık değişim grafiği

Deneysel çalışmadan elde edilen veriler dikkate alınarak sınır ve başlangıç koşulları belirlenmiştir. Ayrıca, geçici rejim analizlerinin başlangıç sınır koşulları daha değerli sonuçlar elde etmede önemli bir role sahiptir. Başlangıç koşullarında kabin içi ve dışı sıcaklığı -19 °C olarak belirlenmiştir.

Tablo 2. Başlangıç ve sınır koşulları

Dış ortam sıcaklığı	-19.0°C
Simulation time and time step	40 min/0.1 s
Yüzey	*Sınır Şartları*
Cam ve dış yüzeyler	Konvektif sıcaklık
Dış yüzeyler	Adyabatik sıcaklık
Isı Transferi: *T=T (Şekil 3 sıcaklık profili)*	
Çıkış (Geri akış özellikleri)	
Ölçülen basınç (çıkış)	0 Pa

Çözümlerde taşınım terimleri için ikinci derece ayrıklaştırma yöntemi ve hız-basınç ilişkilendirilmesinde SIMPLE algoritması kullanılmıştır. Çözüm metotları Tablo 3'te gösterilmiştir.

Geçici rejimde enerji için yakınsama kriteri 10^{-6}'dan daha az sürekli rejimde ise tüm değişkenlerin yakınsama kriteri 10^{-3} 'ten küçüktür. Zaman adımı için Fluent'e tanımlana zamana bağlı sıcaklık değişim profilindeki zaman adımı ile aynı olacak 0.1 saniye verilmiştir.

Tablo 3. Çözüm Metodu ve Türbülans Modeli

5. TARTIŞMA ve SONUÇ

Bu çalışmada ön cam buz çözme işlemi için HAD analizleri ve deneysel çalışmalar gerçekleştirilerek sonuçlar karşılaştırmalı bir şekilde incelenmiştir. ANSYS Fluent yazılımı kullanılarak gerçekleştirilen analizlerde model, araç kabini boyutlarında tasarlanmış ve analizlerin sınır şartları deneysel çalışmadaki duruma benzer alınmıştır. Deneysel çalışma için ticari bir araç için klimatik kabin içinde zamana bağlı buz çözme testi gerçekleştirilmiş ve sonuçları değerlendirilmiştir.

Yapılan analizler ve deney verilerindeki buz çözme süreleri karşılaştırılmış ve benzer sıcaklık ve buz çözme dağılımları gözlenmiştir. Bu duruma göre aşağıdaki sonuçlar çıkarılmıştır:

Ön cam üzerindeki hava akışı, HAD simülasyon araçları kullanılarak buz çözücü nozulun tasarım yinelemeleriyle düzeltilebilir ve optimize edilebilir olduğu görülmüştür. Ayrıca kısa bir süre içinde çeşitli tasarımlar sayısal yöntemlerle değerlendirilerek çok fazla tasarım esnekliğinin de sağlanabileceği görülmüştür.

Hava akışı ve sıcaklık modeli analiz sonuçlarının deneysel sonuçlarla uyumlu olduğu görülerek sonuçlar doğrulanmıştır. Bu sonuçlar göz önünde bulundurularak, tasarım aşamasında HAD analizlerinden faydalanılabilir olduğu sonucuna varılmıştır.

Sayısal çalışmalardan elde edilen sonuçlar ile taşıt iklimlendirme sisteminin buz çözme performansı taşıt ön camı üzerindeki buz katmanının sıvılaşma oranları incelenerek başarıyla tahmin edilmiştir. Prototip parçaların ve maliyetli iklimsel rüzgâr tüneli testlerinin yokluğunda sayısal çalışmalardan elde edilen buz çözme performansının iyileştirilecek alanların belirlenmesine yardımcı olabileceği öngörülmüştür.

Buz çözme performans tahmini için HAD analizlerinin ilk aşama yatırımı, prototip parçalarının ve testlerin sayısını önemli ölçüde azaltma potansiyeline sahip olduğu ve bu da zaman çizelgesini ve ilgili maliyetleri azalttığı görülmüştür.

Buz çözme analizinin sonucunda araç modelinin birebir boyutlarında ve benzer geometride yapılan analizlerin deney verileri ile doğrulaması sağlanmıştır. Bu veriler ışığında, özellikle kış aylarında iklim şartlarının zorlu olduğu bölgelerde sürüş güvenliği sağlamak amacıyla buz çözme hızının optimizasyonunun sayısal analizler ile sağlanabileceğini göstermiştir.

ABSTRACT

Kinematic and dynamic model of valve train system was investigated in order to optimize the valve train system for V type engine. In this paper, it was dealing with kinematic and dynamic single camshaft with push rod valve train system for V4 engine. For designing a new valve train system, it needs some certain decision before starting modelling. This may be most important issue for designing a system which is less emission and more efficiency for engine. Before starting design, it was decided to type of engine, number of cylinder, size of cylinders. Then, it was calculated the air which needs engine to get enough torque in certain time with FEV Virtual Dynamics for determined valve timing. After that, engine and valve train system was drawn with CATIA V5. After drawing all needed parts, engine was assembled with CATIA V5 Assembly Module to get kinematic system of engine. Furthermore, to analysis dynamic of system, it was studied ADAMS View. With this software, it was also determined gears which can be used for camshaft and crank shaft. The aim is to create a way which helps to design a new valve train system with overhead valve train system for V type engine.

Keywords: Valve train, kinematic analysis, mechanism design, internal combustion engine

1. INTRODUCTION

Valve train is a mechanism which has been used for controlling intake and exhaust valves. Intake side of mechanism is controlling entrance of the air or air-fuel mixture for explosion inside the cylinder. After combustion, waste gases must be removed from the system. Here is working space for exhausted valves. For recent years, there are plenty of engines created for high speed and high torque but it can easily be realized that the controlling of this system is extremely difficult, because it must be thought also high efficiency and power at the same time. It means that valve train system is required for timing of intake and exhaust and according to valves locations, it can be determined the compression ratio. So, valve train system is essential for internal combustion engine design (1-3). If any timing irregularity happens, valves can be damaged by piston hitting. Whereas, valves can be located far away from the pistons, but this time, compression ratio is exceedingly decreased. So, it means that valve train system's timing and location is one of the major issue for designing a new engine.

Intake valve was opening by vacuum after piston leaves from the top of cylinder. After that, intake valve could close by itself because of the force which was stored on the spring it while opening, but engines have boundary RPM value because of the pumping losses. So, it proved us that optimization of valve train was necessary to get more efficiency and more torque from the engines (Teodorescu et al, 2007). Developments on this topic are still going on, furthermore some studies are using camless systems to overcome problems.

Moreover, there are also some studies on systems which are variable timing, camshaft design is not considered in that articles. These kind of studies are high technology for now and usage area is little bit narrow. They are being used for race cars or luxury cars. Some examples of used variable valve timing engine for engine brands (URL1). Alfa Romeo Spider 2000 is the first car which is used the variable valve timing (URL2).

In this papers, it dealt with valve train system which name is Overhead Cam Shaft Engine. These valve train systems include cam shaft, push rod and its follower, rocker arm, shaft of rocker, valve, spring, retainers, beds of valve and push rod. The type of engine was decided as a V4 engine. It should be noticed that all components should not contact as perpendicular to each other.

Aim of this study is to design an optimized valve train for new engine configuration. According to this aim, kinematic and dynamic analyses have been investigated with FEV Virtual Dynamics, CATIA V5, ADAMS View.

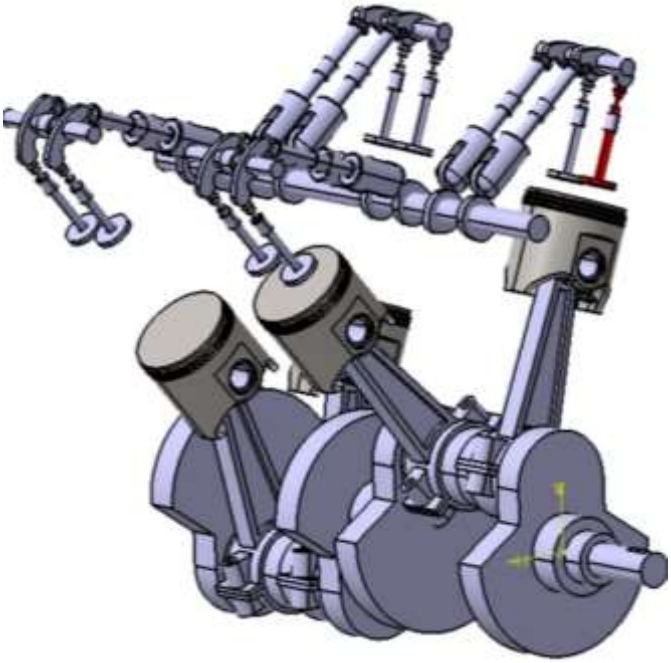

Figure 1. Engine and Its Valve Train from Catia V5

2. Multi Body Valve Train Model

In this period, valve train system has been improved and optimized until now and there are various types of valve train system. Such as, direct acting, end pivot rocker arm, center pivot rocker arm, center pivot rocker arm with follower, OHC pushrod.

2.1 Kinematic Equation of Over Head Valve Train Mechanism

Kinematic equation is used for location, velocity and acceleration of the parts which are used in systems. After finding this equation, all instantaneous information of the system can be solved easily. Kinematic equation of the system can be obtained from Freudenstein equation (Uicker, 2003). According to method of Freudenstein;

$$(S_1+A_1).e^{i\alpha 1}+A_2.e^{i\alpha 2}+A_3.e^{i\alpha 3}+A_4.e^{i\alpha 4}+A_5.e^{i\alpha 5}=A_6+S_2 \quad (1)$$

As it is shown that;

- S_1=Cam Lobe contact point
- A_1=10 mm (Follower of cam)
- A_2= 90 mm (Push Rod)
- A_3= 16 mm (Rocker Arm, Push Rod Side)
- A_4= 21 mm (Rocker Arm, Valve Side)
- A_5= 60 mm (Valve)
- A_6= 83.124 mm (Horizontal distance of valve center)
- S_2= 30.847 mm (Variable, Valve vertical distance from cam center)
- α_1 = 87.5° (Constant)
- α_2 = 57.5° (Constant)
- α_3 = 12.5° (Variable)
- α_4= 150° (Variable)
- α_5= 270° (Constant)

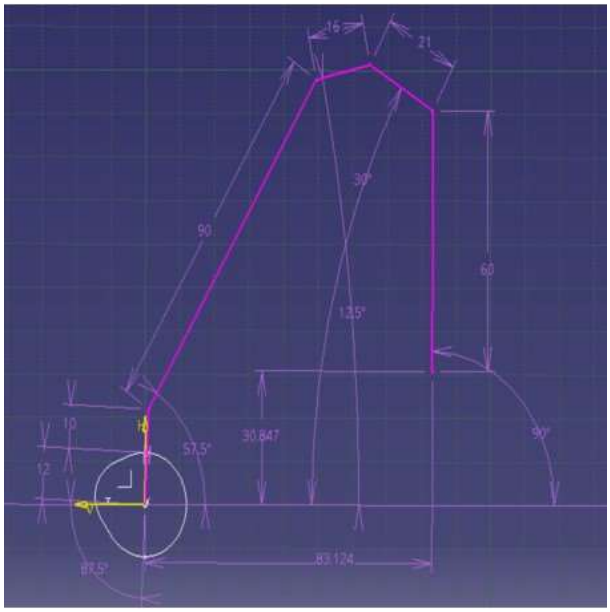

Figure 2. Illustration of the System

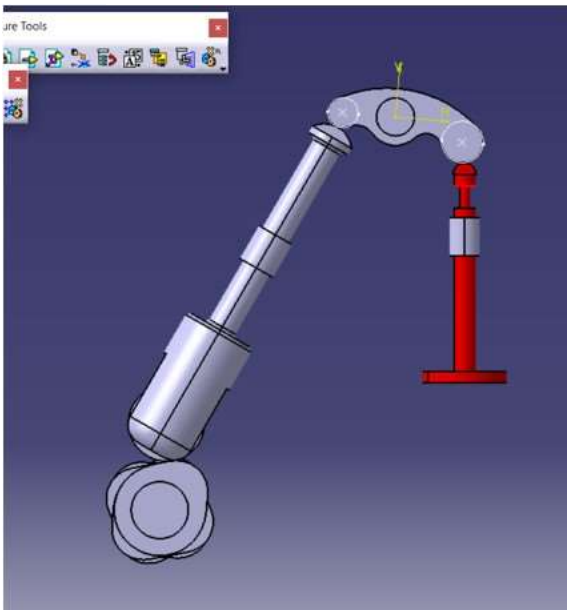

Figure 3. Valve Train System

To calculate easily, system was turned 30° counter clockwise and got the kinematic equation of the system.

2.2 Dynamic Equation of Over Head Valve Train Mechanism

Dynamic equation of the system is used for analyzing the system. According to analyze the system, it is found the equation numerically with respect to force, frictions and damping. The equation must be written with all components (Teodorescu, 2007). Here is general dynamic equation;

$$m_i\ddot{z}_i + c_{ei}(\dot{z}_i - \dot{z}_{i-1}) + k_{ei}(z_i - z_{i-1}) - k_{ei+1}(z_{i+}1 - z_i) - c_{ei+1}(\dot{z}_{i+1} - \dot{z}_i) + F_i = 0 \quad i = 1, 2 \qquad (2)$$

According to this dynamic equation, the system can be analyzed clearly.

2.3 Over Head Valve or Push Rod Valve Train

This is the valve train type, which is dealt with in this paper. As already mentioned, this system includes cam shaft, push rod and its follower, rocker arm, shaft of rocker, valve, spring, retainers, beds of valve and push rod. To control the valves, many components must work together very well but at the same time, using this system allow to need less working place to design. This is mostly used in heavy duty vehicles. All components will be explained below.

Figure 4. Push Rod Valve Train System (Jelenschi, 2012)

2.3.1 Cam Shaft

The camshaft has been used in IC engines to control intake and exhaust valves. It is rotated according to the crankshaft thanks to the gear train. Ratio between crankshaft and camshaft is 0.5 due to crankshaft. It means that when crankshaft rotates 720^0, camshaft is rotated 360^0 because of four stroke engine. It is made from cast iron or steel and is so important to define power, torque and RPM of the engine. To get cam lobe, there are several steps;

- Calculate mass of air in cylinder for combustion
- Calculate the time in order to take enough air inside of cylinder from certain valve area
- Opening and closing acceleration of the valve
- Take lobe point data into CAD software and create a 2D lobe geometry

During the design of cam shaft, the aim is to get max lift area with low negative and positive accelerations. When the lift time of both acceleration and deceleration are decreased, it causes magnitude of total acceleration. So, it turns as vibration, losses and more power to run the system. Additionally, to optimize the cam profile, it must be considered relationship between cam profile, cam speed and stiffness (Qin and Chen, 2014).

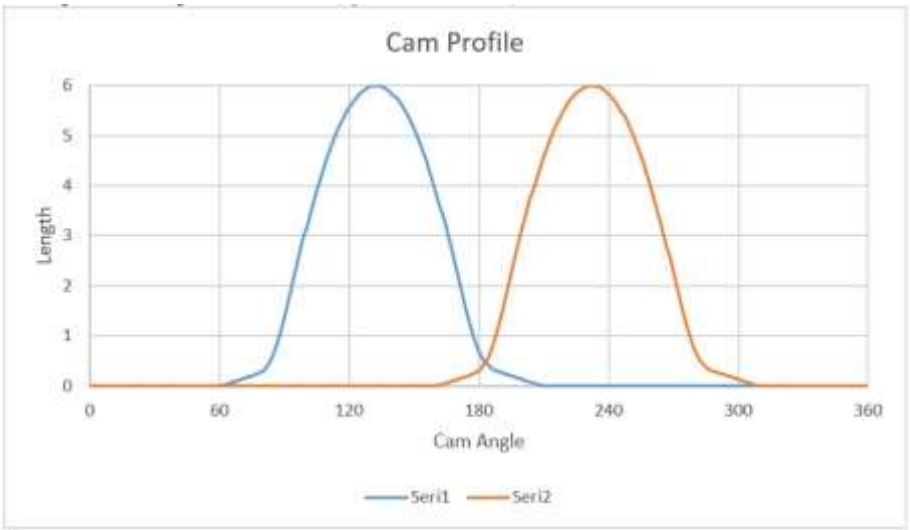

Figure 5. Cam Intake and Exhaust Profile

Blue line is the intake cam profile, orange line is the exhaust cam profile.

Maximum height and event length are considered by air demand on maximum power speed. Event length affects maximum cylinder pressure and maximum height provide adequate airflow. So, after determining other parameters, such as deceleration-acceleration, type of engine compression ratio, cam lobe profile can be drawn by 2D lobe. After that, thickness is given 2D camshaft profile for final shape of the camshaft. After creating exhaust and intake cam lobe, other cylinder's lobes are located with respect to distance between cylinders and angle of opening order. Location of lobes and position are vital for properly working engine.

It should be known that cam lobes properties have been controlled with 3 properties; cam radius, radius of roller, eccentricity or offset of the follower. Additionally, to manufacture cam shaft, cutter radius cannot be bigger than curvature of cam lobe, if cam is concave (Flores, September 11, 2013).

2.3.2 Roller and Push Rod Design

Push rod and its follower transmit the motion from cam lobe to rocker arm. Push rod follower connected with cam lobe was chosen as a wheel in order to decrease the friction which is arise between components.

In order to decrease friction, the contact dwell times and sliding distances must be less, it causes that system needs thicker oil films. If it can be chosen right angle and right size of push rod and its follower, less wear happens and there are more options to choose materials which can be used. It can also help to decrease the emission (Bell, 1998).

Push rod and its follower must be located to cam lob with between 30^0 and 60^0 in order to decrease contact pressure. So, it helps to decrease lost power because of the friction (Flores, September 11, 2013).

2.3.3 Rocker Arm Design

Rocker arm is used for transmitting the motion from push rod to valve and valve spring. It is connected with to components of system because rocker arm transmits the motion to valve in order to control it and valve of spring is turned to back the system to beginning position of system.

In order to decrease the friction at rocker arms, direct acting tappet system should use, but this paper dealt with OHV (Push rod valve train). DAT system allows to use less lubricants (Bell, 1998).

2.3.4 Valve and Valve Spring Design

Valve is the main components to move and its spring helps to go back to beginning positon of valve. Valve area must be as much as large to intake fresh air or air-fuel and exhaust as much as possible and easier. Valve accelerations must be as little as possible to optimize the system because of the vibrations, because, for high RPM, valve's accelerations are extremely getting higher. To design valves, it must be considered valve accelerations, valve area, cam profile, cam speed and stiffness (Qin and Chen, 2014)

Springs are located on spring retainers and these retainers are fixed to engine block. To choose optimum spring, firstly it must be determined the characteristic of system (Lee and Patterson, July 1, 1997). Spring stiffness and valve train behavior are directly connected to each other (Nikita et all, 2018). To choose the spring of valves, it must be analyzed that the spring natural frequency and camshaft speed are available to each other. Spring force and inertia force have also been calculated and compared (Rai et al, 2014).

3. Simulation of System

Simulation is the preprocess of manufacturing. It also helps people to avoid mistakes and to predict improvements and capacity of machines. In order to design this kind of system, it is needed to see before manufacturing, because this kind of systems work with huge power, which can be unstoppable. During the process with programs, people can see all components and it can be made better because working with frequency, high power and combustion can be dangerous for human health. This paper was dealt with only inertial forces due to RPM defined to crank shaft.

3.1 Catia V5 Kinematic

The system which was dealt with was designed with CATIA V5. With CATIA V5, the system was also assembled. After designed all components and assembled them, it was used Digital Mockup module, Kinematic, to see the system is run. As already mentioned, to simulate the system, it was used many constraints to define relations between

components, such as, roll curve between cam lobe and follower, slide curve between push rod and rocker, cylindrical between push rod and its bed, revolute between roller of push rod and push rod.

CATIA V5 Kinematic can also allow to determine phase angle of cam shaft, which is necessary to give supplier in order to manufacture the cam shaft.

3.2 Adams View

ADAMS View allows to analysis the system as dynamic with respect to inertial forces and boundary conditions. When it is imported to file which is constrained with CATIA V5, it can be easier to establish a dynamic model. After importing the file from CATIA V5, all components must be defined inertial with respect to their geometry and their materials, each component must defined one by one. After that, Booleans command is used to fix some part of drawing because the file which was imported from CATIA V5 is not defined as assembled, for example, connecting rod and its cover. Then, it must be defined constrains to decrease the degree of freedom of components, such as, revolute for crank, translational for piston head, etc. After that, all forces, which are caused by components to each other, must be defined as contact in forces section. The other force had to be defined is spring constant to create a spring between rocker arm and spring retainer. ADAMS software is also machinery tool to create gear for cam and crank, as already mentioned, these two components must work together with gear train. To create gear train, command gear in machinery section was used for running mechanism. Firstly, type of gear was decided as spur, method was decided as simplified, geometries and locations were defined, connection was defined and gears was created. After that, all parameters, which are needed, can be obtained from ADAMS View analysis.

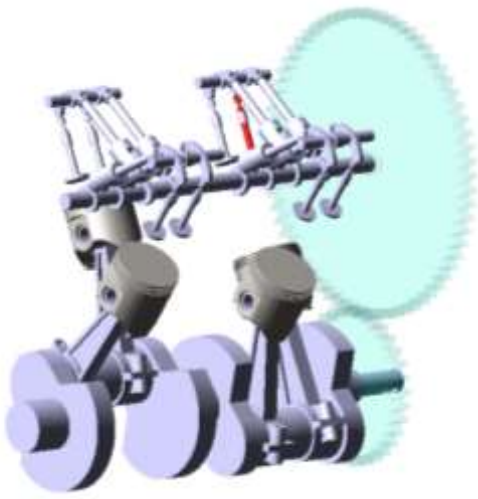

Figure 6. View from ADAMS View 2020

To simulate contact system, it must be considered viscous effect and pressure because of the combined boundary and fluid film but for this simulation, it can only be a future study topic for now (Teodorescu, 2007).

Result and Discussion

To compare the results, positions of valves have been examined for Z direction. To analyze the results, one valve was selected from each cylinders. Pointed valve is the beginning of the valve numbers. That valve is valve 1 for first cylinder. After that, selected valves are first, fourth, fifth and eighth valves.

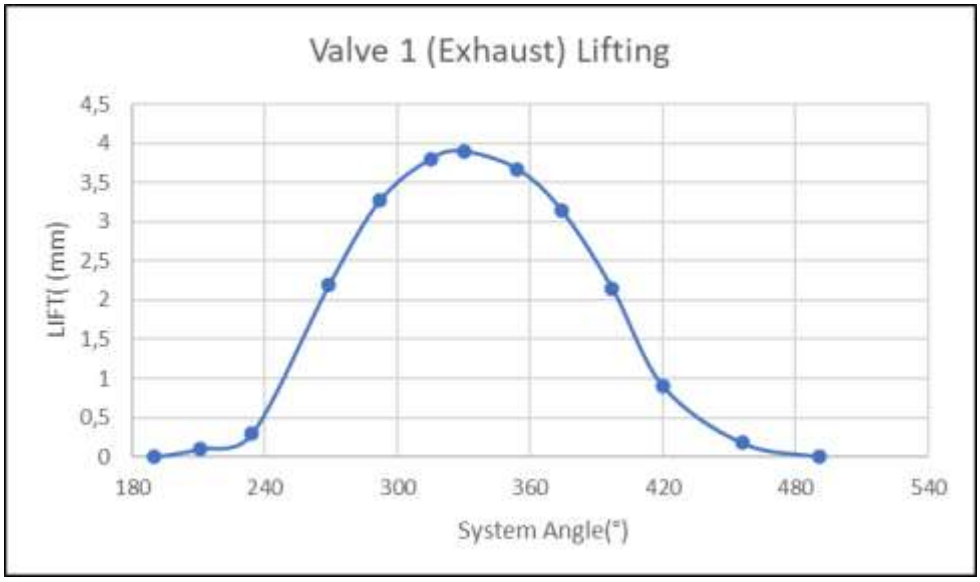

Figure 7. Valve 1 Lifting Distance from Catia V5

The top of value for first valve is 3,88 mm at when crank angle is 331°. To draw path of valve, 13 points was taken into Excel.

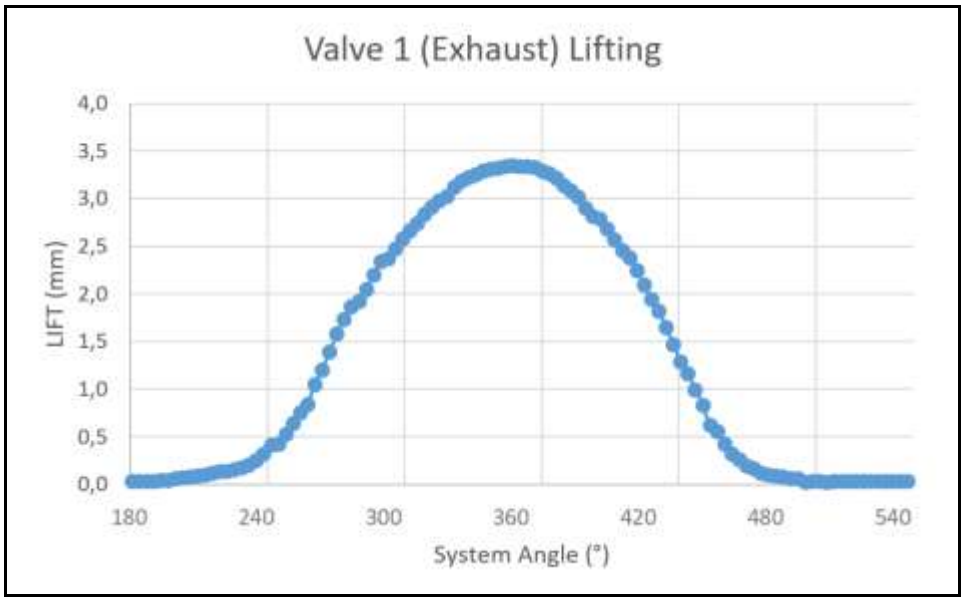

Figure 8. Valve 1 Lifting Distance from ADAMS View 2020

The peak value for first valve is 3.35 mm at ADAMS analysis.

Here is measurements of distances of valve 1 (intake) from both software. There are some differences between them because of points which are from Catia, because, from Catia, only 13 points was taken to draw a graph.

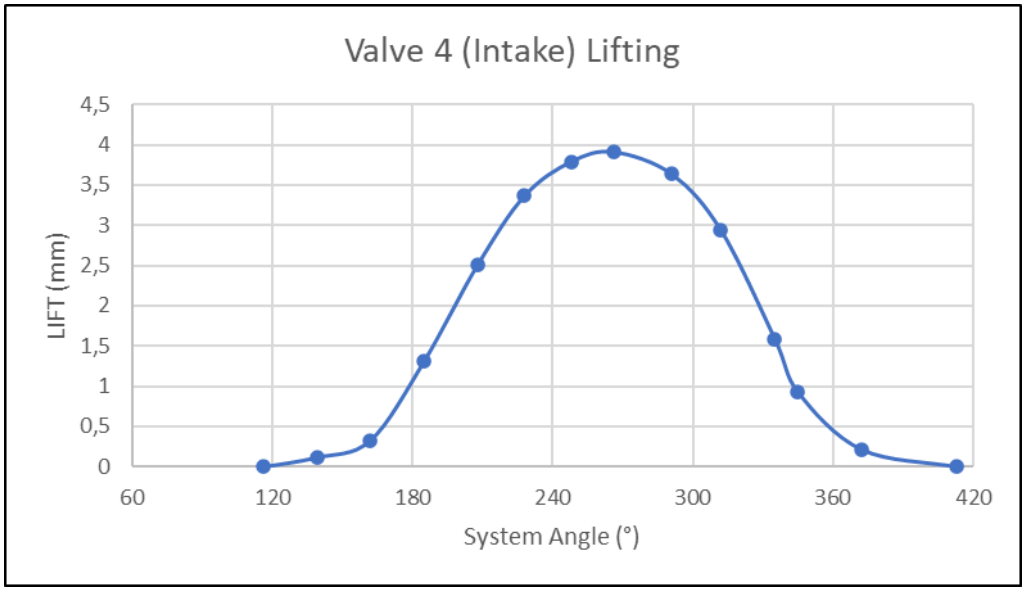

Figure 9. Valve 4 Lifting Distance from Catia V5

Valve 4's peak value is 3,912 mm at when crank angle is 266°.

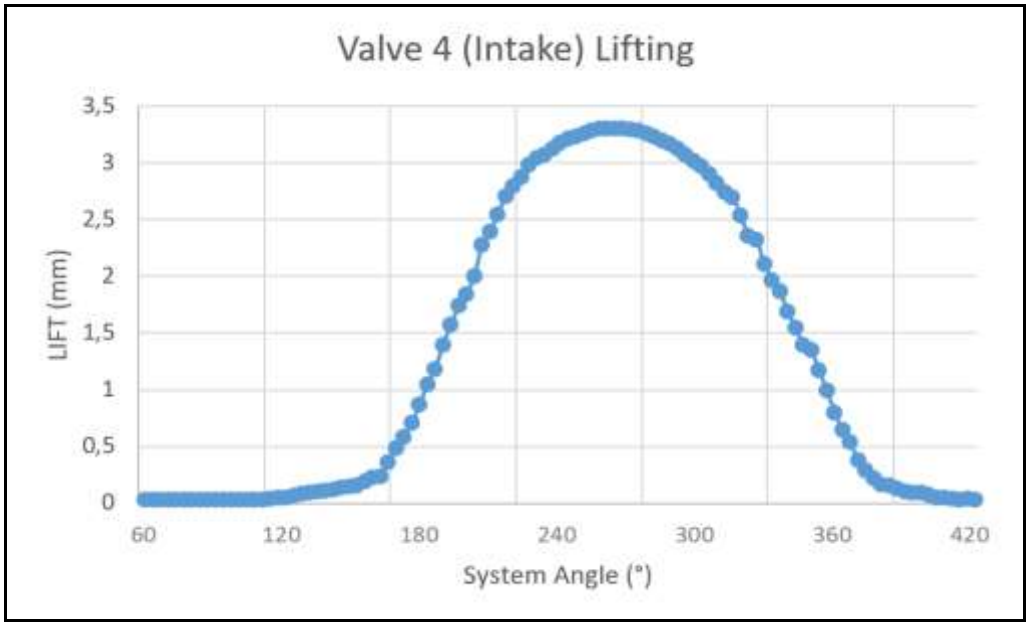

Figure 10. Valve 4 Lifting Distance from ADAMS View 2020

Highest lift distance is 3,31 mm for ADAMS analysis. There are some small differences between these two graphs which were drawn from different software. It seems that these differences are because of some vibrations.

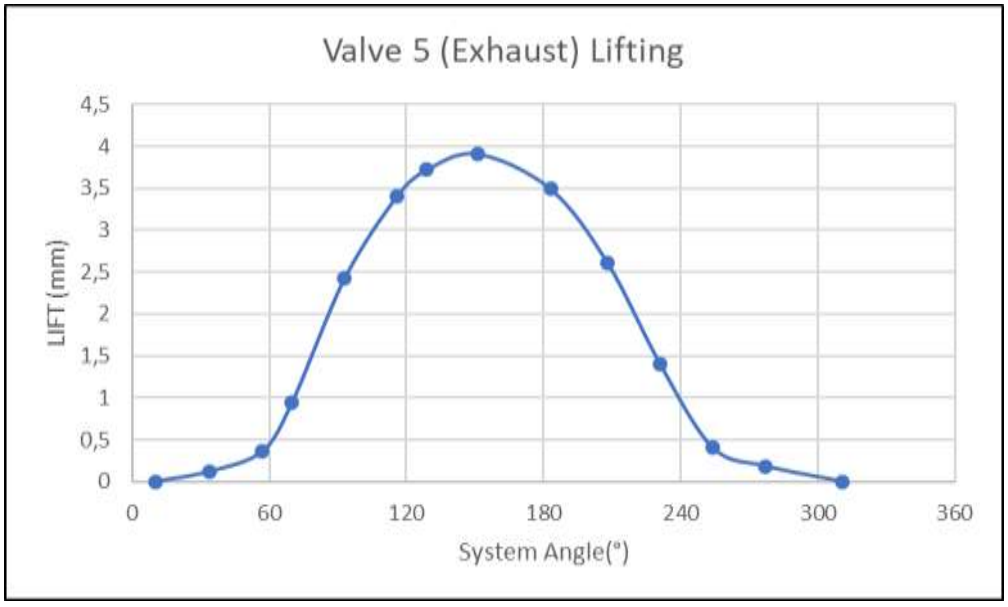

Figure 11. Valve 5 Lifting Distance from Catia V5

Its peak value is 3,91 mm, when system angle is 151°.

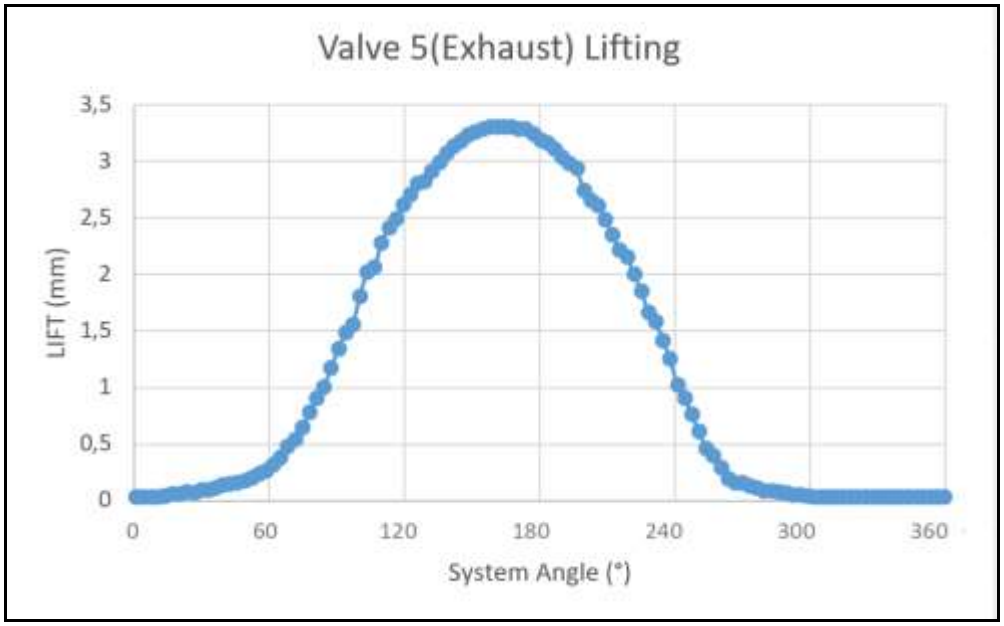

Figure 12. Valve 5 Lifting Distance from ADAMS View 2020

The peak value is 3,3 mm for ADAMS View 2020 analysis. This is the third valve which was investigated and it is clear to see similar irregularities happened because of the vibrations, but type of path and position of peak points are exactly where they were already found.

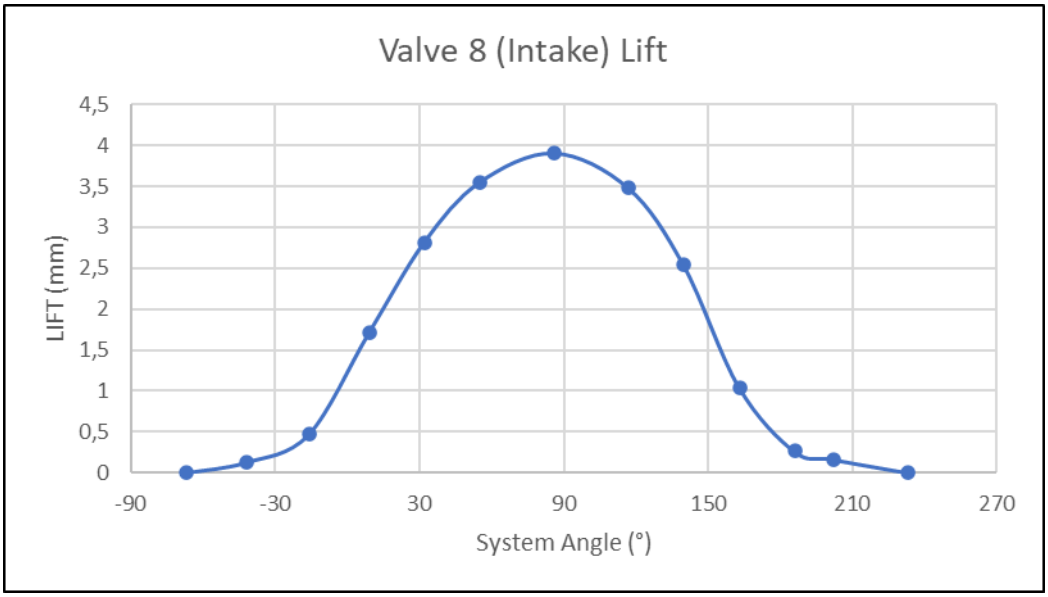

Figure 13. Valve 8 Lifting Distance from Catia V5

Maximum lifting distance is 3,912 mm, when crank angle is 86°.

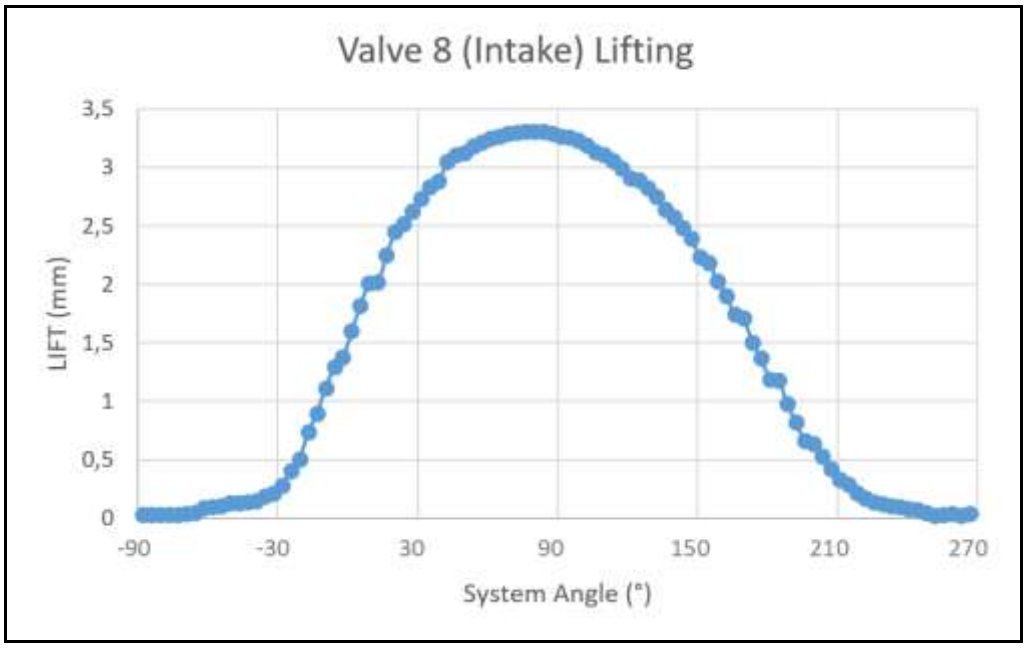

Figure 14. Valve 8 Lifting Distance from ADAMS View 2020

Maximum lifting distance is 3,3082 mm for ADAMS analysis.

There are small differences between peak points. It can cause used spring, because it cannot be used spring in Catia Kinematic. Catia Kinematic works with exact solid parts, which are rigid, but ADAMS works with the closest to reality. Such as, it can be defined penetration and clearance distance between components in ADAMS interface. The real reason why small differences with peak values happened is these defined clearance and penetration distances.

To conclude, these two programs must be used together for production of cam shaft in order to understand probability of mistakes of production of cam shaft. It is also possible to verify the design to be used in production through the multi-body dynamics software.

Conclusion

In order to increase efficiency of engine and decrease emission of engine, this system should be designed according to some rules and parameters. In this work, it found that where it started, what it considered, and what it decided before starting to design.

Components should be selected with compliance, to decrease the contact pressure, their location and type of contact should be defined before starting design.

The springs are vital, in order to optimize the system, it should be correctly selected.

To verify the design, ADAMS View must be used and it helps to understand the consistency of components. In the design period of production, it must be considered clearance distance between components because this working part of engine is exposed to thermal expansion. So, in order to get closer the investigation to reality, ADAMS View must be used together with designing program.

Future work can be that in-cylinder pressure can be defined according to piston position, then bearing forces and vibrations can be found clearly. It also can be added spring optimization.

ÖZET

Artan nüfusla beraber tarım ürünlerinde talep giderek artmaktadır. Bu talebe cevap verebilmek için tarımda makineleşmede dramatik bir artış olmuştur. Makineleşmedeki artışla birlikte özellikle tarımsal traktörlerin kullanımı yaygınlaşmıştır. Traktörler günümüz tarımının vazgeçilmez araçları olsa da bu araçların emniyetli sürüşündeki zafiyetler ağır kazaların yaşanmasına ve yolcuların ağır yaralanmasına ya da ölmesine sebep olmaktadır. Özellikle devrilme ile gerçekleşen kazalar çok acı sonuçlar doğurmaktadır. Bu gibi sonuçları önlemek için takla demiri ve kabin gibi pasif güvenlik önlemleri bulunsa bile, bu ekipmanların bilinçsiz kullanımı sonucu kazalar yaşanmaya ve insanlar ölmeye devam etmektedir. Traktörlerde ani dönüş hareketlerinin yapılması, engebeli yol koşullarında çalışılması ve ağır yüklerin taşınması gibi sebepler traktörün devrilmesine neden olmaktadır. Bu çalışma kapsamında traktörün devrilmesini önlemek için asimetrik fren uygulayarak devrilmeyi önleyen bir kontrolcü tasarımı oluşturulmuştur. Öncelikle aracın matematiksel modeli oluşturulmuştur. Tasarım parametrelerinin duyarlılık analizi yapılmış, devrilmeye en çok etki eden parametreler dinamik sürüş modeli kullanılarak belirlenmiştir. Daha sonra asimetrik frenleme ile ilgili bilgi verilmiş ve oluşturulan model MATLAB/SIMULINK üzerine aktarılarak kontrolcü tasarımına geçilmiştir. Kararlılıkta etkili olan önemli parametrelerin neler olduğu gösterilmiş ve kontrolcü ile kararlılıktaki artış gösterilmiştir.

Anahtar Kelimeler: tarımsal traktör, tasarım duyarlık analizi, yalpa hareketi, devrilme, kararlılık

IMPROVEMENT OF DYNAMIC STABILITY PARAMETERS WITH ASYMMETRIC BRAKING IN AGRICULTURAL TRACTORS

ABSTRACT

With the increasing population, the demand for agricultural products is gradually increasing. In order to meet this demand, there has been a dramatic increase in mechanization in agriculture. With the increase in mechanization, the use of agricultural tractors has become widespread. Although tractors are indispensable tools of today's agriculture, the weaknesses in the safe drive of these vehicles cause catastrophic accidents and serious injury or death of passengers. Especially the accidents with overturning have produced very painful results. Even if passive safety measures such as roll bars and cabins are in place to prevent such consequences, accidents occur and people die as a result of the unconscious use of these equipment. In tractors, reasons such as sharp turns, working in rough road conditions and carrying heavy loads cause the tractor to tip over. Within the scope of this study, a controller design that prevents tipping over by applying an asymmetric brake to prevent the tipping over was created. First of all, the mathematical model of the tool was created. Sensitivity analysis of design parameters was carried out to determine the parameters affecting the tip over using dynamic driving models. Then, information about asymmetric braking was given and the model was transferred to MATLAB / SIMULINK and the controller design was completed. It is shown that some parameters affect the stability substantially and there is an increase in stability with the controller.

Keywords: agricultural tractor, design sensitivity analysis, yaw motion, roll motion, stability

1. GİRİŞ

Tarım, tüm dünyada yapılış şekli ve ürünleri yapıldığı coğrafyaya göre farklı olsa da, insanların beslenme ihtiyaçlarını gidermek için gerçekleştirdiği en temel faaliyet alanlarında biridir. Dünya nüfusundaki artışla birlikte her geçen yıl

tarım ürünlerine olan talep artmakta ancak olması gerekenin aksine her yıl tarım alanları kentleşmenin kurbanı olmaktadır. 2050 yılında nüfustaki artışla birlikte tarım ürünlerine taleplerinin 2016 yılındaki tarım ürünleri taleplerine oranla %70 artması öngörülmektedir (Çalışkan ve diğ, 2018). Tarım alanları azalırken tarım ürünlerine olan talebin artmasının tarımda makineleşmeyi zorunlu hale getirmektedir.

Tarımda makineleşmenin artmasıyla birlikte verim artmakta, daha az iş gücü ve maliyetle daha fazla üretim gerçekleştirilmektedir. İnsan gücünden kat kat daha fazla olan motor gücü sayesinde iş kapasiteleri artmaktadır. Teknolojinin ilerlemesi ile de tarımsal amaçlarla kullanılan makinelerin güçleri her geçen yıl artmaktadır. Bu artan güçlerle birlikte tarım makinelerinin insan ve işçi güvenliği gözetilerek emniyetli olarak üretilmesi büyük önem taşımaktadır.

Türkiye İstatistik Kurumu (TÜİK) ve Emniyet Genel Müdürlüğünün Hazırlamış olduğu 2019 Karayolu Kaza İstatistikleri Raporuna göre 2019 yılında ülkemizde 1 milyon 168 bin 144 kaza meydana gelmiştir. Ayrıca ölümlü veya yaralanmalı kazalara karışan araç sayısının 280 bin 700 ve bu araçların %1 lik bir kısmının da lastik tekerlekli traktörler olduğu rapor edilmiştir (URL1). Traktörler tarım amacıyla kullanılmasından dolayı, karayollarından daha sıklıkla tarımsal alanlarda veya tarımsal alanlara ulaşım amacıyla tali yollarda kullanılması sonucu bu istatistiklerin daha da fazla olabileceği düşünülmektedir.

Daha güvenli olduğundan dolayı son yıllarda kabinli traktör kullanımı artış göstermiştir. Ayrıca ülkemizde 2001 yılından itibaren üretilen traktörlerde devrilmeye karşı emniyet çerçevesi bulunması zorunlu tutulmuştur. Ancak bilinçli kullanımın düşük olması sebebiyle sürücünün açıkta ve takla demiri olmadan kullanım örneği oldukça fazladır. Ayrıca emniyet kemeri kullanım oranının düşük olması, takla demiri ve kabinli traktörlerde güvenliğin tamamiyle sağlanmasını engel olmaktadır.

2018 yılında yapılmış olan Konya İli Çumra İlçesi Tarım İşletmelerinde Meydana Gelen Traktör ve Tarım Makineleri Kaynaklı Kazaların Belirlenmesi amacıyla yapılan anket araştırmalarında, kazayı yapan kazazedelerin %32.60 oranında yara almadığı, %32.60 oranında kazazedenin kazayı hafif yaralı ve %11.60'ının ise ağır yaralı olarak atlattığı bulunmuştur. Ayrıca, kaza yapan kazazedelerin %7'sinin fiziksel olarak engelli kaldığı ve %16.30'unun ise vefat ettiği belirlenmiştir. Kaza yapanların %47.2 oranla kazadan psikolojik olarak hiç etkilenmediği sonucuna ulaşılmıştır. Yine ilgili araştırmaya göre tarım makinelerinde kaza sayılarının yüksek olmasında bir etken olarak, kaza yapanların %27.9'luk oranın tarım makinesini ehliyetsiz kullandığı, kazaya karışan tarım makinelerinin %18.9'luk oranla 18 yaş altında sürücüler tarafından kullanıldığı ve kaza yapanların sadece %7'sinin üniversite seviyesinde eğitim aldığı görülmüştür. Araştırmada kaza başına kazadan etkilenen kişi sayısının 1.74 olduğu ve bunun da traktörlerde tarım işçisi taşımanın bir sonucu olduğu saptanmıştır (Alçayır, 2018).

Aşağıdaki Tablo 1.1'de sonuçları görülen 2018 yılında yapılan başka bir anket araştırmasında Kırklareli ilindeki meydana gelen kayıt altına alınmış traktör ve tarım makineleri kazaları ele alınmıştır. Araştırma sonucuna göre ölümlü kazaların çoğunlukla aşırı hız ve dikkatsizliğe bağlı olarak traktör veya romörkün devrilmesinden meydana geldiği rapor edilmiştir (Baran ve diğ, 2018).

Tablo 1.1: Kırklareli Traktör kazaları hakkında kaza, nedeni ve sonucu anket sonuçları (Baran ve diğ, 2018).

KAZA	MAKİNE	KAZA	NEDENİ *	KAZANIN SONUCU
1	Traktör	Kabin Camı Kırılması	Taş fırlaması	Bir gün süreyle hastanede tedavi
2	Traktör	Devrilme	Aşırı hız	Ayakta tedavi
3	Traktör	Devrilme	Arazi eğimi	1 kişinin ölümü
4	Traktör	Kabin kapısına elin sıkışması	Dikkatsizlik	120 gün hastanede tedavi
5	Traktör	Çarpışma	Dikkatsizlik	Yaralanma yok
6	Traktör	Kuyruk milinden el yaralanması	Dikkatsizlik	Ayakta tedavi
7	Traktör	Devrilme	Aşırı hız	Traktörde bulunan 2 kişi ölmüş
8	Traktör	Karayolunda çarpışma	Dikkatsizlik	Hafif yaralanma
9	Traktör	Tarlada devrilme	Acemilik	1 kişinin ölümü
10	Traktör	Tarla yolunda devrilme	Fren patlaması	Yaralanma
11	Traktör	Devrilme	Aşırı yük	2 kişinin yaralanması
12	Traktör	Traktörle makine arasında kalma	Dikkatsizlik	Yaralanma
13	Römork	Devrilme	Aşırı yük	Ağır yaralı (Çalışamaz durumda)
14	Römork	Düşme	Dikkatsizlik	Basit yaralanma
15	Römork	Bağlantı sırasında el sıkışması	Dikkatsizlik	45 gün tedavi
16	Römork	Düşme	Yüksek gabari	Çeşitli kırıklar ve 40 gün tedavi
17	Römork	Bağlantı sırasında el sıkışması	Dikkatsizlik	7 gün ayakta tedavi
18	Römork	İki römork arasına sıkışma	Dikkatsizlik	3 gün hastanede tedavi
19	Römork	Düşme	Dikkatsizlik	Özürlü kalma

Traktörlerin arazi koşullarına uyum sağlamak için ağırlık merkezi yüksek olarak tasarlanması, bahçe traktörlerinde iz genişliğinin küçük olması, yük taşınırken gereğinden fazla yükleme yapılması, bağlanan çeki araçlarının fren devrelerinin bağlanmaması gibi faktörler dinamik olarak traktörlerin kararsız davranmasına sebebiyet vermektedir. Sürücülerin deneyimsiz, bilinçsiz ve tedbirsiz olması da bu faktörlere etkilendiğinde traktör kazalarında maddi hasarlı kazaların yanında ölümcül kazaların da sıklıkla görülmesi kaçınılmaz olmuştur.

Bu araştırmada tarımsal traktörlerin dinamik davranışı incelenerek, kararlılığı etkileyen faktörler üzerinde durulacak ve kararlılığı artırıcı bir sistem tasarlanacaktır. Ayrıca,, tasarım parametrelerinin duyarlık analizi ile devrilme üzerine etkisi olan parametreler belirlenmiştir. Bu sistem ile tarımsal traktör kazalarında etkin rol oynayan dinamik etkenlerin izlenerek kontrol edilmesi amaçlanmaktadır.

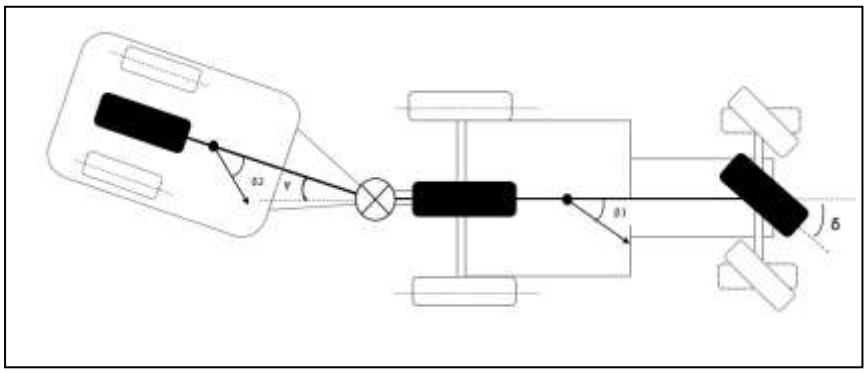
2. MATERYAL VE YÖNTEM

2.1. Dinamik Modelin Kurulması

Taşıtların matematik modelinin oluşturulması, taşıt ile ilgili pek çok problemin incelenmesine olanak verir. Bunlar çok basit olabildikleri gibi oldukça kapsamlı modeller de olabilmektedir. Modellerin bilgisayar programlarında oluşturulması ve çözülmesi, modelin kaç serbestlik derecesine sahip olmasıyla ve karmaşıklığı ile aynı oranda kolaylık sağlayabilmektedir (Milani, 2015). Literatürde kara taşıtları için geliştirilen pek çok model bulunmaktadır. Bunlara örnek olarak, doğrusal bisiklet modeli, doğrusal olmayan bisiklet modeli, çift izli taşıt modeli vb. verilebilir. Bu çalışmada doğrusal bisiklet modeli seçilmiştir. Çünkü doğrusal bisiklet modeli, sağladığı basit doğrusal denklemler ve kabuller sayesinde daha öngörülebilir sonuçlar verir.

2.1.1. Doğrusal Bisiklet Modeli

Doğrusal bisiklet modeli taşıtların dinamik davranışının incelenmesinde kullanılan önemli modellerden biridir. Bu modelin özünde ise aracın her bir aksındaki tekerleklerin tek bir tekerlek ile temsil edilmesi yatmaktadır (bkz. Şekil 2.1). Araca etkiyen tüm kuvvetlerin yine bu hayali tekerlekler üzerinden araca etkidiği varsayılır. Bu model genellikle düşük yanal ivmelerde yalpalama düzenlemesi, idare vb. ile ilgili çalışmalarda düzlem hareketinin analizi için kullanılır (Oberoi, 2011). Doğrusal bisiklet modelinin motor, süspansiyon ve fren sistemi barındırmadığı kabul edilir. Bu yüzden modelde aracın yunuslama (pitch) ve devrilme (roll) durumu gözlenememektedir. Ancak kurulan modelde devrilme özelliği denklemler ile eklenmiştir.



Şekil 2.1: Traktör ve römork için basitleştirilmiş doğrusal bisiklet modeli.

2.1.2 Genel Hareket Denklemleri

Taşıtın dinamik davranışının analiz edilmesi için Bölüm 2.2'de kullanılan model kısaca tanıtıldı ve Şekil 2.1'de taşıtın basitleştirilmiş bir modeli oluşturuldu. Buradan yola çıkarak araca ait denklemler ve parametrelerin tanımları ilgili kaynaktan alınmıştır (Milani, 2015). Parametrelerin değerleri Tablo 2.1'de verilmiştir.

Traktörün yanal düzlemindeki kuvvetlerin dengesinden:

$$\dot{m}_1\left(u_1\dot{\Psi}_1 + \dot{V}_{y1}\right) - m_{1s}(h_{1s} - h_{1r})\ddot{\emptyset}_1 = F_{y1f} + F_{y1r} + F_{cy} \quad (1)$$

Traktörün yalpa düzlemindeki dengesinden:

$$-I_{1xz}\ddot{\emptyset}_1 + I_{1zz}\ddot{\Psi}_1 = aF_{y1f} - bF_{y1r} - l_{1c}F_{cy} \quad (2)$$

Traktörün devrilme düzlemindeki dengesinden**:**

$$I_{1x'x'}\ddot{\emptyset}_1 - I_{1x'z'}\ddot{\Psi}_1 = m_{1s}g(h_{1s} - h_{1r})\emptyset_1 + m_{1s}(h_{1s} - h_{1r})(\dot{V}_{y1} + u_1\dot{\Psi}_1) - (K_{1f}^* + K_{1r}^*)\emptyset_1 - (C_{1f} + C_{1r})\dot{\emptyset}_1 + K_{12}(\emptyset_2 - \emptyset_1) - F_{cy}h_{1cr} \quad (3)$$

Römorkun yanal düzlemindeki kuvvetlerin dengesinden:

$$\dot{m}_2(u_2\dot{\Psi}_2 + \dot{V}_{y2}) - m_{2s}(h_{2s} - h_{2r})\ddot{\emptyset}_2 = F_{y2} - F_{cy} \quad (4)$$

Römorkun yalpa düzlemindeki dengesinden:

$$-I_{2xz}\ddot{\emptyset}_2 + I_{2zz}\ddot{\Psi}_2 = -dF_{y2} - l_{2c}F_{cy} \quad (5)$$

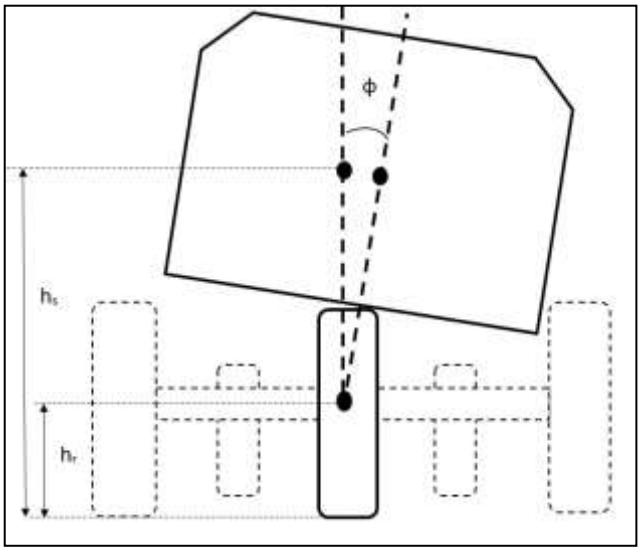
Römorkun devrilme düzlemindeki dengesinden:

$$I_{2x'x'}\ddot{\emptyset}_2 - I_{2x'z'}\ddot{\Psi}_2 = m_{2s}g(h_{2s} - h_{2r})\emptyset_2 + m_{2s}(h_{2s} - h_{2r})(\dot{V}_{y2} + u_2\dot{\Psi}_2) - K_2^*\emptyset_2 - C_2\dot{\emptyset}_2 - K_{12}(\emptyset_2 - \emptyset_1) - F_{cy}h_{2cr} \quad (6)$$

2.1.3 Devrilme Hareketini İçeren Bisiklet Modeli

Modelimizin kurulması adımları arasında sıradaki aşama, bisiklet modele devrilme hareketinin dâhil edilmesidir (bkz. Şekil 2.2). Bu proje kapsamında traktörün devrilme karakteristiği incelenmiş ve bunun önlenmesi için çalışılmıştır. Bu model, bağımsız olarak hareket eden bir devrilme düzlemi modeli ile birleştirilmiş bir bisiklet modelinin kombinasyonu olarak değerlendirilebilir (Cheng ve diğ., 2011). Büyük yanal ivmelerin gerçekleşmediği varsayılır. Böylece yanal yük transferi ihmal edilebilir. Bu model, dönme serbestlik derecesini modele eklerken doğrusal hareket denklemlerini kullanma yeteneğini korur ve sistemin toplam serbestlik derecesini 5'e çıkarır (Sampson ve diğ., 2000).

Bu modele göre taşıtın devrilme analizi yapılırken taşıtın toplam kütlesinin iki temel kütleden meydana geldiği varsayılır. Bunlar yaylı ve yaysız kütlelerdir. Yaylı kütle, bir taşıtın süspansiyonu ile taşınan kütlesidir. Taşıtın şasisi, motoru, vites kutusu, koltukları gibi parçalar yaylı kütleye dahildir. Yaysız kütle ise süspansiyon tarafından taşınmayan kısımlardır. Taşıtın tekerlek aksları, fren bileşenleri ve süspansiyon bileşenleri taşıtın yaysız kütlesini oluşturan bileşenlerdir (Wong, 2005).



Şekil 2.2: Traktör İçin Devrilme Düzlemi.

2.1.4 Devrilme Hareketini Hareket Denklemleri

Daha önceki bölümlerde tanıtılan bisiklet modele devrilme hareketinin de eklenmesi ile elde edilen hareket denklemleri şu şekilde gösterilebilir:

Traktörün yanal düzlem:

$$\dot{m}_1 u_1(\beta_1 + \Psi_1) - m_{1s}(h_{1s} - h_{1r})\ddot{\emptyset}_1 = Y_{\beta 1}\beta_1 + Y_{\Psi 1}\Psi_1 + Y_{\delta 1}\delta_1 + F_{cy} \tag{7}$$

Traktörün yalpa düzlemi:

$$-I_{1xz}\ddot{\emptyset}_1 + I_{1zz}\dot{\Psi}_1 = N_{\beta 1}\beta_1 + N_{\Psi 1}\Psi_1 + N_{\delta 1f}\delta_{1f} - l_{1c}F_{cy} \tag{8}$$

Traktörün devrilme düzlemi:

$$\begin{aligned} I_{1x'x'}\ddot{\emptyset}_1 - I_{1x'z'}\dot{\Psi}_1 &= m_{1s}g(h_{1s} - h_{1r})\emptyset_1 + m_{1s}u_1(h_{1s} - h_{1r})(\beta_1 + \Psi_1) - (K_{1f}^* + K_{1r}^*)\emptyset_1 - (C_{1f} + C_{1r})\dot{\emptyset}_1 \\ &\quad + K_{12}(\emptyset_2 - \emptyset_1) - F_{cy}h_{1cr} \end{aligned} \tag{9}$$

Römorkun yanal düzlemi:

$$\dot{m}_2 u_2(\beta_2 + \Psi_2) - m_{2s}(h_{2s} - h_{2r})\ddot{\emptyset}_2 = Y_{\beta 2}\beta_2 + Y_{\Psi 2}\Psi_2 + Y_{\delta 2r}\delta_{2r} - F_{cy} \tag{10}$$

Römorkun yalpa düzlemi:

$$-I_{2xz}\ddot{\emptyset}_2 + I_{2zz}\dot{\Psi}_2 = N_{\beta 2}\beta_2 + N_{\Psi 2}\Psi_2 + N_{\delta 2r}\delta_{2r} - l_{2c}F_{cy} \tag{11}$$

Römorkun devrilme düzlemi:

$$I_{2x'x'}\ddot{\emptyset}_2 - I_{2x'z'}\dot{\Psi}_2 = m_{2s}g(h_{2s} - h_{2r})\emptyset_2 + m_{2s}u_2(h_{2s} - h_{2r})(\beta_2 + \Psi_2) - K_2^*\emptyset_2 - C_2\dot{\emptyset}_2 - K_{12}(\emptyset_2 - \emptyset_1) + F_{cy}h_{2cr} \tag{12}$$

Küçük açı kabulü varsayılarak kinematik kısıt denklemi ise şu şekilde olur:

$$\beta_2 = \beta_1 + \frac{h_{1r} - h_{1c}}{u_1}\ddot{\emptyset}_1 - \frac{h_{2r} - h_{2c}}{u_2}\ddot{\emptyset}_2 - \frac{l_{1c}}{u_1}\dot{\Psi}_1 - \frac{l_{2c}}{u_2}\dot{\Psi}_2 + \Psi_1 - \Psi_2 \tag{13}$$

Kayma açılarının hesabı için kullanılan denklemler, tekerleklerin yanal sertlik katsayıları da hesaba katılarak şu şekildedir:

$$\alpha_{1f} = -\beta_1 - \frac{a\Psi_1}{u_1} + \delta_1 \tag{14}$$

$$\alpha_{1r} = -\beta_1 + \frac{b\Psi_1}{u_1} \tag{15}$$

$$\alpha_2 = -\beta_2 + \frac{d\Psi_2}{u_2} \tag{16}$$

Traktörler bahçe, tarla tipi ya da daha büyük işletmelerde kullanılmak üzere çok çeşitli boyutlarda ve özelliklerde üretilmektedir. Yapılan modelde gerçekçi sonuçlar elde edebilmek amacıyla gerçek bir traktörün boyutsal parametreleri üzerinde çalışmaya özen gösterilmiştir. Daha önce yapılmış araştırmalarda kullanılmış traktör boyutsal parametrelerini ve çeşitli parametreler için karakteristik özellik denklemlerini kullanarak modelde kullanılacak olan parametreler elde edilmiştir.

Xie'nin tezinde araştırma için kullanmış olduğu genel amaçlı kullanımı olan 4 ton sınıfı John Deere 4020 modeli kütle ve atalet özellikleri için referans kabul edilmiştir (Xie, 1985). İlgili makalede traktör için yaylı ve yaysız kütle oranları belirtilmediği için, yol araçlarındaki bu oran incelenmiş ve genellikle %10-20 arasında değiştiği gözlenmiştir. Tarımsal araç üzerinde çalışıldığı için yaysız kütle, toplam araç ağırlık oranının %20'si kabul edilmiştir. Matlab lineer bisiklet modelinde kullanılan taşıt parametreleri duyarlılık analizi tablosu Tablo 2.1'de verilmiştir.

2.2.Duyarlılık Analizi

Araştırmada kullanılan tarımsal traktöre ve römorka ait çeşitli boyutsal parametreler 4000 kg sınıfındaki iki farklı traktörün kullanıldığı, iki farklı çalışmadan derlenerek elde edilmiştir. Ulaşılamayan büyüklüklerde çeşitli varsayımlar ve yaklaşık hesaplama yöntemlerine başvurulmuştur (Xie, 1984) (Zheng ve diğ, 2019).

Tablo 2.1: Traktör römork kombinasyonu parametreleri ve yapılan duyarlılık analizi sonuçları

				%10 değişimin traktör dinamiğine yüzde etkileri			
				Traktör		Römork	
	İlk Değer	Değişim	Son Değer	Devrilme Açısı	Yalpa Hızı	Devrilme Açısı	Yalpa Hızı
h_{1s}	0.8	10%	0.88	25.0	0.1	4.9	0.0
h_{1r}	0.48	10%	0.528	-15.7	0.1	-3.2	0.0

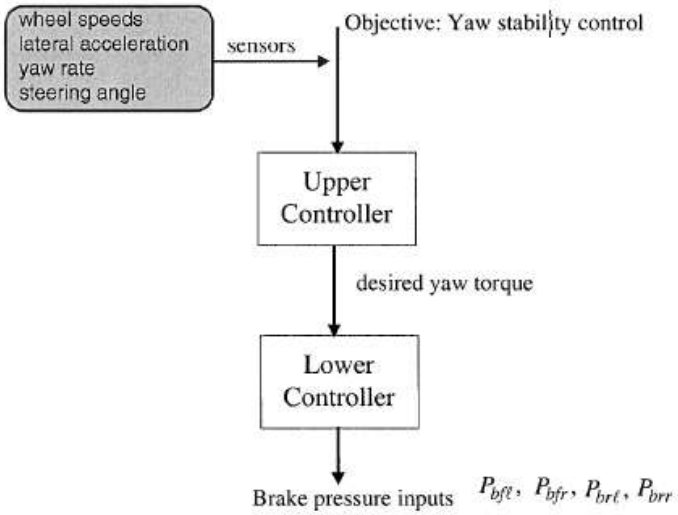
Traktör devrilme ve savrulma kazalarında, ölüm ve kaza sayılarını azaltmak amacıyla traktör ve römork tasarımında ayrıca traktör ve römorkun uygun şekilde eşleştirilebilmesi için traktör ve römorkun dinamik kararlılığı önemli bir konudur. Aşağıdaki Tablo 2.1'de gösterildiği üzere, bu çalışmada dinamik simülasyonları yapılan traktör ve römork parametrelerinin her birinin tasarım parametreleri ayrı ayrı %10 arttırılarak simülasyonları tekrarlanmış ve her bir parametrenin devrilme ve yalpa açılarına etkileri hesaplanarak duyarlılık analizi tamamlanmıştır. Tabloda traktör-römork dinamiğine olumsuz etki eden parametreler etki büyüklüklerine göre kırmızı tonlarında, olumlu etki eden parametreler ise etki büyüklüklerine göre yeşil tonlarında işaretlenmiştir. Buna göre traktör yaylı kütle yüksekliğinin dolayısıyla traktör ağırlık merkezi yüksekliğinin traktör devrilme durumunda en fazla etki eden parametre olduğu aynı zamanda aks ve tekerleklerden oluşan yaysız kütle yüksekliğinin de düşük olmasının devrilme riskini azalttığı görülmektedir. Ayrıca yaylı kütle ve yaysız kütle ağırlık merkezi arasındaki mesafenin büyük olmasının da devrilme eşiğine olumlu etki yaptığı unutulmamalıdır. Yalpa açısı karakteristiğine gelecek olursak en çok etkileyen parametreler taşıtın boylamsal uzunluk parametreleridir. Bununla birlikte lastiklerde oluşan yanal kuvvetin artması da yalpa riskini arttıracağı için lastik yanal sertlik katsayılarının doğru seçimi de önem arz etmektedir.

2.3. Kontrolcü Tasarımı

Traktör-römork kombinasyonunun farklı yol koşullarında kullanılması ve tasarımı gereği ağırlık merkezinin yolcu taşıtlarına göre daha yüksekte bulunması gerek savrulma gerekse devrilme açısından daha riskli bir konumda olmasına yol açar. Engebeli veya kaygan bir yolda taşıt sürücünün kontrolünden çıkabilir ve bu durumda sürücünün refleksleri iki konuda yetersiz kalabilir. İlki sürücü aracın kararlılığı hakkında yorum yapamaz ve direksiyonu fazla kırabilir veya fren pedalına basarak tekerleklerin kilitlenmesine yol açabilir. Bu durum traktörün devrilmesine yol açabilir. İkincisi ise trafiğe açık alanda yol alan taşıt manevra sonucu devrilme veya savrulma riskiyle karşı karşıya kalırsa sürücünün trafikteki diğer taşıtların emniyetini de göz önüne alarak karar vermesi çok düşük bir olasılıktır. Bu yüzden taşıtı ve sürücüyü bu riskli durumlardan uzak tutmak için devrilme ve savrulma sınırlarında devreye giren ve taşıtı olması gereken kararlılık aralığına geri getiren bir kontrolcü bulunmalıdır.

Literatürde bu işlevi yerine getirecek çeşitli kontrolcü tiplerinden bahsedilmiştir. Bunlardan en çok kullanılan ve üzerinde çalışılan kontrolcüler, aktif direksiyon yönlendirme, diferansiyel frenleme, aktif süspansiyon ve bağımsız tork kontrolcüleridir. Bu çalışmada diferansiyel frenleme kontrolcüsü kullanılarak traktör üzerinde asimetrik frenleme yapılmıştır. Bu kontrolcünün diğerlerine göre avantajları daha az maliyetli olması, traktör üzerine daha kolay uygulanabilir olması, farklı yol koşulları sebebiyle oluşabilecek bozulmalardan etkilenmemesi, taşıtın manevra kabiliyetini engellememesi ve taşıtın hızını azaltıp yanal ivmenin düşmesine sebep olarak devrilme riskini azaltması söylenebilir (Bo-Chiuan & Huei, 2001).

Diferansiyel frenleme kontrolcüsü iki ana bölümden oluşmaktadır: üst kontrolcü ve alt kontrolcü. Üst kontrolcüde kayma modu kontrolcü (sliding mode controller) algoritması kullanılarak traktörün devrilmesini ve savrulmasını engellemek için gerekli olan ek moment hesaplandı. Alt kontrolcüde ise üretilecek ek momentin tekerleklere fren kuvveti olarak hangi oranda ve nasıl iletileceği kontrol edildi. Kontrolcü mimarisi Şekil 2.3'de gösterilmiştir.



Şekil 2.3: Diferansiyel frenleme kontrolcüsü şeması (Rajamani, 2006)

2.3.1 Üst Kontrolcü Tasarımı

Kararlılığı sağlayabilmek için gerekli moment aşağıdaki gibi hesaplanır (Rajamani, 2006):

$$\Psi_{ref} = \frac{\dot{x}}{l_f + l_r + \frac{m\dot{x}^2(l_r C_f - l_f C_r)}{0.5 C_f C_r L}} \tag{17}$$

$$\beta_{ref} = \frac{l_r - \frac{l_f m\dot{x}^2}{C_r L}}{l_f + l_r + \frac{m\dot{x}^2(l_r C_f - l_f C_r)}{0.5 C_f C_r L}} \tag{18}$$

$$\Psi_{\text{üst_sınır}} = 0.85\frac{\mu g}{\dot{x}} \tag{19}$$

$$\beta_{\text{üst_sınır}} = \tan^{-1}(0.02\mu g) \tag{20}$$

$$\Psi_{hedef} = \Psi_{ref} \; if \; |\Psi_{ref}| \leq \Psi_{\text{üst_sınır}} \tag{21}$$

$$\Psi_{hedef} = \Psi_{\text{üst_sınır}}\ sgn(\Psi_{ref})\ if\ |\Psi_{ref}| > \Psi_{\text{üst_sınır}} \tag{22}$$

$$\beta_{hedef} = \beta_{ref}\ if\ |\beta_{ref}| \leq \beta_{\text{üst_sınır}} \tag{23}$$

$$\beta_{hedef} = \beta_{\text{üst_sınır}}\ sgn(\beta_{ref})\ if\ |\beta_{ref}| > \beta_{\text{üst_sınır}} \tag{24}$$

Kayma yüzeyi aşağıdaki gibi tavsiye edilmiştir (Rajamani, 2006) :

$$s = \Psi - \Psi_{hedef} + \xi(\beta - \beta_{hedef}) \tag{25}$$

$$\dot{s} = \dot{\Psi} - \dot{\Psi}_{hedef} + \xi(\dot{\beta} - \dot{\beta}_{hedef}) \tag{26}$$

ξ parametresinin değeri aşağıdaki gibi belirlenebilir (LiQiang & Yue, 2014):

$$\xi = \begin{cases} 0 & \beta < \tan^{-1}(0.02\mu g) \\ \dfrac{\beta}{\tan^{-1}(0.025\mu g)} & \tan^{-1}(0.02\mu g) \leq \beta \leq \tan^{-1}(0.025\mu g) \\ 1 & \beta \geq \tan^{-1}(0.025\mu g) \end{cases} \tag{27}$$

Gerekli ek moment aşağıdaki gibi hesaplanır:

$$\frac{\rho + \cos(\delta)}{I_z} M_b = \left[\left(-\frac{l_f}{I_z}(C_f\alpha_f)\cos\delta\right) + \left(-\frac{l_r}{I_z}(C_r\alpha_r)\right) - \dot{s} + \dot{\Psi}_{hedef} - \xi(\dot{\beta} - \dot{\beta}_{hedef})\right] \tag{28}$$

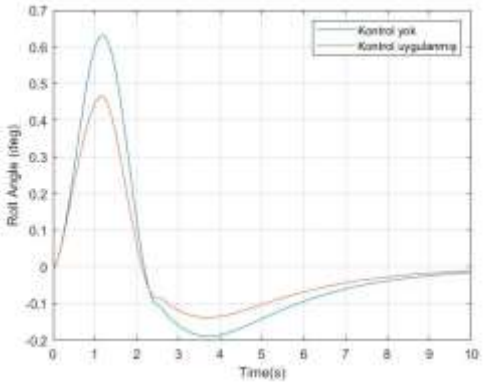
2.3.2 Alt Kontrolcü Tasarımı

Alt kontrolcü sayesinde üst kontrolcüde hesaplanan ek momenti üretebilmek için tekerleklere hangi oranda frenleme uygulanacağına karar verilir ve fren kuvvetleri aşağıdaki denklemle hesaplanır. Buna göre diferansiyel fren kuvveti:

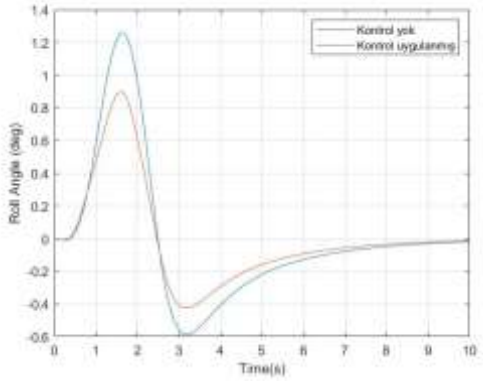
$$\Delta F_x = \frac{2M_b}{l_w} \tag{29}$$

3. SİMÜLASYON SONUÇLARI

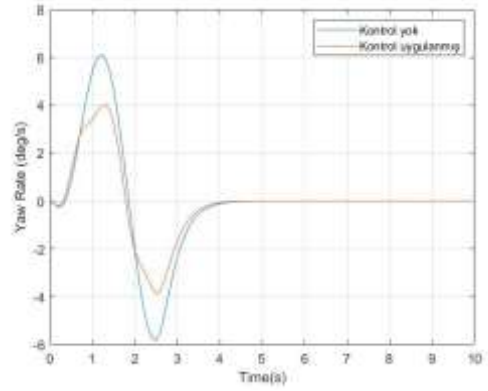
Önceki bölümlerde açıklanan modeller Matlab/Simulink ortamında simüle edilmiştir. Simülasyon sonuçları Şekil 3'te görüldüğü gibidir.



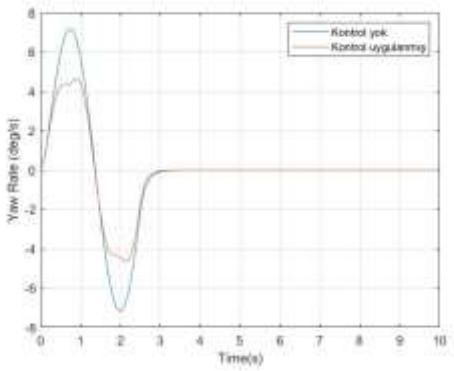
Şekil 3.1.a: Kontrolcüsüz ve kontrolcü uygulanmış durumda traktör devrilme açıları.



Şekil 3.1.b: Kontrolcüsüz ve kontrolcü uygulanmış durumda römork devrilme açıları.



Şekil 3.1.c: Kontrolcüsüz ve kontrolcü uygulanmış durumda traktör yalpa açıları.



Şekil 3.1.d: Kontrolcüsüz ve kontrolcü uygulanmış durumda römork yalpa açıları.

Kontrolcü, 30 km/h hızda şerit değiştirme hareketi yapan ve kontrolcü olmadan römorkun yuvarlandığı bir traktör-römork kombinasyonuna uygulanmıştır. Grafiklerde görüldüğü üzere devrilme ve yalpa riskleri önemli oranda düşürülmüştür. Asimetrik frenleme sayesinde traktör devrilme açısında %26.4, römork devrilme açısında %28.65, traktör yalpa hızında % 35 ve römork yalpa hızında % 33.7 oranlarında iyileşme sağlanmıştır.

4. SONUÇLAR

Duyarlılık analizleri yapılarak bir traktör ve römork çiftinin devrilme açısı ve yalpa açısına etki eden tasarım parametreleri belirlenmiştir. Bu tasarım parametreleri araç devrilme ve yalpa karakteristiklerini iyileştirmek için kullanılabilir. Yapılan simülasyonun sonuçlarına göre kontrolcünün sisteme eklenmesiyle traktör ve römork çiftinin devrilmesine sebep olabilecek dinamik etkenlere verilecek cevaplar iyileştirilmiştir.

Bu iyileştirme oranlarının daha da yükselebilmesi için römorka da bir kontrolcü uygulanması faydalı olacaktır. Ayrıca aktif direksiyon yönlendirme ve aktif süspansiyon gibi farklı kontrolcülerin de ek olarak uygulandığı sistemlerde çok daha büyük iyileştirme oranları görülecektir.

TEŞEKKÜR

Bu çalışmada yardımlarından dolayı Dr. Öğretim Üyesi Oğuz Altay ve Prof. Dr. Ata Muğan'a teşekkür ederiz.

ABSTRACT

In automotive industry, there is an increasing demand for weight reduction by using thinner sheets in automotive exterior panel. So, finite element simulation of dent resistance of automotive exterior panels has become a very important step in automotive body design. The purpose of the simulation is to evaluate the exterior panel denting resistance characteristics and provide an objective measurement of panel denting resistance under the typical events like shopping carts, hail hitting the panels. Not only all activities in simulations such as determining the points where force will be applied according to test configuration, positioning the indenter to normal of panel surface without penetration, take the high time but also these operations are closely related to the experience of virtual analysis engineer. Moreover, during the solution of the analysis convergence problems arise due to the nature of the buckling analysis and the waste of time is increased. Based on this, it will be useful to automate the process. In this paper, an Abaqus User Subroutine that calculates the reaction force as a target by using variable displacement and stops the current step of the analysis when the target achieved was written in Fortran language for solving convergence problems during the analysis. At the end of the study, it was revealed how much time wasting was prevented according to the current situation.

Keywords: Automation, buckling, dent resistance, finite element simulation, subroutine

1. INTRODUCTION

Nowadays, there is great concern about mass reduction of vehicles in automotive industry. Therefore, not only using more light weighted materials but also using of thinner gauged high-strength steel sheets or thicker aluminum sheets are getting increase. As a result, exterior panel dent resistance simulations that refers to resist again elastic or plastic deformation due to dynamic and quasi-static loads become one of the key design parameters in automotive design.

Over the last past years, studies regarding automation of finite element simulations panels in terms of pre-post processes were carried out as a result of digitalization. Gerngross and Pellegrino implemented a material model by using a user-defined in Abaqus due to not available viscoelastic material model for finite elements and verified a set of cylindrical balloons analytically. Also, the results observed experimentally to compare with analytical results (Gerngross and Pellegrino, 2007). Bortoleto et al. developed a computational tool, using Abaqus and Fortran, for analyzing the complete problem of heat treatment issue and thermal stresses which includes the phase transformations, microstructure and material properties. Thus, it was possible to extend functionality of Abaqus with Fortran subroutines by considering metallurgical and microstructural behavior of steel materials by themselves. Also, numerical results were compared with the literature results to agree with them (Bortoleto continued, 2009). The design criteria for high strength carbon fiber reinforced polymers are often chosen as compression strength of material due to being as low as 50 to 60 percent of the tensile strength. In order to make simulation of the failure modes in composites correcly, some effects such as yielding properties of the matrix material and kink-band should be teken into account. Therefore, Sørensen et al. presented a model by using UMAT user subroutine in Abaqus (Sørensen continued, 2009). Liu et al. implemented bone remodeling algorithms via Abaqus user subroutine USDFLD that performs the remodeling simulation in one single analysis without complicated postprocessing routines and also made workflows easier for designers, researchers and physicians (Liu continued, 2010). Luo and Zhao developed the second realize of Abaqus by using the manual of Abaqus. They put a new strategy forward in order improve efficiency and overcome the worse convergence of the Simple Generic Algorithm (Luo and Zhao, 2011). Park and Paulino created a potential-based

cohesive zone, called as PPR model, in Abaqus by using a user-defined element UEL subroutine. By this implementation, this model can be formulated within in the standart finite element framework for a two-dimensional analyses. At end of study, they compared thet computational results of the model with the analytical solutions in order to agree. They also provided the source code of the UEL subroutine for educational purposes (Park and Paulino, 2012). Ure et al. developed Linear Matching Method whose calculations are primarily carried out using the UMAT subroutine in Abaqus. In addition, the development of a Abaqus/CAE plug-in is discussed to aid wider adoption of the LMM as an analysis tool for industry (Ure continued, 2012). Castillo et al. studied on a FEM debond onset and growth at fibre-matrix interfaces in a single fibre. They provided the Linear Elastic Brittle Interface Model by using a user subroutine UMAT in Abaqus (Castillo continued, 2014). A user-defined element (UEL) subroutine is implemented by Chester et al. in the Abauqs for fluied diffusion and large deformations of elostomeric gels. They described the detail of a specialized form of the constitutive equations and the governing partial differantial equations of the theory (Chester continued, 2015). Ming and Pantalé developed a VUMAT subroutine that is an efficient and robust numerical algorithm for implementation of elasplastic constitutive laws in Fortran Language for Abaqus/Explicit. By this subroutine, they used more complex method that allows to obtain improved precies results instead of Abaqus' itself time integration scheme with only few a computational time (Ming and Pantalé, 2018).

The present paper focused on the implementation of UAMP subroutine written in Fortan language that uses displacement to reach calculated reaction force as a target and and also flags to skip next step in ABAQUS. This subroutine changes the displacement by calculating gradient of the reaction force under remaining time of the step in case needed. Thus, the convergence problems of dent resistance simulations mostly in automotive exterior were reduced due to there is no need inverse of the matrix for solving equations during the current step of analysis. Since the negative eigenvalues can be calculated which is not possible in the force method as a result of Newton Raphson, graph of the buckling behavior could be extracted. Moreover, it has been revealed how much time has been saved via this method at the end of the study.

2. MATERIAL AND METHOD

As known from the literature, the finite element models are generated in solvers such as Abaqus, Ls-Dyna etc. are usually nonlinear. The models involve from a few to thousands of variables. In terms of these variables the equilibrium equations obtained by discretizing the virtual work equation can be written symbolically as **Eq. (1)** below (ABAQUS Analysis Theory Manual, 2017):

$$F^N(u^M)=0 \tag{1}$$

Where F^N is the force component conjugate to the Nth variable in the problem and u^M is the value of the Mth variable. Due to history dependent simulations, the solution must be developed by a series of "small" increments. As a result, solving is required for each increment to discretization of few to thousands of variables equilibrium statement Eq. (1) and the increment size should be chosen. Generally, finite element solvers use Newton's method as a numerical technique for solving the nonlinear equilibrium equations. According to this choice, the convergence rate obtained by using Newton's method compared to the convergence rates exhibited by alternate methods such as modified Newton or quasi-Newton methods for the types of nonlinear problems. The basic formalism of Newton's method is as **Eq. (2)** follows (ABAQUS Analysis Theory Manual, 2017):

$$x_1 = x_0 - \frac{f(x_0)}{f'(x_0)} \tag{2}$$

This process may be repeated as many times as necessary to get the desired accuracy. In general, for any x-value x_n, the next value given by **Eq. (3)** below [13]: (ABAQUS Analysis Theory Manual, 2017):

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} \tag{3}$$

Dent resistance simulations are usually unstable problems due to buckling. It is often necessary to obtain nonlinear static equilibrium solutions for unstable problems, where the load-displacement response can exhibit the type of behavior sketched in **Fig. 1**. During periods of the response, the load and/or the displacement may decrease as the solution evolves. It is assumed that the response is reasonably smooth that sudden bifurcations do not occur. The basic algorithm remains the Newton method; therefore, at any time there will be a finite radius of convergence. Further, many of the materials (and possibly loadings) of interest will have path dependent response. For these reasons, it is essential to limit the increment size (ABAQUS Analysis User's Manual, 2017).

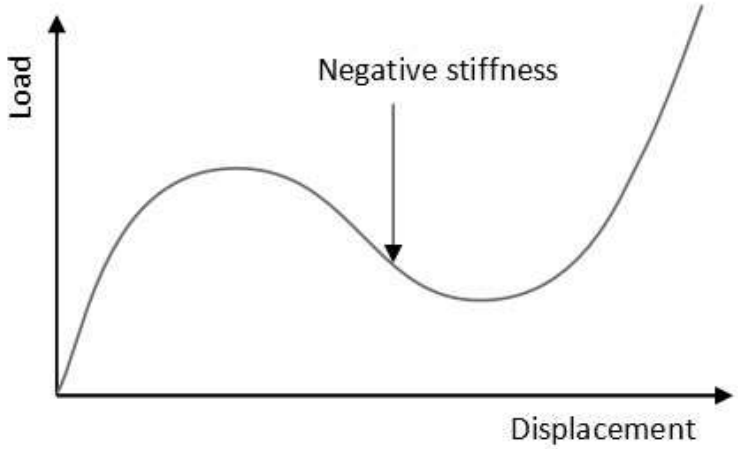

Figure 1. Typical load-displacement curve for instabilities

Several approaches are possible for this type of behavior. One is to treat the buckling response dynamically, thus actually modeling the response with inertia effects included as the structure snaps. Another approach would be to use dashpots to stabilize the structure during a static analysis for solving unstable problems but in this case the accuracy of the results is often far from reality. In almost cases displacement control can provide a better solution, even when the conjugate load (the reaction force) is decreasing as the displacement increases. For this purpose, a solution dependence introduced an UAMP subroutine in Fortran language that provides all data information about every increment pass developed.

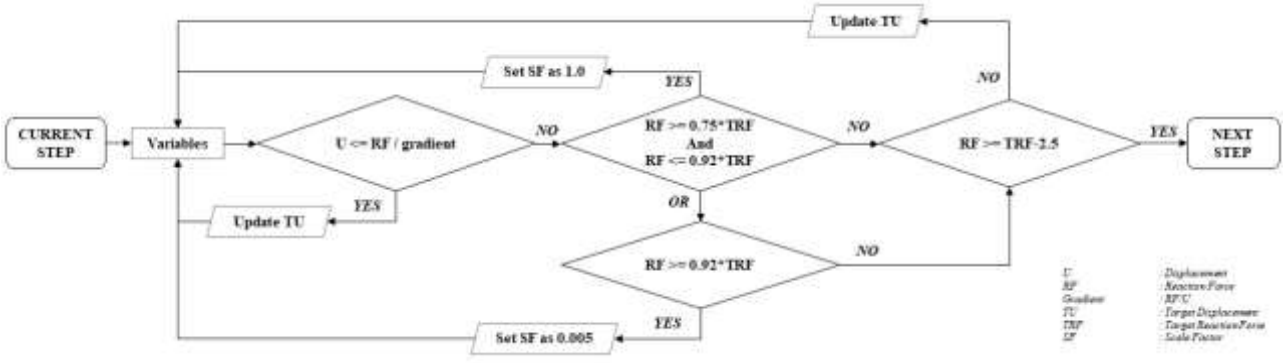

Figure 2. Algorithm of UAMP subroutine

The methodology of UAMP subroutine can be summarized as shown in **Fig. 2**. All variables pass to identify values at first increment in current step. Gradient is calculated for changing ratio of stiffness and thus, target displacement is updated in case current displacement is far away this value in a short remaining time step. At every increment, the relationship between reaction force and target reaction force is controlled. Scale factor is updated according to this information. If the reaction force reaches 75% percentage of the target reaction force, the scale factor reduced from two to one but when 92% percentage is reached, the scale factor is set as 0.05 to minimize displacement for next step due to its proximity to the target. The force difference is set as 2.5N between the reaction force and the

target reaction force to flag the current step as completed. UAMP automatically updates the target displacement if this value is not satisfied. Thus, the target reaction force can be calculated within small errors that can be neglected.

Since the displacement method used in UAMP, buckling behavior that cause convergence problems in Newton's method due to negative eigenvalues can be easily observed. In addition, the computational times are improved since the stiffness matrix does not need to be inversed as in the Newton's method. When this situation is taken into account at more than one force applying point, it is obvious how much time saving will be.

3. NUMERICAL STUDIES

Loading conditions, constraints and other properties such thickness, material etc. should be defined correctly to solve complicated denting resistance and complicated behavior of buckling. Technical terms that used during the whole study can be found at **Table 1**.

Table 1. Technical terms

Technical Term	Explanation
Buckling	Recoverable, localized reversal of curvature failure
Permanent Dent	Residual visible deformation
Hard-Oil Canning	When the panel reverses before pusher. Therefore, the panel and pusher can lose contact between each other in a short time. It can be easily observed from load displacement curve because of hard slope.
Soft-Oil canning	When the panel reverses at the same time with the pusher. Panel and pusher do not loose contact between each other but It can be observed from load displacement curve drop.
Panel Initial Stiffness	Minimum deformation value when a light load is applied.
No Damage Threshold	Minimum load value that panel surface resists without a permanent dent.
Pusher Cover	8 mm thick a foam layer on the pusher contact surface.
Slam Zone	Area of hood to be subjected to incidental damage during closing.
Wipe Zone	Area of hood that is reachable for a human hand during car washing.

Fig. 1 shows a typical stiffness curve of automobile panels. From figure, it is seen that the panel deformed with increasing load has three different stiffness zones. Stiffness in the first region that starts from base statement of the graph to **Point-A** can be defined as a function of properties depending on parameters such as Young Modulus, material, thickness, sheet form and boundary conditions. In this region, bending and compression membrane stresses are effective in the panel. Generally, this region acts as elastic. When the load applied on the panel increases, the panel form changes from the convex form to the concave form and the rigidity of panel decreases. So, the panel show unstable behavior in this region between **Point-A** and **Point-B**. Transition in this unstable region can take place in hard or soft form. In case of soft form, the contact between the panel and the indenter is not lost due to collapse but in case of hard transition vice versa. The stresses acting in this zone are combination of bending and tensile stresses. After that, the tensile membrane stresses in the panel start increasing and another zone arise that starts with **Point-B**. In this region, the panel stiffness increases again with the increasing load. Although, there are various analytical studies, no analytical solution has yet been found for the stiffness calculations of the second and the third region.

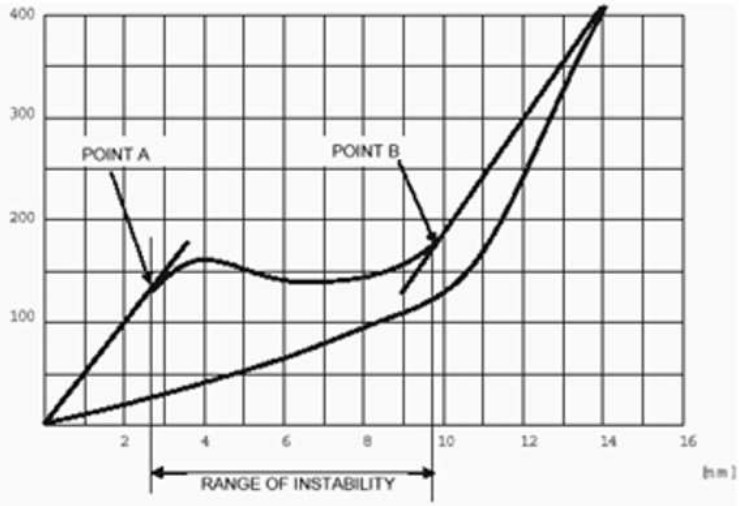

Figure 3. A Typical Force - Displacement Curve

Generally, the finite element models mostly body in white generated via shell because, almost 95% of an automotive structure is created from thin sheet parts that are suitable for shell theorem. In this study, the finite element model of hood was created via Altair Hypermesh 2017.3 as shown **Fig. 4** All mechanism of hinges and lock mechanism were involved the finite element model. Except some parts, 2D mesh that consist of full integration quad elements and full integration triangle elements for transition were used whole model. Also, mesh detail of clamp area and latch mechanism are can be seen from section cut.

Figure 4. Mesh structure of the hood panel assembly

Structural or non-structural Adhesives that are not suitable for shell theorem are modelled with 3D solid continuum elements (non-reduce) as shown **Fig. 5-a**. Moreover, fasteners such as spot welds were created via CONN3D2 element as point that generated during analyses by importing include file as shown **Fig. 5-b**. They had beam section property with 5mm rod attribute. Bolt connections were implemented via BEAM element that type of rigid elements.

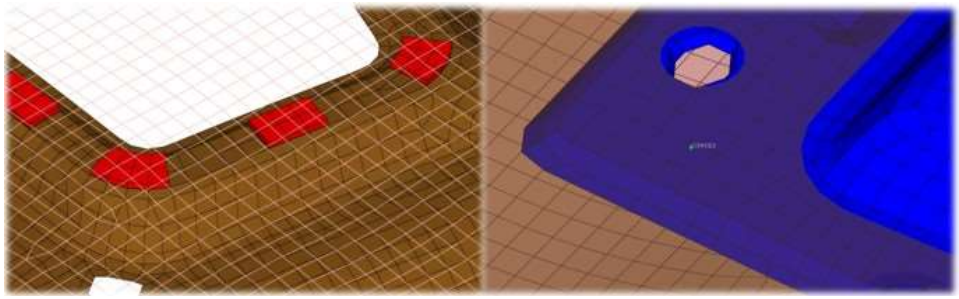

Figure 5. a) 3D mesh structure of adhesives b) 1D mesh structure of fasteners

A part as called as intender which consist of a cylindrical pusher and a cover diameter to apply vertical load during the analyses was used. The indenter's finite element model was created via hybrid elements. The cylindrical pusher has 80 mm. diameter top hat. The indenter cover is 7.5 mm thick and made from high-density foam sheet.

Detailed FEM of the indenter can be seen from **Fig. 6-a**. The indenter's material had a hyperelastic behavior in simulations. When the indenter pushed to rigid wall, the behavior of the intender pusher and the indenter of cover act like graph below. Shape change of the indenter under force also can be seen from **Fig. 6-b**. Wireframe with blue color represents initial position of the indenter and red color represents deformed shape of the indenter. Moreover, nonlinear material properties such as FEP04, FEP13, FE220BH, FE340F were applied for each other parts as the indenter.

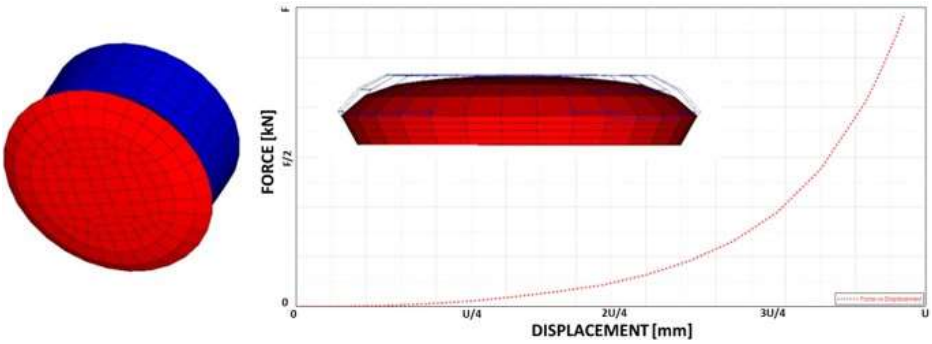

Figure 6. a) Finite element model of the indenter b) Behavior of the indenter on a rigid wall

Element quality is a crucial point of finite element analyses. Sometimes, it is called as main issue for convergence problems. Therefore, it is necessary to achieve a certain element quality shown at **Table 2**.

Table 2. Summary of element quality

Quality	Value	Pass Criteria
Tria Ratio per Components	4.16	≤ 5.00
Warpage	17.76	≤ 20.00
Aspect Ratio	4.99	≤ 5.00
Skewness	44.92	≤ 45.00
Jacobian	0.61	≥ 0.60

Dent resistance's finite element analyses consist of local models. Generally, half or quarter of finite element model with cut body in white is used except sub-assemblies such as moving parts due to their mechanisms. The boundary conditions of the hood panel assembly can be seen from **Fig. 7**. Latch point was constrained in lateral and vertical directions except transitional. Also, bump stopper locations were just constrained to its local surface normal. The boundary conditions for the four-bar hinge can be seen also from **Fig. 7**. The body side hinge has two moving links whose hinge pin is freely allowed to rotate and one link whose hinge pin is freely allowed to rotate and translation. The body side hinge bolts were constrained in all degree of freedom as it will be bolted to the body in white.

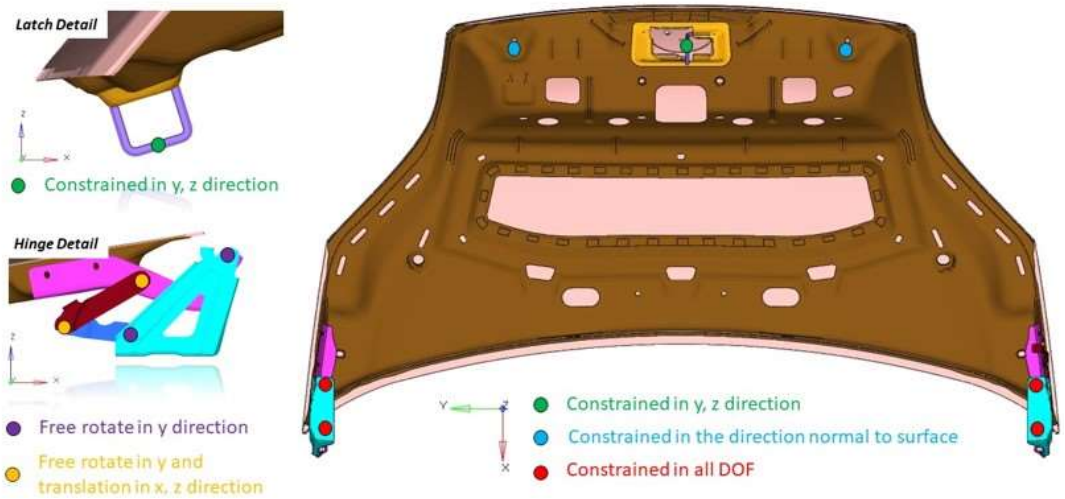

Figure 7. Hood boundary conditions

Hood's main area was divided to specific load application zone according to test specifications as shown **Fig. 8** that explained in **Table 1**. The wipe zone and the slam zone have different pre-defined pass criteria. The positions of indenter were created inside these zones and only red one was selected specifically for this study.

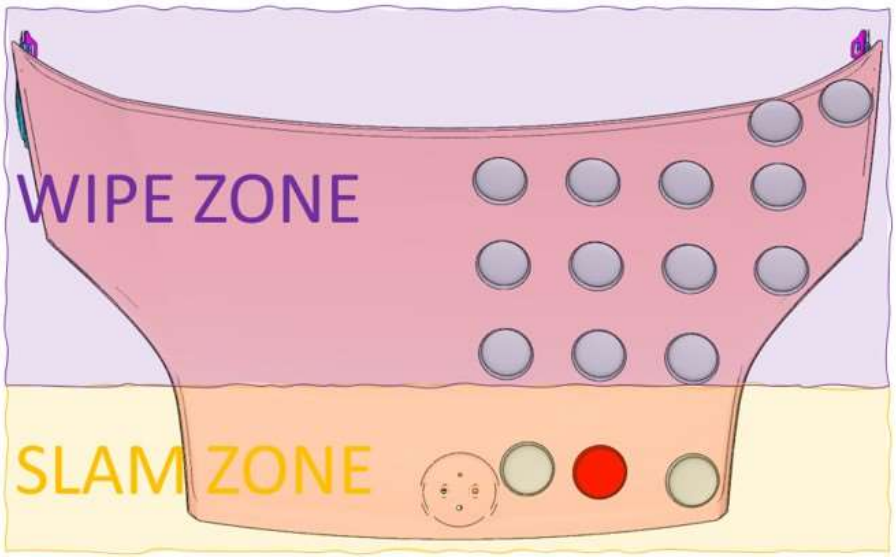

Figure 8. The indenter positions for hood

Fig. 9 shows how the indenter was positioned surface normal of the hood panel. The indenter is constrained in all degree of freedom except surface normal to the panel.

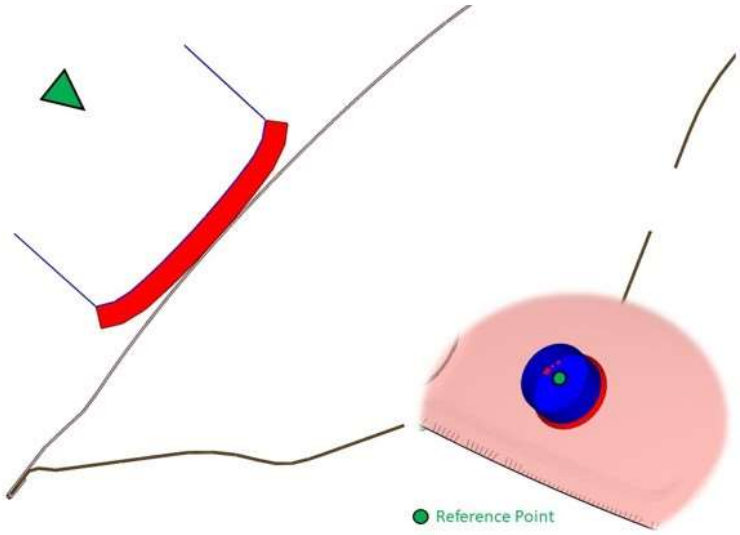

Figure 9. Loading conditions of the indenter

Two different analyses, the force method and the displacement method, were performed via Abaqus v6.14 nonlinear implicit solver. In displacement method, a user-variable UAMP subroutine was defined in run file via "*AMPLITUDE" keyword for changing the target displacement after each converged iteration. Also, a sensor added the reference point of the indenter to check the displacement of indenter and the reaction force of the indenter in local surface normal direction.

4. RESULTS

Results were post-processed by using Hyperview 2017.2.3. Displacement, stress, equivalent plastic strain and reaction were requested for output. Normalize values of the maximum displacement for the loading condition can be seen from **Fig. 10**.

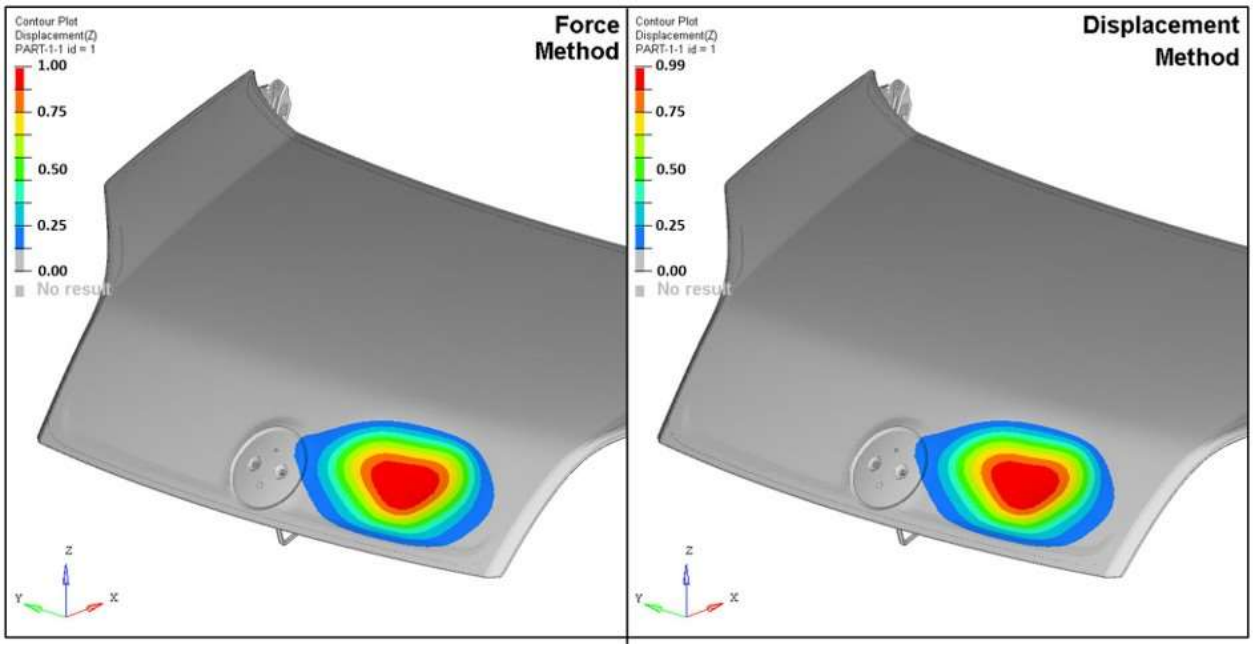

Figure 10. Maximum normalize displacement contour for each method

Normalize values of the permanent displacement after loading condition can be seen from **Fig. 11**. Although, a buckling has been seen, it was recovered due to elastic which is described.

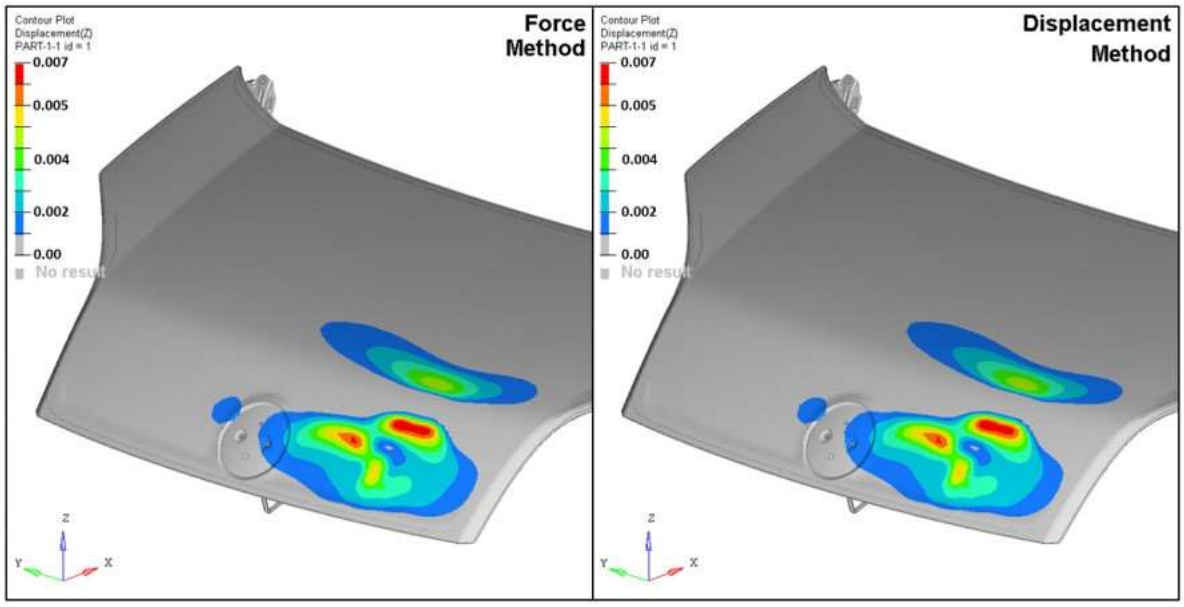

Figure 11. Permanent normalize displacement contour for each method

Fig. 12 shows the buckling after loading condition. Generally, this behaviour is checked to understand the buckling is recoverable or not.

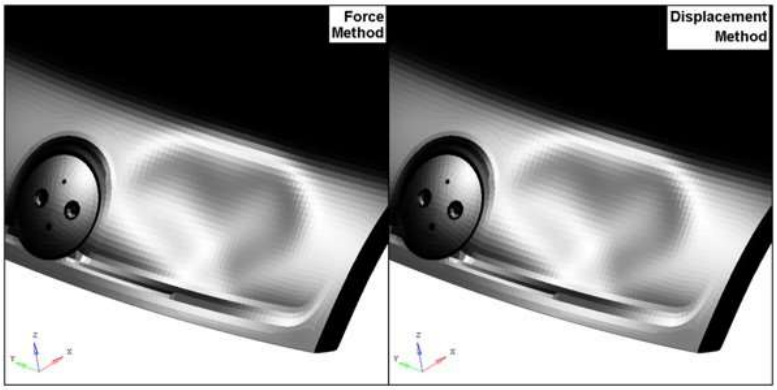

Figure 12. Buckling behaviour after loading condition

It is also known that dents higher than 0.5mm can be seen easily. In order verify this situation, the results were checked via colored light under the permanent displacement contour as shown **Fig. 13**.

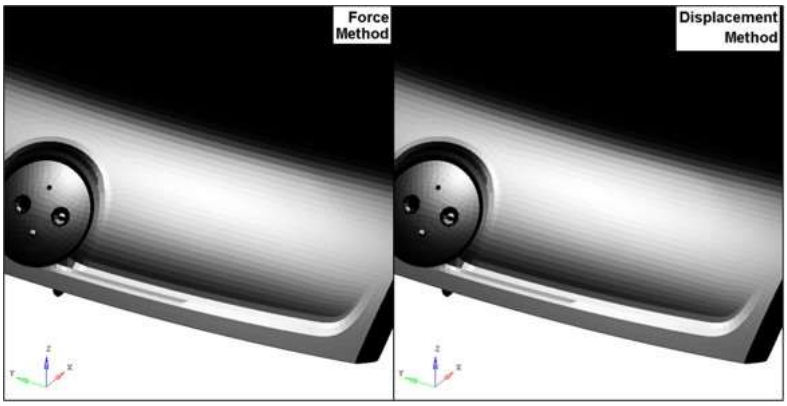

Figure 13. Visible dent control for each method

Force-displacement graph of the current force applying point shown as **Fig. 14**. It is plotted by using the indenter's reference node force and reaction force values and the hood's reference node displacement values. Unstable area due to stiffness change can be seen by starting from 0.05U mm and 0.25U mm After this point, the stiffness of the panel got higher similar to Fig. 3 because of the increasing tensile membrane stresses in the panel. Both curves behaved the same respect to the figure below except one region that called as unstable or instability. In the force method, the buckling behavior in this region could not be captured graphically due to negative eigenvalues. On the other hand, the displacement method exhibits this behavior very well by revealing negative eigenvalues since it does not need to reverse in matrix operations. The difference between the applied force and the read reaction force and the maximum displacement reached is acceptable.

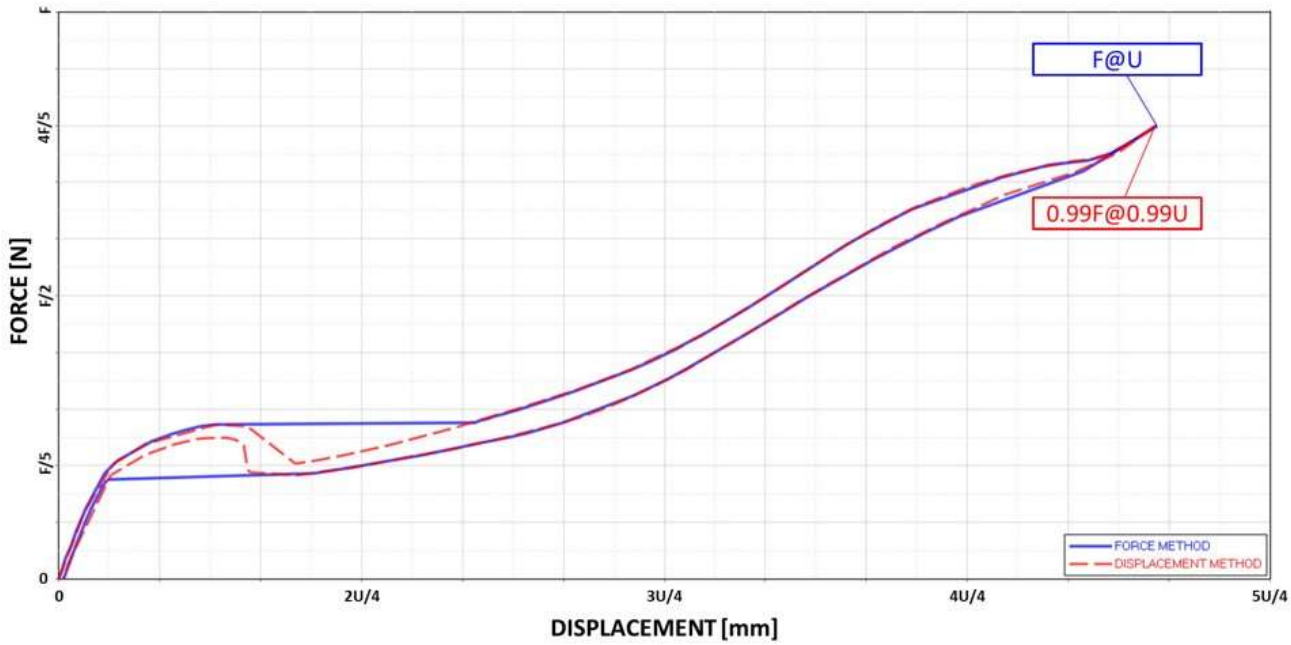

Figure 14. Force – displacement curve of the indenter for current position

5. DISCUSSION AND CONCLUSION

In this study, an Abaqus UAMP subroutine written in Fortan language for using displacement method to reach calculated reaction force instead of force method. Two methods were used in hood's panel structure to verify comparasion. Also, it has been revealed how much time has been saved via displacement method. Summary of results for comparasion of two method can be seen from **Table 3**.

Table 3. Summary of results

Value	Force Method	Displacement Method	Diff
Force [N]	F	0.99F	% 0.17
Maximum Displacement [mm]	U	0.99U	% 0.18
Permanent Displacement [mm]	U_p	U_p	% 0.00
Visible Denting	NO	NO	Compatible
Job Time [hh:mm:ss]	02:52:32	01:12:55	%58.3
Buckling Behaviour in Graph	NO	YES	Better

As can be seen from the table, the displacement method has achieved the same target force and displacement values as the force method. Morever, the job time of the analysis decreased as a half of the force's method job time and improved. In this way, extra time was gained for product development in early phases of automotive design. It is aimed to develop this study by using this method for similar analyses.

ABSTRACT

Welding is usually used in the automotive industry for joining steel sheets. Resistance spot welding is one of the most used welding methods in the automotive industry. Resistance spot welding has a number of advantages when it is compared to the other welding methods, such as easy applying, suitable for automation, not needing filler metal etc. Although spot welding has been a known process for many years, it is one of the most studied welding methods because it is used so much in the automotive industry. In this study, the effects of various electrodes nose types on nugget shape and tensile strength of the resistance spot welding are investigated numerically. Firstly, resistance spot welding analyses are performed in Simufact welding software, and the nugget cross-sections are investigated. The width, height dimension of the weld nugget is recorded for each nose type. After the resistance spot welding results are used as an input data for the tensile tests. The tensile test is also conducted in Simufact welding software, and the maximum tensile forces are recorded. As a result of the study, it is found that the nose type has a small effect on the tensile strength of the resistance spot welding.

Keywords: Resistance spot welding, finite element analysis, different nose types

1. INTRODUCTION

Welding processes are frequently used in the automotive industry for joining different and same types of steel sheets. Today, resistance spot welding is the most used method in the automotive industry. There is average of between 4000 and 6000 resistance spot welding in passenger vehicles. For this reason, resistance spot welding always maintains its importance in the automotive industry (Özgül and Arslan, 2018). (Doruk, 2016) describes the importance and the applications areas of resistances spot welding in the automotive industry.

Many researchers are interested in resistance spot welding and its application in their studies. (Tuncel and Aydın, 2019) investigated the tensile properties of resistance spot welded ultra-high-strength steel Usibor 1500 experimentally. Tensile shear load and elongation values are increased with increasing weld current and welding time. (Pereira, 2010) investigated effects of process parameters on the strength of resistance spot welding for 6082 – T6 aluminum alloy experimentally. They found that an increase in the weld current and time increased the nugget diameter and coarsened the microstructure. (Deng, 2018) investigated the effects of electrode surface topography on aluminum resistance spot welding by using microstructural analysis and mechanical property testing. (Aras, 2018) is investigated the mechanical properties of high-strength steel by using resistance spot welding. The hardness properties, tensile strength, and fracture types are investigated experimentally. (Tutar, 2018) optimized the welding parameters of resistance spot welding process parameters by using the Taguchi method for TWIP steels.

In this study, the effects of different electrode nose types on the shape of the weld nugget and the tensile strength of the resistance spot welding are investigated numerically. Both welding and tensile tests are performed by using the finite element method with Simufact welding software. The dimensional comparison of weld nugget and the maximum tensile strength of the resistance spot welding are performed.

2. MATERIAL AND METHOD

2.1. Finite Element Model of the Resistance Spot Welding

The effects of various nose types on the tensile strength of the resistance spot welding are investigated numerically by using the finite element method in this study. The finite element analyses are conducted in the Simufact Welding 8.0 software resistance spot welding module. The general finite element analysis procedure is divided into six stages. These are the creation of the geometry, the definition of the material properties, the creation of the mesh structure, the definition of the boundary conditions, run and evaluation of the results. This procedure is applied sequentially for the finite element analysis in this study.

Firstly the electrode types are defined. Five different electrode noses, which are named as B0 – E – F – F1 and G type, are used in the finite element analysis. The used nose types are seen in figure 1. The diameters of the electrodes are defined as 6 mm, and the electrode material is defined as Cu.

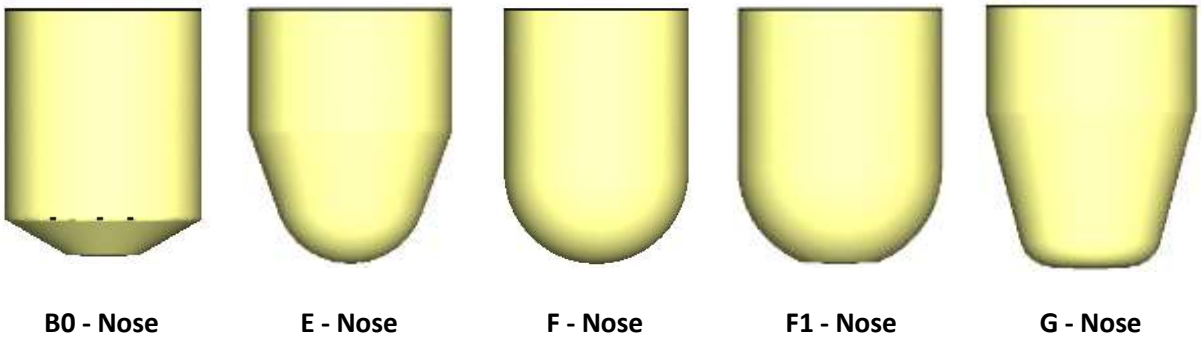

Figure 1. Different electrode nose types

The test samples are designed 100 mm length and 40 mm width and 1 mm thickness overlap as seen in figure 2. according to the ANSI/AWS/SAE/D8.9-97standard [8]. The material of the test samples is defined as SHGA370 galvannealed steel. The mechanical and thermal properties of the SHGA370 are automatically defined in Simufact material. These properties are automatically imported from the Simufact material to the Simufact welding. Thermal conductivity and Specific heat capacity are defined as a function of temperature. The solidus temperature is 1466 ºC, and the melting temperature is defined as 1517 ºC. Contact heat transfer coefficient (α) is defined as 1000 W/m^{2}K, emission coefficient (ε) is 0.6, and the initial temperature of the analysis is defined as 20 ºC.

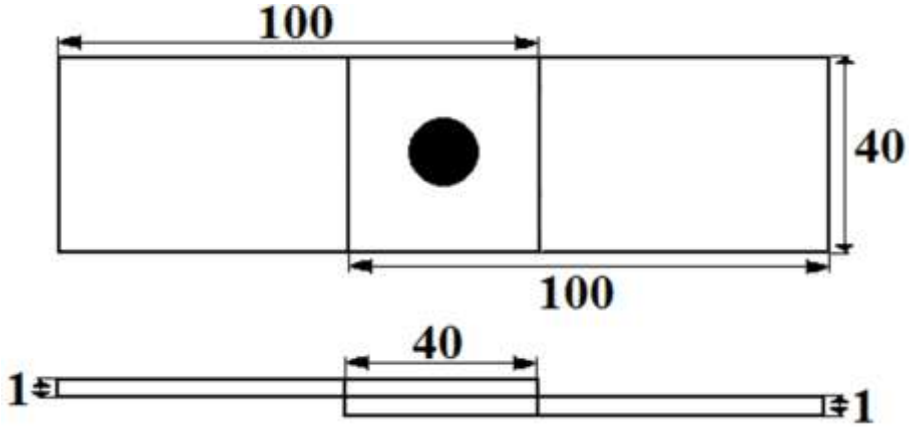

Figure 2. General dimensions of the test sample

Mechanical properties of the SHGA370 are also defined for the tensile test analysis. Young modulus density is defined as the function of temperature, and the Poisson ratio is defined as 0.3. After the definition of the geometry and material properties of the finite element analysis, the mesh structure is defined. The mesh structure is created in two stages. At first, 1 mm mesh is applied to the sheets as a coarse mesh. Then 10 mm diameter on the welding area has meshed with 0.25 mm element size. In this way the solution time and the hard disk space requirements are minimized. The mesh

structure of the resistance spot welding and tensile test analysis consists of approximately 20000 hexahedral elements and 45000 nodes. The general and detailed view of the mesh structure is shown in figure 3.

Figure 3. Mesh structure of the RSW analysis

The boundary conditions of the finite element resistance spot welding analysis are defined after the creation of the mesh structure. The welding time is defined as 0.5 s, for welding 150 s for cooling, and the electrode force is defined as 2kN, and the welding current is 8000 A. The variation of the electrode force and welding current depending on the time is given in figure 4. These values are taken the same for all analyses.

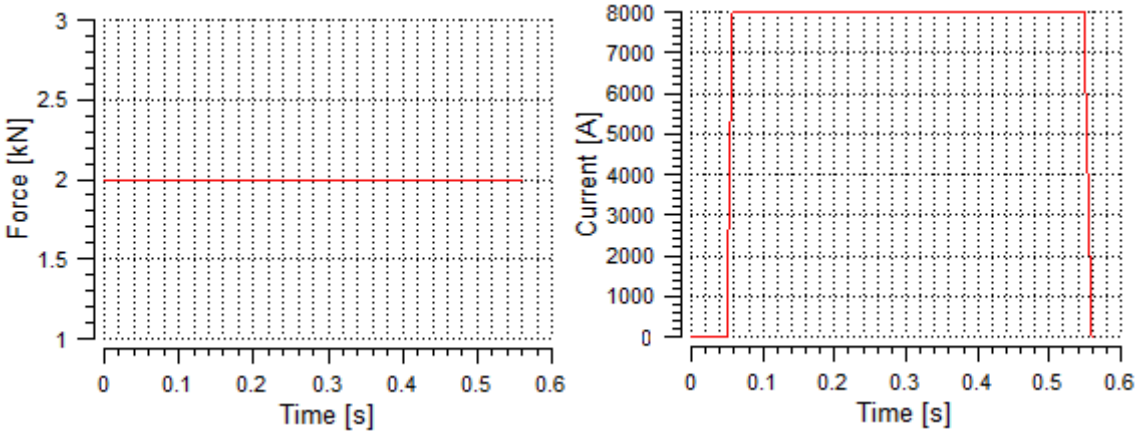

Figure 4. The variation of the electrode force and welding current

Clamp and bearing elements are also added to the analysis for the stabilization of the sheet during the resistance spot welding analysis. The bearing elements are added to the lower side of the sheets, and the clamp elements are added to the upper side of the sheets, as seen in figure 5. 100 N clamp force is also applied to the sheets during the resistance spot welding analysis. After the definition of the boundary conditions of the analysis, the finite element model is run. The analyses have reached the solution in approximately 25 minutes of a workstation with 2 Intel (R) Xeon (R) CPU E5-2650 processors and 64 GB RAM.

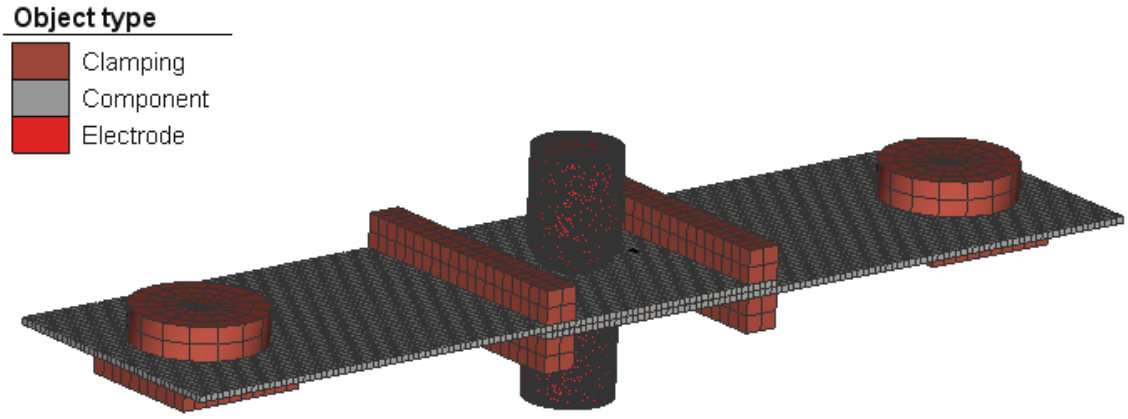

Figure 5. The boundary conditions of the resistance spot welding

2.2. Finite Element Model of the Tensile Tests

The tensile tests are conducted after the resistance spot welding analysis for the definition of the effects of the various electrode nose types on the tensile strength of the resistance spot welding. The solutions of the resistance spot welding analysis after 150 s cooling time are used as input data for the tensile test analysis.

The mesh structure of the tensile test analysis is taken the same as the welding analysis. Unlike welding analysis, two fixing elements are added to the analysis, and the clamps are converted into moving clamps. The moving clamps moved 4 mm forward, as seen in figure 6. The tensile test lasts 8 s, and the results of the tensile force is recorded for each 0,1 s.

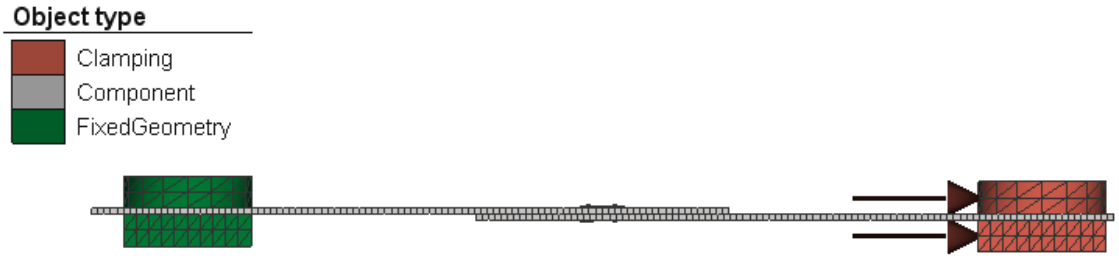

Figure 6. The boundary conditions of the tensile test analysis

3. RESULTS AND DISCUSSION

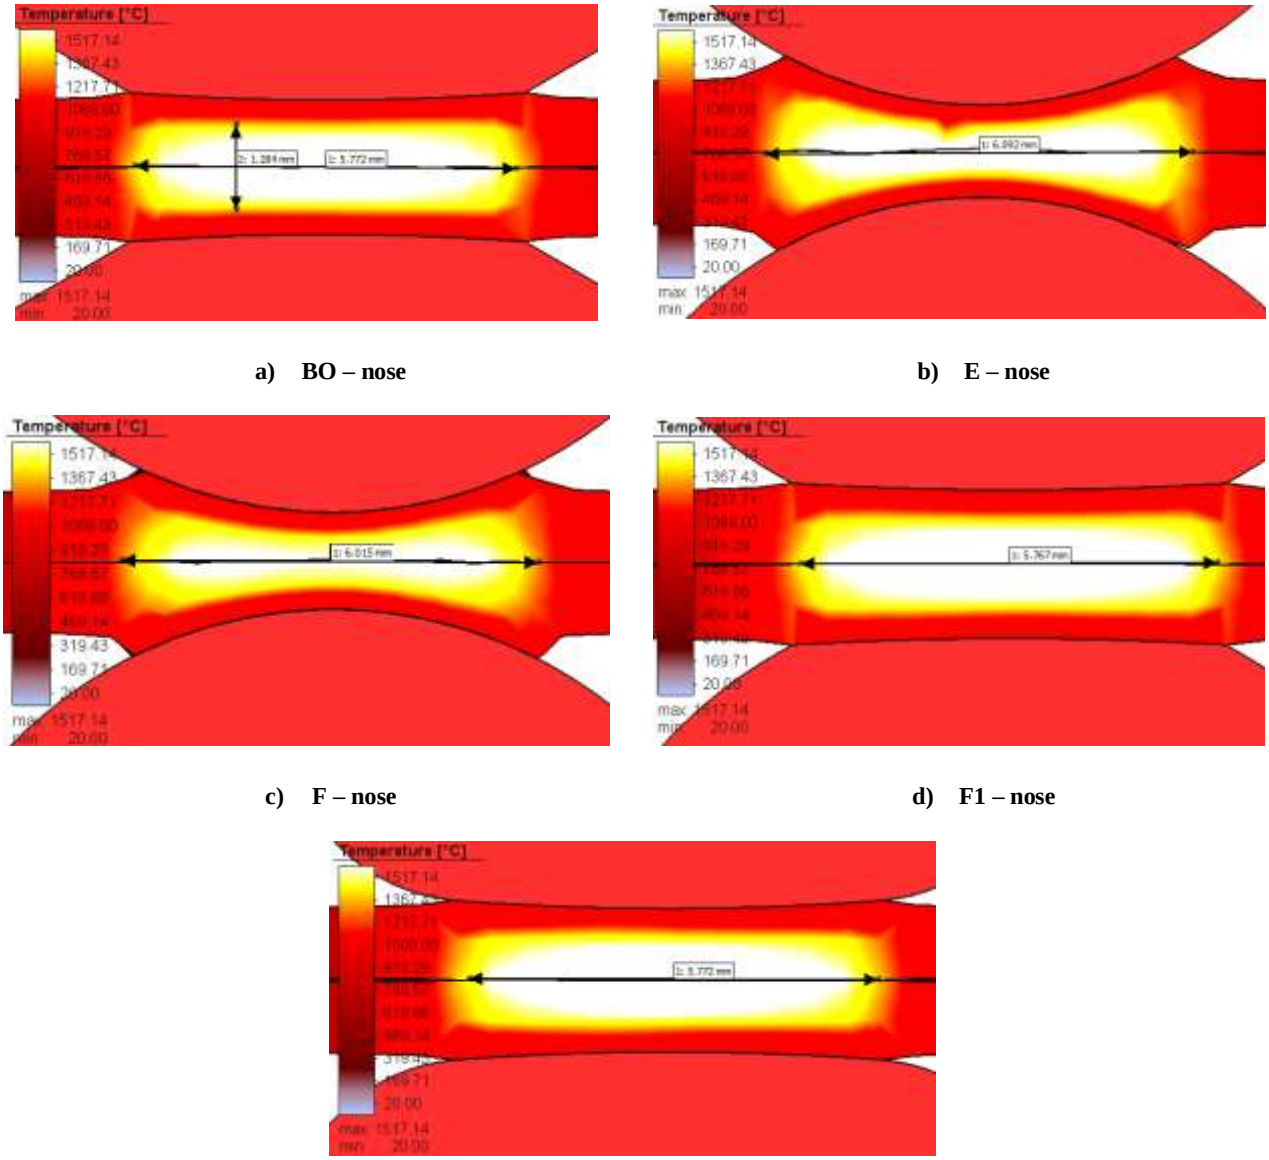
The finite element analysis of resistance spot welding and tensile tests are repeated five times for each electrode nose type. Totally ten finite element analyses are conducted in this study, and the effects of various electrode nose types on the tensile strength of the resistance spot welding are investigated numerically.

At first, the weld nuggets cross-sections are compared, and the effects of electrode nose type on the weld nuggets cross-sections are investigated. The comparisons of the cross-sections of the weld nuggets are seen in figure 7. According to the maximum temperature distribution of the resistance spot welding analysis, both sheet metal parts are successfully welded to each other. Moreover, It has been determined that the welding areas are symmetrical and smooth for all electrode nose types. The depth of penetration of the electrode varies depending on the electrode nose type. The penetration of the electrode is maximum for the F and E-nose types, and for the other types of noses, the penetration is nearly the same. It can be said that penetration increases with the increase in the sphericity of the electrode nose.

The nugget width and the height are measured for various nose types. The width and height dimensions of the weld nuggets according to the nose shape are given in table1. It is seen that the maximum weld width is seen for E-nose type and F – nose type approximately 6 mm. The weld width decreases 5.7 mm for B0 – F1 and G nose types. It can be said that E – F nose types have the same weld width. On the other hand, B0 – F1 and G nose types have equal weld widths between them. Similarly, the height dimensions of the weld nuggets behave the same as weld width. Due to more penetration, the height of the weld nugget decrease for the E and F nose type; approximately the height is measure 0.7 mm for the E and F nose types. However, the weld height increase by 1.2 mm for the B0 – F1 and G nose types.

.**Table 1.** The base dimensions of the weld nuggets

	B0 – nose	E – nose	F – nose	F1 – nose	G – nose
Width (mm)	5,772	6,0792	6,015	5,767	5,772
Heigth (mm)	1,229	0,740	0,771	1,202	1,200



a) BO – nose **b) E – nose**

c) F – nose **d) F1 – nose**

e) G – nose

Figure 7. Resistance spot welding cross section comparisons

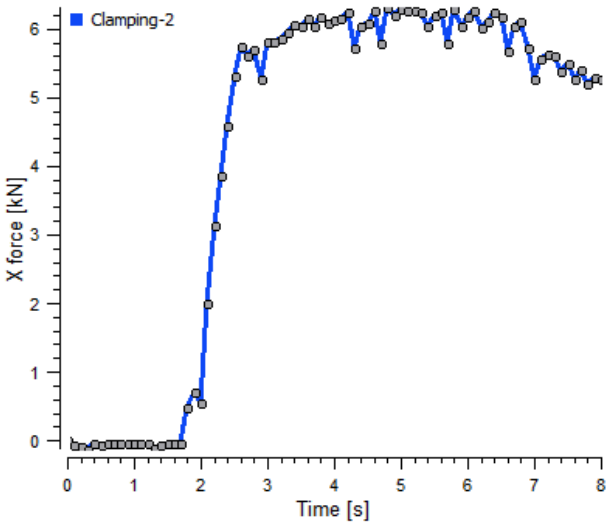


Figure 8. Tensile test analysis results for B0 – nose

Tensile test analysis result for the B0 – nose type is given in figure 8. The maximum tensile force is recorded at nearly 6.31 kN for B0 – nose type. Maximum tensile force results for various nose types are given in table 2. The maximum tensile force is seen for the E – F nose types, which have the maximum weld width. The tensile test force for other nose types is approximately 6.3 kN. It can be said that the maximum tensile force has directly related to the weld width. When the weld width increases, the durability of the resistance spot welding is increased.

Table 2. The finite element tensile tests result for different nose types

Nose Type	Tensile Force (kN)
BO – nose	6.31
E – nose	6.61
F – nose	6.58
F1 – nose	6.30
G – nose	6.27

4. CONCLUSIONS AND FUTURE WORK

In this study, the effects of electrode nose type on the tensile strength of the resistance spot welding are investigated numerically. Single lap resistance spot welding is modeled by using Simufact welding software. Five different nose types are investigated in the finite element analysis. After the welding analysis, a tensile test is applied to the virtual welding samples, and the results are evaluated. As a result of the numerical studies, the nose type seems to have little significance on the tensile durability of the resistance spot welding. When the nugget width increases, the tensile durability of the resistance spot welding is also increased.

After this numerical study, this paper's results will be verified by using experimental test techniques, and the validation of the finite element analysis will be done.

ABSTRACT

This study is performed to understand the microcellular structure of polypropylene plastic produced by chemical foaming with injection molding. A novel technique by Computed Tomography (CT) was used to understand three-dimensional foaming structure and compared with the physical two-dimensional measurement results by microscope imaging. The automotive polypropylene grade with medium impact 20 kJ/m^2 was studied to understand the distribution of microcellular voids in the structure. The chemical foaming agent was constant as 1.5 wt % and core-back mold process is used to develop microcellular regions. The cell size of voids found to be changing with respect to the position from injection gate. The melt flow direction and pressures have important contribution to the cell size. The void size decreases by moving away from the injection gate where the injection pressure increases. The maximum cell radius in the sections have decreased from 1 mm to 0.2 mm depending on the location of the component. In the study, CT has been performed as a fast and non-destructive testing solution to define the chemical foaming structure within the component after injection molding. The microscopy image in two dimensions is not adequate to predict the volume of the voids. On the other side, CT can predict volume of the voids and distribution of the voids in the foamed structures.

Keywords: Computed Tomography, Chemical Foaming, Non-Destructive Testing

1. INTRODUCTION

Depending on the application of automotive parts, foam-cell structures provides a weight reduction between 5% and 20% [1]. Recently chemical foaming agents are added to the polymer melt stream of thermoplastic olefins (TPO) and polypropylene (PP). The chemical foaming agents are added to have reduced material usage without decreasing mechanical properties [2]. Core back is a molding process where a controlled expansion eases the foaming. After the pressure drop, the nucleation site attracts gas molecules and cell expands during the cooling. When the melt strength of the polymer increases, the cell stops growing. The chemical foaming agents (CFA) have different chemical structure which requires varying degradation temperature. There are exothermic solutions which yields N2 gas or endothermic solutions which yields CO2 gas. The main drawback of this solution is the chemical byproducts remains in the product which can further interact with the additive packages in the material [3]. By the terminology cell size smaller than 100µm is accepted as micro-cellular structures. And the heterogenous cell size distribution in this process is typically unwanted which results into cell sizes higher than 100µm [4]. Such micro-cellular structures in the polymer matrix is formed as the material do not tend to shrink in the mold. The foaming process release the internal stress in the product and decrease the warpage.

The type of polymer and additives have influence on the foaming process. Fillers tends to increase the formation of nucleation sites which have impact on the cell size and distribution [5]. Impact modifier lowers the melt strength which hardens the control of cell size distribution. As the cell size increases, the mechanical properties of the polymer decrease.

In the conventional solid injection technique, the mold cavity is filled with 95% of the screw stroke and continue filling additional material under higher pressure. In the chemical foaming process, the foaming increases the internal pressure where foamed material fills the mold cavity.

Foaming process can be controlled by different parameters including type of foaming agent, amount of foaming, additives, injection pressure, mold pressure, mold temperature, injection gate position and many other [7]. In this study, a medium impact grade with IZOD notched 20k J/m2 was used to understand the effect on cell growth.
Mold designers are using FEM models to optimize injection molding process parameters by different software such as Moldflow. For foamed process, there are additional packages to simulate the process with higher accuracy [8].
Since the decomposition of the chemical foaming agent is difficult to control and non-uniform foam formation is initiated in the beginning of the process [7]. Coalescence influence the cell density and cell size. Coalescence occurs in the matrix by the rupturing of cell walls during foaming and must be controlled to have uniform cell density [9]. As the thickness of the part increases by core back method, lower densities are achieved by the cell size increases. Higher cell size lowers the skin layer which decreases the flexural stiffness.

2. MATERIALS AND METHOD

2.1 MATERIALS

In this study, LyondellBasell Hostacom CR 1171 G was chosen. The talc content which is important for nucleating site and impact modifier effect which is important for melt strength is presented in Table 1. The chemical foaming agent has been chosen as 1.5 wt % from Clariant Hydrocerol ITP 825.

Table 1. Comparison of PP solid materials

Properties	Unit	Test Method	Hostacom CR 1171 G
Melt Flow	g/10min	ISO 1183 Method A	8
Talc Mineral	%	ISO 3451/1	13
Flexural Modulus	MPa	ISO 178	1800
IZOD Notched Impact	kJ/m2	ISO 180/A	20

2.2 INJECTION PROCESS

The injection process with core-back system was used in this study by keeping the initial cavity thickness as 1.8 mm. After injecting the material into the cavity of the mold, the chemical foaming agent is activated by decomposition. The mold temperature is kept constant as the expansion of the foamed cell increase. The mold is expanded with additional 0.7mm before the melt strength is increased during cooling. The holding time kept constant for each trial. The injection machine used in this trial was Krauss Maffei 1600 Tons with valve gate system, screw diameter was 105 mm, and max stroke was 916 mm.
The injection parameters are listed in Table 2.

Table 2. Injection Parameters

Description	Unit	Value
Mold Surface Temperature	C	40
Melt Temperature	C	220
Hold Pressure	bar	25
Hold Time	s	1.5
Injection velocity	mm/s	120

2.3 ANALYSIS by MOLDFLOW

The injection process was modelled with MOLDFLOW, the parameters were listed in Table3.

Table 3. Moldflow Analysis Parameters

Description	Unit	Value
Mold Surface Temperature	C	40
Melt Temperature	C	240
Filling Control	s	3
Velocity/pressure switch-over	mm	12
Core-Back	mm	0.7
Cooling Time	s	20
Valve Gate	s	Open 0 - Close 3.6

The Pressure at velocity/pressure switchover with Feed, the maximum pressure was calculated as 64MPa and void radius were defined as lower than 0.01 mm with homogenous distribution on surface of the part Figure 1.

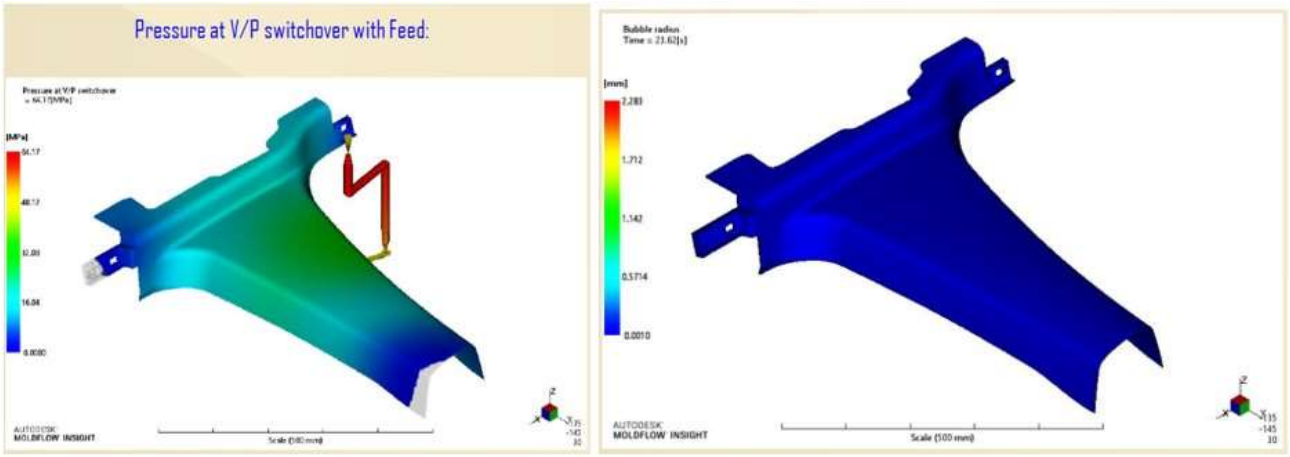

Figure 1. The Pressure at velocity/pressure switchover with Feed (left) and void radius (right)

2.4 SAMPLING DESCRIPTION

4 sampling points were chosen to understand the distribution of cell sizes in the component Figure 2. For microscopy images x-z plane and y-z plane sections has been analyzed.

Figure 2. The sampling points of the analysis were done from 4 different locations

3. RESULTS

3.1 MOLDFLOW ANALYSIS

In the mold flow analysis, the sections are taken to measure the void radius, Figure 3. The void radius is homogenously distributed on the x-z plane around 0.5 mm. As the pressure drop is lower away from the injection gate, the size of the voids is lowering to 0.4 mm. As moving away from the injection gate, the size of the void is lowering to 0.3 mm. Mold flow is basically used to estimate the size change of voids which gives theoretical estimations. The individual voids are not presented in the sections but the average void size is presented.

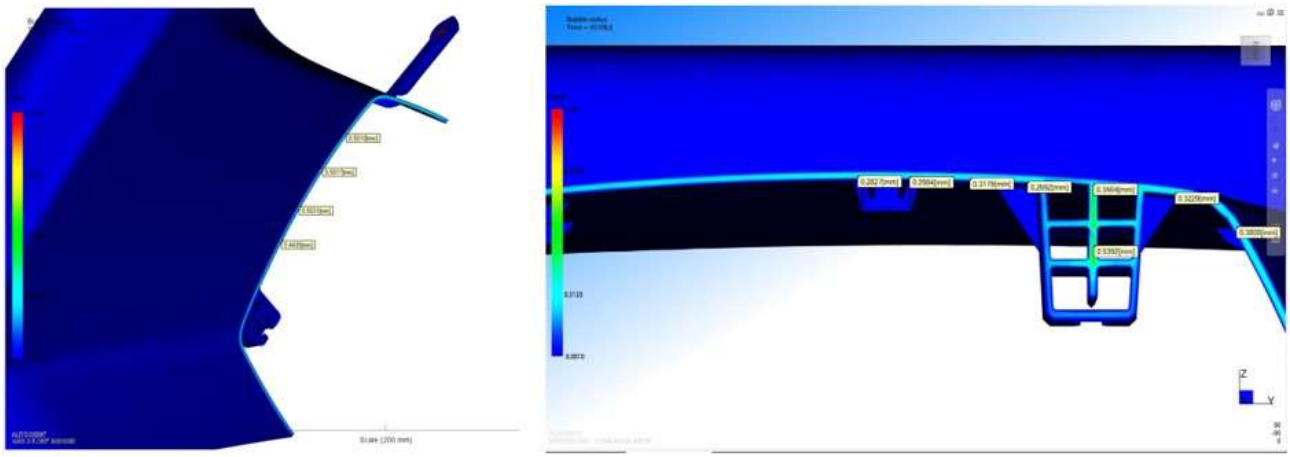

Figure 3. The void radius close to the injection gate (left) and away from the injection gate (right)

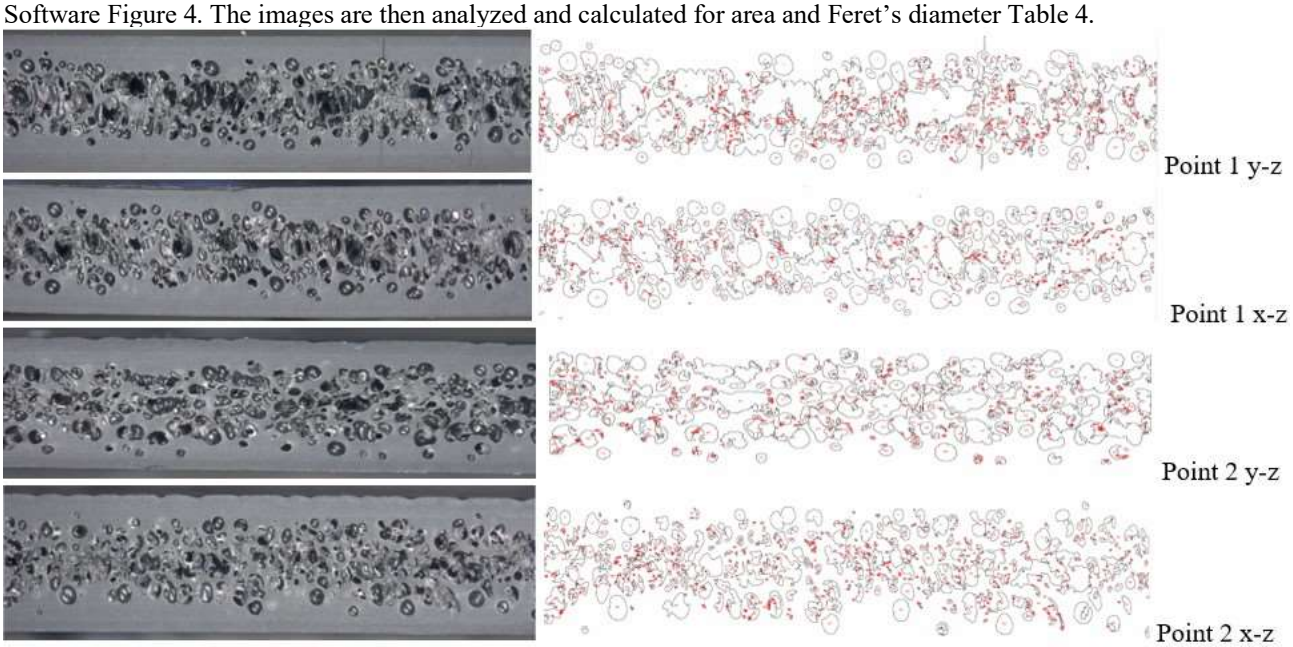
3.2 IMAGING BY MICROSCOPY

Microscopic imaging was done with Zeiss Stemi 508 at 10X magnification. Then, the image is processed with ImageJ Software Figure 4. The images are then analyzed and calculated for area and Feret's diameter Table 4.



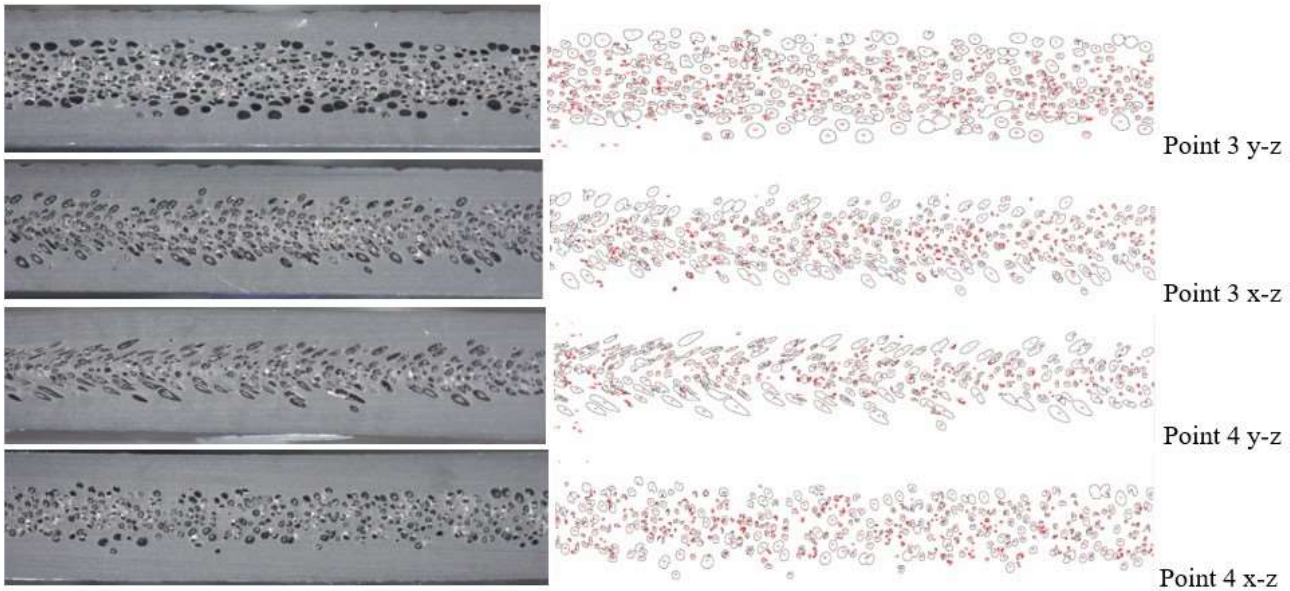


Figure 4. The TIFF image from microscopy (on the left) and compiled binary image in ImageJ (on the right)

Table 4. Measured data by ImageJ software

Sectioning Points	Sectioning Planes	Number of Voids	Max Area (mm^2)	Max Feret's Diameter (mm)	Max Calculated Radius (mm)	Max Estimated Volume (mm^3)
1	x-z	579	0.509	1.944	0.972	0.66
	y-z	783	0.961	2.018	1.009	1.29
2	x-z	685	0.196	0.983	0.492	0.12
	y-z	537	0.379	1.358	0.679	0.35
3	x-z	596	0.202	0.977	0.489	0.13
	y-z	573	0.065	0.496	0.248	0.019
4	x-z	544	0.053	0.395	0.198	0.014
	y-z	454	0.158	1.049	0.525	0.11

Considering the four different points on the component, the calculated maximum void radius varies between 0.198 mm to 1.009 mm. The max void radius in x-z plane along the section Point 2 and Point 3 is not changing with values around 0.5 mm which has been also estimated in mold flow analysis. On the other hand, considering the microscopy images, the void cell characteristics are different at Point 2 and Point 3 in x-z plane. As point 2 is closer to the injection gate then Point 3, the high injection pressure at Point 3 changes the shape of the void from spherical to elliptic. Also, at point 4 in y-z direction, the voids are more elliptic with high injection pressures. As the polymer moves through the mold, which is being cooled, the melt temperature decreases which increases the injection pressure by moving away from the injection gate. Therefore, as the polymer skin has low temperature and the core has higher temperature, the core of the melted polymer moves with the pressure direction during the foaming process. The void shapes are elliptic at Point 3 x-z plane and eventually at Point 4 y-z plane which can be explained by the melt flow directions at these sections.

At Point 1, the max radius of x-z and y-z planes are close to 1 mm where the injection pressure is similarly distributed in both directions. In addition to that, images at Point 1 and estimated max volumes (estimated as a sphere and calculated by multiplying 4/3 by the area and half of the diameter observed) revealed that the void volume is not homogeneous on different directions. Even though, it can be observed from the image that the spherical voids are located close to the skin of the component, the core of the component is not homogenous and spherical. Therefore, it can be observed that the chemical foaming was not under control in this section of the component.

At Point 3 and Point 4, the lastly filled sections have lower maximum radius in both x-z and y-z planes which was also observed in mold flow analysis. These sections have lower temperatures in the core-back time during cooling, thus the melt strength of the polymer is higher which decreases the formation of larger void cell size. The lower cell size with homogenous distribution can be attributed as a controlled foaming. The lower density with homogenous low cell size is preferred to have a lightweight component. It should be balanced in such a way that the cost of the foaming agent should be accommodated by the overall weight loss on the component.

3.3 X-RAY MICRO COMPUTED TOMOGRAPHY

CT is a tool for deriving finite element meshes of the cellular material. As being introduced in the introduction, previous works with the macroscopic morphologies in the foamed polymeric structures were mapped using CT. Images are collected and then reconstructed to 3D image with voxels. As the X-ray radiation is collected with the mass density of the material, macroscopic morphology of the material is formed rapidly.
This method is widely used to examine variety of complex-shaped materials, including metals, ceramics polymers, and soft tissues. Since the method is non-destructive, the internal structure can be analyzed on a macro scale in each region of the part even without damaging the part. In this study, Point 1, Point 2, Point 3 and Point 4 were cut for microscopic imaging and same specimens were measured by CT Figure 5.

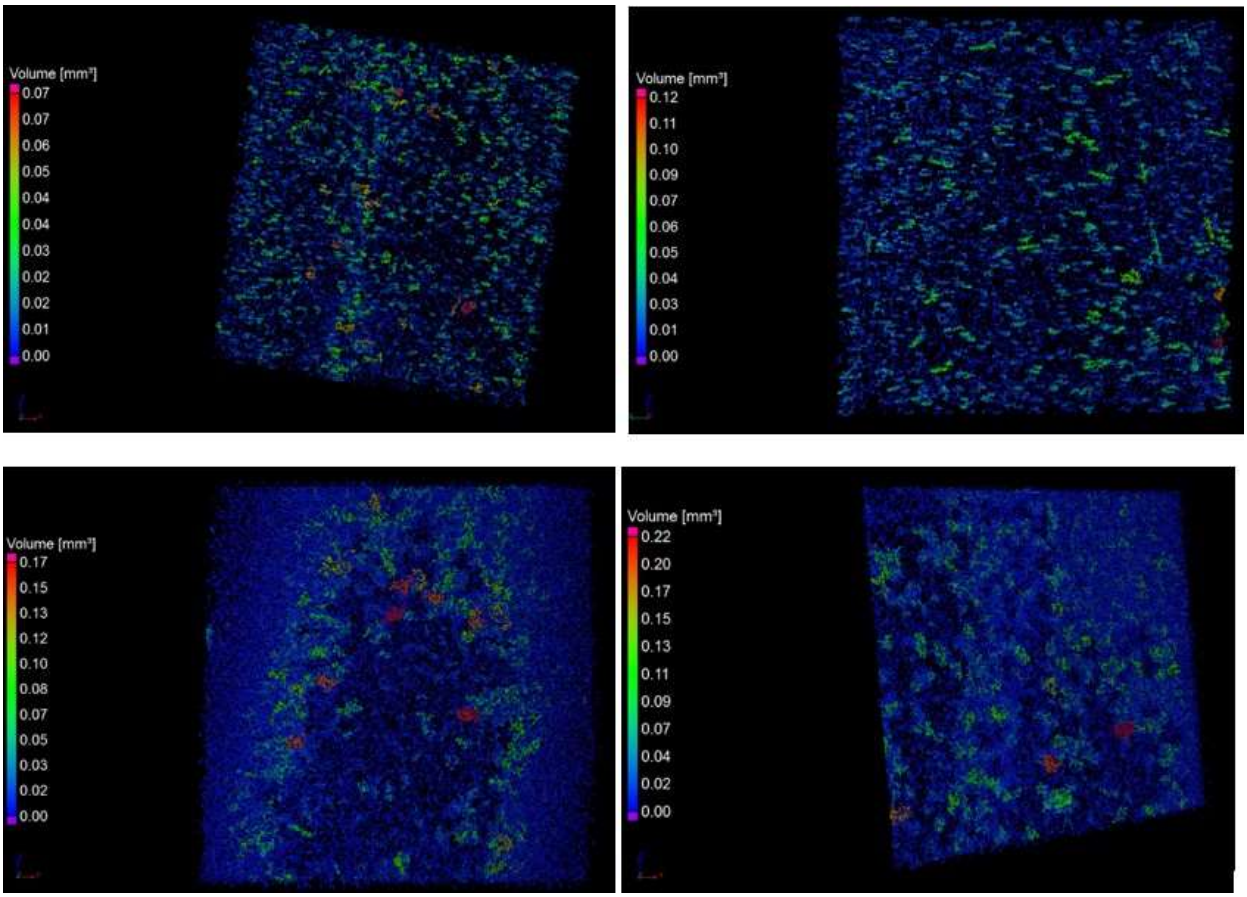

Figure 5. The Point 1 (upper left), Point 2 (Upper right), Point 3 (lower left) and Point 4 (lower right) was measured with dimensions 25 mm x 25 mm

Nikon XT H 225ST was used in the scanning of the samples. The x-ray rays produced by a source (x-ray tube voltage 80 kV and 80 mA) are sent to the sample to be examined. With the detector located on the back of the sample, the patterns of X-rays passing through the object depending on the material and geometry are captured with different shades of gray. In this study, the radiographic 2D gray-scale image was collected which is then converted to 3D image. The image processing software was used to calculate the voids in the 3D image.

Table 5. CT measurement results

Point	Number of Voids Observed In 25mm x 25mm	Max Void Radius (mm)	Maximum Volume (mm^3)	Defect Void Volume Ratio (%)
1	11099	0.88	0.07	2.0
2	11881	1.00	0.12	2.2
3	28167	0.99	0.17	4.0
4	23230	0.99	0.22	3.8

The CT scan has shown that the number of micro voids at Point 3 and Point 4 are higher than Point 1 and Point 2 which was not observed in microscopic imaging. As the void radius decreases, the number of voids increases in a unit volume where the sections were chosen as 25 mm x 25 mm and the thickness was 2.5 mm. The highest void volume ratio was observed at Point 3 with 4.0 % where the overall cell sizes were smaller.
The maximum void radius observed was around 1 mm at Point 2, Point 3 and Point 4 whereas a lower value was measured for Point 1. The high void volume with high average void radius is expected to decrease the weight of the component in a typical foaming process.
In this study, it has been observed that Point 3 and Point 4 have higher void volume ratio with homogenous distribution which was controlled by mold temperatures and high pressure during the injection.

4. CONCLUSIONS

Chemical foaming with core-back method has been investigated by different techniques to understand the foamed structure. The chemical foaming formation has drivers which influence the final cell structure. The melt strength of polymer, the ratio of foaming agent and the complexity of the structure are important derivatives. In this study, it has also been concluded that the distance to the injection gate and the injection pressure have also influence on the cell formation. The higher injection pressure decreases the cell radius and change the cell shape to elliptic from spherical. Mold flow analysis alone can predict the maximum cell radius but not enough to describe the cell size distributions. Microscopic imaging is a good technique when combined with a data processing to define the cell size locally but not enough to predict the overall voids on the component. Computed tomography on the other hand can define the characteristics of a component in three dimensions. The void volumes can be observed more precisely after data processing on the interested section of the component. As the cell structure have influence on the flexural stiffness of the component, understanding the cell structure distribution in a chemical foaming process is important to better design the component. There is a balance between cell size distribution and the weight of the foamed component which can be better understood when considering each imaging techniques.

ABSTRACT

Earing is a defect observed at the periphery of the drawn sheet after cup drawing process. This defect is stem from the planar anisotropy of the material and causes loss of material due to the trimming operation after the drawing process. Therefore, accurate prediction of the number and magnitude of ears plays an important role in the decreasing of scrap in the manufacturing. In this study, cup drawing process of commercial pure titanium was simulated using finite element (FE) method. Hill48 anisotropic yield criterion was used in the analyses to describe the anisotropy of the material and parameters of Hill48 were calculated based on the Lankford's coefficients. After numerical studies, the predicted earing profiles and the thickness distributions in rolling and transverse directions were compared with the experimental data. Despite Hill48 captured the radius profile of the partially drawn cup accurately, the criterion predicted smaller cup height values at the periphery when the sheet was fully drawn. As regards to the thickness distributions, predictions in both directions were in good agreement with the experimental data but slightly overestimated.

Keywords: Earing profile, cup height, thickness, finite element method, anisotropic yield function

1. INTRODUCTION

Sheet metals show anisotropic behavior due to the rolling process or thermomechanical processes (Yoon continued, 2000) (Yoon continued, 2006). Anisotropy causes a non-uniform material flow, and it leads to the occurrence of several defects in the manufacturing. Cup drawing is an important process in which the three-dimensional products can be produced. At the final stage of the process, a wavy profile is observed at the periphery of the formed cup due to the non-uniform material flow into the die cavity. This wavy form is called as earing defect and ears have to be trimmed off before the part is delivered to the customer. Therefore, it leads to scrap and the accurate prediction of this defect is required to reduce the material costs. To this end, FE analyses are frequently used in today's modern manufacturing environment to investigate this kind of defects before the process.

In the literature, there are a lot of studies which is related to predict the earing profile. Chung and Shuh investigated the earing behavior of AA2008-T4 aluminum alloy in cup drawing test using FE method. It was recorded that the numeric results were compatible with the experiments (Chung and Shuh, 1992). Yoon et al. assessed the earing defect of the AA2090-T3 aluminum alloy using FE method (Yoon Continued, 2000) (Yoon continued, 2006). The results obtained from this work were consistent with the experimental results. Yoon et al. also investigated the earing profile of the AA5042-H2 (Yoon continued, 2010). Chatti and Chtioui evaluated the effect of the combined hardening on the several forming processes including the cup drawing process. It is recorded that the combined hardening affected the numerical results (Chatti and Chtioui, 2011). Abedini et al. evaluated the earing issue of AA2090-T3 and AA7075-T6 alloys and they pointed out that the non-associated flow rule (Non-AFR) improves the prediction accuracy of cup drawing simulations (Abedini continue, 2018). Shi et al. investigated the earing in deep drawing for AA3014-H19 aluminum alloy using crystal plasticity based finite element model. They indicated that the work hardening, crystal elasticity and texture evolution have no substantial impact on earing, whereas the effects of friction, anisotropy and lubrication are highly important (Shi continued, 2018). Zhang et al. assessed the earing prediction of the AA2008-T4 aluminum alloy in terms of solution time for different yield functions (Zhang continued, 2018). Aside from the aluminum alloys, several

studies have been carried out to see the earing behavior for different materials (Tikhovskiy, 2008) (Huang and Lu, 2011) (Singh continued, 2018).

However, this defect is also depending on the magnitude of the anisotropy (Yoon continued, 2010) which makes the definition of the yield function important. It was observed that the Lankford's coefficients are highly important to detect the earing profile, while the yield stress ratios for different material orientations are important to estimate the amplitude of the ears (Singh continued, 2018). In the present work, cup drawing process of commercial pure titanium was simulated using FE method. Hill48 yield criterion was used in the description of the anisotropy of the material. Radius profile of the partially draw cup, earing profile of fully drawn cup and the thickness distributions in rolling and transverse directions were investigated and finally numerical results were compared with the experimental data in order to validate FE model.

2. MATERIAL AND METHOD

2.1. Model Description

Cup drawing is a metal forming process to produce the cylindrical or square cups. Blank is placed between the blank holder and die, and blank is subjected to flow into the die cavity by the movement of punch during this process. In this study, a cylindrical cup drawing process was simulated. Tool geometry used in this work, was demonstrated in the Fig. 1.

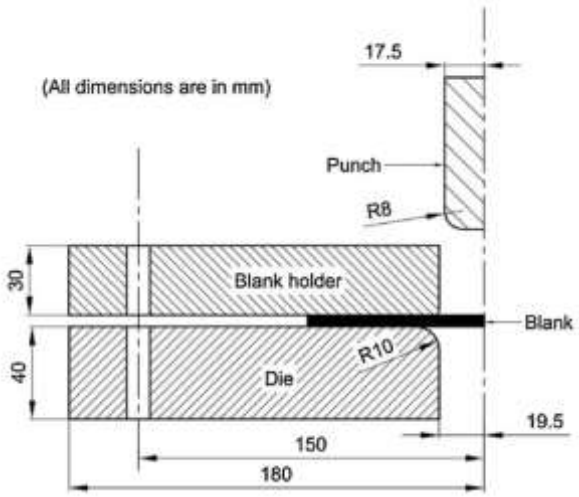

Figure 1. Dimensions of the tools (Singh continued, 2018)

Commercial pure titanium sheet was chosen as test material with 1 mm thickness. Titanium is widely used in automotive industry due to its high strength and low density. Engine connecting rods, engine valves, valve spring seat and exhaust system of a car are made from this material. Mechanical properties and the Swift law parameters of the commercial pure titanium were listed in the Table 1 and Table 2, respectively. Swift hardening law is given in Eq. 1.

$$\sigma_{true} = C(\varepsilon_0 + \varepsilon_p)^p \quad (1)$$

Table 1. Angular variations of r values and yield stresses (Singh continued, 2018)

	σ_0 [MPa]	σ_{45} [MPa]	σ_{90} [MPa]	r_0	r_{45}	r_{90}
Commercial Pure Titanium	195	240	265	1.71	2.21	2.67

Table 2. Parameters of the Swift law (Singh continued, 2018)

	C [MPa]	p	ε_0
Pure Titanium	541.5	0.25	0.0097

2.2. Hill48 Anisotropic Quadratic Yield Criterion

In this study, Hill's quadratic anisotropic yield function was used (Hill, 1948). Yield function proposed by Hill is expressed as Eq. 2.

$$2f = F(\sigma_{yy} - \sigma_{zz})^2 + G(\sigma_{zz} - \sigma_{xx})^2 + H(\sigma_{xx} - \sigma_{yy})^2 + 2L\tau_{yz}^2 + 2M\tau_{zx}^2 + 2N\tau_{xy}^2 = 1 \quad (2)$$

Here, F, G, H, L, M and N are the anisotropy parameters to be calibrated. These parameters can be obtained either using Lankford coefficients or yield stress ratios. Identification procedure considers the Lankford's coefficients (r based) is expressed by the statements which are given in Eq. 3-6 (Firat, 2008).

$$F = \frac{r_0}{r_{90}(1+r_0)} \quad (3)$$

$$G = \frac{1}{1+r_0} \quad (4)$$

$$H = \frac{r_0}{(1+r_0)} \quad (5)$$

$$N = \frac{(r_0+r_{90})(1+2r_{45})}{2r_{90}(1+r_0)} \quad (6)$$

Detailed identification procedure was explained in the references (Hill, 1948). Associated flow rule given in Eq. 7, was used to obtain the plastic strain increments.

$$d\varepsilon^p = d\lambda \frac{df}{d\sigma_{ij}} \quad (7)$$

In the equation above, $d\varepsilon^p$ is the plastic strain increment and $d\lambda$ denotes the plastic multiplier. Isotropic hardening rule was assumed in this work.

2.3. Finite Element Model

Simulations were performed using Msc. Marc software. Die, blank holder and punch were modeled as rigid surfaces. Fully integrated hexahedral solid elements were used for the mesh layout of blank. Quarter part of the blank was created using Msc. Apex software and mesh layout was transfered to the Msc. Marc software. Friction coefficient was assumed as 0.1. Blank holding force was applied as 5750 N for the quarter part (Singh continued, 2018). FE model of the process and the blank mesh layout were demonstrated in Fig. 2. Two elements were considered in thickness direction.

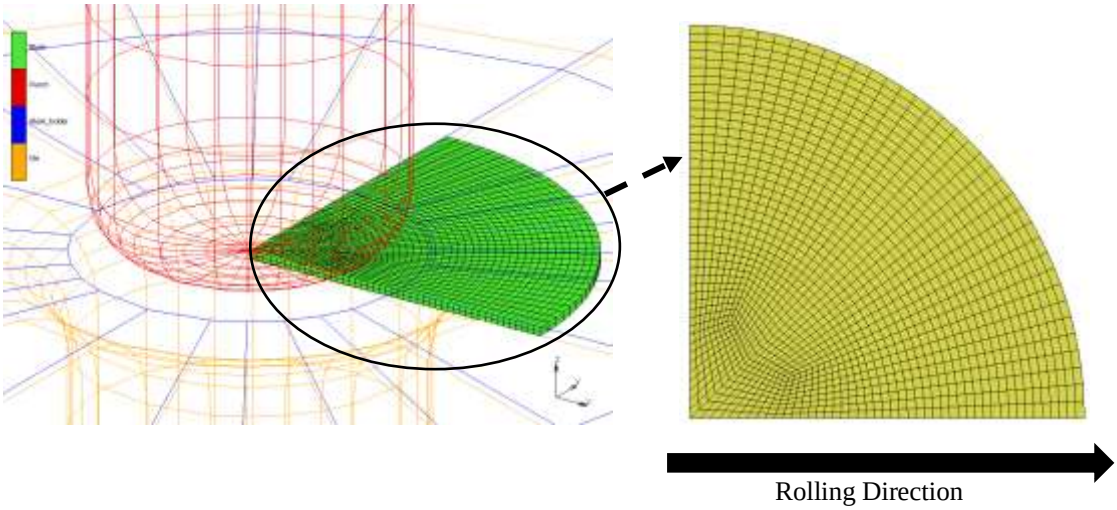

Figure 2. Finite element model of the cup drawing process

2.3. Material Characterization

Anisotropy parameters of Hill48 criterion were calculated by using equations between 3 and 6. The computed parameters are listed in the Table 3.

Table 3. Anisotropy parameters of Hill48 criterion

	F	G	H	L	M	N
Hill48	0.236	0.369	0.631	1.5	1.5	1.640

Here, L and M are taken as 1.5 due to considering the out of plane properties as isotropic. Yield loci, angular variations of r value and yield stress ratios can be seen in Fig. 3, 4 and 5, respectively.

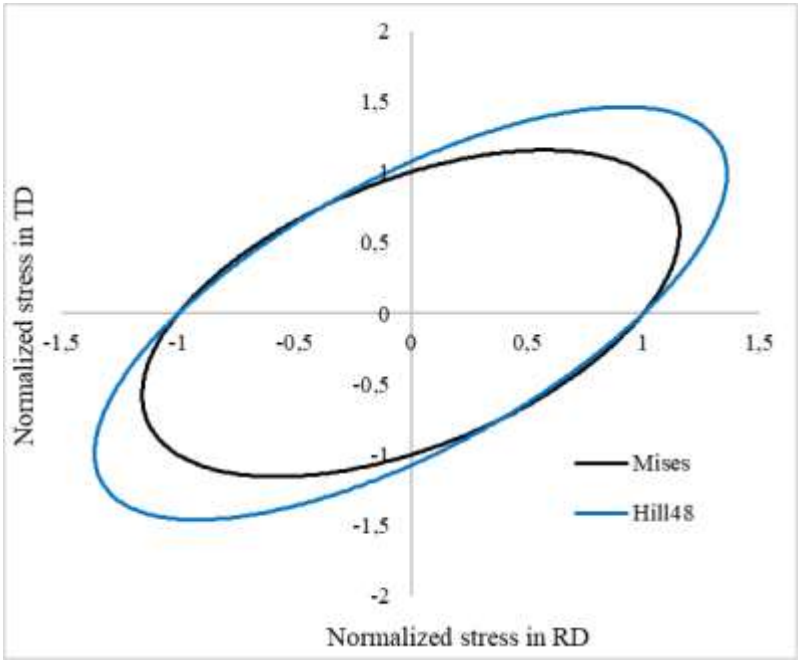

Figure 3. Yield locus of von Mises and Hill48 criteria

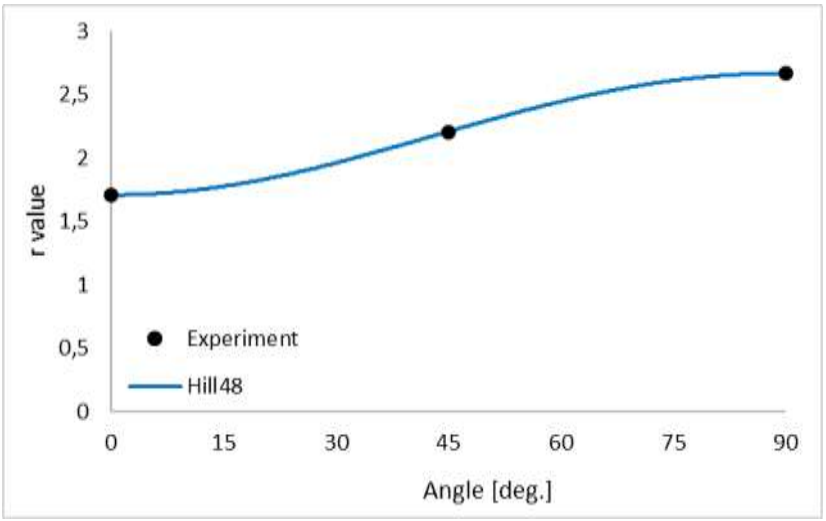

Figure 4. Experimental and predicted r value variations in the sheet plane

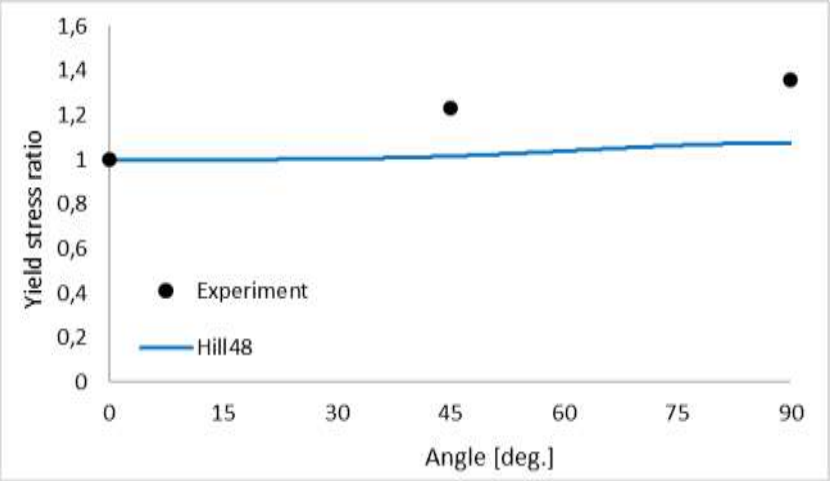

Figure 5. Experimental and predicted yield stress ratio variations in the sheet plane

It was seen from the Figure 4 and 5 that, Hill48 criterion could capture the r value directionalities due to the Lankford's coefficients-based identification procedure. However, yield stress ratio directionalities could not be captured and approximately the same yield stress ratios in different material orientations were predicted in the sheet plane.

4. RESULTS AND DISCUSSIONS

In the present work, earing profile of commercial pure titanium was investigated using Hill48 yield criterion. Firstly, the flange profile of the partially drawn cup was considered and numeric results were compared with the experimental results and the results is shown in Fig.6.

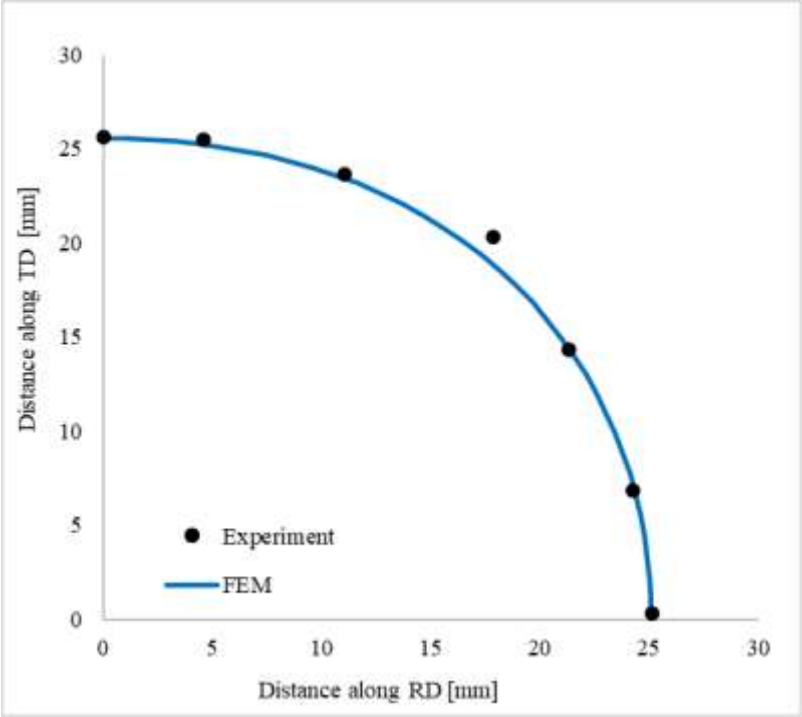

Figure 6. Flange profile of a partially drawn cup

It was seen from the Fig. 6 that Hill48 criterion could accurately predict overall flange profile. Cup height values and earing profiles of fully drawn cup can be seen in Fig. 7 and Fig. 8, respectively.

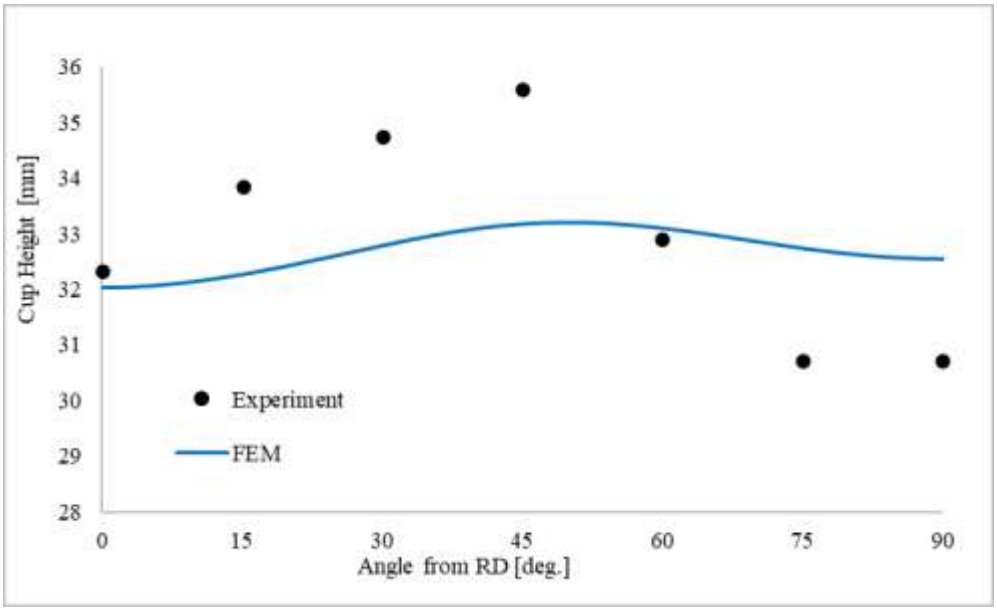

Figure 7. Cup height values predicted by simulations

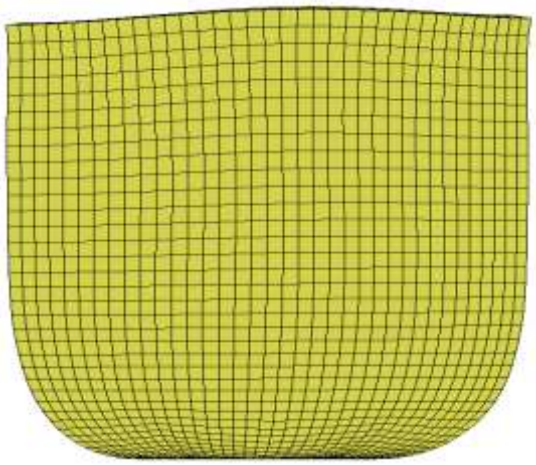

Figure 8. Earing profile

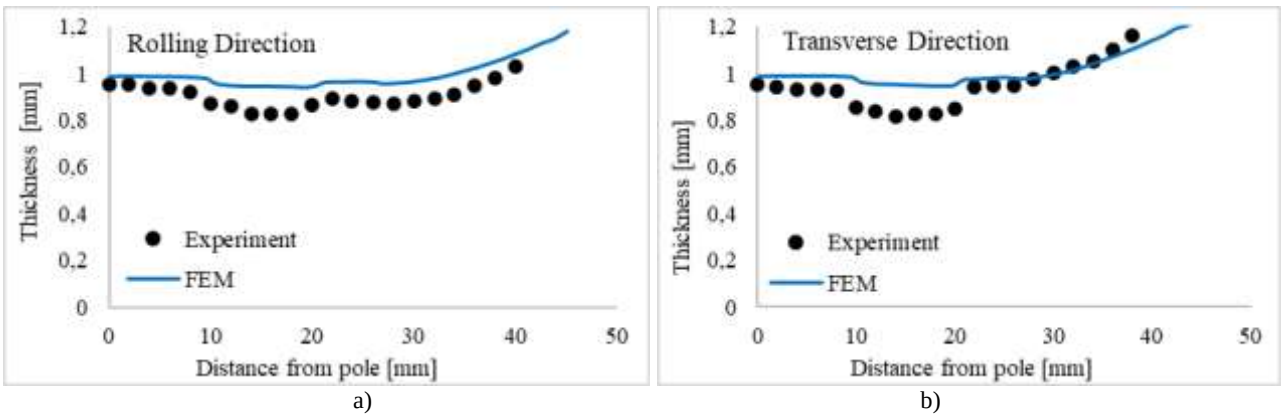
It was observed that the maxium cup height was predicted in diagonal direction which is consistent with the experimental results. On the other hand, Hill48 criterion could not accurately predict the earing amplitude, because it predicted approximately the same value of yield stress ratio in different directions of sheet plane. Accordingly, the change in the cup height values at the periphery of the cup was slightly different. After investigation of the cup profile and ear magnitude, thickness distributions were also considered and the results are shown in Fig.9.



a) b)

Figure 9. Thickness distributions predicted by FE simulations a) rolling b) transverse directions

It is seen from Fig. 9 that some minor deviations between the predictions and experimental data were observed until 20 mm distance from the pole, whereas beyond this limit, numerical results in transverse direction were compatible with the experimental data. Thickness distribution in rolling direction was slightly overestimated.

5. CONCLUSIONS

In the present work, earing profile of commercial pure titanium in cup drawing process was evaluated using Hill48 anisotropic yield criterion. The anisotropy parameters of Hill48 criterion were calculated based on the r values. Implicit Msc. Marc software was used for the finite element simulations. The conclusions can be summarized below:

- Overall flange profile of the partially drawn cup was successfully captured.
- Hill48 criterion predicted lower yield stress ratios when compared to the experimental data, therefore smaller ear magnitude values were predicted.
- Minor deviations were observed between experimental and predicted thickness values near the pole but far from the pole, thickness values were in good agreement with the experiment especially in transverse direction.

BATTERY THERMAL ANALYSIS METHODOLOGY: CELL TO PACKAGE

Efe AFACAN[1], Mehmet Süha İŞİ[2]

[1,2] FEV Turkey, Electrification Department, Istanbul, Turkey
[1] Corresponding Author: Efe AFACAN, afacan@fev.com

ABSTRACT

The lithium-ion battery technology provides high power, high energy, high capacity, long life, reliability, and durability that are demanded by battery electric vehicles and hybrid electric vehicles. On the other hand, this technology brings its own challenges that engineers spend significant effort and time to cope with. The thermal management is one of the main challenges related to lithium-ion batteries, that must be considered within the research and development process of battery packages. Understanding the thermal behaviours of batteries under operation conditions and predicting required cooling power to keep battery temperature in optimum range are vital, and convenient solution is conducting thermal simulations in the beginning of the design process. Evaluating thermal performance of battery packages requires time and effort-consuming simulations which must predict heat generation inside battery and heat dissipation around battery. In this study, a methodology that covers required thermal modelling techniques was presented and modelling steps were explained through a demonstrator study.

Keywords: Cylindrical lithium-ion cell, Electric vehicle battery pack, Modelling, Cooling, Thermal analysis

1. INTRODUCTION

Increasing number of electric vehicle sales around the globe has created an enormous demand for electrical energy storage systems. Range of the electric vehicles is one the main road blockers, and the industry conducts numerous development projects for better batteries. Currently, lithium-ion based cells are the best option and are used in most of the new electric vehicle models.

The lithium-ion technology in batteries offers higher power and energy density comparing with nickel metal or lead acid batteries (Guangming continued, 2014). Lithium-ion batteries have many advantages, but this technology comes with different requirements. One of them is operating temperature that requires precise control. During operation, lithium-ion cells generates heat due to chemical reactions and ohmic resistance that needs to be dissipated out of cell (Guangming continued, 2014). Performance and lifetime of the lithium-ion cells decrease dramatically, if they are not used in the recommended working temperature range. In addition to this, higher cell temperatures can also lead thermal runaway that would cause extreme heat and hazardous gases (Bandhauer continued, 2011) (Ma continued, 2018). These conditions bring obligations that makes it very critical to understand dynamic thermal behaviour of cells and to predict how they behave under different driving conditions.

The one-dimensional (1D) modelling approach offers so many advantages depending on details of output that are analysed for. In parallel to this, there are so many different 1D modelling applications related with thermal analysis of batteries in the literature. Approach is based on fundamental theoretical equations. It provides low resolution results however shows a sufficient perspective for comparing or evaluating different concepts. On the other hand, a three-dimensional (3D) modelling approach consumes more time to be prepared and more computing power to be solved.

Nowadays, a typical battery thermal management system in an electric vehicle includes critical components such as cooling plates, modules, busbars, and power distribution units. These components have detailed designs and complex geometries and their behaviours should be analysed for operating under extreme temperatures. Complex geometries and advanced physical phenomena are points where the 3D modelling approach has more advantages compared with the 1D modelling approach.

This study presents a battery package thermal modelling methodology that utilizes advantages of both 1D and 3D models. Method gives brief perspective about 1D electrical, thermal and cell model of a lithium-ion battery cell while it also takes into account Computational Fluid Dynamics (CFD) and Conjugate Heat Transfer (CHT) simulations applied for cell, cooling plate and battery model.

2. METHODOLOGY

The aim of this study is to create a methodology that presents convenient modelling and design techniques and to describe an order for them in order to reach optimum analyse results within a sufficient time interval. Possible road blockers or performance issues regarding thermal behaviours can be identified as early as possible in projects by this methodology. In this context, a framework which covers 1D and 3D modelling techniques as well as Computed Aided Design (CAD) and validation processes, has been thoroughly examined.

Figure 1. Battery Thermal Analysis Methodology

Preliminary studies described a framework which is iterative and continuously developed by feedbacks and providing output between each process. Figure 1 shows how the methodology flows. The initial step is the Cell Model Validation. Identifying the thermal dynamics of cell that will be used in the battery package is crucial and puts sequential processes into the right direction. The Cell Model Validation step covers 1D electrical and thermal modelling as well as cell modelling. Aim is to validate 1D cell model by an experiment. According to variance between 1D cell model results and experiment results, thermal model can be adjusted. After getting validated results from 1D cell model, heat generation output can be used in 3D cell model.

Estimation of required cooling power per cell is obtained from the Cell Model Validation step and can be used in the Battery Design step to form initial module, cooling plate and battery designs. In the 1D Analysis step, further modelling can be studied according to the battery layout, battery management system (BMS) limitations, cooling plate features or battery operational limits.

The comprehensive 3D Analysis step requires at least concept level CAD files and due to the nature of meshing, more modelling time compared with the 1D Analysis step. However, output of cooling plate model reveals detailed temperature distribution around the plate and provides hints regarding efficiency of coolant flow inside the plate. Heat transfer coefficient, pressure drop inside the cooling plate, and temperature distribution across the cells inside the package can be obtained within the 3D Analysis step. Then, those valuable output can generate feedback for the Battery Design step. The Battery Model Validation step can be initiated after getting experimental test results of the related package. Aim is to establish correlation between the analysis results and the experiment results.

3. ONE-DIMENSIONAL MODELLING

Analysing using 1D modelling techniques has various advantages over other detailed and high compute power demanding techniques like Finite Element Analysis (FEA) and CFD. Creating and conducting the 1D modelling technique can produce faster results on rough geometries or even give an initial insight about the concept. Prediction of average temperature, capacity usage of a lithium-ion cell under a selected drawn current or calculation of the current that is drawn by a single cell in a battery pack under selected driving cycles are examples that suit well with the capabilities of 1D modelling. On the other hand, 1D modelling technique is not able to provide exact results in 3-Dimensional geometries. It is because there are numerous large and in detail designed components (like cooling plate, battery packs etc.) inside an electric vehicle battery system where the temperature changes through geometry matter more instead of the average temperature.

This paper presents brief information about 1D cell model that covers thermal and electrical models that were generated to predict thermal behaviours of a single cell under selected currents that are drawn. Fundamental thermal and electrical behaviours of a lithium-ion cell were modelled using 1D modelling technique in the scope of this work. Models were created using MATLAB software that is very popular in the industry.

3.1 Cell Model

Cell model covers two other models which are electrical and thermal models. Depends on the current drawn and charging / discharging time, electrical model provides internal resistance value to thermal model. Meantime, thermal model calculates heat generation and heat dissipation according to cooling power applied to cell. Figure 2 presents an overview of one-dimensional cell model.

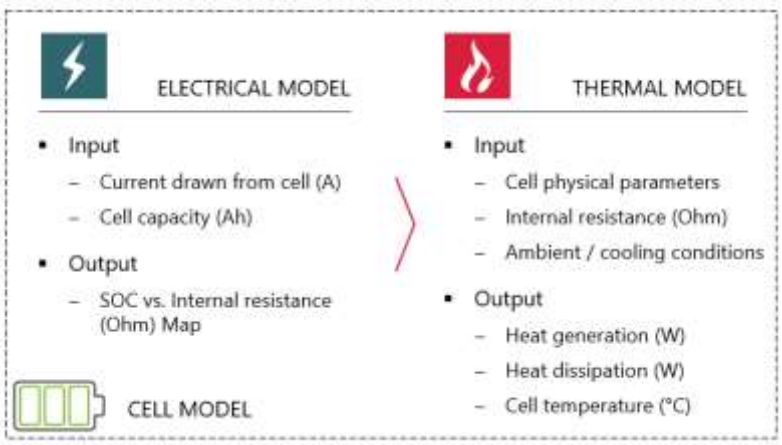

Figure 2. One-Dimensional Cell Model

Cell model also requires heat capacity properties and mass of cell's raw materials. Accumulated heat on a cell determines the temperature change of the cell which also depends on the thermal mass of that cell.

In this modelling study, first simulation was conducted to check accuracy of model output. In order to validate this model, conditions of three experiments were modelled. Then, cell temperature results of experiments and simulation outputs were compared. Current drawn on cell level were selected and three constant values, which are 0.2C, 0.5C, 1C sequentially, have been applied in the duration of 7400 seconds, 2960 seconds, 1480 seconds, respectively. Model values were as follows: Ambient and initial temperature of cell was set to 25°C (experiment conditions) and heat transfer coefficient of free convection was inputted as 5 W/m^2K.

3.1.1. Electrical Model

The capacity of each cell was set to maximum level in the beginning of each simulation. State of Charge (SOC) refers to the level of charge of a cell or a battery relative to its capacity and is one of the most effective parameters that takes role in heat generation (Roth and Doughty, 2004).

$$SOC_{n+1} = SOC_n + \sum_1^n i/capacity_{total} \quad (1)$$

In the Equation 1, *I* is the current (Ah) and *capacity* is the total amount of nominal capacity (Ah) (Kang continued, 2020). Equation is defined in the electrical model using MATLAB software and this model provides instant SOC values of simulated cell during simulation.

The internal resistance of cell is continuously fed by values obtained from 'SOC – Internal Resistance Map'. Dynamic behaviour of internal resistance of battery cell is also considered. Although, there are numerous ways to define internal resistance in the literature, it wasn't considered in the scope of this study and 'SOC-Internal Resistance Map' that was generated by cell experiments was readily used. In addition to this, 'SOC – Internal Resistance Map' information can be obtained from manufacturer as well.

3.1.2. Thermal Model

In the literature, there are two main thermal phenomena that occur inside and outside of a battery cell. First one is the heat generation inside the cell and the second one is the heat dissipation from outside of cell (Abada continued 2016). Equation 2 refers to the energy balance of heat inside the cell.

$$\frac{d}{dt} Q_{acc} = \rho C_p \frac{\delta T}{\delta t} = \dot{Q}_{gen} - \dot{Q}_{dis} \quad (2)$$

Qacc refers heat accumulated inside cell. *Qgen* is total heat generated inside the cell and *Qdis* is the total heat loss of cell. *T*, ρ and *Cp* show cell temperature (K), cell density (kg/m^3) and heat capacity of cell (kJ/(kg.K)), respectively.
The amount of heat generated inside a cell fluctuates under different conditions and in different stages of the battery operation. It depends on SOC, charging / discharging status, cell age, cell temperature and chemical composition of cell. Although there are so many studies that used electrochemical models to simulate thermal behaviour of a battery cell, this study did not focus on chemical modelling details (Kang continued, 2020). Bernardi et al. has been widely investigated and discovered that heat inside battery cell can be expressed with thermodynamic energy balance. This balance covers electrical work, reversible work, and entropy (Bernardi continued, 1985). Simplified form of the equation is mentioned in Equation 3.

$$q = I(U - V) - I\left(T\frac{\delta U}{\delta T}\right) \tag{3}$$

In Equation 3; *q, I, U, V and T* refer overall heat generation inside cell (W), current drawn from cell (A), open circuit voltage (V), terminal voltage (V) and cell temperature (K), respectively. First part of the equation indicates heat loss that is caused by ohmic resistance.

$$q_{ohm} = I(U - V) = I^2R \tag{4}$$

Equation 4 shows generated heat due to ohmic resistance and internal resistance is shown as R. Xie et al. pointed out that main part of the total heat generated inside high-power cells is generated due to ohmic resistance (Xie continued, 2018). In this methodological study, ohmic heat losses were accepted as main heat source and other sources were neglected.

The other thermal phenomenon, heat dissipation, takes place via three different heat transfer types. Heat dissipates out of cell via conduction, convection and radiation (Walker and Ardebili, 2014) (Bolsinger and Birke, 2019). During this study, radiation was omitted as it was not effective as conduction and convection inside battery packs that are working under 60°C (Kang continued, 2020). Conduction heat transfer type is mentioned in Equation 5 and convection heat transfer type is mentioned in Equation 6.

$$Q_{con} = -kA\frac{dT}{dx,y,z} \tag{5}$$

$$Q_{conv} = hA(T_{surfaces} - T_{environment}) \tag{6}$$

In Equation 5 and 6; *k, A, dT and h refer* conduction heat transfer coefficient (W/m.K), heat transfer surface (A), temperature difference between two points and convection heat transfer coefficient (W/($m^2.K$)), respectively.

Temperature of the cell depends on relationship between heat dissipation and heat generation. During charging or discharging, batteries generate ohmic losses which causes heat generation. In order to keep cell temperatures in a safe and efficient range, heat dissipation should be higher than heat generation. Equations were modelled using MATLAB software.

4. THREE-DIMENSIONAL MODELLING

One of the advantages of the 3D modelling technique in comparison with the 1D modelling is the capability of considering the thermal behaviours on detailed geometries. Therefore, a more correct simulation method for detailed cooling plate, module and package designs is the 3D CFD modelling. Literature review shows that CFD has been used successfully in various battery thermal simulations for a long time (Hu continued, 2019).

According to the subject methodology of this study, 3D Analysis are fed with output of 1D Analysis. Thus, 3D modelling is linked to 1D simulations. After the heat generation data is obtained in 1D simulations, it is inserted into the boundary conditions of 3D simulations.

Data unit of generated heat per time in the 1D simulations is W/s. This data is transferred to 3D model as tabular format along with other boundary conditions which are thermal conductivity, adiabatic cell surface, cooling liquid flow rate, and coolant inlet temperature. The simulation can be started once sufficient mesh data is generated.

4.1. Cell Model

3D Analysis step starts with generating the 3D cell model. It is essential to create and validate the 3D model of a single cell, in order to implement the thermal simulation of the entire battery pack. In the scope of this study, two different 3D cell modelling techniques were examined by using two different geometries as the 3D cell model. These are 'Single-Layer Model' and 'Three-Layers Model'. Complete view of cell CAD data and both Single-Layer Model CAD data and Three-Layers Model CAD data are showed in Figure 3.

Figure 3. Cell CAD data; Cross Section of Single-Layer Model CAD, Cross Section of Three-Layers Model CAD

The Single-Layer Model uses cell CAD data which was designed as a single body, and it uses the heat generation data provided by the 1D Analysis earlier. In this method, unit of the heat data getting from 1D Analysis is W/m^3. Assumption is that the heat was generated homogeneously as there is no layer inside the battery cell. The most important advantage of the Single-Layer Model is that it requires low CPU power.

The Three-Layer Model is the model that is capable to examine the cell geometrically in two different parts which are modelled independently: The jelly roll part where the heat is generated inside a cell, and the aluminium can which is cover of the jelly roll. The jelly roll part of the cell was modelled in 3 layers. The heat generation data generated in the 1D Model were added on these layers as heat flux in unit of W/m^2.

3D CFD Simulation Results				Coorelation with Experimental Results
C Rate (Discharge)	Max. Temp (°C)	Min. Temp (°C)	Surface Avg. Temp (°C)	Surface Temperature (°C)
0.2C	26.21	26.17	26.18	0.69%
0.5C	30.78	30.61	30.7	0.97%
1C	40.24	39.84	40.07	0.17%

Table 1. Comparison of Single-Layer Model CFD Results with Experimental Results

Both cell models were simulated separately, and results were compared with each other and with the manufacturer's experimental results. Both temperature of 'Single-Layer Model' and 'Three-Layers Model' were very close to each other under 0.2C (7400 sec), 0.5C (2960 sec) and 1C (1480 sec) operating conditions. Table 1 shows simulation results of Single-Layer Model under different current drawn. For this reason, Single-Layer Model was selected to be used in package simulations due to the low CPU power demand. A view from simulation result is shown in Figure 4.

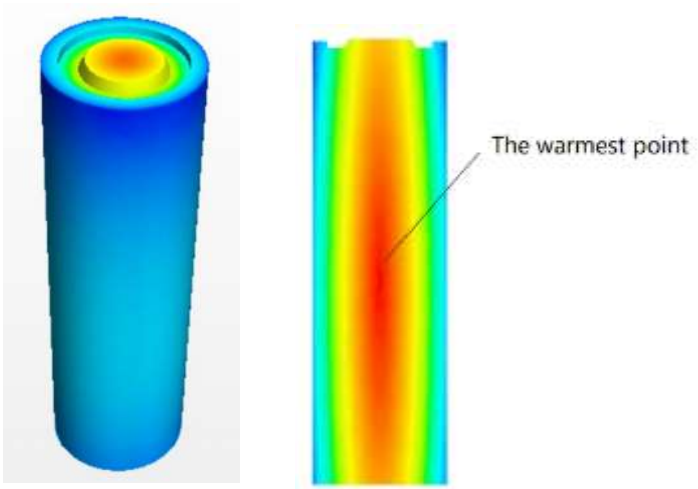

Figure 4. View from CFD Simulation of Single-Layer Model

4.2. Battery Model

The 3D battery model that was examined in this study covered cooling plate and cells themselves. Thus, this analysis step covered both CFD simulation of the cooling plate and CHT simulation of the cells.

As it was mentioned in the literature regarding liquid cooled battery packs, the cell temperature of a battery pack is determined by the heat transfer capability of the cooling plate (Yeow and Teng, 2013). According to previous calculation of required cooling power per cell, cooling plate efficiency was examined. In addition to cooling plate itself, liquid flow inside cooling plate was modelled. Cooling plate geometry optimization was completed with module level CFD simulation results. The thermal performance of the battery cell was improved by investigating different flow rates (2 Lpm, 5 Lpm, 8 Lpm, 10 Lpm) and examining relationship between pressure drop, maximum fluid velocity, the hottest and coldest cell temperatures within the battery package. Various simulations with different flow rate inputs presented necessary design changes. The 3D Analysis was completed with the thermal optimization of the battery package. On the left side of Figure 5, temperature distribution of cooling plate during operation is showed. On the right side, a view of battery package simulation is showed.

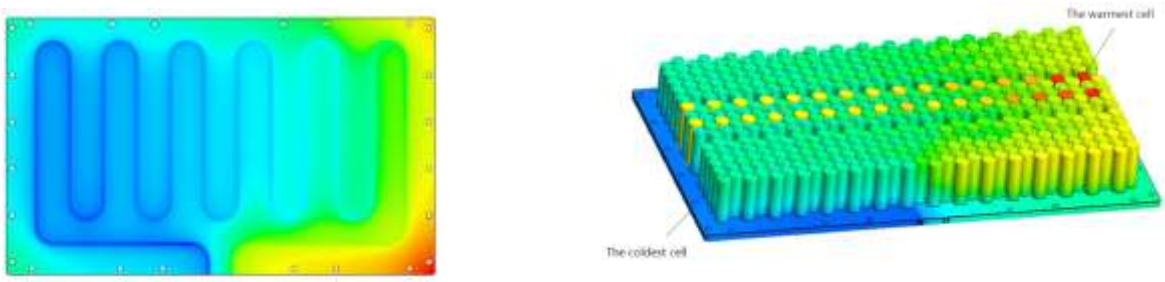

Figure 5. View from CFD Simulation Result of Cooling Plate; View from CFD Simulation Result of Battery Package

5. CONCLUSION

In this paper, the dynamic thermal behaviours of lithium-ion batteries and the importance of controlling cell temperature in a narrow range were discussed. In addition to those, the role of the thermal simulations in research and development process of electric vehicle battery pack was emphasized. A methodology that covers entire process of thermal simulations of a battery was presented. Accompanying that, both one-dimensional modelling and three-dimensional modelling were introduced with theoretical aspects sustained with brief examples and presented sub-models.

Future work will concentrate on thermal tests of whole battery packages. High resolution of experimental data obtained from battery package is expected to reveal crucial perspective to investigate correlations between thermal simulations and real thermal behaviours of the whole battery package.

ABSTRACT

The gradual tightening of emission norms and the increasing use of conventional fuels increase the search for alternative fuels. With the developing drilling technology, while the ease of extraction of natural gas increases, its cost is also decreasing. Both its high lower heating value and less harmful gas emission as a result of combustion make natural gas more attractive. With the increasing control technology, studies on the conversion of compression ignition (CI) engines to natural gas powered spark ignition engines are also increasing. In this study, a diesel engine with a high compression ratio of 17.5:1 was converted into a spark-ignited natural gas engine using a 0/1-dimensional numerical program. Then, the effects of using diesel for the same start of combustion (SOC) times and using natural gas (NG) at different Air/Fuel (A/F) ratios on the performance and emission values were investigated. When the results were examined, it was seen that for similar conditions with CI combustion, NG use provides 14.53% increase in power and 14.86% reduction in fuel consumption. In addition, when the A/F ratio was 31, it was observed that while a 64% reduction was achieved in NO_X emission, the soot emission remained at the levels of 10^6 -10^7 g/kWh.

Keywords: NG, Spark ignition, Compression Ignition, AVL Boost,

1. INTRODUCTION

Although the use of electric vehicles increases, it is predicted that the use of internal combustion engines will continue in both the transportation sector and the stationary power generation sector in the near future (Liu and Dumitrescu, 2018). However, the continued use of internal combustion engines does not mean that conventional diesel or gasoline use will continue. By increasing the use of fuels such as NG, LPG, syngas etc. instead of these fuels, efforts to reduce both emissions release and fuel costs are increasing rapidly. Among these alternative fuels, natural gas is the most remarkable with government incentives and developing drilling technology (Liu continued, 2019a). In the US, the transformation of heavy-duty vehicles using diesel to spark ignition engines using natural gas has gained momentum, especially in recent times. It is estimated that approximately 20% of heavy-duty vehicles operating with diesel will turn into spark-ignition vehicles operating with NG in 2025. (U.S. Energy Information Administration, 2016).

The formation of pollutant emissions such as soot and NO_X is observed with the diesel fuel sprayed on the compressed air forming a rich and poor mixing zone. This happens in engines that use spark-ignition gasoline, mostly in the form of HC and CO emissions. However, in the use of natural gas, it creates a homogeneous air-fuel mixture and reduces both the formation of soot and HC and CO emissions with the low carbon number it contains, while reducing NO_X emissions by decreasing in-cylinder temperatures (Liu continued, 2019b).

Raine et al., (1988) modified naturally aspirated diesel engines with different compression ratios such as 18:1, 15:1 and 13:1 in a way that they can run on natural gas. Afterwards, they investigated the effects of compression ratio as well as ignition timing and air-fuel ratio. The results obtained with the use of only natural gas were compared to the use of only diesel at different speed and load conditions. It was observed that thermal efficiency, exhaust temperature and maximum pressure value increase at high speeds and loads (Raine continued, 1988). Meyer et al. (1992) converted a 320 kW heavy-duty diesel engine to run on natural gas only. They observed an increase in hydrocarbon emissions due to early flame extinction during idling and low load operation. However, a slight increase in power and torque values was observed under high speed and full load, while a decrease in thermal efficiency. In addition, while NO_X emissions improved by 61%, the decrease in thermal efficiency was around 19% (Meyer continued, 1992). Liu and Dumitrescu

(2019) investigated the effects of ignition timing, equivalence ratio and engine speed at low load and speed in a converted diesel engine running on natural gas. During this study, the effects of the special combustion chamber of the diesel engine on the combustion stages were also evaluated. When the results obtained were examined, it was seen that the combustion took place in two stages due to the special design of the combustion chamber. In general, it was concluded that the in-cylinder pressure, temperature and heat release values decreased with increasing equivalence ratio. Liu (2018) modified a diesel engine to run entirely on natural gas. Afterwards, the effects of natural gas components, ignition timing, equivalence ratio and engine speed on combustion characteristics were investigated experimentally and numerically. Experiments examining the equivalence ratio were performed at a compression ratio of 13.1:1 for low-medium load and low speed. With the increase of Air/Fuel ratio, in-cylinder pressure, heat release rate and combustion rate decreased. In addition, with increasing Air/Fuel ratio, the maximum pressure value and the indicated mean effective pressure values decreased, while the thermal efficiency value first increased and then decreased. (Liu, 2018)

In general, it has been observed that there are limited studies in the literature on the conversion of a diesel engine to a spark-ignition engine that can only work with natural gas. While these studies generally have a low compression ratio, it has been observed that the experiments and numerical studies are mostly performed under low loads and speeds. In addition, in these studies, it was seen that rather than performance and emission comparison, extensive information was given about in-cylinder combustion characteristics.

In this study, a 3-cylinder diesel tractor engine was modeled as 0/1-dimension by transforming it with a spark plug assembly instead of a diesel injector and a low-pressure NG fuel injector mounted on the intake manifold. Then, the use of diesel and natural gas at the same SOC times and for the same fuel A/F ratio was compared, and the effects of using natural gas at different A/F ratios on performance and emission values were examined.

2. ENGINE SIMULATION MODEL WITH AVL BOOST

In the study, the model converted from a compression ignition engine to a spark ignition natural gas engine and analyzed in 0/1-dimension with the help of AVL Boost was given in Figure 1. When Figure 1 is examined, it is seen that SB1 and SB2: system boundary conditions, MP1-MP10: measuring points, CO1 and CO2: intercoolers, PL1 and PL2: intake and exhaust manifolds, I1-I3: natural gas injectors, C1-C3: cylinders, 1-30: the connection elements, R1: restrictive element, TC1: turbocharger, and E1: Engine. The analyses were carried out as "general species" in order to obtain emission values. CH_4 was used as an NG fuel surrogate and sent as premixed from the suction port. While the features related to the engine were given in Table 1, the simulation parameters were given in Table 2. As seen in Figure 1, natural gas was injected from the intake ports from multiple points. In both diesel and natural gas usage, the SOC time was taken as +0 CA ATDC for initial analyses while the A/F ratio was set as 26.8. Afterwards, the combustion characteristics and emission changes in the use of natural gas for different A/F ratio were examined without changing the SOC time.

Table 1. Engine Specifications

Specification	**Value**
Displaced volume - total (cm^3)	2930
Number of cylinders	3
Bore / Stroke (mm)	104 / 115
Connection rod (mm)	182
Compression ratio (-)	17.5:1

Table 2. Simulation parameters

3. RESULTS AND DISCUSSION

In this section, the effects of NG use on performance, in-cylinder combustion characteristics and emission values for different A/F ratios in SOC time +0 CA ATDC at 2300 rpm were examined and compared with diesel fuel use. Figure 2 shows the variation of brake power and specific fuel consumption with A/F ratio in NG usage. At +0 CA ATDC, a 14.53% increase in power and a 14.86% decrease in fuel consumption were observed in NG use compared to diesel use. Afterwards, the increase in A/F fuel ratio only in NG use, worsening combustion and decreasing chemical energy decreased the brake power, while fuel consumption increased. NG usage seems more advantageous than diesel usage even for 29.5 A/F ratio in terms of brake power since both fuel consumption and fuel unit cost are lower.

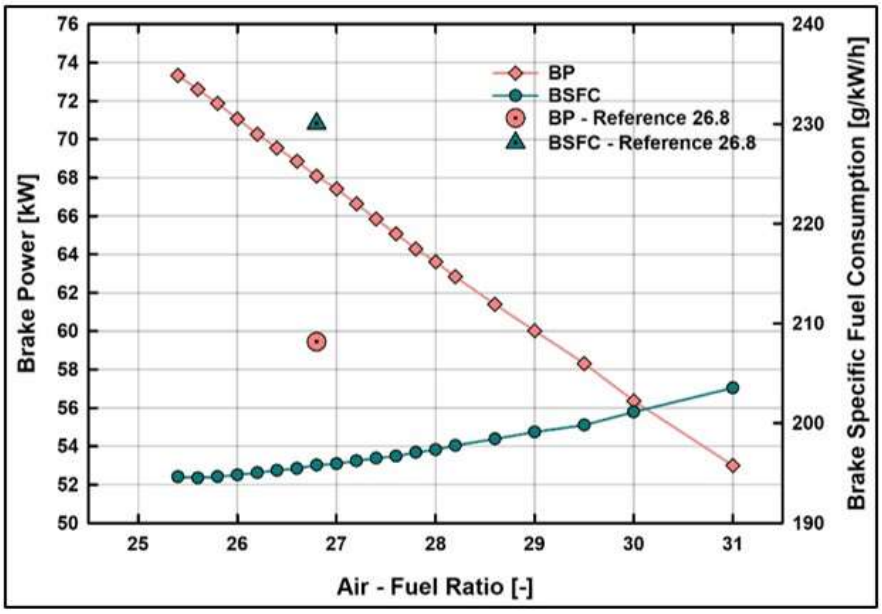

Figure 2. The effect of A/F ratio on brake power and brake specific fuel consumption

Figure 3 shows an increase of 14.55% in BMEP and 17.48% in BTE in NG fuel use compared to diesel fuel use. BMEP and BTE values decreased due to the worsening of combustion with the increasing A/F ratio in natural gas use and the decreased amount of fuel. However, BTE values in NG use were higher than diesel use in all A/F uses, while the limit value for BMEP value was above 29 for A/F ratio. Raine et al., (1988) showed a slight increase in thermal efficiency and mean effective pressure values under high speed and load after the natural gas conversion in a naturally aspirated diesel engine. In addition, it was observed that efficiency and torque values decreased with increasing Air/Fuel ratio. Similarly, Liu et al. (2018) found in their study that BMEP and BTE values decreased with increasing A/F ratio at medium load and low-speed values.

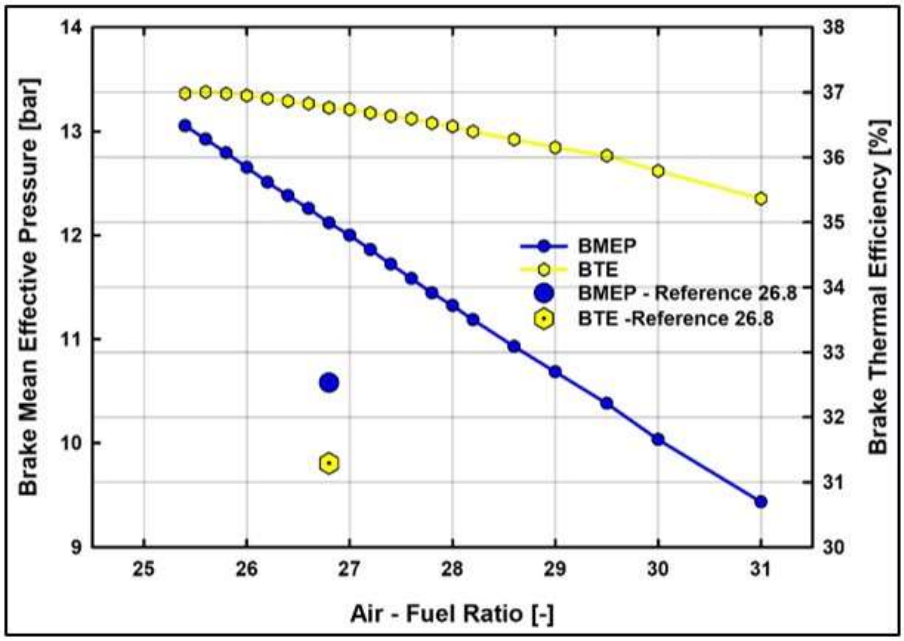

Figure 3. The effect of A/F ratio on BMEP and BTE

When Figure 4 is examined, it is seen that the average temperature and pressure values increased by 2.96% and 23.44% respectively in the use of NG according to the use of diesel fuel. In SI conversion, sending the NG premixed and the high lower heating value had an effect. Then, with the increasing A/F ratio, the in-cylinder pressure and temperature values decreased as the combustion worsens. Liu et al. (2018) showed that the maximum pressure value decreased with increasing A/F ratio at medium load and low speed values.

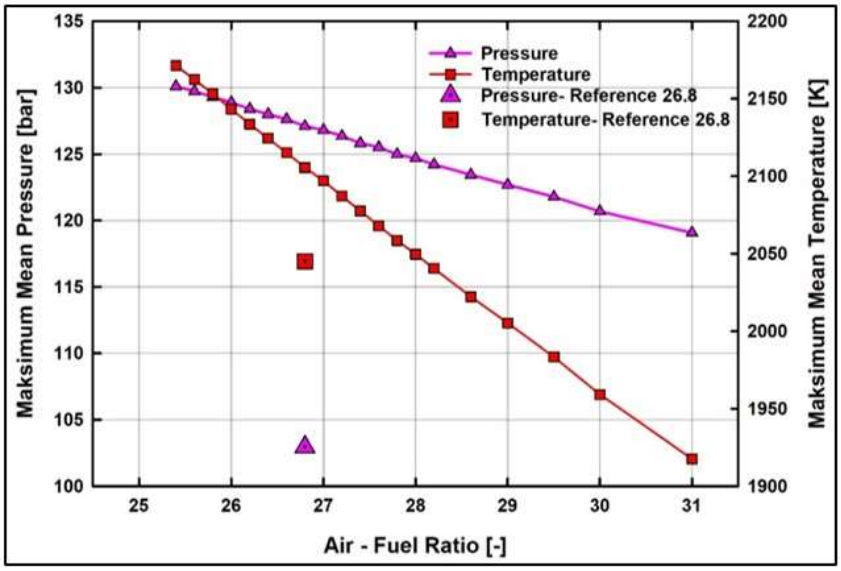

Figure 4. The effect of A/F ratio on maximum mean pressure and temperature

In Figure 5, although the compression pressure in TDC was less than diesel fuel in NG use, the maximum pressure value was higher than diesel. In addition, it was seen that the maximum pressure value in the cylinder decreases with the increasing A/F ratio in NG use.

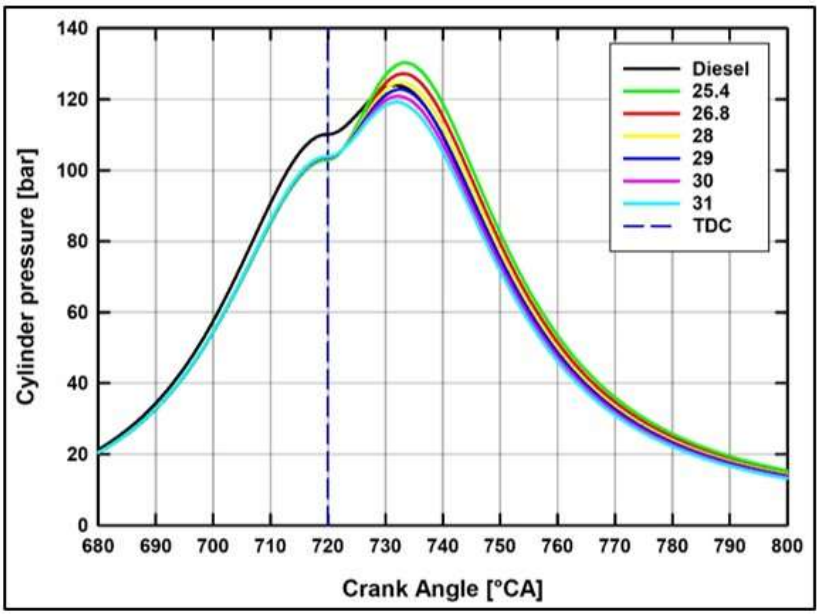

Figure 5. The effect of A/F ratio on in-cylinder pressure

Figure 6 shows the effect of A/F ratio on the in-cylinder heat release rate. The increased amount of A/F decreased both the chemical energy available per cycle and the flame velocity, causing the in-cylinder combustion to deteriorate and the rate of heat release to decrease. This decrease in the rate of heat release also had a negative effect on combustion performance, fuel consumption and THC emissions. Liu et al. (2018) in their study, both in-cylinder pressure, and in-cylinder heat release values decreased with increasing A/F ratio at medium load and low-speed values, which led to a decrease in the brake power produced. In addition, the decrease in the amount of heat generated in the cylinder caused the temperature values in the cylinder to decrease, as can be seen in Figure 7.

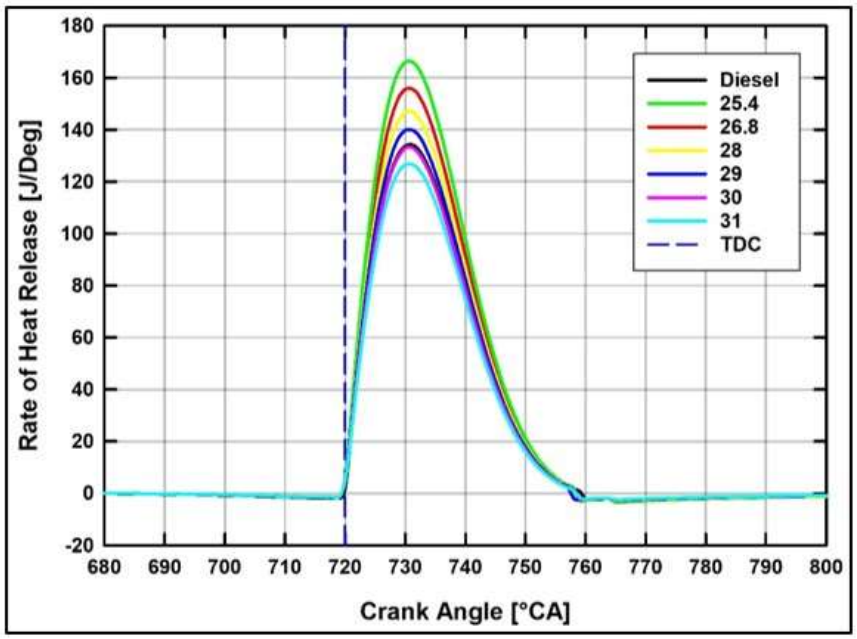

Figure 6. The effect of A/F ratio on in-cylinder rate of heat release

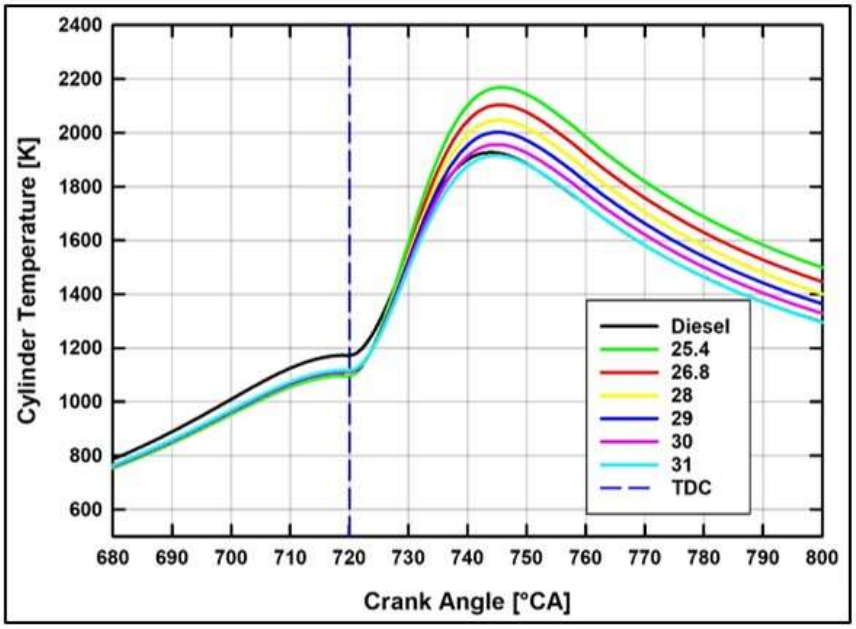

Figure 7. The effect of A/F ratio on in-cylinder temperature

Figure 8 shows the effect of A/F ratio on emission characteristics. The given NO_X and CO values were normalized according to diesel use at a rate of 26.8 H / Y at + 0 ° CA ATDC, and HC values were normalized according to NG use. It was observed that NO_X formation decreased with the decrease in-cylinder temperatures with increasing A/F ratio. When the A/F ratio was 31, NO_X formation was approximately 88%, CO emission 63% less, while HC emission increased 1.54 times.

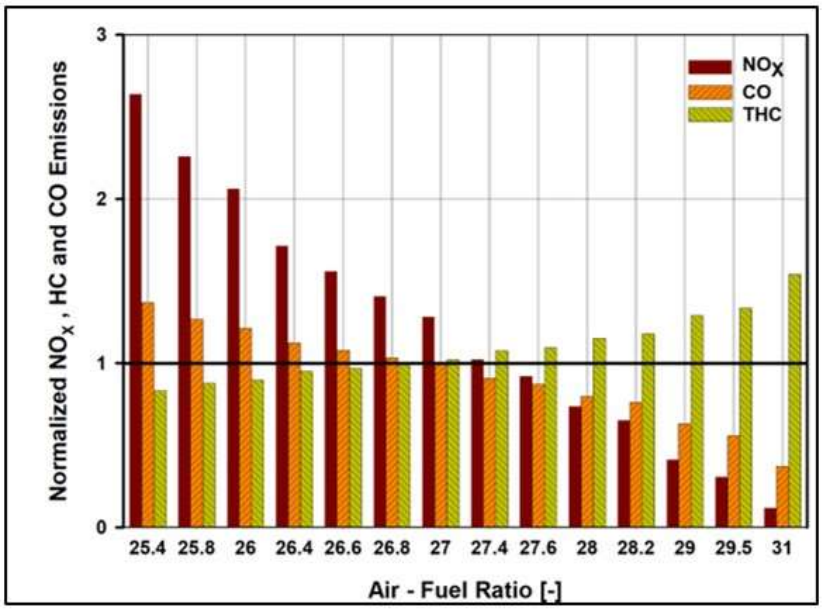

Figure 8. The effect of A/F ratio on emissions

4. CONCLUSIONS AND RECOMMENDATIONS

With the developing injector and control technology, during the rectification of a diesel engine that has completed its service life, the installation of a spark plug on the cylinder head and a low-pressure NG fuel injector mounted on the intake port is an economical approach. With the high compression ratio of the diesel engine, it can work in leaner mixtures and reduce NO_X emissions, especially with low in-cylinder temperatures. If the work done in general is to be evaluated:

1. It was seen that NO_X emission could be reduced by 64% in the study performed with only A/F ratio without any parametric study. It can be said that there is no need to use Selective Catalytic Reduction (SCR) by increasing this ratio with compression ratio, SOC time or combustion chamber changes.

2. In addition, since the formation of soot emission remained in the levels of 10^6 -10^7 g / kWh, there was no need to use Diesel Particulate Filter (DPF).

3. Under the same conditions, fuel consumption decreased while brake power increased due to the fact that natural gas was sent as premixed, the engine was turbocharged and the lower calorific value of natural gas was higher than diesel fuel.

ACKNOWLEDGEMENTS

I would like to express my gratitude to AVL LIST GmbH for providing an AVL Boost software under the University Partnership Program. I would also like to thank Türk Traktör Ziraat Makine A.Ş for providing the necessary information about the engine.

ÖZET

Günümüzde farklı sektörlerde sistem bazlı kullanılan ısı eşanjörleri, genel özellikleri itibari ile birbirine karışmaları engellenen sıcaklıkları farklı iki akışkan arasında ısı değişimini gerçekleştirerek soğutma veya ısıtma ihtiyacını karşılayan sistemlerdir. Isı eşanjörü tiplerinden olan dahili ısı eşanjörleri (IHX), otomotiv sektöründe de kullanılan ve potansiyel soğutma döngülerinin verimliliğini artırma kabiliyeti, hafiflik ve yerleşim kolaylığı sağlayabilmesi nedeniyle efektif olarak iklimlendirme (HVAC) sistemleri altında uygulanmaktadır. Komponentin termal kabin soğutma çevrimindeki görevi, kondenserden gelen yüksek sıcaklıktaki sıvı ile evaporatörden gelen soğuk buhar arasında ters yönlü bir akış oluşturarak akışkanlar arasında ısı transferini gerçekleşmesini sağlar. Bu çalışmada 3 silindirli içten yanmalı motora sahip bir araçta iklimlendirme sisteminde bulunan mevcut IHX dahili ters akışlı ısı eşanjörü detaylı ölçümleri ile birlikte CFD modeli oluşturularak, geometrik olarak; boru çapı, akışkan kanalları, kanat özellikleri vb., fiziksel olarak akışkan ve katı model arası ısı transfer ve akışkan mekaniği metodolojileri olarak steady-state, coupled energy, türbülans akış modeli RANS metodu kullanılarak çalışmalar yapılmıştır. Bu parametreler referans alınarak sistem bazlı olarak akışkanlar arası ısı transferini ve basınç düşüşü performansı hesaplamaları yapılmıştır. Ayrıca, standartlar çerçevesinde gerçekleştirilen test koşulları dikkate alınarak belirlenen akışkan debileri ile CFD sonuçları ve test sonuçları korelasyonları oluşturulmuştur. Mevcut ısı eşanjörünün etkinliği, düşük basınç gaz bölgesinde a C b bar'da, yüksek basınç sıvı bölgesinde 9a C 5a+1 bar'da basınç kaybı ve ısı transferi olarak incelenmiştir. Klima gazı olarak bilinen R1234yf isimli soğutucu akışkanının belirlenen sınır şartları altındaki kimyasal ve termal özellikleri moody diyagramından elde edilerek kanal içinde dahili ters akış ısı eşanjörünün ısı transfer özelliklerinin deneysel ve teorik değerlendirmesi sunulmaktadır.

INVESTIGATION OF PRESSURE LOSS-HEAT TRANSFER EFFICIENCY IN THE INTERNAL FLOW HEAT EXCHANGER IN VEHICLE AIR CONDITIONING SYSTEM AND TEST CORRELATIONS WITH HAD METHOD ANALYSIS

ABSTRACT

Heat exchangers used on a system basis in different sectors are systems that meet the need for cooling or heating by performing heat exchange between two fluids with different temperatures, which are prevented from mixing with each other due to their general characteristics. Internal heat exchangers (IHX), one of the heat exchanger types, are effectively applied under air conditioning (HVAC) systems due to their ability to increase the efficiency of potential cooling loops, lightness and ease of packaging, which are also used in the automotive industry. The function of the component in the thermal cabin cooling cycle creates a reverse flow between the high temperature liquid coming from the condenser and the cold steam coming from the evaporator, allowing heat transfer between the fluids. In this study, firstly, a CFD model was created together with the detailed measurements of the existing IHX internal reverse flow heat exchanger in the air conditioning system in a vehicle with a 3-cylinder internal combustion engine.Steady-state, coupled energy, turbulent flow model RANS method has been used on CFD anaylsis setup. According to these parameters, system-based heat transfer - pressure drop and heat transfer performances calculations were made. In addition, CFD results and test results correlations were made with the fluid flow rates determined by considering the test conditions performed under the standards. The efficiency of the existing heat exchanger was examined as pressure loss and heat transfer at a C b bar in the low pressure gas zone and 9a C 5b+1 bar in the high pressure liquid zone. Experimental and theoretical evaluation of the heat transfer properties of the internal reverse flow heat exchanger in the duct is presented by obtaining the chemical and thermal properties of the refrigerant R1234yf, known as the air conditioning gas, under the specified boundary conditions from the moody diagram.

1. GİRİŞ

Otomobil Üreticileri Birliği'nin istatistiklerine göre global anlamda binek araçların kullanımının yaygın olması ve buna bağlı olarak da emisyon ve enerji sarfiyatı yönünde artış gözlemlenmiştir. Bu nedene enerji tasarrufu ve emisyon azaltımı ile ilgili çalışmaların gerekliliği kaçınılmaz olmuştur.
İçten yanmalı binek araçların (ICE) yakıt tüketimi ve emisyon değerlerinin daha da düşürülebilme çalışmaları göz önünde bulundurulduğunun da günümüzde birçok alanda AR-GE çalışmaları yürütülmektedir. Bu çalışmalar daha çok güç sistemleri olarak adlandırmış olduğumuz ICE motor/Elektrik motor ve alt sistemlerinde gerçekleştiriliyor diyebiliriz. Bu sitemler içerisinde yakıt, motor-kabin soğutma, yağlama, egzoz, hava emiş sistemleri vb. örnek olarak verilebilir. Bu sistemler bünyesinde enerji tasarrufu, emisyon azaltma ve yakıt tüketiminin azaltılması ile ilgili yapılan çalışmaların önemli bir bölümü verimli iklimlendirme teknolojisinin kullanımı, otomotiv klima endüstrisinin gelişimini tetiklemektedir.

Xiang L. ve Cao X. [1], dahili Isı Değiştirici (IHX) teknolojisinin kullanarak klima gazı R134a için soğutma döngüsü performansının iyileştirilmesini teorik olarak analiz etmişlerdir. Wu X vd. [2] soğutma sıvısının sistemden giriş ve çıkış durumuna göre IHX sisteminin performansının araştırılması üzerine çalıştılar. Qian R vd. [3] yapmış oldukları birtakım deneyler sonucunda IHX sisteminin bazen de olumsuz etkiler yaptığı konusunda gözlemlerde bulundular. Mota-Babiloni A [5] ve Navarro E J [6], IHX'in R1234yf ile AC sisteminin soğutma kapasitesini mevcut durumlara göre daha fazla artırabileceği konusunda bildirimlerde bulunmuşlardır. Kwon Y C, Kim D H [7], AC sistemini CO2 ile araştırarak benzer sonuçlar aldıklarını ifade etmişlerdir.

Otomotiv iklimlendirme sisteminde bulunan dahili ısı değiştiricisi (IHX) teknolojisi verimli ve yüksek sıcaklık değişimi performansının yanında yerleşim ve hafiflik yönüyle de oldukça uygun bir komponenttir. Bilimsel araştırmalar sonucu elde edilen deneysel veri ve hesaplamaların çıktıları dahili ısı değiştirici (IHX) için, otomotiv iklimlendirme sisteminde yüksek verimli bir teknolojisi haline gelmiştir. Ancak iklimlendirme sistemi için olumsuz etkilere dikkat etmek ve dezavantajlarını da göz önünde bulundurmak gerekmektedir. Bu dezavantajlar IHX profillerini oluşturan yapının ve akışkan kanallarının oldukça hassas olması darbelere ve titreşimlere karşı korumayı gerektirmektedir.

Endüstriyel uygulamalarda kullanılan soğutma ve ısıtma sistemlerindeki ısı eşanjörleri teknolojileri önemli bir rol oynamaktadır. Dahili ısı eşanjör çeşitlerinden birisi olan çift borulu ısı eşanjörü, düşük tasarım ve bakım maliyetleri nedeniyle kimya, gıda, petrol ve gaz endüstrilerinde yaygın olarak kullanılmaktadır [8]. Literatürde ısı eşanjörlerindeki basınç kayıpları, ısı transferi ve sıcaklık dağılımı ile ilgili birçok sayısal, analitik ve deneysel çalışmalar yapılmıştır. Karmaşık geometriler için sayısal yöntemler daha çok tercih edilir çünkü analitik denklemlerin kesin çözümleri karmaşık ve zordur.

2.1. FİZİKSEL VE MATEMATİKSEL MODEL OLUŞTURULMASI

Isı değiştiricisinde, ısı sıcak su devresinden soğuk su devresine transfer olur. Isı transfer hızı, akışkan kütlenin akış hızının, akışkanın sıcaklık değişiminin ve özgül ısı kapasitesinin bir fonksiyonudur.[9] Çift borulu dahili ısı eşanjör tipinde soğuk ve sıcak akışkan birbirleri ile ters yönde veya paralel yönde akar. Böylece sıcak ve soğuk su arasında ısı transferi meydana gelir [10].

$$\dot{Q} = mxcpx\Delta T \quad (1.a.)$$

İdeal bir ısı değiştiricisinde, dış ortamdan ne ısı alınır ne de dış ortama ısı verilir. Soğuk akışkan tüm ısıyı sıcak akışkandan absorplar. Dolayısıyla ısı transfer hızı:

$$\dot{Q} = \dot{Q}\,e = \dot{Q}\,a = mHxcPHx\Delta TH = mCxcPCx\Delta TC \quad (1.b.)$$

Hacimsel akış için tekrar düzenlenirse:

$$\dot{Q} = \dot{Q}\,e = \dot{Q}\,a = VHx\rho HxcPHx\Delta TH = VCx\rho CxcPCx\Delta TC \quad (1.c.)$$

Basınç kaybı hesaplamalarında kullanılan sıcak ve soğuk fazların genel denklemi:

$$DPihxsl = DPinlet + DPihxsl + DPoutlet \quad (1.d.)$$

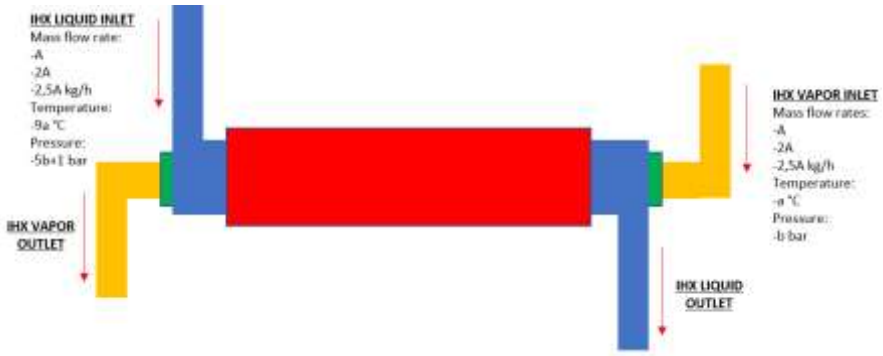
Isı değiştiricisinde, ısı transferini daha iyi anlamak için, Şekil 1'deki gibi giriş ve çıkışları olan sıcak ve soğuk su akışlı bir sistem olarak kabul edilmelidir.

Q̇:Birim ısı transfer hızı

m:Birim akışkan külesi

c:Özgül ısı

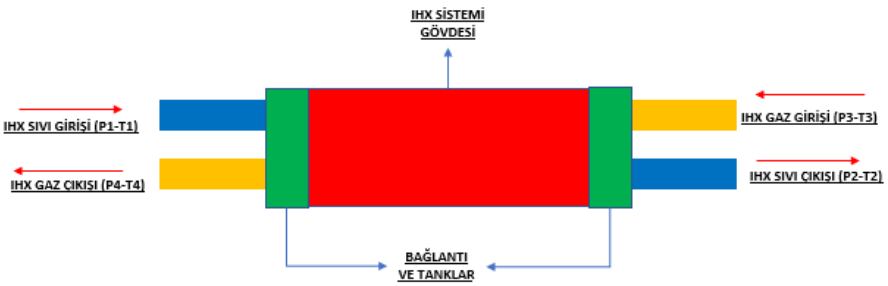
T:Sıcaklık farkı



Şekil 1. Ters Akışlı Dahili Isı Değiştirici Akış Modeli (IHX)

Şekil 2. Ters Akışlı Dahili Isı Değiştirici Kesit Modeli (IHX)

Bu çalışmada mevcutta 3 silindirli içten yanmalı motora sahip bir araçta kullanılan ters akışlı çift borulu bir ısı değiştiricisinde (IHX) standart testlerde belirtilen debi değişikliklerine (A kg/h,2A kg/h ve 2,5A kg/h) göre sıvı ve gaz fazlarında gerçekleşen basınç düşüşleri ve ısı transferleri hesaplamak amacıyla analitik bir model geliştirilmiştir. Oluşturulan matematik model steady-state, coupled energy, K-epsilon türbülans akış modeli, RANS metodu yöntemi kullanılarak gerçekleştirilmiştir. Analitik çözümleri doğrulamak amacı ile sonlu elemanlar analizleri yapılmış olup ve analitik ve sayısal sonuçlar standartlardaki sınır şartlarına göre yapılmış test verileri ile karşılaştırılmıştır.
Analizlerin sonuçlarının karşılaştırmasının yapıldığı ve sınır koşullarının referans alındığı IHX'in verimi şekil 3'te belirtilen figürdeki test koşulları altında bir kalorimetre içinde test edilerek hesaplanmıştır.



Şekil 3. Ters Akışlı Dahili Isı Değiştirici Test Düzeneği Modeli (IHX)

2.2. FİZİKSEL VE KİMYASAL ÖZELLİKLERİN BELİRLENMESİ VE SINIR ŞARTLARININ OLUŞTURULMASI

Test sınır şartlarının bulunduğu veriler içeren tablo Tablo 1 de belirtilmiştir.

Tablo 1. Mevcutta Kullanılan IHX Sistemi Sınır Şartları

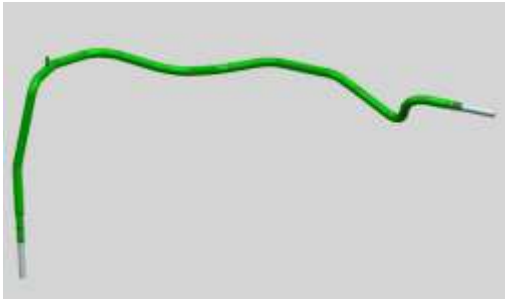
2.3. SİSTEM MODELİNİN SONLU ELEMANLAR YÖNTEMİ İLE OLUŞTURULMASI

İç ve dış borularda akışın ters olduğu durumlar referans alınarak sıvı ve gaz bölümleri için basınç düşüşleri ve aralarındaki ısı transferi sonuçları incelenmiştir. Akışkan olarak klima gazı olan R1234yf (C3H2F4) kullanılmış olup akışkanın, sıkıştırılamaz ve akışkanın konveksiyon özelliklerinin sabit olduğu varsayılmıştır. Yerçekimi ivmesinin etkisi, sistemsel olarak akışın dikey yönünde etki ettiği varsayılmıştır. Analizlerde kullanılmış olan çift borulu dahili ısı eşanjöründe basınç kaybı analizlerinde şekil 4 ve şekil 5'teki modeller, ısı transferini incelemek için kullanılan geometri Şekil 6'da gösterilmiştir.



Şekil 4. Soğuk gaz fazı akış hacmi modeli

Şekil 5. Sıcak sıvı fazı akış hacmi modeli

3. ANALİZ VE TEST SONUÇLARININ YORUMLANMASI

Makale içeriğinde bahsedilen test sınır koşullarına göre belirtilmiş olan test-analiz sonuç tabloları kıyaslandığında simülasyon-test korelasyon değerleri detayları ile incelenmiştir. Isı transferinin basınç kaybı analizlerinde göz ardı edilmesi modellerin tekil olarak kurgulanması modellerdeki basınç düşüşü performansını etkilemektedir. Emiş hattındaki basınç düşüşlerine etki olarak bağlantı noktalarının modellerde olamaması ve ek parçaların da göz ardı edilmesi de deneysel değerler ile analiz sonuçlarının arasında oluşan değişimleri etkilemiştir. Tüm bu varsayımlar ile birlikte sistem göz önünde bulundurularak final model üzerinde kurgulanmış olan akışkanlar arasındaki ısı transferi hesaplamaları test değerleri ile kabul edilebilir hata oranları ile yakınlık göstermektedir. Sistem bazlı olarak IHX ısı transferi değişimi gözlemlendiğinde, soğuk ve düşük basınçlı gaz fazındaki akışkanın iç boru kısmından lineer olarak geçiş sağlıyor olması, sistemin dış kısmından geçiş sağlayan sıcak yüksek basınçlı ve etkileşim yüzey alanı yüksek sıvı akışkan fazı arasındaki ısı transferi performansını artırıcı yönde olduğu doğrulanmıştır. Hesaplamalarda kullanılan debi artışına göre akışkanlar arasındaki ısı transferi miktarının artışı da yapılan simülasyonlar ile doğrulanmıştır.

Basınç kaybı parametresi göz önünde bulundurulduğunda araç mimarisine göre yerleşimi, uzunluk gibi sistemin soğutma verimini etkileyen sınır koşulları altında mevcut ürün optimum düzeyde görevini yerine getirdiği test sonuçlarına göre simülasyonlarla doğrulanmıştır. Basınç kaybının debi oranının artışı ile artması yüksek akış karakteristiklerinde ısı transferinin de arttığının sonucuna varılmıştır.

ÖZET

İçten yanmalı motorların doğrudan veya dolaylı olarak entegre olduğu hibrit taşıtlarda egzoz ses problemi günümüz kentsel yerleşimlerde gürültü kirliliği açısından incelenmesi gereken konulardandır. Ayrıca sürücü ve yolcu odaklı kabin içi konforun ideal seviyede tutlabilmesi anlamında da çalışılması gereken alanlarandır. Motordan çıkan yüksek basınçlı gazların yüksek seviyede ses dalgaları üretmesi sonucu egzoz çıkış ve sistem bazında ses oluşumu meydana gelmektedir.Oluşan bu ses enejisi kaynağı, motor alt sistemleri ve yanma odaklı olup kabul edlebilir düzeylere çekilebilmesi konusunda çalışmalar yürütülmektedir.Aracın farklı kondüsyonlardaki çalışma koşullarında oluşan ses düzeylerinin farklı olması inceleme alanı ve aralığının genişlemesini gerektirmektedir. Bu çalışmada, mevcut 4 silindirli hibrit bir araçta kullanılan hava emiş ve egzoz sistemleri referans alınmış olup, sistemin simülasyon kurulumu mevcut araçtaki egzoz ve hava emiş elemanlarındaki akışkanın tek boyutlu akışkan hacimleri olarak gerçekleştirilmiştir. Araç motoru belirlenen devirlerde çalışırken hava emiş ve egzoz sistemi üzerinde basınç kaybı ve akustik analizler yapılmış olup, finalde tüm sistem modellenerek bu sonuçlar arasında kıyaslamalar yapılmıştır.Modelleme süreci GT-POWER 'da tek boyutlu olarak simulasyon kurulumu yapılmış olup, akışkanlar mekaniği temellerine dayanarak Navier-Stokes tabanlı çözücü sistemi ile simülasyondaki komponentlerin üzerinden basınç dalgası dinamiklerin hesaplanması teorisini kapsamaktadır.Basınç dalgası dinamikleri, gürültünün motorun girişinden itibaren egzoz çıkışına kadar yayılır ve giriş şnorkelinden egzoz borusuna kadar gelen gürültünün hem seviyelerini hem de kalitesini (frekans içeriği) tahmin etmek amaçlı belirlenen sınır şartları içerisinde hesaplamalar yapılmıştır. Çalışmanın sonucu itibariyle hava emiş ve egzoz sisteminin 1 D modelleme mantığı oluşturulmuş olup sınır koşullarına göre elde edilen sonuçlar incelenerek ileriki çalışmalara referans olacak bilgi birikimleri oluşması sağlanmıştır.

ONE-DIMENSIONAL MODELING OF AIR INTAKE AND EXHAUST SYSTEMS IN 4-CYLINDER HYBRID VEHICLES, INVESTIGATION OF PRESSURE LOSS AND ACOUSTIC ANALYSIS

ABSTRACT

Exhaust sound problem in hybrid vehicles with internal combustion engines directly or indirectly integrated is one of the issues that should be examined in terms of noise pollution in today's urban settlements. In addition, it is one of the areas that should be worked on in terms of keeping the driver and passenger oriented cabin comfort at the ideal level. As a result of the high-pressure gases coming out of the engine producing high levels of sound waves, noise formation occurs on the basis of the exhaust output and system. This sound energy source is focused on engine subsystems and combustion, and studies are carried out to reduce the sound levels occurring under different conditions of the vehicle differentiation necessitates the enlargement of the examination area and range. In this study, the air intake and exhaust systems used in an existing 4-cylinder hybrid vehicle were taken as a reference, and the simulation setup of the system was performed as one-dimensional fluid volumes of the fluid in the exhaust and air intake elements of the existing vehicle. Pressure loss and acoustic analyzes were made on the air intake and exhaust system while the vehicle engine was running at the specified speeds, and in the final, the whole system was modeled and comparisons were made between these results. It covers the theory of calculating pressure wave dynamics over components in simulation with Stokes-based solver system. Pressure wave dynamics, the noise propagates from the engine inlet to the exhaust outlet, and calculations have been made within the specified boundary conditions to estimate both the levels and the quality (frequency content) of the noise coming from the inlet snorkel to the exhaust pipe. As a result of the study, the 1 D modeling logic of the air intake and exhaust system was created, and the results obtained according to the boundary conditions were examined and knowledge accumulation that would be a reference for future studies was achieved.

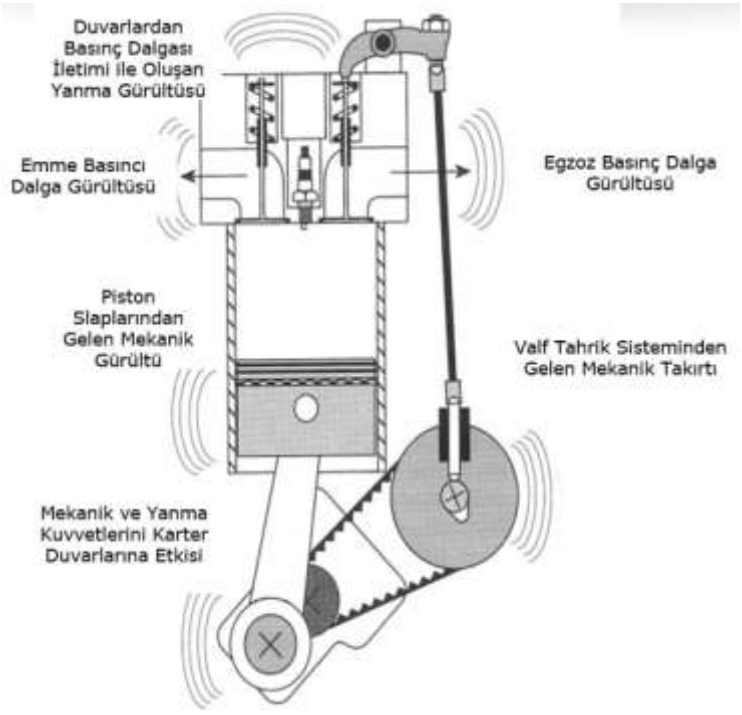
1.GİRİŞ

İçten yanmalı motorların doğrudan veya dolaylı olarak entegre olduğu benzinli ve hibrit taşıtlarda meydana gelen seste motor, hava emiş ve egzoz sistemleri de önemli ölçüde pay sahibidir. Motorda gerçekleşen yanma işlemi sonrasında yüksek basınca sahip egzoz gazlarının dışarıya atılması esnasında meydana gelen ani basınç değişimleri yüksek egzoz gürültüsünün oluşmasına neden olmaktadır.[1] Bu süreçte geri basınç testleri ve akustik testler yapılarak sistem veya komponent bazlı incelemeler ve bunlara bağlı olarak optimizasyon çalışmaları yapılmaktadır. Bu çalışmaların sonucunda araç içi konforun sese bağlı olarak iyileştirilmesi ve gürültü kirliliğinin en aza düşürülmesi hedeflenmektedir. Ayrıca konfor sağlama ve ses oluşumu konularına ek olarak, hava emiş ve egzoz sistemleri motor çalışma mekanizmasında doğrudan entegre sistemler oldukları için beklenilenden çok araç performansı, yakıt tüketimi vb. alanlarına da etkileri oldukça fazladır. Motor verimi, araç performansı,yakıt sarfiyatı ve diğer bir aracın birçok önemli alanında istenilen hedeflere ulaşılabilmesi için sistem tasarımlarının olabildiğince optimum ve teoriye uygun olarak çalışabilmesi gerekmektedir. Özellikle belirtilen bu şartların etkilendiği en önemli alt sistemler olan hava emiş, egzoz ve motor komponentlerini ana kaynaklar olarak değerlendirebiliriz. Hava emiş ve egzoz sistemi genel anlamda motora entegre olan giriş ve çıkış manifoldları ile sınırlanan kısımda çalışma gösteren alt sistemler olarak sınıflandıralabilir. Hava emiş sisteminin görevi hava ve yakıt karışımının yanma odasına olabildiğince verimli ve doğru bir şekilde yönlendirmektir.Egzoz sisteminin görevi ise yakıtın yanmasından sonraki süreçte egzoz gazını yönlendirmek ve alt komponentleri yardımı ile motordan uzaklaştırılmasını sağlamaktır. Hava emiş ve egzoz sistemlerinin temel görevleri ve ana kapsamları yukarıda belirtildiği gibi özet olarak belirtilmiş olsa da çalışma koşullarındaki süreçlerdeki detaylar çok fazla etken içermektedir.



Şekil 1. Temsili Motor İçi Gürültü Kaynakları [2]

Yukarıda temsili olarak gösterilen motor komponent bazılı ses kaynaklarına ek olarak asıl gürültü kirliliğine sebep olan ana unsur yanma sonrası basınç farkından dolayı oluşan sesin egzoz boyunca iletim süreci olarak tanımlamak daha doğru bir yaklaşım olacaktır.Hava emiş ve egzoz sistemlerinin ilk olarak ayrı ayrı modellemeleri yapılarak komponent bazlı simülasyonlar yapılması sonrasında ise sistemelrin entegre olarak modellerinin oluşturulması daha geniş ve çok yönlü çalışmalar oluşmasını sğlayacaktır.Basınç kaybı ve akustik alanlarda yapılan testlerin öncesinde doğrulama amaçlı simulasyonlar hem sürecin hızlanmasında hemde güvenilir çözümler elde etmeye olanak sağlar.Ayrıca 1 D olarak sistem bazlı multifiziksel simülasyon modellerin oluşturulması testler öncesi birçok parametere ve olasılığın incelenebilmesine olanak vermektedir.

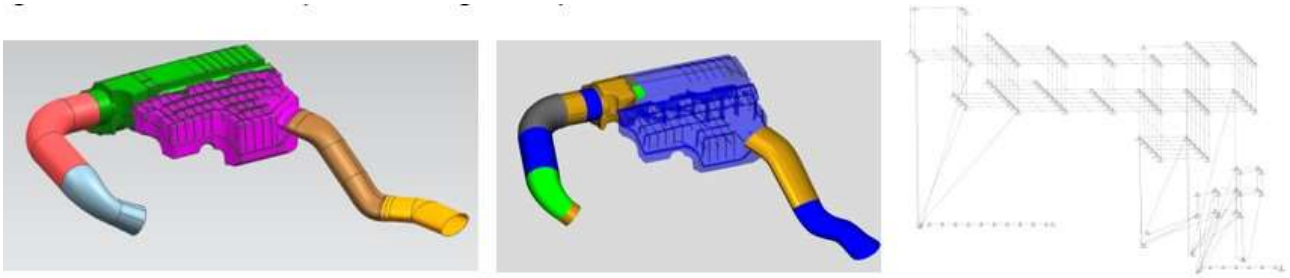
1.a. 1 D Simulasyon ve Modelleme Stratejisi

Akışkanlar mekaniği temellerine dayalı olarak komponent bazlı 3 D modelleme ile basınç kaybı ve akustik simulasyon çalışmaların yapılması mümkündür. Fakat bu simülasyonların modellenmesi ve simülasyon çözümlerinin uzun süreç alması, ayrıca testler öncesi optimizasyon çalışmalarında değişiklikler yapılarak alternatif tasarımların öngörülmesi konusunda elverişli olmaması çalışmalarımızı 1 D olarak gerçekleştirmeye yönlendirmiştir. Sistemler içerisinde bulunan akış hacmine dahil karmaşık geometrilerin doğru ve hızlı modelleme yaklaşımı ile birlikte data dönüştürme sürecinde (3 D CAD'ten 1 D GT-POWER modeline geçirilmesi), modelleme sürelerinde önemli ölçüde kısaltma sağlayıp, otomatik ağ örgüsü oluşturma özelliği ile bağlantı (geçiş) bölgelerindeki hataları en aza düşürme konusunda sağladığı kolaylıklar programın doğru sonuçlar elde etme konusundaki efektif ve güvenilirliğini artırmıştır.

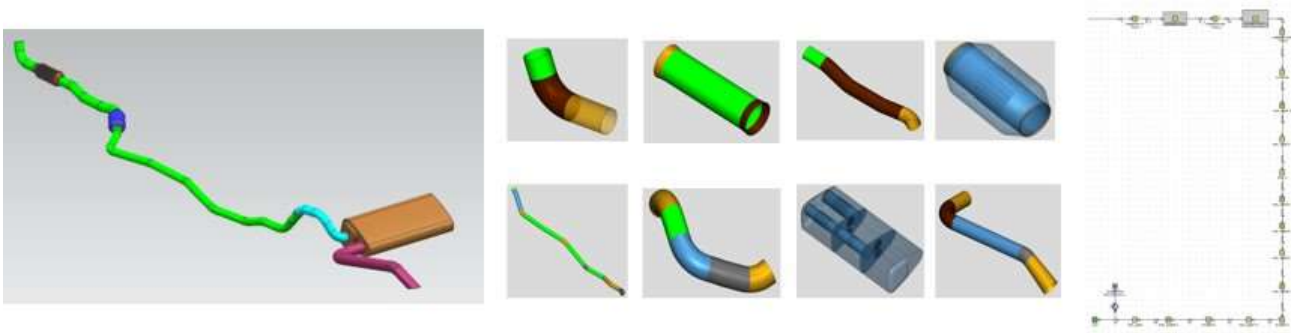
Tek boyutlu modelleme yaklaşımında tüm hava emiş, silindir içi; giriş, sıkıştırma, yanma, genleşme ve çıkış işlemlerinin gerçekleştiği tek bir hacim olarak kabul edilir.Bu hacim, üç boyutlu yaklaşımın aksine, alt alanlara (kontrol veya sonlu hacimler) bölünmez. Denklemler sistemi (enerji, süreklilik, gaz durumu) yalnızca zamanla değişen tek bir hacim için yazılır (üç boyutlu yaklaşımda - denklem sistemi her kontrol hacmi için çözülür). [3]

Hava emiş ve egzoz sistemi komponentleri olan hava emiş kutusu, rezanatör, manifold, fleks malzeme, filtre ve borular da dahil olmak üzere GEM3D üzerinden 3 D data düzenlemesi yapılarak 1 D alana aktarılmıştır. Bu süreçte egzoz ve hava emiş sistemlerindeki komponentler ayrıklaştırma metodu kullanarak, her bir ayrıklaştırma işlemi uygulanan parçalar arası geçişler akışkan sürekliliği olarak tek modül olacak şekilde modellenmiştir.Bununla birlikte modelleme sürecinde susturucu iç yapısı tamamiyle gerçeğe yakın bir şekilde modellenmiş olup 1 D üzerine aktarımı sağlanmıştır.Sistem içerisindeki her bir komponentin belirli bir modelleme kriteri bulunmaktadır.Örneğin hava emiş sistemi modelleme işleminde filtre yapısı pürüzlü geçirgen malzeme teorisi olarak bilinen Porous Media metdolojisi kullanılarak modellenmiştir.Egzoz kısmın susturucuların iç yapısı akustik ve NVH sınır şartlarını sağlayabilmek amaçlı bir tür sönümleme işlevi görmektedir.İç yapısı perdeler ve delikli borulardan oluşmaktadır ve belirli kısımlarda elyaf örgüsü sarılıdır.Basınç kaybı ve özellikle akustik analizlerde doğru ve güvenilir sonuçlar alabilmek açısından modellemenin olabildiğince gerçeğe uygun olarak yapılması gerekmektedir.

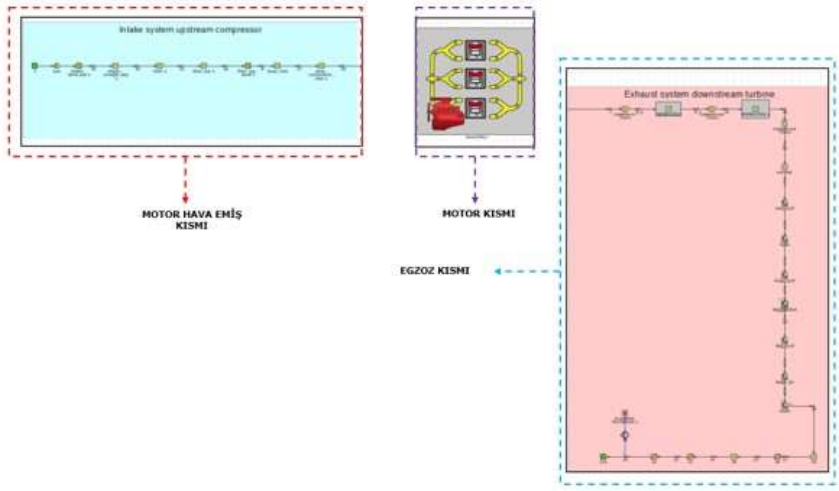
Klasik CFD analizlerde kullanılan ağ örgüsü oluşturma yönteminden farklı olarak GT-POWER dahilinde bulunan 1 D olarak akışkan hacmi oluşturulmuştur. Sistemlerde bulunan herbir parça özelinde detaylar modellenerek hava emiş ve egzoz sistemleri analizler için hazır hale getirilmiştir.



Şekil 2. Hava Emiş Kutusu Akışkan Hacmi 3 D -GEM3D ve 1 D Modelleri



Şekil 3. Hava Emiş Kutusu Akışkan Hacmi 3 D-GEM3D ve 1 D Modelleri



Şekil 4. Hava Emiş Sistemi,Motor ve Egzoz Sistemi 1 D Genel Modeli

1.b.Matematiksel Model Oluşturma ve Parametrelerin Belirlenmesi

Matematiksel model, Reynolds temelli sisteme dayalı momentum (Navier-Stokes), enerji (Fourier-Kirchhoff) ve kütlenin korunumu (süreklilik) denklemlerini referans alarak oluşturulmaktadır.

- Kütle korunumu: (1.a.)

$$\frac{dm}{dt} = \sum m$$

- Enerji korunumu: (1.b.)

$$\frac{de}{dt} = \sum mh + sources$$

- Momentum korunumu: (1.c.)

$$\frac{dmu}{dt} = -(Adp)/dx \sum mu - sources$$

- Basınç Kaybı: (1.d.)

$$(\Delta \boldsymbol{p}) = \boldsymbol{K}*\mathbf{1}/\ \mathbf{2}\ \boldsymbol{\rho U 2}$$

K:Kayıp Katsayısı,

P:yoğunluk (kg / m3)

U:akışkan hızı (m / s).

- Ses Basıncı Seviyesi ve Parçacık Hızı: (1.e.)

$$\textbf{İç Direnç: } \boldsymbol{Za} = \boldsymbol{p/u} = \boldsymbol{\rho 0} \times \boldsymbol{c0}$$

p, rms ses basıncı (Pa)

u, rms parçacık hızı(m / s)

ρ0 ortamın yoğunluk (kg / m3)

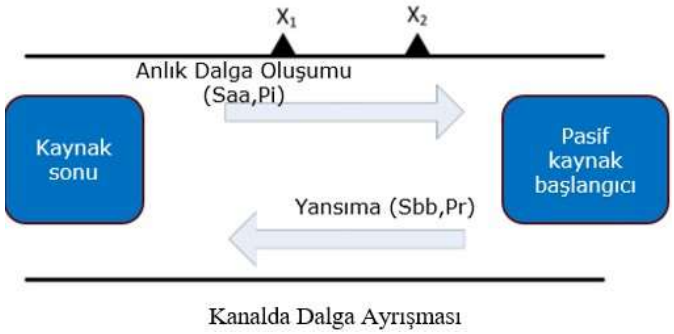
c0 ses hızı (m / s).

Belirtilen akışkanlar mekaniği temel eşitlikleri çerçevesinde basınç kaybı ve akustik hesaplama süreçleri yapılmıştır.

Şekil 5. Bir Boyutlu Kanalda Akışkan kontrol Hacmi

2.Akustik ve Basınç Kaybı Test-Ölçüm Teknikleri

Egzoz sistemindeki herhangi bir noktadaki ses basıncı seviyesi, birden çok ileri ve geri doğru hareket eden dalgaların anlık bir kombinasyonu olarak tanımlanabilir. Bu, Şekil 5.2'de şematik olarak gösterilmektedir, burada SAA ve pi ve SBB ve pr sırasıyla anlık ,yansıyan (güç) spektrumları ve ses oluşan ses basıncını ifade eder.



Kanalda Dalga Ayrışması

Chung-Blaser ve Seybert-Ross-Tao belirli noktalarda ölçülen karmaşık akustik alanları çözebilen deneysel teknikler geliştirmiştir: (ileri ve geri hareket eden dalgalar için.) [5]Dalga ayrıştırması, aşağıdaki denklemler kullanılarak elde edilmektedir:[5]

- Anlık dalga spektrumları (SAA) (1.f.)

$$\boldsymbol{SAA} = [\boldsymbol{S11} + \boldsymbol{S22} - \boldsymbol{2C12}\cos \boldsymbol{k}(\boldsymbol{x1} - \boldsymbol{x2}) + \boldsymbol{2Q12}\sin \boldsymbol{k}(\boldsymbol{x1} - \boldsymbol{x2})]/\boldsymbol{4}\sin\boldsymbol{2k}(\boldsymbol{x1} - \boldsymbol{x2})$$

$$\boldsymbol{SBB} = [\boldsymbol{S11} + \boldsymbol{S22} - \boldsymbol{2C12}\cos \boldsymbol{k}(\boldsymbol{x1} - \boldsymbol{x2}) - \boldsymbol{2Q12}\sin \boldsymbol{k}(\boldsymbol{x1} - \boldsymbol{x2})]/\boldsymbol{4}\sin\boldsymbol{2k}(\boldsymbol{x1} - \boldsymbol{x2})$$

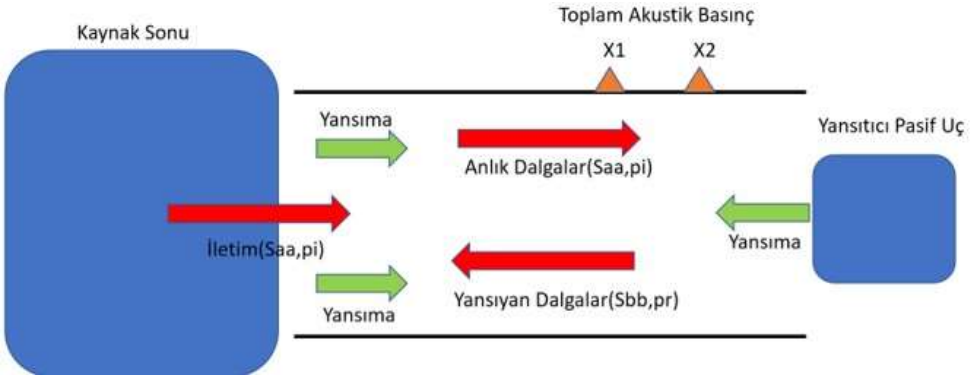
Şekil 6. Üst Akımlı Kanalda Dalga Ayrışımı Teorisi



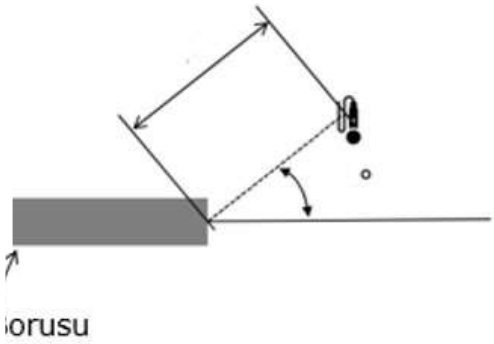
Şekil 7. Alt Akımlı Kanalda Dalga Ayrıştırma Teorisi

Egzoz ve hava emiş sistemlerinde herhangi bir noktadaki meydana gelen ses basıncı seviyesi, dalgaların çoklu ileri ve geri hareket dalgalarının anlık olarak toplanması olarak tanımlanabilir.

Bir mikrofon veya basınç dönüştürücü ile belirlenen bir noktada ölçülen ses basıncı seviyesi, ölçüm noktasının hem bulunduğu konum ve akış boyunca bulunan sistemlere bağlıdır.Sistem bütünlüğü altında bulunan komponent özelliği ve bağlantı noktaları arası geçiş kaynaklı kayıplar oluşmaktadır.Gelen dalga ile sitemden çıkan iletilen dalga arasındaki ses gücü seviyesinde farklar oluşur.Bu oluşum iletim kaybı olarak tanımlanır.

Belirlenen standartlar çerçevesinde güvenilir test-analiz korelasyonları yapabilmek için hava emiş ve egzoz bölgelerinde ses ölçümü yapmak amaçlı yerleştirilen mikrofon konumları önemlidir.Yapılacak olan sanal simülasyonlarda da bu durum dikkate alınarak gerçeğe en yakın sistem modellemesi yapılmalıdır.Mikrofon modelleme sürecinde test aracı genel özellikleri(araç silindir sayısı,ağırlık,tekerlek çapları,sürücü ve yolcu ağırlıkları vs.) gibi fiziksel bilgiler egzoz çıkış kısmının yere yakınlığının belirlenmesi için gereklidir.Ayrıca araç fiziksel bilglerinin

yanısıra test edilen koşullarında bilgileri önem arzetmektedir.Test koşullarına göre mikrofon yerleşimi simülasyon üzerinde tanımlanır.



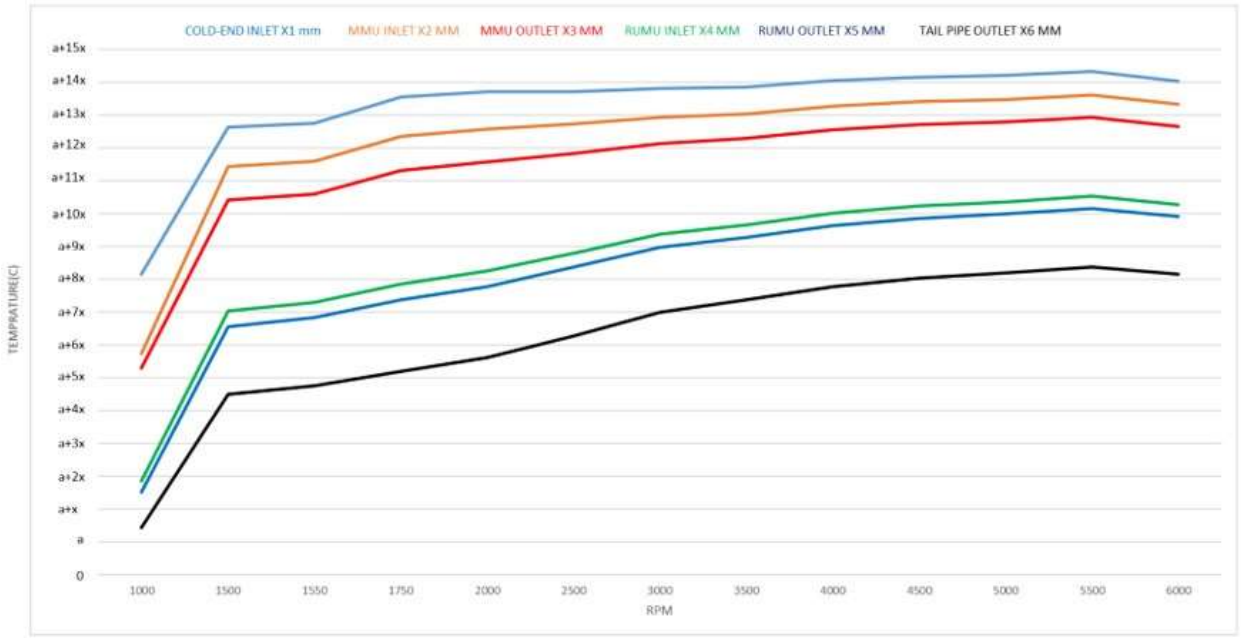
Şekil 8. Egzoz Sesi Ölçümü Mikrofon Konumu

2.Simülasyon Sonuçlarının Elde Edilmesi

Analizler hava emiş ve egzoz sistemleri bazında basıç kayıpları ve akustik olarak irdelenmiş olup sonuçlar grafiksel olarak belirtilmiştir.Sistem ve komponent bazlı basınç kaybı ve akustik özellikler motor içi ateşleme sonucu(herbir silindir için) egzoza iletilen ses dalgalarının oluşturduğu gürültü düzeyleri test sonuçlarıyla kıyaslanmıştır.

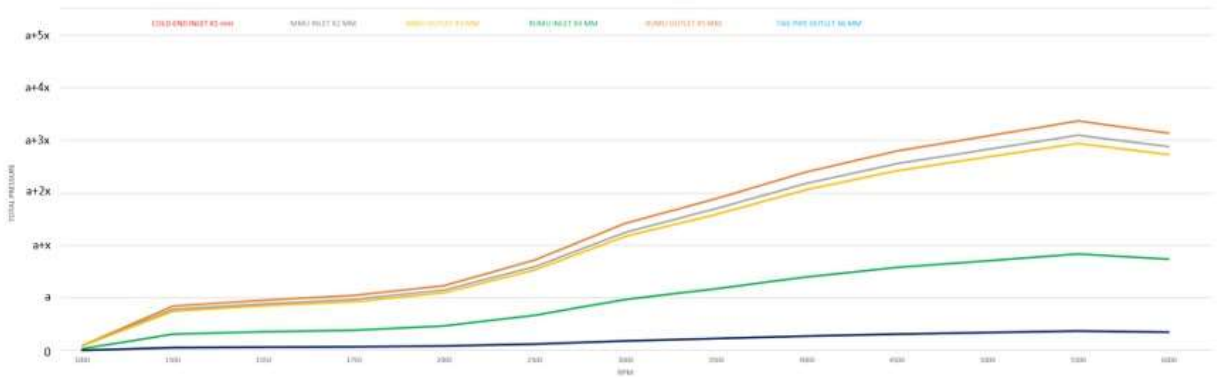
2.a.Egzoz Sistemi Basınç Kaybı ve Sıcaklık Hesaplamaları

Egzoz sisteminde belirlenen motor kondüsyonlarında herbir noktalardan alınan sıcaklık değerleri grafiksel olarak aşağıdaki gibi gösterilmiştir:



Şekil 9. Motor ve Egzoz Sistemi Komponent Girş-Çıkış Sıcaklık Değerleri

Egzoz sistemi dahilinde belirlenen motor kondüsyonları altında sistem ve komponent bazlı basınç kaybı grafikleri aşağıdaki gibi belirtilmiştir:

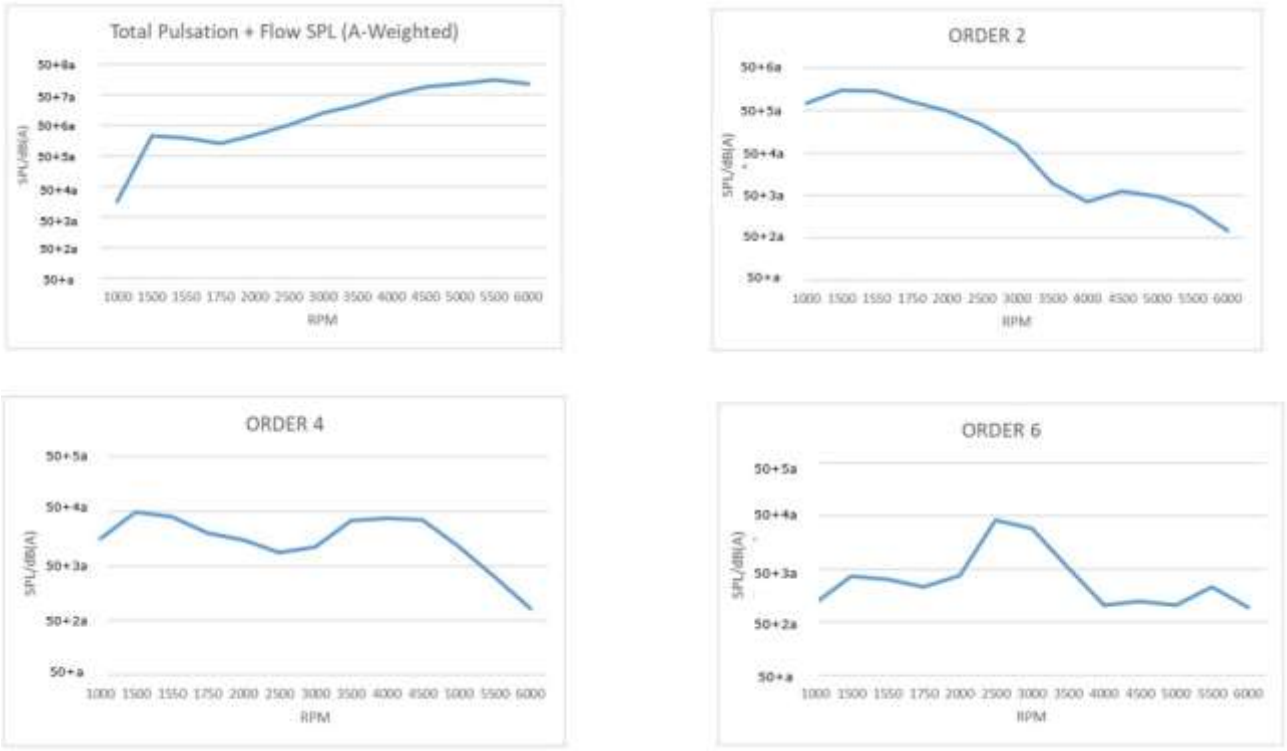


Şekil 10. Motor ve Egzoz Sistemi Komponent Giriş-Çıkış Basınç Kaybı Değerleri

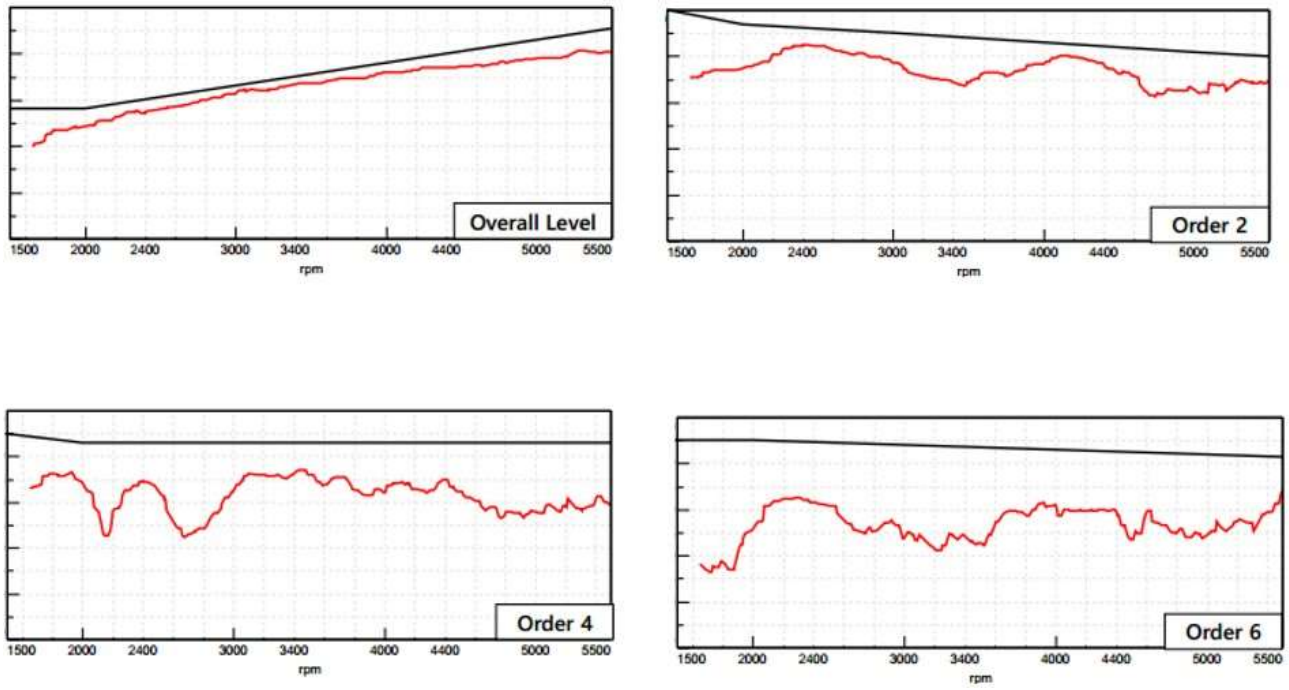
Basınç kaybı ve sıcaklık grafikleri komponent bazında test değerleri ile kıyaslanmış ve kabul edilebilir sapma oranları ile çalışmalar valide edilmiştir.

2.a.Egzoz Sistemi Akustik Hesaplamalrı

Akustik hesaplamalar egzoz çıkışında meydana gelen toplam ses düzeyi ve her bir silinirdeki ateşleme durumlarından kaynaklanan ses düzeyleri de göz önüne alnarak yapılmıştır.Aşağıdaki grafiklerde test sonuçları ve simülasyon sonuçları bulunmaktadır.Sonuçlar kıyaslandığında oluşan ses düzeylerinin sınır değerler altında olduğu ve eğrisel trend değerlerin simülasyon-test korelasyonu açısından uyum gösterdeği görülmektedir.



Şekil 11. Egzoz Çıkışı Akustik Analiz Sonuçları(orders)



Şekil 12. Egzoz Çıkışı Akustik Test Sonuçları(orders)

3.SONUÇ

Bu çalışmada günümüz otomotiv sektöründe nvh ve ses konularının dahilinde olan egzoz ve hava emiş sisteminin bütünü ile entegrsayonlu bir şekilde mutifiziksel olarak modellenmesi, sistem bazlı akış karakteristiği incelenerek elde edilen verilerin test sonuçları ile karşılaştırılması ve korelasyonu yapılmıştır. Ayrıca bu çalışmada geleneksel CFD modelleme metodolojisinin dışında yeni ve uygulanabilirliği çok daha yüksek olan 1D modelleme tekniği kullanılmıştır. [6]1 D modelleme tekniğinde sistem ve komponent bazlı yapıların doğru fizik koşullarında modelleme detaylarından da bahsedilerek modelleme stratejilerine de değinilmiştir. Tüm bu konular dahilinde oluşturulan simülasyon ile test değerlerinin hedef değerlerinin altında olduğu ve korelasyonların sağlandığı sonucuna varılmıştır. İleriki aşamalarda bu makale konusundan farklı olarak komponent ve sistem bazlı birçok optimizasyon ve alternatif çalışmalar yapılarak sistemin iyileştirilmesi üzerine çalışmalar yürütülecektir.

ÖZET

Fren sistemi otomobil üzerinde kritik öneme sahip olduğundan tüm kullanım koşulları dikkate alınarak test edilmelidir. Sürüş esnasında ön fren balata sıcaklığındaki değişimler aracın frenleme performansını etkilemektedir. Bu deneysel çalışmada otomobillerde farklı yükleme şartlarının ön fren balata sıcaklığı üzerindeki etkisi incelenmiştir. Ayrıca, araç hızı ve frenleme ivmesi verileri de dikkate alınmıştır. Denemeler binek bir araç üzerinde, belirlenmiş bir rota kullanılarak üç farklı yükleme koşulunda yapılmıştır. Testler esnasında dış ortam sıcaklığı yaklaşık 23 °C olarak ölçülmüştür.

Anahtar Kelimeler: Frenleme performansı, yol deneyi, otomobil yükleme şartı, fren balata sıcaklığı

INVESTIGATION OF THE EFFECT OF DIFFERENT LOADING CONDITIONS ON FRONT BRAKE LINING TEMPERATURE IN CARS

ABSTRACT

Since the brake system is critical on the car, it should be tested considering all usage conditions. Changes in the temperature of the front brake pad while driving affect the braking performance of the vehicle. In this experimental study, the effect of different loading conditions on the front brake pad temperature in automobiles was investigated. In addition, vehicle speed and braking deceleration data were also considered. Trials were carried out on a passenger vehicle using a specified route under three different loading conditions. During the tests, the outdoor temperature was measured as approximately 23 ° C.

Keywords: Braking performance, road test, automobile loading condition, brake pad temperature

1. GİRİŞ

Fren sistemi, otomobil üzerinde güvenlik açısından oldukça kritik bir öneme sahiptir. Hareket halindeki otomobilin hızını düşürmek, güvenli bir şekilde durmasını sağlamak ve duran aracın hareketini engellemek fren sisteminin başlıca görevleri olarak özetlenebilir. Otomobil hareket halinde iken bir kinetik enerjiye sahiptir. Fren sistemi bu kinetik enerjiyi fren balatası ve fren diski arasındaki sürtünme ile ısı enerjisine dönüştürür (Qi ve Day, 2007). Frenleme süresince oluşacak sıcaklık artışı fren balatası ve fren diski arasındaki sürtünme katsayısının düşüşüne, sürtünme elemanlarının erken aşınmasına ve fren hidroliği sıcaklığında artışa neden olabilir. (Valvano ve Lee, 2000; Lee, 1999; Abu Bakar vd., 2010)
Ilm ve arkadaşları, yapmış oldukları çalışma neticesinde 150 ºC disk yüzey sıcaklığında sürtünme katsayısının 0,55, disk yüzey sıcaklığı 250 ºC'ye yükseldiğinde ise sürtünme katsayısının 0,23 olduğunu belirtmişlerdir (Ilm vd., 2000). Satapathy ve arkadaşları, aracın toplam kinetik enerjisinin büyük çoğunluğunun frenleme esnasında ön tekerlek fren balataları tarafından absorbe edildiğini belirtmişlerdir. Bu durumun ön fren disk yüzeyinde 370 °C'e kadar yüksek sıcaklık oluşumuna sebep olabileceğini ortaya koymuşlardır (Satapathy vd., 2004). Aleksendric ve Duboka, sürtünme elemanları temas noktasında anlık olarak 600-800 °C görülebileceğini ve oluşan yüksek sıcaklığın fren etkinliğini büyük ölçüde azaltacağını vurgulamışlardır (Aleksendric ve Duboka, 2007). Bijwe ve arkadaşları, sürtünme

katsayısındaki düşüşün yaklaşık 300 ºC disk yüzey sıcaklık değerlerinde başladığını vurgulamışlardır (Bijwe vd., 2005). Etemoğlu ve arkadaşları, yaptıkları çalışmada araç hızı, disk malzemesi, araç ağırlığı ve sürtünme katsayısının fren sistemi sürtünme elemanları üzerindeki etkilerini incelemiş ve aracın hafifletilmesinin frenleme sırasında oluşan sıcaklık üzerinde ciddi etkisi olduğunu göstermişlerdir (Etemoğlu vd., 2018). Erdem ve Altıparmak, fren disk sıcaklıklarındaki artışın taşıtın frenleme performansına etkilerini durma mesafesi testleri ile incelemişlerdir. Isınan fren disklerinin aracın durma mesafesini artırdığını belirtmişlerdir (Erdem ve Altıparmak, 2014). Adamowicz ve Grzes, çalışmalarında sonlu elemanlar modeli kullanarak sabit hızla tekrarlayan frenlemeler esnasında oluşan ısı transferinin disk fren sistemi ısıl davranışı üzerindeki etkilerini ortaya koymuşlardır (Adamowicz ve Grzes, 2011).

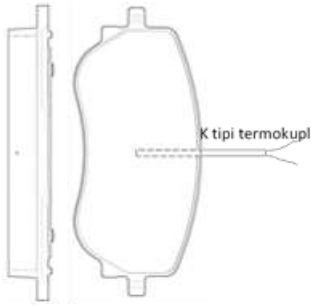
Bu çalışmada, binek bir aracın farklı yükleme şartlarının ön fren balata sıcaklığı üzerindeki etkisi incelenmiştir. Otomobilin kullanım ömrü boyunca sıklıkla yüklenebileceği 3 farklı yükleme şartı belirlenmiştir (Tablo 1). Testlerde, araç ortalama hızı, dış ortam sıcaklığı ve araç ivmesi verileri de dikkate alınmıştır. Testler aynı sürücü tarafından önceden belirlenmiş sabit bir rota kullanılarak yapılmıştır.

Tablo 1. Otomobil yükleme şartları

Test	Yükleme şartı
Test-1	Sürücü (Referans ağırlık)
Test-2	Sürücü + 1 Yolcu (%6 ağırlık artışı)
Test-3	Sürücü + 4 Yolcu (%23 ağırlık artışı)

2. MATERYAL VE YÖNTEM

Ocak 2021 tarihli TÜİK (Türkiye İstatistik Kurumu) bültenine göre; 2020 Aralık ayı sonu itibariyle trafiğe kayıtlı toplam taşıt sayısı yaklaşık 24 milyondur. Bu taşıtların %54,3'ünü otomobiller oluşturmaktadır (URL 1). Bu sebeple testlerde otomobil kullanılmıştır.
Testler için rota belirlenirken sürücülerin kullanabileceği tüm yol tipleri (şehir içi, şehirler arası, otoyol, dağ yolu) değerlendirilmiştir. Yol tiplerinin toplam rota içerisindeki oranları belirlenirken, yolların kullanım sıklıkları dikkate alınmıştır. Testler yaklaşık 280 km uzunluğunda bir rota kullanılarak kuru zeminde yapılmıştır. Test sonuçlarını etkilememesi için sürüşler aynı sürücü tarafından belirlenen zaman dilimlerinde gerçekleştirilmiştir.
Test esnasında ön fren balata sıcaklığı ölçümü için iç balata içerisine yerleştirilen K tipi termokupl kullanılmıştır (Şekil 1).



Şekil 1. Balata termokupl pozisyonu

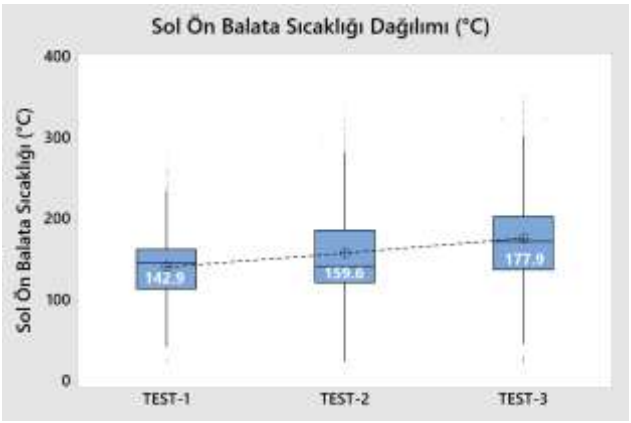
Dış ortam sıcaklık verisi için araç tavanına K tipi termokupl yerleştirilmiştir. Araç hızı ve fren merkez silindir basıncı verileri aracın CAN veri iletim sisteminden alınmıştır. Ayrıca, aracın ivme verisini alabilmek için araç ağırlık merkezine yakın bir konuma yerleştirilen ivme sensörü kullanılmıştır (Şekil 2-a). Frenlemeler esnasında ölçülen değerler eş zamanlı olarak Şekil 2-b'de gösterilen veri toplama ünitesi tarafından kayıt altına alınmıştır.

(a) (b)

Şekil 2. a) İvme sensörü b) Veri toplama ünitesi

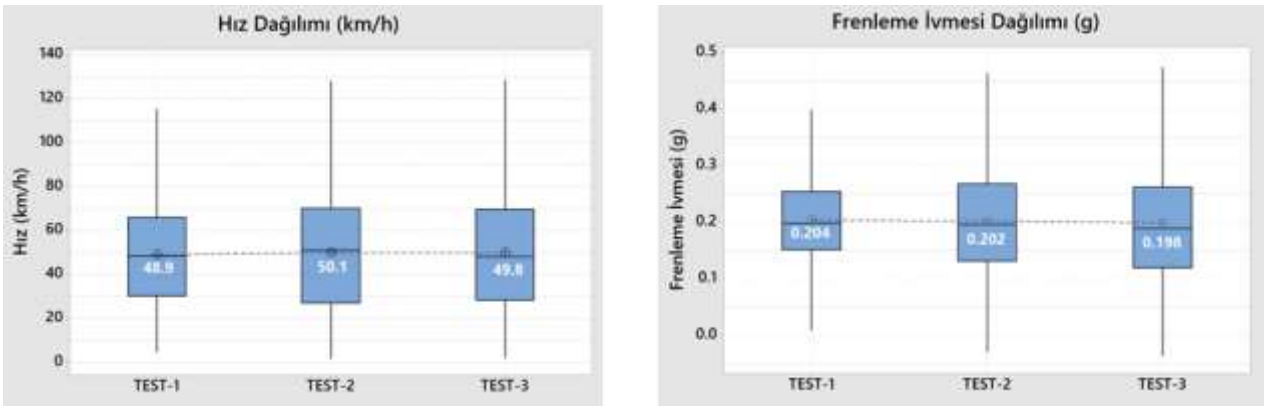
3. BULGULAR

Testlerde her bir frenleme için sol ön balata sıcaklık verisi alınmıştır. Test-1 için sol ön balata sıcaklık değerleri; ortalama 142,9 °C ve maksimum 281,6 °C olarak bulunmuştur. Test-2 için sol ön balata sıcaklık değerleri; ortalama 159,6 °C ve maksimum 345,6 °C olarak bulunmuştur. Test-3 için sol ön balata sıcaklık değerleri; ortalama 177,9 °C ve maksimum 355 °C olarak bulunmuştur (Şekil 3).



Şekil 3. Sol ön balata sıcaklığı dağılımı

Ortalama araç hızı ve ortalama frenleme ivmesi verileri Minitab programı kullanılarak "One-Way ANOVA" yöntemi ile istatistiksel olarak analiz edilmiştir. Yapılan hipotez testi sonucunda 3 testin ortalama araç hızı ve ortalama frenleme ivmesi verileri arasında farklılık olmadığı bulunmuştur. Hız ve frenleme ivmesi dağılımları şekil 4'te verilmiştir.



(a) (b)

Şekil 4. a) Hız dağılımı b) Frenleme ivmesi dağılımı

4. SONUÇ VE ÖNERİLER

Analiz sonuçları incelendiğinde sol ön balata ortalama sıcaklığı Test-1 yük şartında 142,9 °C olduğu görülmüştür. Otomobil yükü %6 artırılarak yapılan Test-2'de sol ön balata ortalama sıcaklığı 159,6 °C değerine ulaşarak 17 °C yükselmiştir. Otomobil yükünün %23 artırıldığı Test-3'te ise sol ön balata ortalama sıcaklığı 35 °C yükselerek 177,9 °C değerine ulaşmıştır. Rota içerisindeki sıcaklık profilleri incelendiğinde ulaşılan maksimum ön balata sıcaklık değerleri sırası ile Test-1'de 281,6 °C, Test-2'de 345,6 °C ve Test-3'te 355 °C olarak bulunmuştur. Elde edilen sonuçlara göre araç yükünün artırılması sol ön balata ortalama sıcaklığı üzerine sınırlı seviyede etki etmiştir. Buna karşılık maksimum sıcaklık değerleri üzerinde yüksek oranda etkili olmuştur.

Gelecek çalışmalarda farklı sürüş profillerinin etkisi bu yöntem ile incelenecek ve ticari araçta da test edilecektir.

ABSTRACT

The riveting process is a mechanical method to fasten multiple independent parts in a permanent way done by riveting machinery. Considering assembly by riveting operations for quite complex mechanisms and expected precision due to its potential effects, a new approach both for measurement and control of riveting is needed.This approach called adaptive, is prepared to be a flexible and appropriate infrastructure for next step which is closed loop control by deep learning and artificial intelligence. The key elements of the system control are the PLC, server, and microcontroller of servo motor. The rotary encoder and current transmitter of servo motor and laser measurement system are used for measurement of designed system critical parameters. Statistical Process Control (SPC) rules and principles are also embedded to server to be a part of decision-making system. Therefore, a three stages intervention algorithm is used to provide a better control on riveting process and a better precision on product. It was observed that applied algorithm provided a better control on riveting diameter by usage of simultaneous three stages intervention. Moreover, the effectiveness of new adaptive approach is confirmed by obtained results of first production batch which contains 300 parts, data records on server and the graphics showing the interaction between the input and output. It can be clearly said that applied adaptive closed loop control study can be considered as an infrastructure for deep learning and artificial intelligence applications.

Keywords: Riveting, Closed Loop, Statistical Process Control, Deep Learning, Artificial Intelligence

1. INTRODUCTION

Closed loop control systems are often used basic and application independent control systems in industry. In very basic principle, an initial reference signal command an actuator and its action measured by a sensor. A feedback signal sent by this sensor processed and compared to the initial reference signal, so the difference used for correction on actuator during operation cycle. According to the study of He et al. (2020) safety level of closed-loop control systems has been effectively quantified by structural reliability concept based probabilistic models. Bayesian Network (BN) is a powerful graphical one of the probabilistic analytical theories. The reliability assumptions by order for controller, actuator, sensor are 0,925, 0,871, 0,837 and for whole closed-loop control system is 0,708 regarding BN [1].

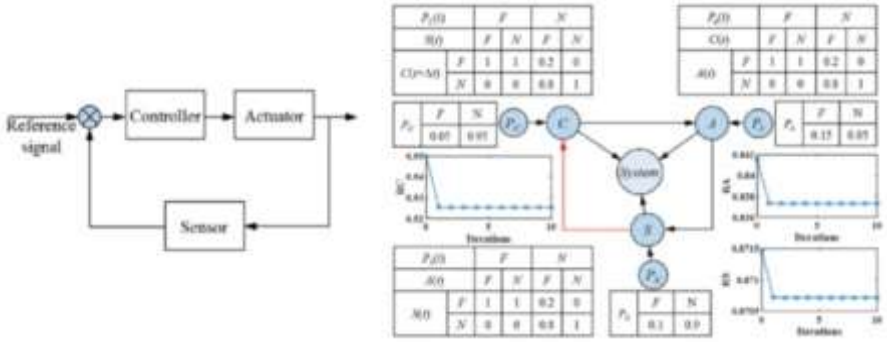

Figure 1. A Simple Closed-Loop Control and Its Cyclic Bayesian Network Based on Dynamic Bayesian Network [1]

There are several methods to join or fasten independent parts such as adhesives, welding, soldering, brazing, screwing, punching, clipping, pressing, clinching, crimping or riveting. A rivet is a fastener joining mechanically multiple independent parts in a permanent way by a fastening process called as riveting done by hand tool or riveting machine.
Various kind of rivets are available regarding applications and requirements such as tubular, semi tubular, blind, oscar, drive, flush, friction-lock, self-piercing and solid structural rivets. The solid structural rivets is the used one for the application subject to this study, therefore, following riveting process and also riveting machine functioning, both are explained according to solid structural riveting. The riveting process contains seven sequences as contact, radial compression, head forming, tail or lug forming, head dimensioning, compression end and elastic returns according the

study of Markiewicz et al. (1998) [2] .The rotary head of riveting machine called “touche” contact on a rivet and start to press it while turning. While contacted end of the rivet called tail become shortened longitudinally, expand simultaneously regarding its initial shank diameter and gets dumbbell shape. Therefore independent parts are fastened in between two heads of the rivet. A simple riveting example and also various rivet types and their nominations are shown by Figure 2.

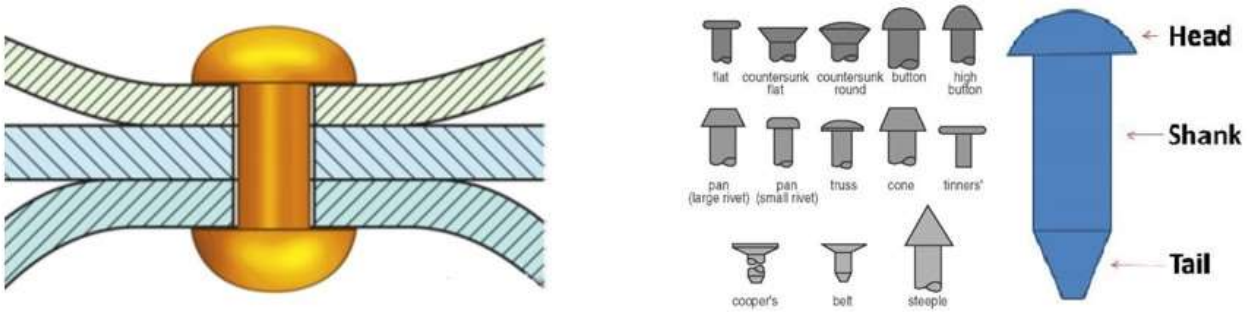

Figure 2. A Solid Structural Riveting and its Various Kinds [3]

The process flow of rivet manufacturing is shown by Figure 3. Primary material of rivet is called fil machine wrapped on the reels and their weights are approximately 1.000 kgs. This fil machine is coated by phosphate to facilitate the next operation called cold forging which gives the required shape to the part. Cold forging is done by automatic machines in multiple sequential steps. Following operation is heat treatment and improve mechanical properties of rivet. Considering environmental conditions affect the rivets during life time, coating is the protective process against corrosion. The next process, End of Line (EOL) is a 100% control operation done by specific machinery functioning based on Eddy Current principals. The last step of manufacturing flow is the packaging and delivery accordingly.

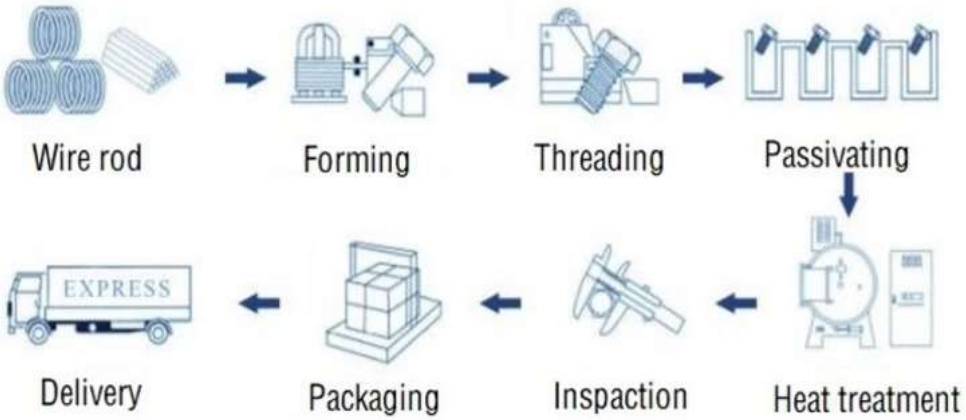

Figure 3. Rivet Manufacturing Process [4]

This study is done on the riveting process of connection part used between seat belt buckle and the vehicle body or seat pedestal. The raw material of rivet is 19MnB4 and its hardness is between 265 to 310 HV. The product subject to this study is shown by Figure 4.

Figure 4. Studied Product and its Riveting

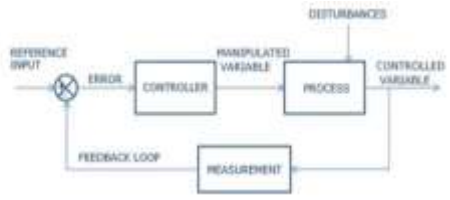

Figure 5. Closed Loop Control, Direct Measurement [5]

The primary objective of this study is to measure directly the effect occurred on product in other words certain dimensions created by the action of actuator on the product itself as shown principally by Figure 5 and accordingly make the corrections and adjustments regarding Statistical Process Control (SPC) principles as a base to the evaluation of the corrective action for actuator by deep learning (DL) and artificial intelligence (AI) applications. A secondary

objective is to obtain a more accurate adaptive closed-loop control system and a better reliability than 0,708 BN assumption.

2. SYSTEM DEFINITION

Riveting process is done by riveting machine. Rotary head usually driven by an electric motor. Both asynchronous and servo motors are used to drive the rotary head. The servo motor precision and also control abilities via its own microcontroller are much better than asynchronous motors with travel control by linear encoder. It is obvious that the consistency of riveting dimensions is highly sensitive to position control and traditional controls are not enough precise as confirmed by the study of Liu et al. (2020) therefore servo motors are preferred for sensitive applications [6]. A servo riveting machine as one of the key elements of the system is shown by Figure 6 and the block diagram of the system is shown by Figure 7.

Figure 6. A Servo Riveting Machine

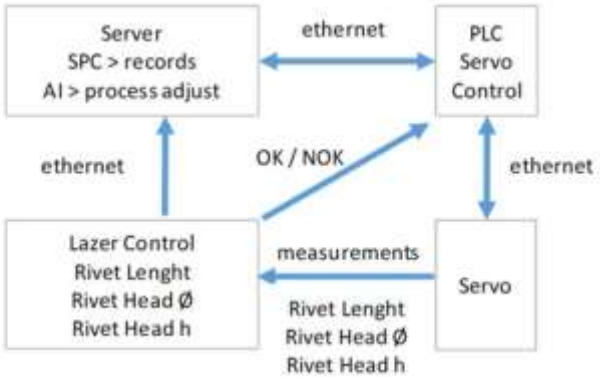

Figure 7. System Block Diagram

The basic idea for planned adaptive closed loop control system is to control the complete system by PLC as master and microcontroller of servo motor as slave. Finally all data records will be kept on the server. Another function of the server is to make real time SPC calculations based on data records and undertake master role instead of PLC in the future to control the system while deep learning and artificial intelligence applications will be established. All communication between the units will be done via ethernet during the cycles. The main actors of the system are the actuator means rotary head driven by servo motor and the sensors means lazer measurement unit, servo encoder and servo transmitter.

The fundamental components of the control system and required information for treatment are defined by Table 1 in three phases such as conventional/previous application, current application and digital transformation solution studied as adaptive closed loop control.

Table 1. Fundamental Components of Control System and Information for Treatment

	Level		Previous			Current			Digital Transformation		
	Riveting Machine		Mechanical			Servo			Servo		
	Process Adjustments		Manual			Manual			Automatic via SPC & AI		
#	Info	Unit	Sensor	Communication	Control	Sensor	Communication	Control	Sensor	Communication	Control
1	Position Info	mm	Linear Encoder	PLC Input	PLC	Servo Encoder	Ethernet	Servo µc	Servo Encoder	Ethernet	Servo µc
2	Travel Info	mm	Linear Encoder	PLC Input	PLC	Servo Encoder	Ethernet	Servo µc	Servo Encoder	Ethernet	Servo µc
3	Rotation Info	1/0	Ind Proximity	PLC Input	PLC	Servo Encoder	Ethernet	Servo µc	Servo Encoder	Ethernet	Servo µc
4	RPM Info	rpm	-	-	PLC	Servo Encoder	Ethernet	Servo µc	Servo Encoder	Ethernet	Servo µc
5	Torque Info	Nm	-	-	PLC	Servo I transmitter	Ethernet	Servo µc	Servo I transmitter	Ethernet	Servo µc
6	Time Info	s	PLC Timer	-	PLC	PLC Timer	Ethernet	PLC	PLC Timer	Ethernet	PLC

The prominent difference between current application and digital transformation solution is the process adjustment since the collected information, their sources and communication channels are same. Adjustments, in other words setups or operation parameters are made by operators manually for current control system even it is an improved one regarding previous applications. The difference occurs at this very moment for digital transformation solution such as automatic process parameters adjustment according to Statistical Process Control (SPC) rules and principals as a preparatory and transition period before the final step which is automatic adjustment and self-decision making systems based on deep learning and artificial intelligence applications.

The elements of the system described as block diagram by Figure 7, shown as on site application assembly line by Figure 8. Except the hydraulic unit at the right side of the Figure 8, assembly line contains two rotary tables. Servo riveting machine is placed on first rotary table which is at the left side. Lazer measurement system is placed at second rotary table.

Riveted part has been transferred to second rotary table by a robot after riveting operation done by servo riveting machine at first rotary table. The riveting diameter and height, both are controlled by blue lazer of lazer measurement system and the data transmitted by ethernet recorded in the server. On the other hand simultaneously an OK or NOK confirmation signal sent additionally to PLC in order to check the conformity of riveting diameter regarding lower and upper limits.

The recorded diameter and height data are evaluated statistically and used for standard deviation calculation for each and every measurement. Other calculations done via recorded data by server are for definition of lower and upper control limits to use for travel adjustment of the servo riveting head which will result on both riveting diameter and height during next cycle.

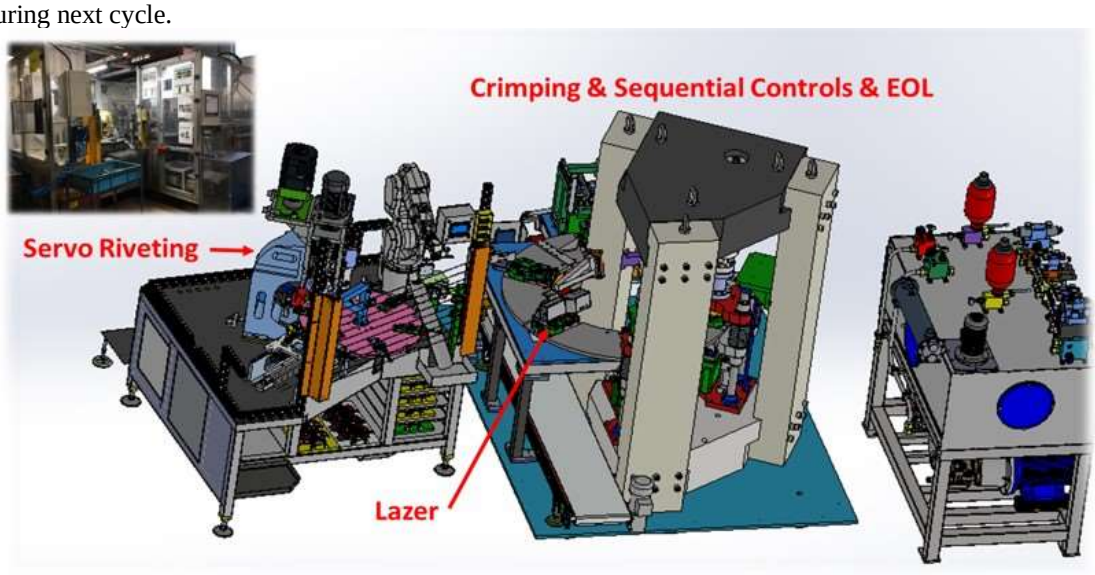

Figure 8. Automatic Assembly Line Including Riveting Operation

3. EXPERIMENTAL STUDY

3.1. Problem Definition

The dimensions occurred following riveting operation basically the riveting diameter and the height are both important especially if the mechanical strength is significant, application is sensitive and a certain precision is required due to its effects on product such as sealing, friction, pull-off force, tensile strength etc. since the riveting is used to combine independent components to make an assembly. Tate and Rosenfeld (1946) studied about loads carried by individual bolts shows that the strain distribution is varied with load and at low loads is approximately uniform [7]. Wang et al. (2015) confirmed by their research that incorrect definition of riveting parameters may cause initial cracks depending on excessive stresses occurred or improper operation triggering loose rivet [8]. Therefore, the stability and also conformity of riveting dimensions to keep the necessary mechanical strength should be measured precisely first and corrected accordingly after evaluation regarding two options. The first option is to make the intervention on actuator means riveting head for correction regarding pre-defined and correlated data about the travel or riveting time or angular speed or combination of them. The second option is to use deep learning and artificial intelligence application for self-decision making system about travel, riveting time and angular speed.

3.2. Method

System definition done for this study based on progressive and adaptive correction about the travel of riveting head regarding pre-defined and correlated data as a first step. The SPC rules are applied on recorded data in order to go one step further regarding conventional pre-defined and correlated data approach about corrective action on actuator. Therefore, while SPC results included into calculations for definition of corrective action of riveting head creates a constantly updated reference system, will support also next step study as a base. System infrastructure is appropriate for next step which will be creating a self-decision making system based on deep learning and artificial intelligence applications. Sensing elements of the system are lazer measurement system and servo itself by its encoder and current transmitter. The positioning, travel and rpm information received via encoder and the current linked to torque received by current transmitter are the information about the actuator. On the other hand, lazer measurement system gives the riveting diameter and height information directly received from product as a real result of actuator on product including other affecting parameters such as the fluctuations of sheet metal thickness, rivet hardness and rivet length before riveting.

Application of machine learning algorithms together with SPC rules are highly recommended to monitor dynamic processes by numerous recent researches and studies such as Psarakis (2011) [9], Park et al. (2012) [10], De Ketelaere et al. (2015) [11], Rato et al. (2016) [12], Bacher and Ben-Gal (2017) [13], Shao et al. (2017) [14], Chou et al. (2020) [15], Singer and Cohen (2021) [16] considering incapable traditional control systems.

The significance of next step to create a self-decision making system out of human intervention based on deep learning and artificial intelligence applications comes to the scene at this very moment in order to evaluate the effects of above mentioned parameters correctly and decide the action to be done by actuator based on data records of millions of riveting operation instead of experience based on human interventions. Therefore system and algorithm definition accordingly is the key and most important parameter to consider for this study in order to establish appropriate infrastructure for next step which will bring all advantages of digital transformation to the manufacturing by the help of full transparency and traceability. Another valuable effect is the easy deployment of this application to other similar areas and processes.

3.3. System Configuration and Technical Information of Fundamental Elements

The basic technical information of fundamental elements of the system such as Lazer Measurement System with technical specifications from Cavo, PLC and Servo Motor with technical specifications from Siemens shown by Tables 2, 3 and 4.

Table 2. Lazer Measurement System Technical Data

Lazer Measurement Device

Communication	Profinet		5	ms
General	X axis lazer projection area		65	mm
	Z axis lazer projection area		34	mm
	X axis resolution		5	µm
	Y axis resolution		2,5	µm
	Z axis resolution		15	µm
	Camera µC Speed		320	fps

3.4. System Algorithm

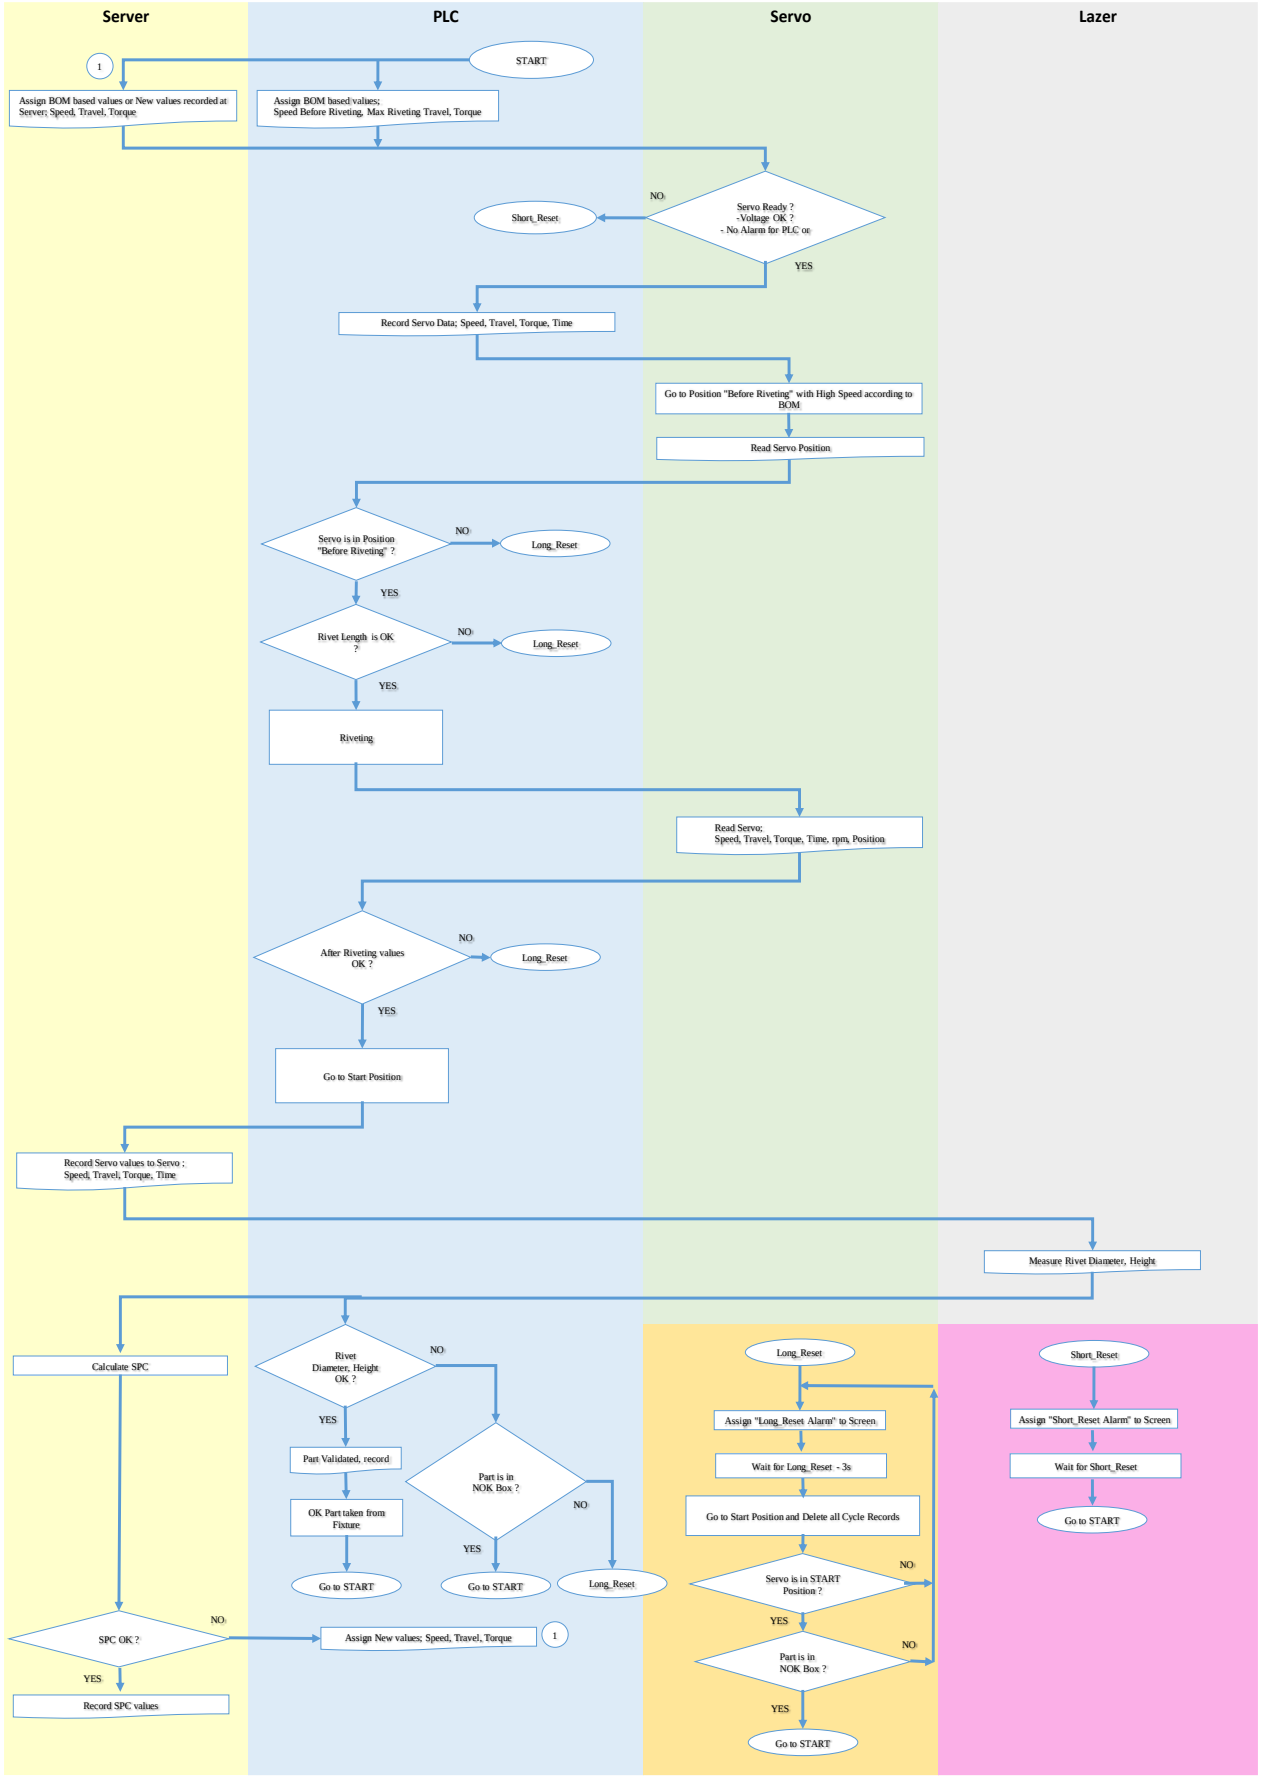

Figure 9. System Algorithm

3.5. Calculations and Fundamental PLC Blocks

Servo Motor Riveting Speed is 75 rpm, so, Tour per Second;

$$\frac{75}{60} = 1{,}25\ \text{tour/s} \tag{1}$$

Minimum Servo Travel is 5/10.000 mm, so, Travel per Second;

$$5 * 1{,}25 = 6{,}25\ \text{mm/s} \tag{2}$$

Theoretical communication speed between Servo Control Unit and PLC is defined as 125µs in technical data sheet. Since practical results are quite different than theoretical given values by experience, practical communication speed has been measured on system and found as 5 ms, therefore, practical communication speed is considered for calculations.

Maximum Control Cycle Quantity per Second;

$$\frac{1000}{5} = 200\ \text{cycles/s} \tag{3}$$

Minimum Servo Travel can be controlled;

$$\frac{6{,}25}{200} = 0{,}03125\ \text{mm/cycle} \tag{4}$$

Minimum Servo Travel chosen is 0,05 mm/cycle taken into account that the minimum servo travel is 0,03125 mm/cycle, so, system is able to react and also control the actuator according to command signals.

There are four main LAD blocks for PLC programming as follows;

1. Enable a memory bit to activate SPC lower and upper limits is shown by Figure 10,
2. Servo Travel Adjustment, 100 pulse (50µm) if SPC lower and upper limits exceeded is shown by Figure 11,
3. Servo Travel Adjustment, 200 pulse (100µm) if rivet ϕ is out of ±10% of previous one is shown by Figure 12,
4. Servo Travel Adjustment, 400 pulse (200µm) if rivet ϕ is out of min or max limits is shown by Figure 13,

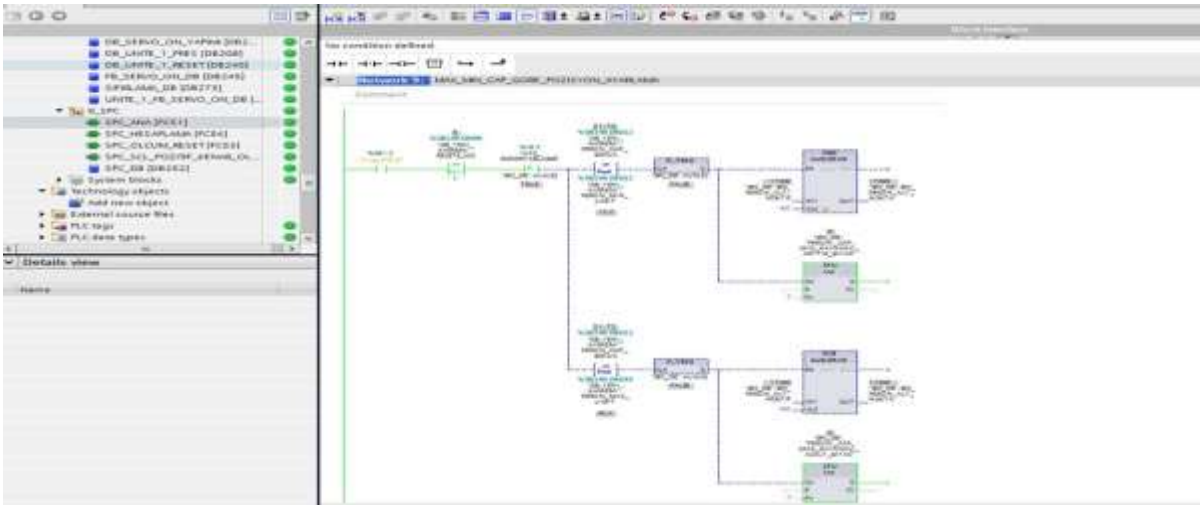

Figure 13. Servo Travel Adjustment, 400 Pulse (200µm)

4. RESULTS AND DISCUSSIONS

A production batch of 300 parts has been manufactured for trial and all mentioned parameters in algorithm has been real time recorded on server successfully as shown by Table 5 following PLC program modification according to the algorithm shown by Figure 9. Four main LAD blocks shown by Figures 10-13 are integrated into PLC software and SPC calculations embedded into server. Not any out of tolerance riveting, in other words, not any nonconformity observed for production of 300 parts and more importantly a better distribution for diameter values obtained comparing with previously applied conventional control method.

The servo travel corrections generated by control system and fluctuations of riveting diameter are in correlation in between. The graphics for travel corrections and diameter changes are shown by Figure 14. Most important difference between adaptive closed loop control and the previous conventional control system is also the biggest advantage of adaptive closed loop control. While previous closed loop control system prevents that the actuator means riveting head driven by servo motor exceeds the given limit which is down position parameter defined by operator manually, adaptive closed loop control system receives the rivet diameter information directly from product and applies corrective actions on actuator by travel corrections automatically without human intervention for each and every cycle to keep the targeted dimension within limits defined by SPC calculations which is also progressive and constantly updated by every cycle.

Figure 14. Servo Travel Corrections versus Riveting Diameter Fluctuations

5. CONCLUSION

The chosen method for this study is based on progressive and adaptive riveting head travel correction driven by constantly updated reference system built on SPC results included into calculations for definition of corrective action concept. The aim for SPC rules application on recorded data is to go one step further regarding conventional control approach by pre-defined and correlated data based corrective action on actuator. Therefore, this concept will support also next step study as a base. System infrastructure is appropriate to create a self-decision making system based on deep learning and artificial intelligence applications. Investigated effect during the study is directly the difference for fluctuation tendency of riveting diameter between adaptive closed loop control and conventional control approaches. Established algorithm providing a better control on riveting diameter by the help of almost simultaneous 3 stages intervention. The results of first production batch contains 300 parts, data records on server and also the graphics showing the interaction between the input and output confirm the effectiveness of new adaptive approach. Although new algorithm shows its benefits on results, the travel adjustments of servo riveting machine is still done by pre-defined values such as 50 µm, 100 µm and 200 µm even SPC rules are embedded into calculations. Obtained result from 300 parts presents an improvement 0,98 % regarding 14,40 mm lower diameter limit and 1,83 % regarding upper diameter limit 15,60 mm. The importance of the study is having a narrow band fluctuated process compared to previous conventional control system allowing production of out of limit riveting to catch them by EOL.

Bajracharya analysed and indicated in his MSc Thesis (2006) that a part of the parameters affecting riveting quality are controllable in the process such as squeeze force, rivet length, rivet diameter tolerance, hole countersunk depth and hole diameter tolerance [17]. This means that the not only controllable ones but, combination of the applied process parameters and variations of other numerous effects such as sheet thickness, rivet hardness, clamping force and hole structure and diameter is directly affects the quality of riveting proven by the study of Lei et al. (2017) [18] despite they are in accordance to defined tolerances, will be balanced in next step by multiple and simultaneous corrective interventions on process parameters. Therefore, this preliminary study is a well prepared infrastructure to make the correction by intervening to actuator not only for travel adjustment but at the same time for rpm, riveting time and also for applied force or torque regarding the self-decision made by deep learning and artificial intelligence application based on whole collected data.

POWER DIODE TYPES USED IN 12V AUTOMOTIVE ALTERNATORS AND IMPACTS ON ALTERNATOR PARAMETERS

Eray ARIK, Matthieu Mallevaey, Dinçer Kökden
[1,2] Valeo Powertrain systems
eray.arik@valeo.com

ABSTRACT

This paper introduces the impact of the alternator diode on the vehicle network and explains the test methodologies for each important parameter. Valeo company uses 4 general rectifier modules on their alternators depends on the need for different requests and sanctions by its customers. This paper will explain the different diode technologies and describe the main activities realized by the alternator makers since several years to reduce the consumption of the vehicles. New technologies introduction have bigger constraints and increase the alternator cost to the complexity of the technologies used by the diodes makers. As explained in this paper, the alternator, which provide the entire electrical power during driving session, has a big influence on the electrical network and on the C02 emission of the car. Ripple on the main supply line, EMI noise considerations due to switching, high voltage spike protection, thermal degradation and battery discharge prevention are also key factors to evaluate while developing rectifier of generator, and should be tested carefully before supplying the OEMS.

Keywords: Alternator, Diodes, VDA, MOSFET

1. AUTOMOTIVE ALTERNATORS

An alternator is a type of widely known electric generator used in modern automobiles to charge the battery and to power the electrical system when its engine is running (URL 1). It is an AC synchronous machine with a winding claw rotor inserted inside a generally 3-phase stator, which is fed by a DC source and becomes the source of the magnetic field. The AC signal generated at the stator due to the time varying rotation of the magnetic field is rectified by a diode rectifier and the output voltage of the alternator is controlled by a regulator which is self-excited (Doffe, Kadiri, 2010).

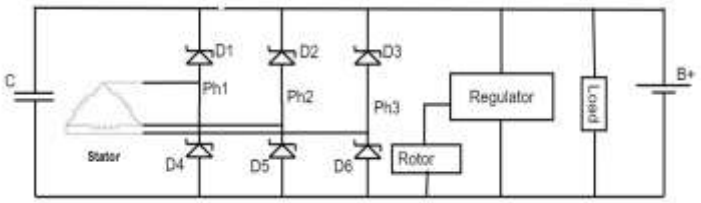

Figure 1. Alternator schematic

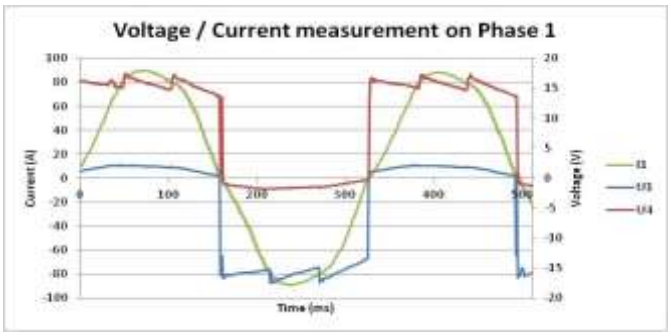
The recitification is done by 6 diodes in a 3-phase, and 12 diodes in 6-phase bridge circuit, which is inserted in to the aluminum heat sink shaping the mounting bracket of alternator.



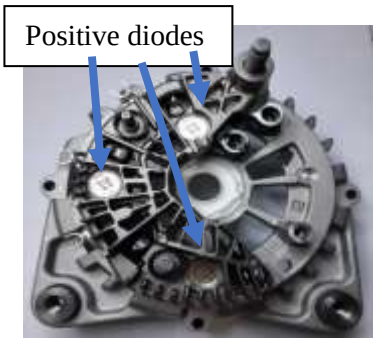


Figure 2. Phase current of stator and measured voltages on positive and negative diodes

2. RECTIFIER DIODES AND PERFORMANCE CHARACTERISTICS

Initially, a number of criteria may be generated in order to select potential components for this specific application. The family of semiconductor devices that will be considered will come from high efficiency Schottky, Zener, and MosFET technology.

- The maximum frequency of the generated voltage is 2.4 kHz at 24000 rpm (for six poles pair's alternators). This relatively low frequency does not require fast reverse recovery time of the component. Nevertheless, it is still a consideration for EMI compatibility (Electromagnetic test compatibility – EMC).
- The vehicle's battery is always connected to the vehicle's power system. During park mode, the rectifier is exposed to a maximum reverse voltage of 12 V at an ambient temperature of 25° C. At this time, the diodes' leakage current needs to be minimized in order to avoid battery drain.
- The forward voltage drop of the diodes will greatly influence the efficiency of the power generation, thus it needs to be as low as possible.
- The ambient temperature under the vehicle's bonnet, when the motor is running and warmed up is approximately 100°C - 120°C. Due to the high amount of current additional power will be dissipated through diodes during rectification. Thus, Diode thermal behavior must withstand those severe conditions.
- When sudden load interruptions, high voltage spikes can occur due to high inductive characteristics of stator. To protect automotive electronic equipment from this high-energy pulse, zener functionality should be used to clamp the voltage and short circuit the stator current to the ground.
- Diode junction capacitance does not have a significant effect on overall performance at lower frequencies such as 2.4 kHz due to motor speed. However, considering high frequency EMI compatibility, it will have a high dv/dt current noise. Thus, it should be taken into account as well.
- Additional to above performance parameters, diodes withstand all test conditions which automotive EMC standards / Original Equipment Manufacturer (OEM) standards require such as ESD pulse, repetitive surges, transient voltages etc (Sarafianos, Logan, 2014).

3. DIODE IMPACT ON VARIOUS ALTERNATOR CHARACTERISTICS

Considering different OEM requirements and to meet different performance characteristics, Valeo has been using 3 types of diodes in 12 V alternator rectifiers whose names are given below; The distinction between them mostly depends on the Rds on characteristics, thermal resistances and nominal rated current at specified temperatures.

- Standard type PN Zener diode
- Low Loss Diode (LLD)
- Ultra Low Loss Diode (ULLD)

In the next section, the different behavior of the diodes and the impact on various alternator performances will be discussed, and test results will be shared according to related ISO or customer standards.

3.1. Diode Vf Characteristics And Efficiency Increase Of Alternator

The rectifier losses "Prec" are obtained by calculating the diodes losses (Doffe, Kadiri 2010). They are the summation of the conduction losses and the switching losses. In a first approach, we neglect the switching losses.

$$P_{REC} = N_d . I_F \left(\frac{V_0 . \sqrt{2}}{\pi} + \frac{R_0 . I_F}{2} \right) \quad (1)$$

Where P_{REC} is total rectifier losses, N_d is number of diodes, I_F is direct current in diodes and V_0 is intrinsic voltage of the diodes.

Conduction losses are the average dissipated power in the diode during the forward conduction phase given in Equation below (URL 2). Since each diode is in conducting state during ½ of the complete phase period, the losses in one diode can be calculated as below.

(2)

$$P_{COND}(T_j) = \frac{1}{T_{SW}} \int_0^{T_{SW}} V_F.(I_F.T_j).I_F(t).dt$$

Alternator and diode suppliers have worked to improve the efficiency of diodes. Diodes have two types of losses: voltage drop and leakage current. Leakage current being negligible, Valeo with its suppliers focused on efficiency enhancement of diodes on the voltage drop, and more specifically, on diode junction voltage while keep the mandatory zener function.

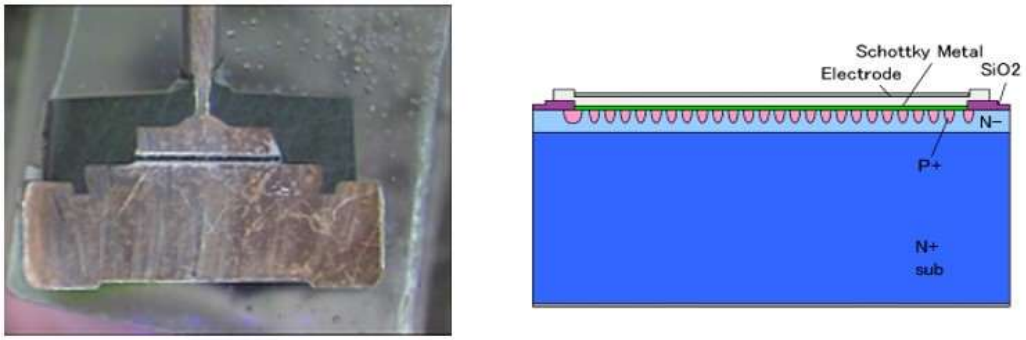

Figure 3. Vertical Cross Section of a high efficiency diode (left) and the construction schematic of LLD diode (right)

To improve the losses, they combine Schottky diodes with a zener structure by modifying the silicon die inside the press-fit packaging.

Beside diode technology, Valeo studied to implement MOSFET technology on rectifier bridges with active rectification. One of the examples of this bridge is ULLD, which has an integrated MOSFET, comparator and drive IC in the same diode packaging shown below and working autonomously without external drive as in the case with the standard diode.

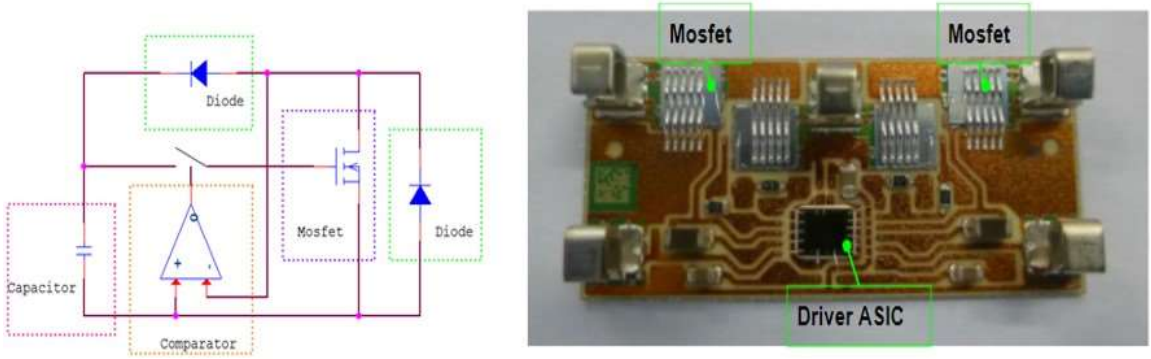

Figure 4. ULLD diode schematic (left) and mosfet module (right)

The other technology Valeo used is EG Mos type bridges, which have conventional mosfets, and external modules including comparator and gate drive circuit, which excite the gate of mosfets according to the phase voltage amplitudes. Four different rectifier configurations were chosen to see the efficiency effect on the complete alternator. Chosen diodes have below Vf with forward current performance.

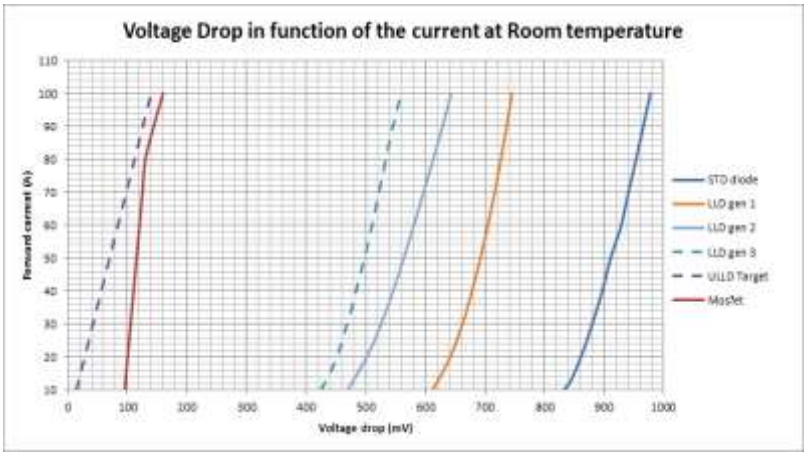

Figure 5. Forward voltage drop with function of forward current

To understand the effect of rectifiers on efficiency, VDA test was repeated on the same alternator using 4 different rectifiers while keeping all the other alternator components the same. According to VDA and ISO standards, the average alternator efficiency is defined as following (ISO 8854, 2012):

$$Eff_{avg} = \sum_{i=1}^{4} Eff_i \,.\, H_i \tag{3}$$

(4)

$$Eff_i = \frac{U_i I_i}{T_i V_i} \tag{5}$$

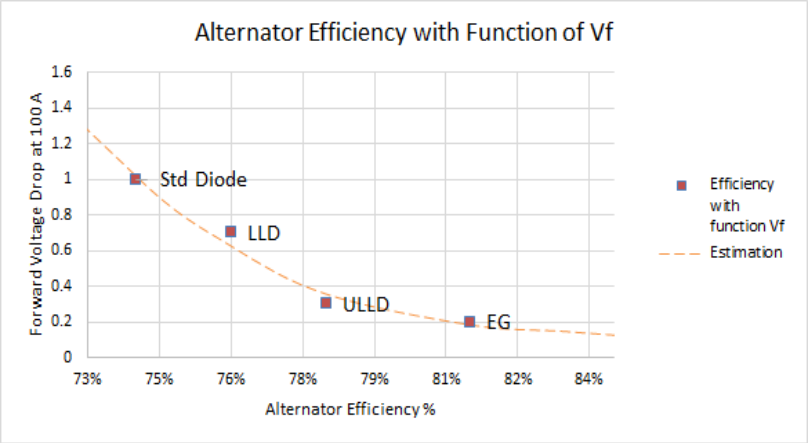
$$H = [0.25 \quad 0.4 \quad 0.25 \quad 0.1]$$

(6)

$$V = [1800\ rpm \quad 3000\ rpm \quad 6000\ rpm \quad 10000\ rpm]\, 2\pi/60$$

Where: U_i is the alternator output voltage, which is set to the 14.3 V for all steps, I_i is the alternator output current which is set to the half of the nominal for all steps, T is the measured torque and V is the alternator speed in rad/s. Speed value should be converted to Hz from Rpm in Efficiency formula.

It can be seen that diodes can have an impact of 8 % of efficiency increase on a complete alternator. The efficiency of the alternator has been improved by the use of so-called high efficiency diodes or low losses diodes instead of conventional diodes.



Rectifier Type	Voltage drop at 100 A	Efficiency
EG Mosfet	0.2	81.3 %
ULLD	0.3	78.2 %

Figure 6. Alternator efficiency with function of diode Voltage drop

An improvement on the alternator efficiency produces improvement in CO2 emission savings, which are calculated according to the calculation procedure given in the Technical Guidelines of Regulation (EC) 443 / 2009 of the European Parliament and of the Council (URL 3).

Following the referenced calculation procedure, the minimum alternator efficiency to reach the threshold of 1 g CO2 / km for Diesel fueled vehicles is 75 %, and 74% for petrol and petro-turbo fueled vehicles compared with 67% efficient base alternator.

If the alternator efficiency is 75%, then we find the following CO2 savings:

- Diesel : 1.101 g CO2 / km
- Petrol : 1.167 g CO2 / km
- Petro-turbo : 1.237 g CO2 / km

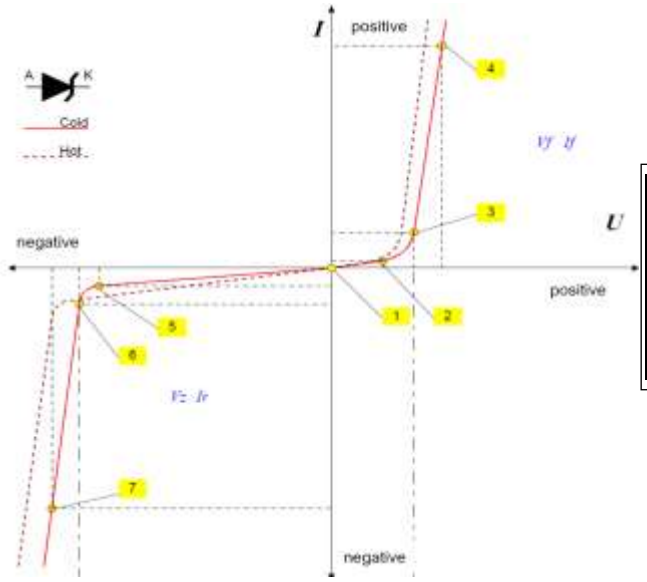
3.2. Leakage current and any effect, test results vs temperature

During standard operation of diode, in reverse polarity state of PN junctions, opposing regions of charged ions create a strong electric field across the PN junction. Due to this field, small amount of reverse current flows in reverse direction. This small current is called the reverse saturation current, and tends to maintain a relatively constant value for a fixed temperature at all voltages.

The IR magnitude depends on diode block voltage capability and junction temperature degree and contribute power dissipation while diode in off-state status shown in below formula. It is known that the diode will switched between forward and reverse polarity modes, thus each diode will be exposed to battery voltage during reverse polarity period. In addition, when the car is on park, the diode will be exposed to the battery voltage continuously in reverse mode (URL 4).

$$P_{loss\ during\ reverse\ polarity} = \int_{0}^{T\ reverse} V_{BR}(t).I_{iR}(t) \tag{7}$$

IR also has specifications by different PN junction temperatures for user's application reference, for example TJ=25°C,



1	Zero current / Zero Voltage
2	Minimum forward voltage
3	Voltage drop at 1 A
4	Voltage drop at 100 A

TJ=125°C

Figure 7. Zener diode IV curve (left) and characteristic points of curve (right)

The below test verifies the leakage current of the diode in Valeo production plant for each alternator. We also check the stability of the leakage current with the ΔIr. We measure the leakage current several times during a short period and we verify the difference between the highest and the lowest value.

Diode Type	Reverse Polarity (V)	Ir (µA)
Standard	18	0.3
LLD	18	20
ULLD	18	10

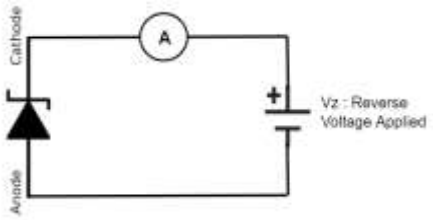


Figure 8. Leakage current measurement procedure (right) and results for different Valeo diodes (left)

3.3. Tj, Thermal resistance Rth-c and Temperature Limit

Tj is the allowable operating diode junction temperature and diodes cannot be used to exceed this temperature range in order to prevent malfunction. I_f Average value (maximum sustainable average current) is defined at a specific temperature (TA=25°C) and can affect diode heat dissipation. The junction temperature can be calculated using the formula:

$$T_J = T_{case} + (I_F.V_F).R_{th} \quad (8)$$

Where T_J is junction temperature, T_{case} is measured temperature on the case, R_{th} is junction to ambient thermal resistance, I_F is Forward current and V_F is Forward Voltage drop.

In order to simplify the design and the thermal acquisitions on bench, we define with the diodes suppliers the derating curve by considering the worst-case scenario in terms of thermal resistance and voltage drop of the diode. This will define the following curve, called the derating curve, where the junction temperature is defined in function of the current and the case temperature.

Figure 9. Max forward current with function of case temperature

Our standard diodes panel has a junction temperature of maximum 225°C for most of our applications. With the introduction of the LLD diodes, the junction temperature has been reviewed to fit with the technology choice.

As the LLD are based on the schottky diodes, the leakage current becomes an issue and generates a thermal runaway if the junction temperature is too high. Nevertheless, as the Voltage drop becomes lower, the losses in conduction decrease. Below a thermal comparison on the same alternator between Standard diodes and LLD diodes.

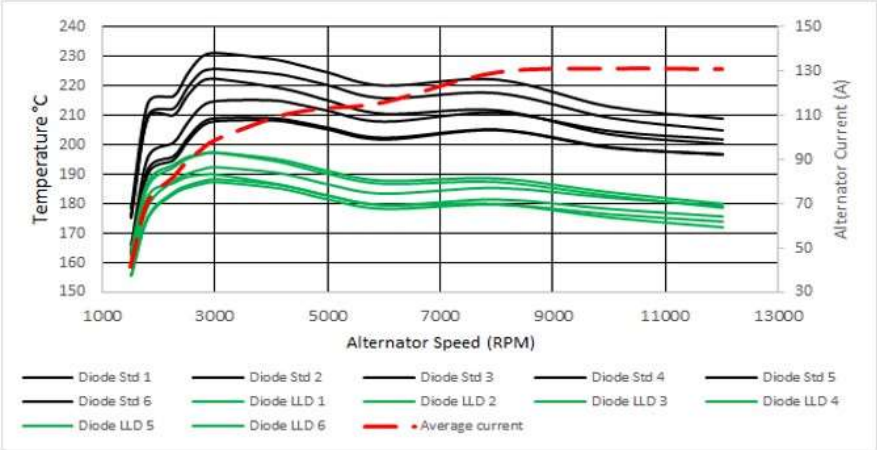

Figure 10. Thermal comparison between standard diode and low loss diode

Differences between same types of diodes are linked to the diode position on the alternator on the aluminium material around for thermal cooling. Due to the local tempertaure difference on the surfaces and aerothermal differences in the product design, the Ron resistance will not be same between each diode and this will cause different temperature increase gradients for all.

3.3. Junction Capacitance and Reverse Recovery

It is a widely known that, fast current and voltage transitions lead to broad frequency contents in the emissions from Switch-Mode devices. The rise and fall times should thus be chosen with this fact kept in mind. A decrease in rise and fall time from the switching element, usually a MOSFET or diode in switching applications, is obtained by increasing the gate resistance. This is perhaps the simplest way of controlling the frequency contents. However, an extended fall and rise time also gives an increased power dissipation, which needs to be considered if efficiency and cooling is a critical issue (Gustav, Niklas, 2018).

The time to charge the junction capacitance of a previously conducting diode and to discharge the junction capacitance of a previously blocking diode, which is referred to as the commutation time, becomes larger. The other result of diode junction capacitance is the frequency content of reverse recovery phenomenon, which is present in most of the diodes after stored charge has been removed from, junction capacitance needs to be charged to the steady-state voltage (URL 5). However, because of the series-resonant circuit due to the line inductance and load characteristics, the voltage across

(rectifier voltage) and the current trough will resonate on the rectified voltage as ripple. The other capacitive loads in the output line will also affect the ripple amplitude and the frequency.

$$t_{rr} = \pi . \sqrt{L_s . C_T}$$

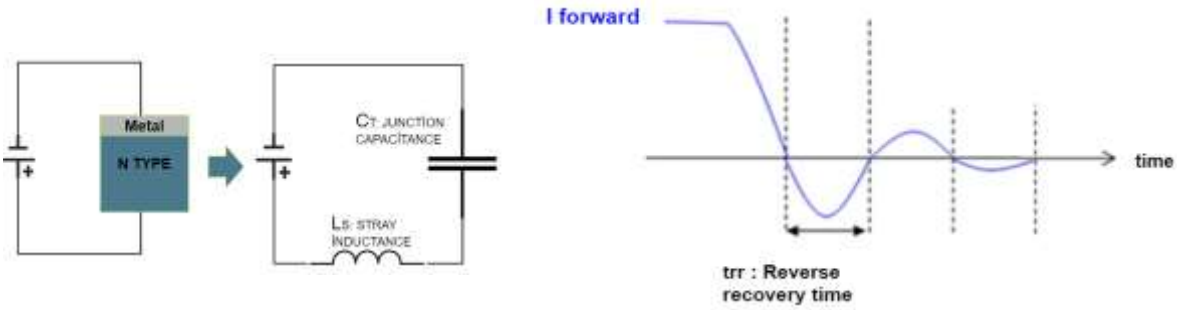

Figure 11. Diode equivalent circuit and reverse recovery

The reverse recovery time, T_{rr}, can differ much between different types of diodes. Schottky diodes have a very short recovery time since they are majority carrier devices and do not suffer from minority carrier storage problems.

Diode Type	t_{rr} - ns
Standard	3400
LLD	1000
ULLD	2000

Table 1. Reverse recovery times of Valeo diodes

3.4. Alternator Output Voltage Ripple

Voltage ripple of the alternator output voltage is the result of the parasitic ringing triggered at the diode commutation instants caused by the interaction of the capacitance of the alternator including b+ capacitor, junction capacitance, parasitic capacitances and the inductance of the load line. It includes the time of the basic ripple and the peaks caused by the commutation of the diodes.

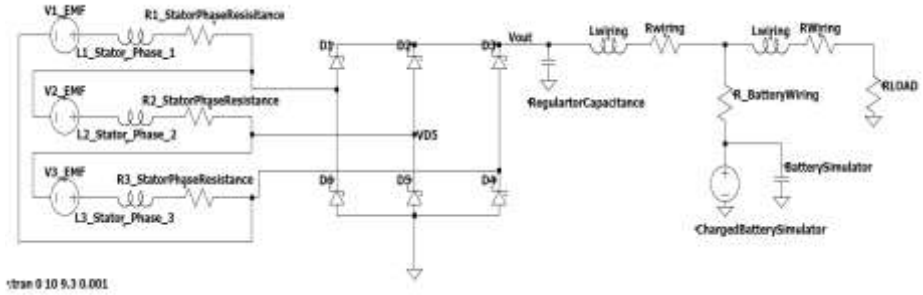

Figure 12. Ripple voltage simulation circuit with inductive and capacitive load

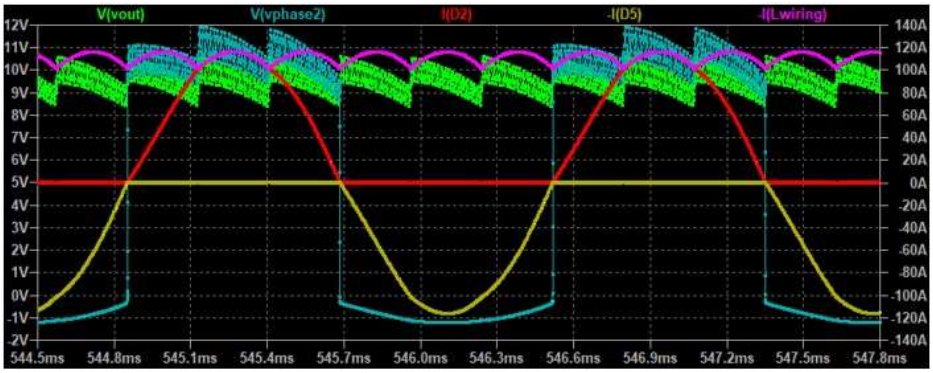

Figure 13. Simulation results of voltage ripples, current ripples and phase voltage, diode currents

The over-oscillation corresponds to the moment where the current is interrupted in a phase where the voltage decreases. In these conditions, there is a discontinuity in the total current. The load circuit inductance tends to oppose this current decrease by inducing an over-voltage, then an oscillation that fades away with a time constant and a period specific to the load circuit.

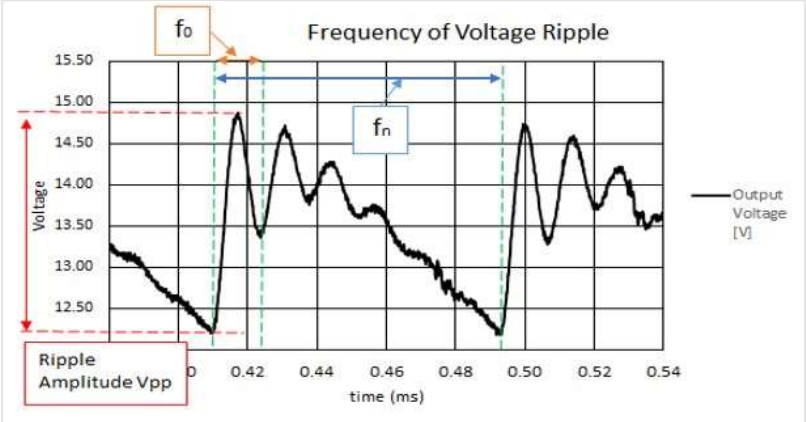

Figure 14. Test results of ripple voltage and frequency contents of ripples

$$V_{pp} \sim \frac{I_{load}}{2\pi . fn . C_{out}} \tag{10}$$

$$f_n = \frac{Mechanical\ Speed\ (RPM) . P(number\ of\ Poles\ of\ Rotor)}{60} \tag{11}$$

The Frequency of this resonance (fosc) could be determined by a simple formula due to the resonance between B+ capacitor and the inductance of the load wiring and load:

$$f_{0-osc} = \frac{1}{2\pi . \sqrt{L_{load} . C_{out}}} \tag{12}$$

OEM specifies for the health of the electrical board network a maximum Ripple peak to peak in order to ensure the right power supply of the electric component in the vehicle. Below is an example of this specification depending on the alternator rotational speed.

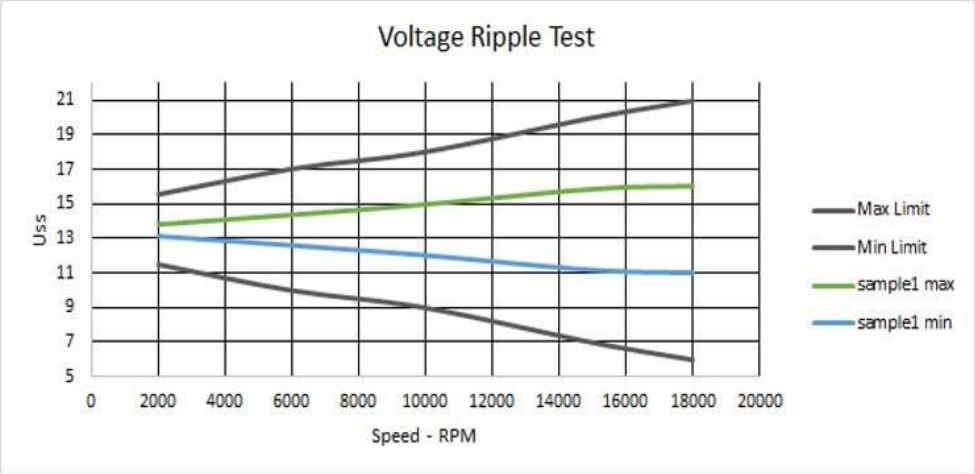

Figure 15. Test results of ripple amplitude at different speeds and OEM limits

3.3. Zener Voltage breakdown, Load dump protection

In order to protect the electronic components in the vehicle and to determine their durability in advance, the dangerous signals in the supply line have been determined. One of the pulses considered and missioned from the alternator is the load dump (Bosch 2007).

When an important load is suddenly disconnected, the alternator's output current does not change instantaneously. Subsequently, the stored magnetic energy in the stator coils of the alternator drives the output voltage up.

$$V_{induced} = -N\frac{dB}{dt} = -NL\frac{dI}{dt} \tag{13}$$

The result, in the worst-case scenario, is a transient energy with a typical pulse width of approximately maximum 400ms and a peak voltage as high as the breakdown voltage of the diodes. This high-energy pulse can cause catastrophic damage to electrical components or subsystems if not properly protected and limited. Without the Zener voltage of the diodes, the voltage could be greater than 100V. The 12V alternator have today a maximum output voltage of 32V with the current diode breakdown voltage.

This transient energy is a direct result of the rapid decrease of the current demands by the loads. The surge in output voltage will decay exponentially until the energy stored in the rotor coil is removed (Dimech, 1991). The time for this transient energy is linked to the contact time of this coil (if no consumers are connected to the alternator).

This operational case can be found on the application (loosened connection leading to cuts, breakage of corroded cable or voluntary disconnection of the battery with motor idling). It is defined in most of the Customer Specifications Sheets.

The load dump test is done by switching off the load circuit and the battery when the alternator is supplying full load current or defined percent of the capacity. A record of the maximum voltage and timing to recover the nominal voltage is performed during the test. Also, this test is performed several times to measure the robustness of the system.

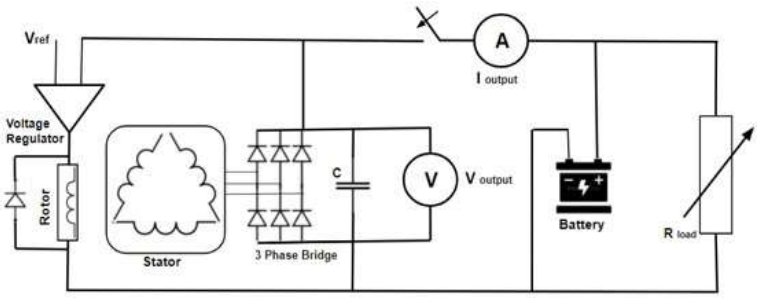

Figure 16. Load dump test circuit

Below test was done with an alternator supplying 265 A at 13.5 V at 15 000 rpm speed. As can be seen at the figure below, the load current line is interrupted once in 60 seconds repeatedly while the alternator keeps working. During the test, the maximum voltage peaks and durations of the load dump pulses are measured.

The maximum measured Voltage needs to be below 32 V is the general sanction requested by many OEM car manufacturers. Depending on this demand, power absorption capabilities and breakdown voltage values of zener diodes are selected according to this limit.

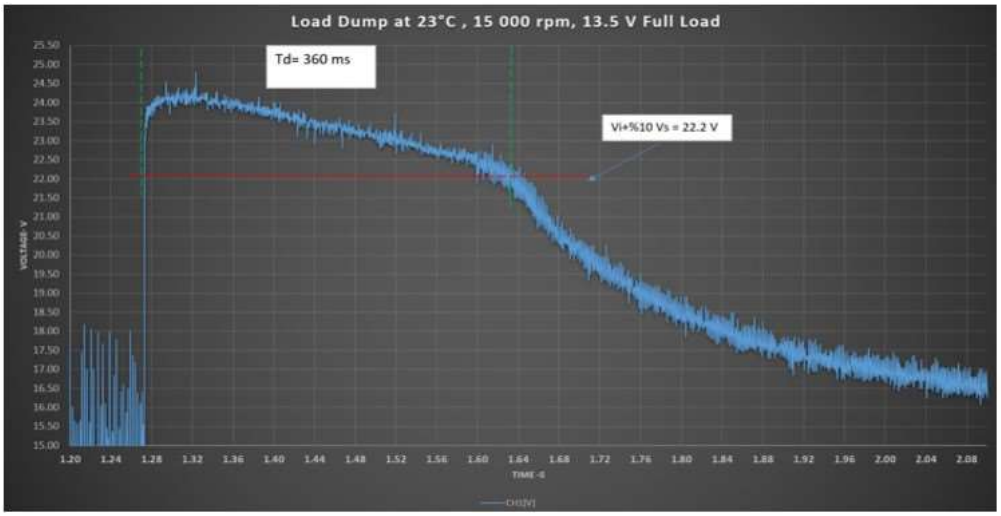

Figure 17. Load dump results for one load interruption

4. CONCLUSION

For reduction of CO2 emissions, different types of rectifier configurations are used in Valeo alternators mounted in vehicles with internal combustion engines (ICE). Compared with conventional zener diodes used in rectification, thanks to the LLD, ULLD, and EG MOSFET type rectifiers, efficiency is increased up to 8pts according to the VDA procedure. As explained above, this efficiency increase has a direct effect on carbon emissions from an automotive and environment protection point of view. Together with emission, it has been given by the test results that the diodes used in the rectifier have a direct effect on the voltage characteristics in the supply line in the automobile, on the emission noise propagation and on clamping of dangerous voltage pulses, which might be occurred due to load dump.

An Alternator diode is selected according to the customer requirement in terms of efficiency and electrical output performances. This diode is qualified according customer and internal specifications to offer to the final driver the best compromise between performances and reliability. The progress in the semiconductor industry leads to better performances of our alternators provided today on the market.

ÖZET

Günümüz otomobillerin teknolojisinde ağırlıklı olarak enerji kaynağı olarak petrol ve doğalgaz gibi fosil yakıtlar kullanılmaktadır. İnsan nüfusunun artışına paralel olarak dolaşımdaki otomobil sayısı da hızla artmaktadır. Petrol ve doğalgaz gibi fosil yakıt kaynak rezervlerinin hızla azalması, fosil yakıtlı araçların çevreye ve insan sağlığına zararlı olması, ABD ve Avrupa birliği ülkelerinde her geçen daha ağırlaşan emisyon limit ve kuralları nedeniyle otomobil firmaları alternatif enerji kaynakları kullanmaya ihtiyaç duymaktadırlar.

Otomobillerde kullanılabilecek enerji kaynaklarından alternatif enerji kaynaklarından biri de hidrojendir. Hidrojen, bilinen tüm yakıtlarda birim kütle başına en yüksek enerji içeriğine sahiptir. İşlem sonucunda atmosfere atılan ürün sadece su buharıdır. Taşıdığı enerji kolaylıkla elektrik enerjisine dönüştürülebilmektedir. Hidrojen, verimlilik oranı en yüksek enerji kaynaklarından birisi olduğu için otomobil sektöründe yakıt hücresi pazarı hızla büyümektedir. Hidrojen; otomobiller, otobüsler ve ticari araçlar dahil olmak üzere yakıt hücreli araçlara güç sağlamak için kullanılmaktadır. Bu çalışmada farklı araç üreticilerinin üretmiş olduğu yakıt hücreli elektrikli araçlar incelenmiş, bu araçların teknik alt yapı ve yerleşim karşılaştırılması yapılarak araç mimarisine olan etkileri ortaya koyulmuştur.

Anahtar Kelimeler: Hidrojen Tankı, Yakıt Hücresi, Batarya, Araç Mimarisi

FUEL CELL ELECTRIC VEHICLE (FCEV) TECHNOLOGY AND ITS EFFECTS ON VEHICLE ARCHITECTURE

ABSTRACT

In today's automobile technology, fossil fuels such as petroleum and natural gas are generally used as energy sources. In parallel with the increase in the human population, the number of cars in circulation is increasing rapidly. Automobile companies need to use alternative energy sources due to the rapid decrease in fossil fuel resource reserves such as petroleum and natural gas, the harmfulness of fossil fuel vehicles to the environment and human health, and the increasing emission limits and rules in the USA and European Union countries.

One of the alternative energy sources that can be used in automobiles is hydrogen. Hydrogen has the highest energy content per unit mass of all known fuels. The product thrown into the atmosphere as a result of the process is only water vapor. The energy it carries is easily converted into electrical energy. As hydrogen is one of the most efficient energy sources, the fuel cell market is growing rapidly in the automobile industry. Hydrogen; It is used to power fuel cell vehicles, including cars, buses and commercial vehicles. In this study, the fuel cell technology was integrated into a light commercial vehicle and a fuel cell architecture was created in a light commercial vehicle. In this study, fuel cell electric vehicles produced by different vehicle manufacturers were examined, and their effects on vehicle architecture were revealed by comparing the technical infrastructure and layout of these vehicles.

Keywords: Hydrogen Tank, Fuel Cell, Battery, Vehicle Architecture

1. GİRİŞ

Yakıt hücresi teknolojisi yenilenebilir enerji kaynakları arasında verimlilik, uygulama alanlarının geniş olması ve temiz çalışması açısından daha fazla ön plandadır. Hidrojen alternatif yakıtlar olarak geleceğin enerji taşıyıcısı olarak ön

görülmektedir. Hidrojenin kimyasal enerjisini yanma olayı gerçekleşmeden direk elektrik enerjisine dönüştürebilen yakıt hücresi, içten yanmalı motorlara alternatif olacak bir enerji sistemidir (Kahraman, 2016).

Yakıt pillerinin maliyetinin yüksek olması nedeniyle bu teknolojinin araç üzerine uygulanmasının çeşitli zorlukları bulunmaktadır. Fakat yakıt pillerinin maliyetlerinin düşürülmesi ve kullanımlarının yaygın hale getirilmesi için çalışmalar sürmektedir. Kullanılan yakıtın enerji içeriğine bağlı olarak yakıt pili ile çalışan araçlarda güç üretimi % 40-70 arasındadır (Çetinkaya, Karaosmanoğlu 2005).

Japonya, 2025 yılına kadar 200.000, Birleşik Krallık 2025 yılına kadar on binlerce ve Çin, 2030'a kadar 1 milyon otomotiv yakıt hücreli elektrikli araç (FCEV) üretmeyi hedeflemektedir (Whiston, Azevedoa, Litster, Whitefoota, Samaras, Whitacre, 2018).

1.1. Yakıt Hücresi ve Türleri

Yakıt hücresi, yakıt (hidrojen) ve oksitleyicinin (hava) kimyasal enerjisini doğrudan elektrik ve ısı formunda kullanabilen enerjiye çeviren güç üretim elemanıdır. Yakıt hücreli araçlar, yakıt olarak büyük çoğunlukla hidrojen kullanıldığından, yakıt araca ya direkt hidrojen olarak veya araçta hidrojene dönüştürülen bir hidrojen taşıyıcısıyla verilmektedir (Şenol, Üçgül, Acar, 2006).

Yakıt pilleri öncelikle kullandıkları elektrolit türüne göre sınıflandırılır. Bu sınıflandırma, hücrede meydana gelen elektro-kimyasal reaksiyonların türünü, gerekli katalizörlerin türünü, hücrenin çalıştığı sıcaklık aralığını, gereken yakıtı ve diğer faktörleri belirler. Bu özellikler, sırayla, bu hücrelerin en uygun olduğu uygulamaları belirler. Halihazırda geliştirilmekte olan, her biri kendi avantajlarına, sınırlamalarına ve potansiyel uygulamalarına sahip çeşitli yakıt hücresi türleri vardır.

Tablo 1. Yakıt hücresi çeşitleri ve özellikleri (Şenol, Üçgül, Acar, 2006), (Hirschenhofer, Stauffer, Engelman, Klett, 1998), (Larmine, Andrews, 2000)

1.2. Yakıt Hücresinin Bileşenleri

Bir yakıt hücresi, iki elektrot arasına sıkıştırılmış bir elektrolitten oluşur. Elektrolit, elektronları bloke ederken pozitif iyonların (protonlar) geçmesine izin veren özel bir özelliğe sahiptir. Hidrojen gazı, anot adı verilen bir elektrotun üzerinden geçer ve bir katalizör yardımıyla elektronlara ve hidrojen protonlarına ayrılır. (Pukrushpan, 2003).

$$2H_2 \Rightarrow 4H^+ + 4e^- \quad (1)$$

Protonlar, elektronlar harici bir devreden akarken, katot adı verilen diğer elektroda elektrolit yoluyla akar ve böylece elektrik oluşturur. Hidrojen protonları ve elektronları, katottaki oksijen akışı ile birleşir ve su üretir (Pukrushpan, 2003).

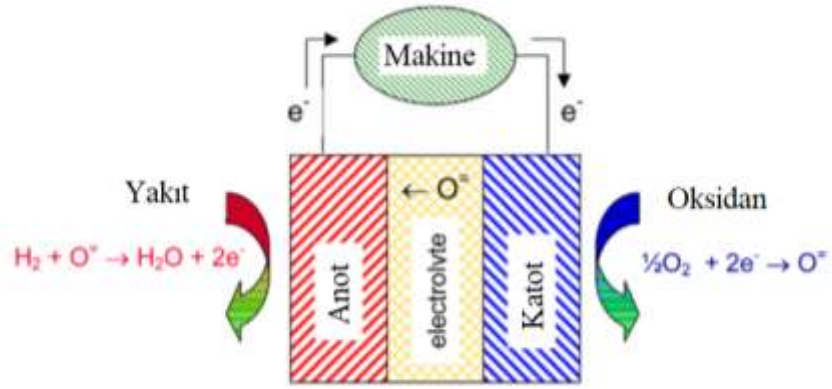
$$O_2 + 4H^+ + 4e^- \Rightarrow 2H_2O$$

(2)

Yakıt hücresinin genel reaksiyonu aşağıdaki formülde gösterilmiştir.

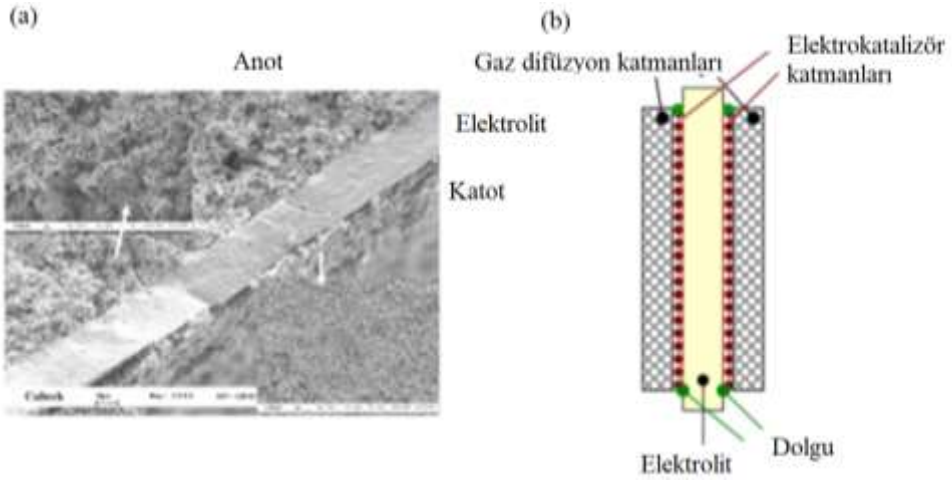
$$2H_2 + O_2 \Rightarrow 2H_2O \quad (3)$$

Bir hücreden üretilen voltaj, yakıt hücresinin çalışma koşullarına ve yakıt hücresine bağlı yükün boyutuna bağlı olarak 0 ile 1volt arasındadır. Yakıt hücresi voltajının tipik değeri yaklaşık 0,7 volttur. Daha yüksek voltaj elde etmek için birden fazla hücre seri olarak bağlanır. (Larminie, Dicks, 2000).



Şekil 1. Bir elektrolit, bir anot ve bir katottan oluşan bir yakıt hücresinin şeması (Haile, 2003)

Polimer Elektrolit Membranda membran, katalizör tabakaları (yani anot, katot) ve gaz difüzyon katmanlarının düzeneği bulunmaktadır. Katalizör katmanları, anot ve katot mevcuttur. Anot, platin katalizör hidrojen moleküllerinin protonlara ve elektronlara bölünmesini sağlar. Katot ise platin katalizör, anodun ürettiği protonlarla reaksiyona girerek su üretmektedir. Gaz difüzyon katmanları, suyu dışarıya çıkartır ve reaksiyona giren maddelerin içeriye taşımaktadır.



Şekil 2. Membran elektrot montajı (a) laboratuvarda elde edilen tipik bir yakıt hücresi yapısının taramalı elektron mikrografı; (b) gaz difüzyon katmanlarının ek olarak dahil edildiği bir PEM yapısının şeması (Haile, 2003)

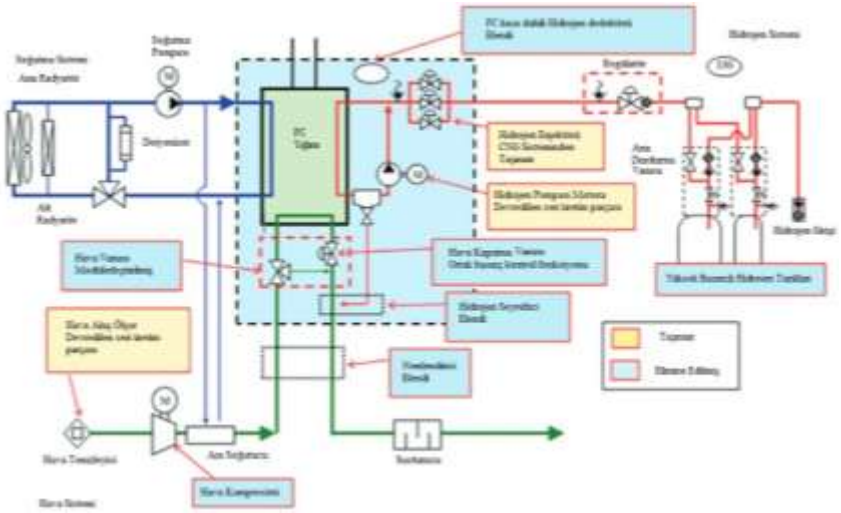
2. FCEV ARAÇLARDAKİ BAŞLICA SİSTEMLER VE BU SİSTEMLERİN GÖREVLERİ

Yakıt pili teknolojisi uygulanan araçlarda kullanılan bileşenler ve bu bileşenlerin araca yerleşimleri geleneksel içten yanmalı araçlardan farklılık göstermektedir. Bu araçlarda içten yanmalı araçlarda olmayan yakıt hücresi yığını, hidrojen

tankları, batarya ve batarya yönetim sistemleri, nemlendiriciler, akım dönüştürücü, yakıt işlemcisi, güç şartlandırması, hava kompresörleri gibi bileşenler de yer almaktadır.

Yakıt hücresi kümesi, üretilen voltajı yükseltmek için hücreleri seri olarak bir yakıt hücresi kümesi halinde birleştirilmektedir. Çünkü bir yakıt hücresi 1 V'tan daha az voltaj üretir. Yakıt tankı, hidrojeni depolamak için kompozit malzemeden yaklaşık 700 bar basınca dayanabilen tanklar üretilmiştir. Hidrojeni tank içerisinde sıvı halde tutar. Tank ağırlığı ortalama 5 kg civarındadır. Hidrojen tankları aracın menzilini belirleyen en önemli bileşendir. Büyük hacme sahip olan bu tanklar dışarıdan gelecek darbelere karşı korunuyor olması ve içerisindeki yüksek basınca dayanıklı olması oldukça önemlidir. Yakıt işlemcisi, yakıtı yakıt hücresi tarafından kullanılabilen bir forma dönüştürmektedir. Güç şartlandırması, ihtiyaçları karşılamak için akımın, voltajın ve frekansın kontrol edilmesini sağlamaktadır. Bu işlem sistem verimliliğini % 2-6 oranında azaltır. Hava kompresörleri sayesinde sisteme atmosferden hava sağlanır ve reaksiyon gerçekleşir. Hava kompresörleri, giriş havasının basıncını ortam atmosfer basıncının 2-4 katına yükselterek verimi arttırmaktadır. Nemlendiriciler ise sistemin kuru kalmasını engelleyerek verimi arttırmaya destek olmaktadır. Reaksiyon sonucunda oluşan elektrik dönüştürücü ile elektrik motoruna gönderilir. Yakıt hücresi yığını içerisindeki tepkimenin sonucunda su ve ısı enerjisi oluşmaktadır. Soğutma fanı aracılığıyla tepkime sırasında oluşan sıcaklık düşürülmektedir.

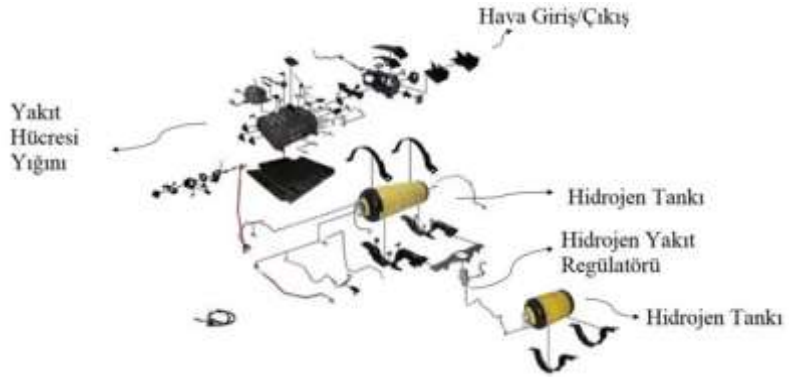
Yakıt hücreli araçlardaki başlıca sistemler ve bu sistemlerin görevleri Şekil 3'te gösterilmiştir.



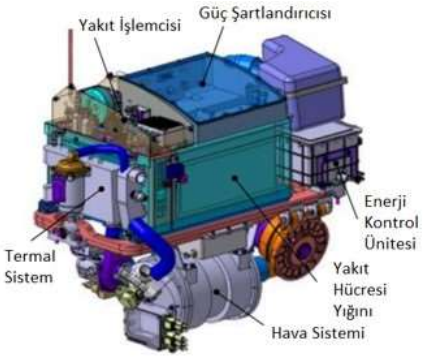
Şekil 3. Toyota Mirai'de yakıt hücresi sisteminin konfigürasyonu (Nonobea, 2016)

2.1. Yakıt Hücresi Yığını

Yakıt hücresi tek başına düşük voltaj üretmektedir. Bu değer 1 volt civarındadır ve araç için yetersizdir. Üretilen voltaj değerini yükseltmek için ayrı yakıt hücreleri seri olarak bir yakıt hücresi kümesi halinde birleştirmektedir. Proton Değişimli Membran tipi yakıt hücresi kullanılmıştır. Proton değişimli membran, yüksek güç yoğunluğu sağlamakta ve diğer yakıt hücrelerine kıyasla düşük ağırlık ve hacim avantajları vardır. Hızlı başlatma süreleri ve uygun güç-ağırlık oranları nedeniyle, otomobiller ve otobüsler gibi binek araçlarda kullanım için uygundur. 45 kW toplam gücü vardır ve orta güç mimarisi için optimize edilmiş güç çıkışı sağlamaktadır.



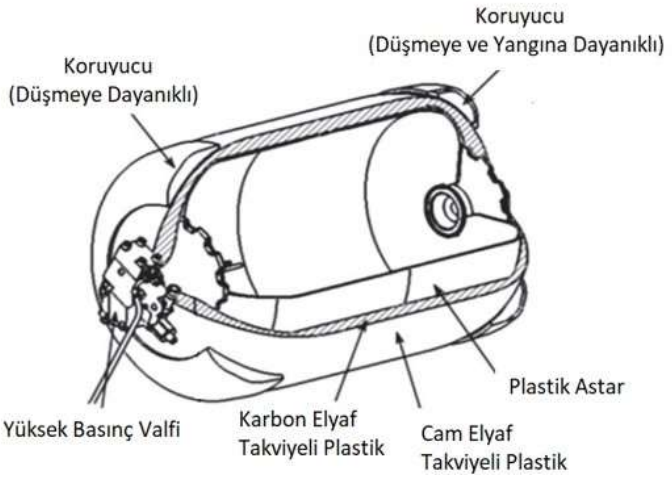
Şekil 4. Araç, yakıt hücresi konfigürasyonu (URL1)



Şekil 5. Hyundai ix35'in yakıt hücresi kümesi ve diğer sistemleri (URL3)

2.2. Hidrojen Tankı

Hidrojeni araç içerisinde güvenilir bir şekilde depo edilmesini sağlamaktadır. İçerisinde sıvı halde hidrojen bulunmaktadır. Ağırlığı yaklaşık 4,4 kilogram ve 700 bar basınca dayanıklı kompozit malzemeden üretilmiştir. Araçların büyük bir kısmında yüksek basınç altında sıkıştırılan hidrojenin kullanıldığı görülmektedir. Hidrojenin 350-700 bar altında depolandığı tankların imalatı oldukça güçtür. Yüksek basınca dayanıklı hidrojen tanklarının genel olarak yapıları; iç bir metal malzeme ve üzerinde düz veya helisel tipte çoğunlukla karbon fiber takviye tabakalarından oluşmaktadır (URL2).



Şekil 6. Yüksek basınçlı hidrojen tankının yapısı (Nonobea, 2016)

2.3. Batarya

Hidrojen enerjisinden elde edilen elektiriğin depolanmasını sağlar. Aracın ilk hareketinde, hızlanma durumunda ve fren anında bataryadan faydalanılmaktadır. Lityum İyon piller kullanılmıştır. Batarya değerleri 10,5 kWh ve 90 kW'a kadar güç üretmektedir. Araç üzerinde genellikle orta taban üzerinde bulunmaktadır. Araç seyir halindeyken yakıt piline destek olmaktadır.

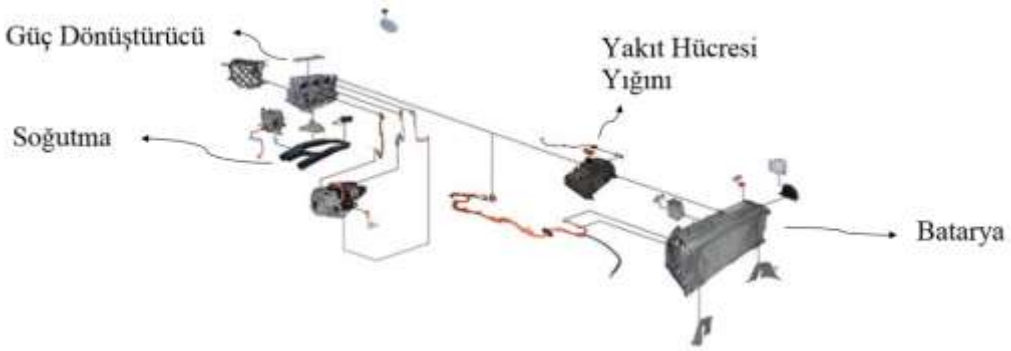
Şekil 7. Stellantis, batarya (URL4)

2.4. Enerji Kontrol Ünitesi

Aracın beyni görevindedir ve sistemin çalışmasını denetlenmektedir. Sistemin kontrollü bir şekilde çalışmasını sağlamaktadır. Yakıt pili ve elektrik motoru arasında bulunan güç elektroniği devresi, gerilim değerinin yükseltilmesi için doğru akım motorlarında DC/DC çeviriciye, Alternatif akım motorlarında ise DC/AC çeviriciye ihtiyaç duyulur. Ayrıca kontrol için mikroişlemci/dijital sinyal işlemcisine, aşırı yükleme şartları ve rejeneratif frenleme için batarya depolama sistemineihtiyaç duyulmaktadır (Şenol, Üçgül, Acar, 2006).

2.5. Güç Şartlandırıcısı

Uygulamadaki akımın, voltajın, frekansın ve elektrik akımının diğer özelliklerini kontrol etmektedir. Yakıt pilinde üretilen elektrik doğru akımdır ve AC/DC çeviriciler doğru akımı alternatif akıma çevirmektedirler. Oluşturulan akımı elektrik motoruna aktarmaktadırlar. Ancak dönüştürme ve koşullandırma system için verimli değildir. Güç şartlandırıcısı, sistem verimliliğini yaklaşık % 2-6 oranında azaltmaktadır. Aracın güvenliği için önemli komponentlerder birisidir.



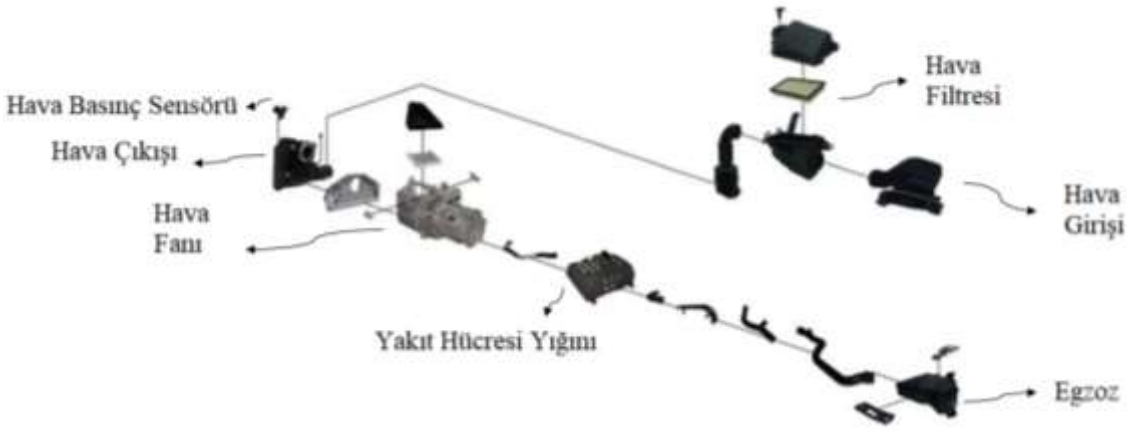
Şekil 8. Araç, güç sistemi konfigürasyonu (URL1)

2.6. Yakıt İşlemcisi

Yakıtı, yakıt hücresi tarafından kullanılabilen bir forma dönüştürmektedir. Hidrojen tankından alınan hidrojeni yakıt piline göndermektedir. Aracın seyir halindeki durumuna bağlı olarak yakıt işlemcisi çalışma durumu değişebilmektedir. Yakıt pili yığınının gerekli hidrojen ihtiyacını sağlamaktadır. Yakıt hücresine kullanılabilir formda hidrojen temin etmektedir.

2.7. Hava Kompresörleri

Optimum oksijen beslemesi için yığına uygun basınç ve miktarda hava sağlamaktadır. Yakıt hücresi sissteminin daha sağlıklı ve verimli çalışması için önemlidir. Yakıt hücresinin performansı reaktif gazların basıncı arttıkça yükselmektedir. Bu nedenle yakıt hücresi sistemi, giriş havasının basıncını ortam atmosfer basıncının 2-4 katına yükselten bir hava kompresörü içermektedir.



Şekil 9. Araç, hava sistemi konfigürasyonu (URL1)

2.8. Nemlendiriciler

Hidrojen yakıt piline doğru giderken verimin artması için nemlendirici tarafından nemlendirildikten sonra yakıt piline gönderilmektedir. Yakıt hücresinin merkezindeki polimer elektrolit membran kuru olduğunda performansı azalmaktadır. Bu nedenle yakıt hücresi sistemi giriş havası için bir nemlendirici içermektedir. Nemlendiriciler, yakıt hücresi sissteminin daha sağlıklı ve verimli çalışması için önemlidir. Gazların nemlendirilmesinin performansa olumlu etki yapmaktadır, fakat nemlendirme miktarının aşırı artmasıyla performansın azalmaya başlamaktadır. Artan nemlendirmenin hücre kanalları içinde biriken su miktarını arttırmaktadır ve bu birikme dolayısıyla reaktant gazların gaz difüzyon tabakasından geçişi zorlanmaktadır ve aktif alana ulaşamayıp performansın düşürmektedir (Kahraman, Çevik, Coşman).

3. YAKIT HÜCRELİ ELEKTRİKLİ ARAÇLARIN (FCEV) KARŞILAŞTIRMASI

3.1. Araçların Teknik Özelliklerinin Karşılaştırması

Araç üreticilerinin ağırlıklı olarak ağır ticari araçlarda uyguladığı bu sistem günümüzde hafif ticari araçlar ve binek araçlarda da uygulanmaya başlanmıştır. Aşağıdaki tabloda Toyota, Hyundai, Honda, Mercedes ve Stellantis gibi üreticilerin yakıt hücre uygulaması yapılmış binek araçlarına ait teknik veriler karşılaştırılmıştır.

Tablo 2. Teknik özellik karşılaştırma tablosu

Marka, Model	Toyota, Mirai	Hyundai ix35	Honda Clarity	Hyundai Nexo	Mercedes-Benz GLC F-CELL	Stellantis
Ağırlık	1.850 kg	1.900 kg	1.875 kg	1.850 kg	2.149 kg	1.952 kg

3.2. Araçların Mimari Özelliklerinin Karşılaştırması

Otomobil üreticilerin kullanmış oldukları mimari çözümlere göre yakıt hücresi, batarya ve hidrojen tankı yerleşimleri farklılık göstermektedir. Bu çalışmada Toyota, Hyundai, Honda, Mercedes ve Stellantis gibi önemli otomobil üreticilerinin yakıt hücreli araç mimari çözümleri incelenmiştir. Hidrojen tankı, batarya ve yakıt hücresi yığınının diğer bileşenlere göre daha büyük hacime sahip olması bu bileşenleri araç mimarisini belirleyici kılmaktadır.
Tank yerleşimi için diğer bileşenlere göre daha fazla alan ihtiyacı olduğu için araç orta taban altı ve arka taban altı tank yerleşimi için kullanılmaktadır. Hidrojen tankı 1, 2 veya 3 adet toplamda 150 litre olabilmektedir. Batarya için kabin içinde ön koltuk altı ve yük taşıma bölgesi kullanılırken taban altında ise orta ve arka alanlar kullanılmaktadır. Yakıt hücresi yığını ise tüm üreticiler tarafından motor boşluğunda konumlandırılmaktadır. Tablo 3'te güncel yakıt hücresi teknolojisine sahip araçların mimari özellikleri karşılaştırılmış. Proje aracı için optimum mimari çözüm belirlenmiştir.

Tablo 3. Mimari özelliklerinin karşılaştırma tablosu

Marka Model	Toyota, Mirai	Hyundai ix35	Honda Clarity	Hyundai Nexo	Mercedes-Benz GLC F-CELL	Stellantis
Yakıt Hücresi Konumu	Motor Boşluğu	Motor Boşluğu	Motor Boşluğu	Motor Boşluğu	Motor Boşluğu	Motor Boşluğu
Hidrojen	Orta Taban	Orta ve	Orta ve	Orta ve	Orta Taban	Orta Taban

Tankı Konumu	Altı	Arka Taban Altı	Arka Taban Altı	Arka Taban Altı	Altı	Altı
Batarya Konumu	Arka Taban Altı	Orta Taban Altı	Orta Taban Altı	Araç Bagaj Bölümünde	Araç Bagaj Bölümünde	Kabin içi Ön Koltuk Altında

4. SONUÇLAR

Bu çalışmada farklı otomobil üreticilerinin sahip olduğu yakıt hücreli araçlarda kullanılan bileşenlerin teknik özellikleri incelenmiş ve bileşenlerin araç üzerindeki konumları araç mimarisi açısından değerlendirilmiştir. Yakıt hücreli araçlarda içten yanmalı araçlarda olmayan yakıt hücresi yığını, hidrojen tankları, batarya ve batarya yönetim sistemleri, nemlendiriciler, akım dönüştürücü, yakıt işlemcisi, güç şartlandırması, hava kompresörleri yer almaktadır.
İncelenen araçlarda kullanılan komponentlerin kapasitelerine bağlı oalrak 400-645km aralığında menzile ulaşılabilmektedir. Araçlarda menzili belirleyen en önemli bileşen olan hidrojen tanklarının kapasiteleri incelendiğinde 700bar basınç altında 110 ila 156 litre aralığında tankların tercih edildiği görülmektedir. Bu yakıt hücreli binek araçların tümünde 45kW-155kW PEM yakıt hücresi yığını tercih edildiği görülmüştür.

Hacimsel özelliklerine bağlı olarak yakıt hücreli araçların mimarisini belirleyen üç ana bileşen bulunmaktadır. Hidrojen tankı, yakıt hücresi yığını ve bataryanın araç mimarisi etkisi aşağıda verilmiştir.

- Hidrojen tankları, büyük boyutları nedeniyle araç mimarisine en çok etki eden komponentdir. Silindirik yapıları ve büyük boyutları nedeniyle genel olarak araç orta ve arka tabanaltında konumlandırılmıştır. Bazı örneklerde bagaj bölgesine pozisyonlandığı görülse de, aracın yük taşıma kapasitesi ve bagaj hacminin kullanılıyor olması nedeniyle kullanıcılar için dezavantaj teşkil etmektedir. Bagaj hacmi önemli bir satınalma kriteri olduğu için yeni nesil uygulamalarda bagaj hacmine etki negatif etki etmeyecek yerleşim çözümleri oluşturulmuştur.

- Yakıt hücresi yığını genel olarak araç motor boşluğunda yer almaktadır. Incelenen araçların tamamında motor boşluğunda konumlandırıldığı görülmüştür. Yakıt hüreli araçlarda içten yanmalı motor bulunmadığı için motor boşluğu bölgesinde yakıt hücresi yığını ve ilave bileşenleri için ideal bir yerleşim alanı bulunmaktadır. Yakıt hücresi yığını ile birlikte yakıt işlemcisi, güç şartlandırıcı, enerji kontrol ünitesi ve kompresor gibi diğer bileşenlerle paket halinde motor boşluğuna entegre edilmiştir.

- Tam elektrikli araçlarda batarya paketleri yerleşimi araç taban altına yapılmakta ve batrya yerleşimi araç mimari platformunu önemli derecede etkilemektedir. Yakıt hücreli araç uygulamalarında kullanılan batarya boyutları daha küçük olduğu araç kabin içi ve taban altında farklı bölgelere entegre edilebilmektedir. İncelenen 6 farklı yakıt hücreli araç mimarisinde araç orta taban, araç arka taban altı , kabin içi koltuk altı ve bagaj bölgesine batarya yerleşimi yapıldığı görülmüştür.

ABSTRACT

Virtual platforms emerged to test automated driving systems to ensure safety and reliability with reduced risk, time and effort. Co-simulation platforms are one of the most promising ones that enable automotive manufacturers to reach their ambitious targets. One of the main challenges acknowledged by the automotive industry related to L3 and L4 vehicles is the control authority transition between the driver and the vehicle, which is referred to as "hand-over." These vehicles require the driver to take control back under some conditions, such as operation design domain boundaries, harsh weather conditions, component/system failure or on the driver's request. In this context, the paper presents the design of a co-simulation platform for a L3 Autonomous Vehicle to test the hand-over functionality. Considering the daily operations of a door-to-door delivery van, a most commonly faced driving situation that can trigger hand-over is generated. To ensure the high-fidelity and robustness of the developed algorithms, the co-simulation platform is built with dSPACE ASM® and MATLAB/Simulink®. To manage the complexity of autonomous systems and enable the re-usability of the block inputs are defined as general-purpose input/output while the system is decomposed into smaller subsystems. This enables the development of autonomous driving functions with reduced time and effort by enabling the reusability of sub-models as well as model exchange between suppliers and automotive manufacturers. The results have shown that the developed platform can be used to generate realistic scenarios, performing numerous virtual tests, and evaluating the effectiveness of the functions prior to the real-world tests.

Keywords: Co-simulation platform, Level 3 Autonomous Vehicle, Hand-Over, Control Authority Transition, Modular, Door-to-door Delivery

1. INTRODUCTION

The world of autonomous driving (AD) has been evolving for decades as research entities and automotive manufacturers are interested in developing safe and intelligent vehicles [1]. That is due to the fact that self-driving technologies can dramatically reduce road traffic accident causalities by taking the driver out of the loop [2]. High precision sensors and high process capabilities enable them to detect the obstacles earlier with reduced reaction time than a human driver [3].

Since driving in a changing environment is a complex dynamic control task, taking the driver out of the loop partially/fully is a real challenge. Therefore, these disruptive technological products should undergo rigorous testing before they are deployed. Specifically, for the SAE levels 3 and 4, where the driver and vehicle have shared responsibility, the number of required functions (e.g. shared control, hand-over), unit test and test cases change radically from regular vehicle tests [4]. This brings safety concerns and makes the development, validation and verification process a real challenge. Level 2 + vehicle development requires many hundreds of millions of kilometres of testing [26]. Unfortunately, in real world there are infinite number of possibilities that the AD system can come across either to avoid or minimize its negative impact on road actors. Performing tests for all possible scenarios either on a test bench or vehicle itself requires both time and resources. These can only be achieved through X-in-the Loop (XiL) platforms e.g. SiL: Software-in-the Loop, HiL: Hardware-in-the Loop, DiL: Driver-in-the Loop. These platforms enable developers to design, configure, visualize virtual environments, in which vehicle models can be evaluated and validated in nearly any possible condition of operation with/without hardware. Moreover, the conditions can be varied without waiting and the vehicle can be tested in critical cases without any risk. To test and validate AD systems different approaches and test

platforms are developed and used. Co-simulation platforms, supporting the model exchange between suppliers and OEMs, is one of these, which have started to play more crucial role than ever before.

In the literature, there have been several studies carried out using on co-simulation platforms to design and test AD algorithms. The software that have been jointly used to build these platforms are given in Table 1. It should be also noted that more than two softwares can also be used based on the needs and requirements.

Table 1. Software platforms used in co-simulation for the development and testing of embedded systems

SW1	SW2	Ref.

SW1: First software, SW2: Second software

Each platform has its own benefits. Nevertheless, usually MATLAB/Simulink is the first preference of the automotive industry and research institutions. That is mainly due to the fact that it is a multi-domain simulation and model-based programming environment. It also allows rapid prototyping by C/C++ code generation. Furthermore, a functional mock-up interface (FMI) to transfer variables among different programs, ability to import and run HD Map data and OpenDRIVE road networks, makes it a suitable platform for the development and testing of ADAS /AD systems [22-24].

In [6] MATLAB-IPG CarMaker co-simulation platform is used to develop and validate the trajectory planning for autonomous high-speed overtaking in structured environments using robust MPC. Actual plant model used to test the controller is the in-built vehicle model of IPG CarMaker.

Similarly, in [22] MATLAB together with IPG CarMaker and PTV Vissim are used to build a co-simulation platform to generate realistic scenarios for testing of AD functions. Highway Chauffeur functionality is presented to demonstrate the effectiveness of the platform.

A stress testing method to increase and obtain critical scenarios in a complex co-simulation by combining Matlab/SIMULINK, IPG CarMaker and PTV Vissim is mentioned by [9]. Also, TFSS is used to generate microscopic traffic flow. Based on real statistical data, two common accident types of scenarios are extracted and used for the mentioned method. Two simulations pass 5000 kilometers.

Various simulation software and modelling tools are described by [16]. Also, co-simulations between CarSim – Simulink and IPG CarMaker – Matlab/Simulink are given as examples. In addition, components of an autonomous-capable electrified vehicle virtual simulation model are added. IPG CarMaker is used to simulate different test cases. The cases are related to Adaptive Cruise Control (ACC) and Automated Emergency Braking (AEB).

IPG CarMaker is an open integration and test platform for Model-Based Designing, testing, and developing vehicle control systems like ABS or ESP, ACC, etc., and all-wheel drive and engine control systems. It can be integrated with Matlab/Simulink quickly due to S-functions, MATLAB, and Simulink API functions added CarMaker features to the Simulink environment. The significant advantage is between Carmaker and Simulink in co-simulation that Simulink blocks can be connected to the CarMaker vehicle platform. The CarMaker blocks are related in the same manner as other Simulink blocks. For simulation control and parameter adjustments and defining manoeuvres and road configurations, CarMaker uses IPGControl under the Graphical User Interface. IPG Control can also be used for data analysis and graphing and a multibody vehicle model that can also be animated and rendered realistically.

[8] Also, the controller considers the vehicle dynamic stability. Overall architecture for path tracking is given in a figure. CarSim – Matlab/Simulink co-simulations are used to compare the proposed controller with the pure-pursuit controller and the classical MPC controller. Actual plant which used in the simulations is a vehicle model from CarSim.

An MPC scheme for in-wheel AV is presented in [10]. Numerical results obtained from CarSim-Simulink co-simulation platform is used to show superiority and effectuality of the proposed method in normal and extreme driving conditions. A weight adaptive mechanism is added to be sure that the controller can handle extreme driving conditions. An automated steering controller based on MPC is proposed by [13]. Again, co-simulation of MATLAB/Simulink is used to validate the controller. D-class Sedan full vehicle is selected from CarSim to be controlled autonomously. The control algorithm is created in MATLAB/Simulink. Also, real-bus experiments are performed and analysed.

A co-simulation platform to test and develop vehicle eco-autonomous driving technologies is proposed by [14]. The platform consists of a traffic environment simulator, eco-autonomous driving software and powertrain and vehicle dynamics model. The traffic environment simulator can generate virtual sensors and traffic environments. Synthetic drive cycles obtained from real-world is used to test the strategies. The co-simulation architecture is given in a figure.

A paper related to power consumption of unmanned road vehicle is presented by [19]. A real-time dynamic vehicle simulator, SCANeR Studio© is co-simulated with MATLAB/Simulink. A comparison between various scenarios of plotting are validated with experiments and through the co-simulation platform.

In [21], a co-simulation survey is made for the state of art technics. Discrete-event-based co-simulation and continuous-time-based co-simulation are focused.

A high-fidelity co-simulation platform to investigate the motion and control of a vehicle platooning system is presented by [26]. This co-simulation platform consists of ADAMS and MATLAB/SIMULINK. The platooning dynamics with multiple vehicles is modelled with ADAMS and non-linear tracking controller is modelled and created in SIMULINK. In the presented co-simulation platform, SIMULINK is the master and the ADAMS is the slave.

In [29] design and implementation of a co-simulation platform to test the AD functions for several scenarios was described that was built on IPG CarMaker, PTV Vissim and MATLAB/Simulink. IPG CM is mainly used for the vehicle model. In [32] Matlab-CarSim co-simulation platform was used to evaluate two-different trajectory planning (TP) algorithms for a cooperative collision-avoidance scenario. Similar to previous work, CarSim was used due to its high-fidelity multibody vehicle dynamics model, whereas Matlab/Simulink was used to implement the TP algorithms.

Even though, the benefit of the co-simulation platforms is clear to automotive manufacturers and technology providers, the number of papers that describes the basic building blocks of these platforms are very limited. Furthermore, there is no publication on building co-simulation platforms for L3AVs, which is expected to hit the roads earlier than full (Level 5) autonomous vehicles. In this context, the aim of this paper, is to introduce a Level 3 AV co-simulation framework mainly to test the handover functionality to assess the performance of the shared responsibility between the driver and the vehicle as well as to develop safety critical test scenarios.

The rest of the paper is organized as follows: in Section 2, vehicle automation and related taxonomy are given. In Section 3, co-simulation platform based on dSPACE ASM and MATLAB is described. In Section 4, implementation method is explained, in Section 5, simulation results were presented for a hand over use case to highlight the advantages and to demonstrate the simulation performance of the proposed platform; and finally conclusion and key findings are presented in Section 6.

2. VEHICLE AUTOMATION AND RELATED TAXONOMY

Different levels of automation have been defined and introduced into the literature. In this paper classification of Society of Automotive Engineers (SAE) International Standard -J30162 is used, as it is the most commonly accepted both by industry and academia. Table 2 shows 6 levels of automated driving (AD) based on control distribution among the human driver, and the AD system. With the increased levels of autonomy, the dependence on the driver is reduced to that of a supervisory role.

Table 2: Vehicle automation based on SAE J30161

Automation Levels	Vehicle Function
 Level 0	No Automation. Human driver has the full responsibility.
 Level 1	Driver Assistance. Automation assist the driver and performs either longitudinal or lateral vehicle motion control, but not complete object and event detection and response (OEDR).
 Level 2	Partial Automation. An automated system can perform some parts of driving, while the human driver continues to monitor the driving environment and performs most of the driving (not complete OEDR)
 Level 3	Conditional Automation. Automation performs the complete dynamic driving task (DDT), but not DDT fallback, within a limited operational design domain (ODD). The human driver must be ready to take back control if necessary.
 Level 4	High Automation. An automated system performs the driving and monitors the environment (Complete DDT)
 Level 5	Full Automation. The automated system performs all driving tasks, under all conditions. Complete DDT and DDT fallback without ODD limitation.

3. CO-SIMULATION PLATFORM

The co-simulation block diagram is shown in Figure 1. Components with different functionality built in different platforms are brought together through interfaces to co-simulate the L3AD system. The blue block are models simulated using dSPACE ASM. The environment block is used to represent the surrounding obstacles and boundaries, whereas the vehicle model defines the dynamics of the vehicle considering the tire dynamics. The vehicle model parameters is given in Table 3.

Table 3. Vehicle parameters

Parameter	Value
Length of the car	4756 mm
Front overhang of the car	911 mm
Rear overhang of the car	740 mm
Wheelbase	3105 mm
Width	2180 mm
Trackwidth	1530 mm
Steering angle range (representative)	(-35°- +35°)

Sensors are modelled in dSPACE ASM and their data are given to the sensor fusion model. The latter, implemented with MATLAB/Simulink functions, first gathers data from all sensors and fuse them by preforming identification, interpretation and processing. Finally, it gives, as output signals, required information on the state of the vehicle the surrounding road and obstacles in the environment to the trajectory planner interface.

MATLAB/Simulink functions are used to simulate the other main components of L3AD systems. As seen in Figure 1, those components are handover switch in purple and trajectory planner and controller. Given the inputs of surroundings from the perception model, the trajectory planner interface first makes calculations on the signals at its inputs to provide the trajectory planner with the required data. Trajectory Planner model generates a safe and adequate reference trajectory considering the vehicle dynamics. The Trajectory Controller uses the generated trajectory to provide the required longitudinal and lateral control signals for the vehicle to follow. Finally, to implement the flow of control over the vehicle in L3AD, a handover switch block is dedicated to monitor potential faults and malfunctioning of other blocks. This block switches the control from the driver to the Automated Driving System (ADS) and vice-versa.

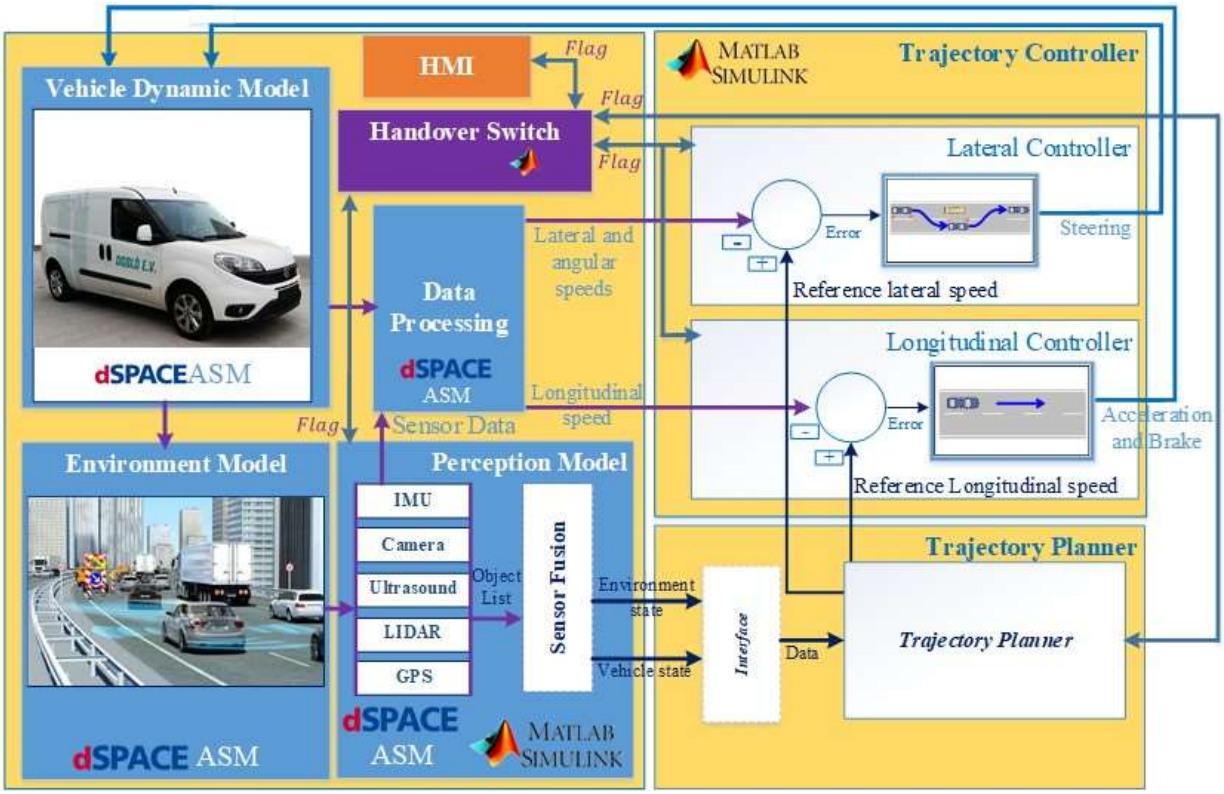

Figure 1: Co-simulation platform high level block diagram

dSpace ASM is a tool suite provides comprehensive simulation solutions for four applications areas which are combustion engines, electric components, vehicle dynamics and traffic environment. ASM platform provides a comprehensive traffic model with vehicle dynamics, road users and environmental objects. Various sensor models in simulated test vehicle detect the other road users and static and dynamic objects in the virtual environment. Platform gives flexibility on simulating road network, complex scenarios and traffic manoeuvres using graphical parameterization tools with preview and clear visualization. Moreover, in system blocks it is easy to supplement or replace components with customer specific models for developing and testing automated driving systems since the implementation of each model is open and traceable right down to the Simulink basic block level. Considering these features, autonomous driving framework is implemented to dSPACE ASM platform. In ASM platform, the main model structure, shown in Figure 2, consists of Soft-ECU, power-train, vehicle dynamics and environment models.

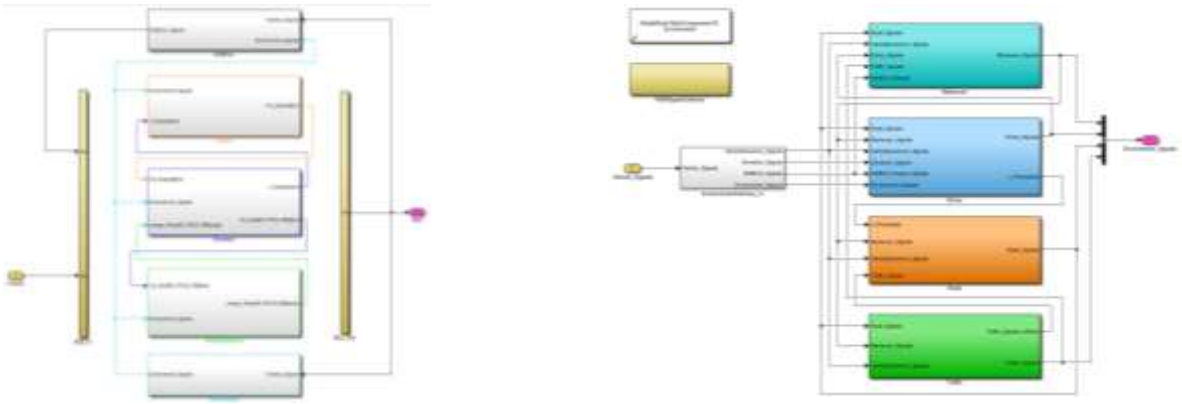

Figure 2: a.) MDL Main Block b.) Environment Blocks

To realize the co-simulation framework on virtual environment, the vehicle is represented virtually by its vehicle dynamic parametrization in the dSpace ASM environment model. Low speed maneuver will be required to pass through static or dynamic objects, the co-simulation block diagram can be seen in Figure 3. Furthermore, this model is active with soft controller in Matlab/Simulink platform. Additionally, the perception model will be created within virtual simulation platform and provides the required signals to the e-ATP trajectory interface. The blocks in colour are from ASM dSpace high-fidelity software and they are used to simulate the vehicle. The grey block is from the Matlab/Simulink platforms.

The blocks are highlighted in different colours. Perception model in blue, behavioural planner and trajectory planner in yellow and longitudinal and lateral controller blocks are in red.

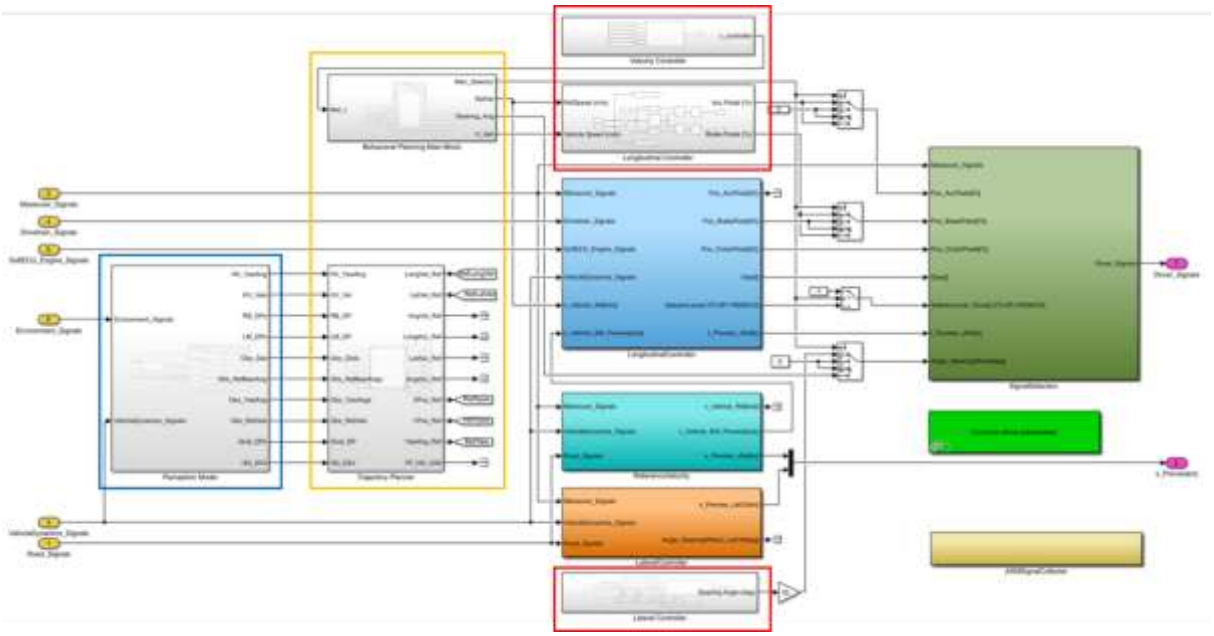

Figure 3: ASM Driver block (Blue: Perception, Yellow: Planning, Red: Controller Blocks)

4. SIMULATION RESULTS

Handover functionality is necessary for L3AD system. It is the phase where the control over the vehicle is transferred between the driver and the L3AD system. In this section, a Handover scenario is built using dSpace ASM and co-simulated. The effectiveness of the co-simulation method proposed in Section 3 is then evaluated.

The ego vehicle is expected to set on a handover flag and give the control back to driver after a fixed time. This is particularly the case when the trajectory planner or the controllers face an unexpected situation that they cannot handle. In those situations, the vehicle is expected to handover the control to driver. An example to these unexpected situations could be a truck blocking the road as seen in Figure 4.

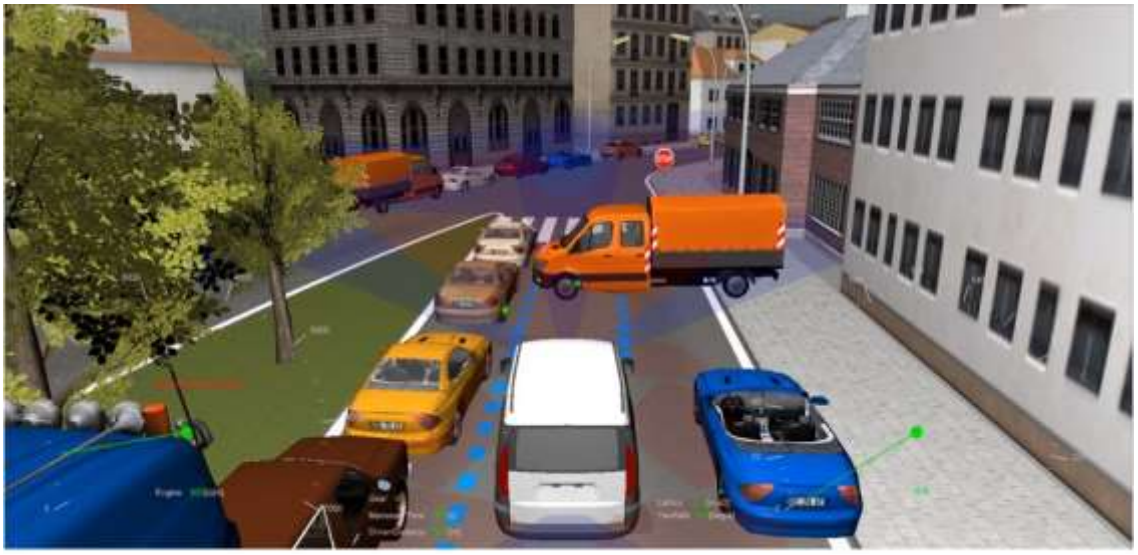

Figure 4: Hand Over Scenario

Decision logic is implemented to decide when the manual driving mode should be activated and the control should be taken from the ADS and given to the driver.

The block is situated in the behavioural planner block of the proposed co-simulation diagram seen in Figure 1. Accordingly it decides which driving mode should be activated and if the control over the vehicle should be shifted between the ADS and the driver. There are two driving modes in a L3AD system; Autonomous Driving and Human Driving. In the Autonomous Driving mode, the ADS to perform manoeuvres autonomously. However, in Human Driving mode, the driver is having control over the vehicle.

A flag $\mathcal{F}_{ADS,h}$ is used by one or more co-simulation blocks, namely the perception, trajectory planning and trajectory control, to signal to the Switch its malfunctioning. In this case, one of the ADS components has either fault or reached its defined limits. If the Switch receives a flag signal from any of those components, $\mathcal{F}_{ADS,h}$ is sent to the HMI to display a warning for the driver. Then, the trajectory controller releases the control of the actuators for the driver to take over. In the Human Driving mode, the Handover Switch sends the flag $\mathcal{F}_{ADS,h}$, which has the value 1, to all components to prevent them from functioning. This will help in reducing the computational cost and thus the overall energy consumption. However, in the Autonomous mode, the $\mathcal{F}_{ADS,h}$ is set to 0, and all components function again to guide the vehicle autonomously.

The equation of $\mathcal{F}_{ADS,h}$ can be written as

$$\mathcal{F}_{ADS,h} = \bigvee_{i} \mathcal{F}_i \; ; \; i = \{P, Tp, Tc, \mathcal{H}\} \qquad [1]$$

Where $\mathcal{F}_P$ is the flag raised by the perception, $\mathcal{F}_{Tp}$ is the flag raised by the trajectory planning, $\mathcal{F}_{Tc}$ is the flag raised by the trajectory control and $\mathcal{F}_{\mathcal{H}}$ is the flag raised by the HMI. Each of these flags has a binary value and one or more flags can set $\mathcal{F}_{ADS,h}$ to 1 with an equal priority. It is assumed that the HMI can take commands from the driver to change the driving mode. If the HMI receives a command from the driver to take control of the vehicle at any time during the operation of the ADS, the HMI block set $\mathcal{F}_{\mathcal{H}}$ to 1. On the contrary, the driver could decide to start the autonomous mode on the HMI and $\mathcal{F}_{\mathcal{H}}$ is set to 0. If there is no malfunction in any of the ADS components, then $\mathcal{F}_{ADS,h}$ is set to 0 and the ADS takes control of the vehicle.

In the case of the driver having control of the vehicle, $\mathcal{F}_{ADS,h}$ is set to 1, the Handover Switch sends this flags to all components . This will avoid having the ADS components , namely the perception, trajectory planning and trajectory control, from functioning while in Manual Driving.

The vehicle goes through three stages to perform a Handover. Those stages are Autonomous Driving, Hand Over to Driver, and Human Driving. The Hand Over to Driver stage is used to represent the Handover process to transfer the

control from the vehicle to the driver. The stages are demonstrated on the vehicle dashboard. During simulation, the dSpace ASM tool named MotionDesk is used to animate the scenario and the dashboard, as seen in Figure 5-7. The three described stages are shown in three different colours to highlight when each stage starts.

Figure 5: Autonomous Driving Mode

In the co-simulated Handover scenario, the vehicle starts with the autonomous driving stage to navigate in an urban street as seen in Figure 5. If the vehicle is faced with a delivery truck blocking the street, the ADS stops the vehicle to avoid the collision. A decision period is started by the ADS to assess if the situation is changed or a handover is necessary. If the truck moves away, the trajectory planner is able to find a trajectory so that the vehicle can continue ahead along the street with autonomous driving. However, if it does not move, $\mathcal{F}_{Tp}$ is raised by the planner from 0 to 1. Consequently, the handover flag $\mathcal{F}_{ADS,h}$ is raised and the handover process is started. The corresponding stage is shown to the driver on the dashboard as seen in Figure 6.

Figure 6: Hand Over Mode

Once this period has ended the control of the vehicle is transferred to the driver. This is indicated to the driver as in Figure 7.

Figure 7: Manual Mode

The vehicle speed during the handover scenario is shown in Figure 8a. The vehicle starts by accelerating to 5 m/s. Then, it continues navigating through the urban street with around 4.5 m/s speed in autonomous mode. After 6 seconds, the truck obstacle is detected and the distance to it is demonstrated in Figure 8b. The vehicle decelerates when the distance to the truck decreases to a critical threshold, here an arbitrary value for this threshold could be set to 3.5 m. It is worth nothing that a more specific and suitable value could be selected considering standards and vehicle actuation to start decelaration and to stop the vehicle at a safe distance from an obstacle blocking the road. If the vehicle is in a full stop, a timer, seen in Figure 9a, is started at the time 14 seconds for the ADS to make a decision. Here, the timer for the decision is set to 3 seconds. Once the timer has ended and the planner was not able to avoid the truck, the Handover flag $\mathcal{F}_{ADS,h}$ is raised at 18s from 0 to 1, as seen in Figure 9b. Then the timer is set again for the handover process period. This period is set to 4 seconds. After this period, the control is transferred to the driver.

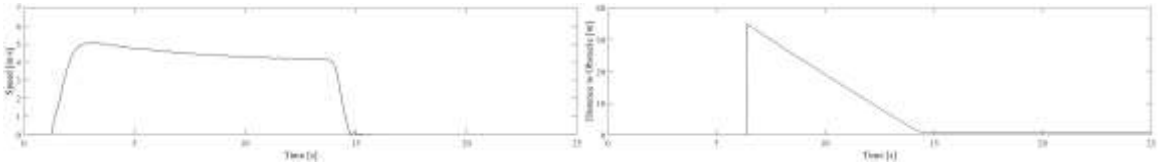

Figure 8: (a.) Speed of the vehicle (b.) Distance to obstacle

5. CONCLUSION

Virtual platforms are indispensable tools to test and validate AD functions. They reduce the number of tests to be done in the real-world and consequently the time and effort. High fidelity co-simulation platforms are one of them. In the design and development process, it is important to ensure the high fidelity, and reusability of the platform completely or partially. This feature enables the model exchange between the suppliers and automotive manufacturers.

In this context, a co-simulation platform aims to test the handover functionality which is an important aspect of Level 3 vehicles is proposed. Proposed platform is based on dSPACE ASM and MATLAB/Simulink, where static and dynamic objects are also integrated to have a more realistic representation of real world traffic. Controller and planner blocks used are designed in Matlab/Simulink, whereas vehicle model used is ASM internal model with the updated vehicle parameters. For visual control of simulation and intuitive model parameterization, ModelDesk® was used. Since the control of the vehicle can be transferred between the driver and the L3AD system according to operating design domain and limits of the functionality, algorithm is designed in a way that it can assess the operating conditions at each instant.

The results have shown that the developed platform can be used to generate realistic scenarios, performing numerous virtual tests. It might be considered as a tool for evaluating the effectiveness of the automated driving functions prior to the real-world tests (Figure 5-9).

ABSTRACT

Studies related to fatigue life prediction go back many years. Because the fatigue life of the engineering material is important for all industries. If material strength is not sufficient under working conditions, this may cause loss of lives and property. It is easy to obtain the fatigue damage under stationary load conditions. However, if the load condition is non-stationary, statistical analysis is required to predict how the load change.

In this study, fatigue damage and life were estimated for notched test specimens under random loading conditions. The results of the shaker test of two different materials, namely aluminum, and steel, were taken as references from the literature. To validate the test results, finite element analyses were performed by using OptiStruct (HyperLife) and Falancs (Simcenter 3D) solvers. Moreover, different damage models were evaluated analytically. For analytical calculation, Python code was generated using formulas of some damage models such as the Dirlik method, Narrow Band approach, Wirsching-Light method, Ortiz and Chen method, and α 0.75 method. In conclusion, results obtained from damage models were evaluated and compared with numerical and physical test results.

Keywords: Fatigue Damage Models, PSD, Vibration Fatigue

1. INTRODUCTION

For many years, determination of the fatigue life has been a significant and difficult problem for engineers, especially for those who design structures such as automobiles, aircraft, bridges, pressure vessels, cranes, etc. Fatigue of engineering materials is commonly regarded as an important deterioration process and a principal mode of failure for various structural and mechanical systems. Although there are no exact figures available, it is believed that between 50 and 90 percent of all mechanical failures in metallic structures are fatigue-related [1].

The fatigue failure of metals is the well-known type of failure that occurs after the repetition of several cycles - from a few to millions - of loads applied to the specimen, or to the component. The simplest fatigue failure everyone can obtain can be produced by the repeated bending of a paper clip made of soft steel. After some reversed cycles (often only five to ten are enough), it will break into two parts. The phenomenon that causes this kind of failure is quite complicated and not yet completely understood in its physical basis, despite studies conducted in recent years and a large investment of researches (laboratories, men, and funds). Breakages due to fatigue are very costly, and many human lives have been lost because of unexpected fatigue failures, or for errors in the fatigue design processes [2].

Throughout their service life, machines, vehicles, and buildings are subjected to loads, the majority of which vary depending on the time in a very complicated manner. These loadings may originate from external excitations such as wind gusts, sea waves, noise, or road roughness, but they may also result from the usage of the structure (e.g., from loading or unloading a container or accelerating a vehicle). In general, all these factors result in a complicated stress distribution at the inner structure of a material that directly affects the fatigue process [1].

Predicting the fatigue damage for structural components subjected to variable loading conditions is a complex issue. The first, simplest, and most widely used method is the linear damage model. This rule is often referred to as Miner's rule (1945). However, in many cases, the linear rule often leads to non-conservative life predictions. The results obtained from this approach do not take the effect of load sequence into account on the accumulation of damage due to

cyclic fatigue loading. Due to the introduction of the linear damage rule many different fatigue damage theories have been proposed to improve the accuracy of fatigue life prediction [3].

The aims of this paper are fatigue damage and life estimation with the power spectral density (PSD) technique and evaluation of some important fatigue damage models in metallic structures. For this study, notched test specimens with two different materials, aluminum, and steel, were analyzed. Vibration fatigue damage values were obtained from two different finite element softwares which are Simcenter 3D and HyperLife. For analytical calculation, generated Python code was used. This generated code includes some important damage model formulations such as the Dirlik method, Narrow Band approach, Wirsching-Light method, Ortiz and Chen method, and α 0.75 method. To obtain the vibration damage value by code, directly the PSD stress curve or the FRF stress curve and applied PSD acceleration are required. This PSD Stress – frequency curve could be obtained from random vibration (RV) analysis via the finite element method. Another way to obtain PSD Stress-frequency curve is to calculate from strain gauges in the physical tests. To evaluate and validate the damage results, shaker table physical test results taken from the literature were used as references [4].

2. RANDOM VIBRATION FATIGUE

RVs are vibrations that can only be described statistically. It is not known when the instantaneous magnitude takes places. Magnitudes are expressed statistically such as standard deviation, mean value [5].

If we give examples of random vibrations in real life;

- Loads on the wheel of a vehicle moving on a rough road
- Earthquake ground motion,
- Ocean wave-length and frequencies
- Wind pressure fluctuations in airplanes and tall buildings
- Acoustic excitation due to rocket and jet engine noise

A typical plot of a randomly varying force, against time, is shown in Figure 1. Although it is possible to plot f(t) for a given time interval, if it has been measured during this interval, it is impossible to predict from this the precise value of f(t) at any value outside the interval. However, the essential features of the process f(t) can be described utilizing statistical concepts. The theory which has been built up to describe these processes is known as random process theory [6].

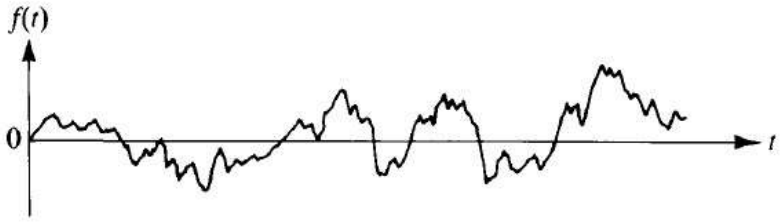

Figure 1. Random vibration curve [6]

2.1. Power Spectral Density (PSD)

The value of this sample gives an overall idea of the severity of the vibration, but the vibration has a continuous frequency spectrum that must be determined to understand its effects on a structure. This frequency analysis is performed using the power spectral density (PSD) which is the ideal tool for describing random vibrations. This spectrum, a basic element for many other treatments, has numerous applications, the first being the calculation of the RMS value of the vibration in a given frequency band [7].

PSDs are obtained by transforming the time-dependent signal into frequency domain with the FFT (Fast Fourier Transform) method and squaring it. PSD is often used as acceleration data. Its unit is (G ^ 2 / Hz).

$$PSD = \frac{1}{2T} |FFT|^2 \quad (1)$$

Figure 2 shows the PSD curves of four typical random processes showing the energy distribution with frequency for different types of random processing. While the energy of the narrowband random process is concentrated in a narrow frequency band (Figure 2.b), the energy of the broadband random process is distributed over a rather wide frequency range as shown in Figure 2.15.c. The energy of the white noise process is evenly distributed over an infinite region. Using such a random process model provides mathematical convenience. However, the white noise process does not physically exist. The harmonic random wave has only two distinct frequencies that are not zero [8].

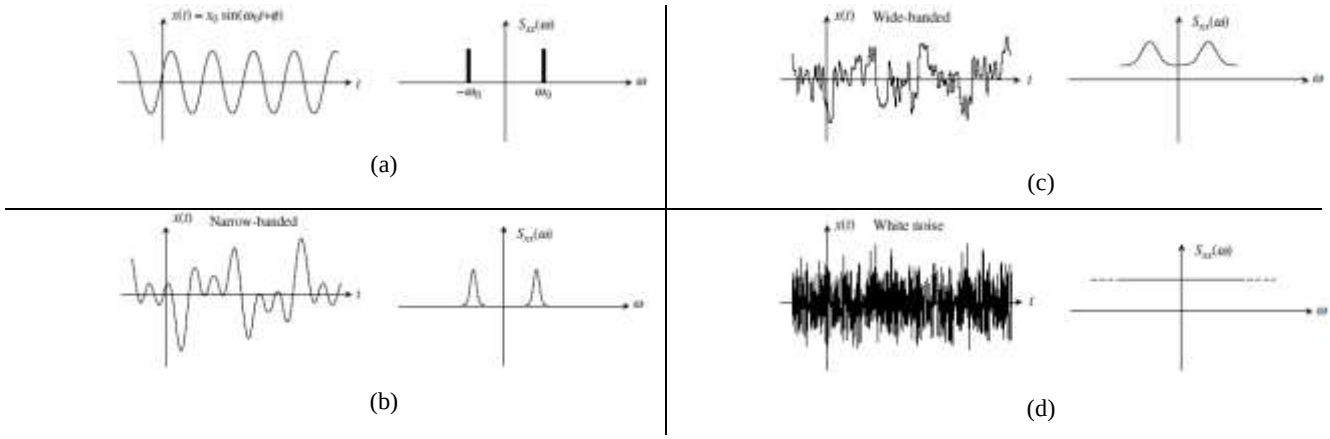

Figure 2. Types of Random Vibrations [8]

2.2. Vibration Fatigue Damage Calculation from Random Loads

The characteristics of the PSD that are used to obtain this information are the nth moments of the PSD function (Figure 3). These moments provide all the information required to calculate fatigue damage [9].

$$\text{nth spectral moments; } m_n = \int_0^{\infty} f^n G(f)df = \sum_{n=0}^{n=\infty} f_n . G_n(f)df \quad (2)$$

In theory, all possible moments are required to fully characterize the original process. However, in practice, we find that $m_0, m_1, m_2, and\ m_4$ are sufficient to compute all of the information required for the subsequent fatigue analysis.

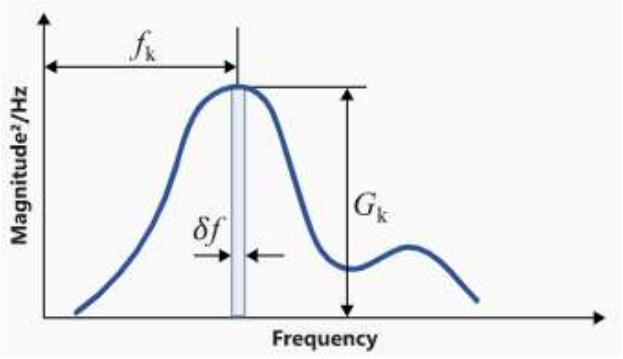

Figure 3. Calculation of PSD Moments [9]

It is useful to note that the ***root means square*** (RMS) value is equal to $\sqrt{m_0}$.

Random stress or strain time histories can only properly be described using statistical parameters. This is because any sample time history can only be regarded as one sample from an infinite number of possible samples that could occur for the random process. Each time sample will be different. However, as long as the samples are reasonably long then the statistics of each sample should be constant.

Two of the most important statistical parameters are the number of so-called zero crossings and the number of peaks in the signal. Figure 4 shows a one-second piece cut out from a typical wide-band signal. E[0] represents the number of (upward) zero crossings, or mean level crossings for a signal with a non-zero mean. E[P] represents the number of peaks in the same sample. These are both specified for a typical 1-second sample. The irregularity factor is defined as the number of upward zero-crossings divided by the number of peaks [9].

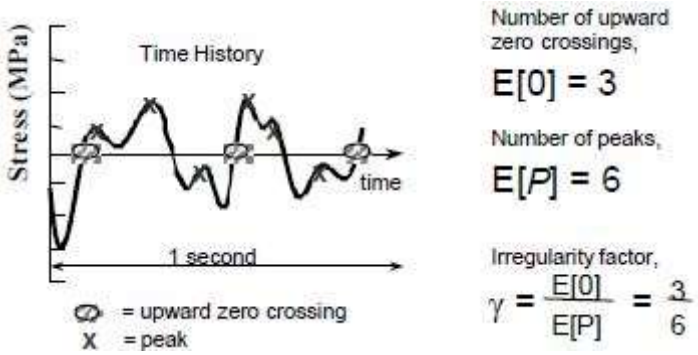

Figure 4. Zero and peak crossing rates [9]

Rice developed very important relationships for the number of upward mean crossings per second (E[0]) and peaks per second (E[P]) in a random signal expressed solely in terms of their spectral moment's m_n

$$E(0) = \sqrt{\frac{m_2}{m_0}} \tag{3}$$

$$E(P) = \sqrt{\frac{m_4}{m_2}} \tag{4}$$

$$\gamma = \frac{E(0)}{E(P)} = \frac{m_2}{\sqrt{m_0 m_4}} \tag{5}$$

Probability density functions (pdfs) are obtained by normalizing any histogram so that the area under a continuous curve representing the height of each bin is equal to 1.0. Once the stress range histogram has been converted into a stress range pdf then there is an elegant and efficient equation to describe the expected fatigue damage caused by this loading history [9].

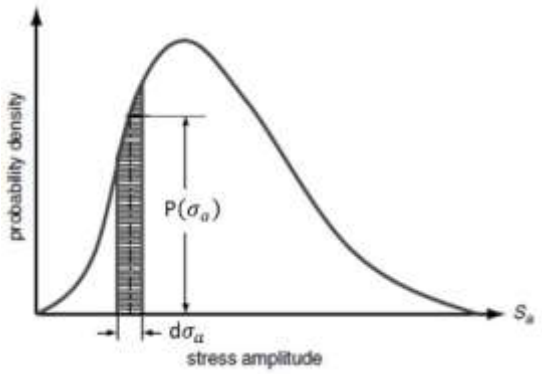

Figure 5. Probability density functions

N(S) is stress range histogram which is equation below;

$$N(S) = E(P).T.P(\sigma_a), \quad \text{T is duration time} \tag{6}$$

T and $P(\sigma_a)$ denote duration time and stress function, respectively.

2.3. Vibration Fatigue Damage Models

The narrow-band approach is only suitable for narrowband operations, while others are also suitable for wide-band loading operations. These are the Narrow-Band approach, the Dirlik method, the Wirsching-Light method, the Ortiz and Chen method, the α 0.75 method, the Benasciutti and Tovo methods.

Methods other than the Dirlik method differ from the others in the way that they provide the correction factor to correct the narrow-band approximation for wide-band processes.

2.3.1 Narrow-Band Approach

The narrow-band approximation is the most basic approximation of damage value and should only be used with narrow-band processes.

$$\text{Narrow Band Damage, } D_{NB} = \frac{E[0].T}{A}.\left(1+\frac{b}{2}\right).(\sqrt{2}.rms)^b \tag{7}$$

Where A is the fatigue strength coefficient and b is the fatigue strength exponent.

As the name indicates this solution is suitable only for a specific class namely a narrow band of response conditions. On the other hand, investigations show that the narrow-band solution is always more conservative than assumptions of broader band conditions. Therefore in the case that you know to have a narrow band condition, you should also use this parameter [10].

2.3.2 Dirlik Method

In 1985, Dirlik [11] provided a solution to the latter based on computer modeling, although there was still a need for a theoretically based solution to the problem [10]. Stress function is,

$$P_D(\sigma_a) = \frac{\frac{D_1}{Q}e^{\frac{-\delta}{Q}} + \frac{D_2\delta}{R^2}e^{\frac{-\delta^2}{2R^2}} + D_3\delta e^{\frac{-\delta^2}{2}}}{2\sqrt{m_0}} \tag{8}$$

Where,

$$\delta = \frac{\sigma_a}{\sqrt{m_0}},\ D_1 = \frac{2(\delta_m-\gamma^2)}{1+\gamma^2},\ D_2 = \frac{1-\gamma-D_1+D_1^2}{1+R},\ D_3 = 1-D_1-D_2$$

$$Q = \frac{5/4(\gamma-D_3-D_2R)}{D_1},\ R = \frac{\gamma-\delta_m-D_1^2}{1-\gamma_m-D_1+D_1^2},\ \delta_m = \frac{m_1}{m_0}\sqrt{\frac{m_2}{m_4}}$$

$D_{1\text{-}3}$,Q, R, δ, δ_m are the parameters related to the identification procedure of stress function. Dirlik's empirical amplitude estimator is far superior to the previously available correction factors in terms of accuracy. Further Bishop provided theoretical verification of the method.

The Dirlik cumulative damage that is;

$$\text{Dirlik damage form I, } D_{f1} = \left(\frac{1}{2^b A}\right)\int_0^\infty S^b\, N(s)dS \tag{9}$$

$$\text{Dirlik damage form II, } D_{f2} = A^{-1}E[P]m_0^{\frac{b}{2}}\left[D_1Q^m\Gamma(1+b) + \sqrt{2}^b\Gamma(1+\frac{b}{2})(D_2|R|^b + D_3)\right] \tag{10}$$

Where Γ is gamma function.

2.3.3 Wirsching-Light method

Wirsching and Lite developed the following correction factor by simulating processes having a variety of spectral shapes [12]. Correction factor of Wisching and Lite method is;

$$\delta_{WL} = x(b) + [1 - x(b)](1 - \varepsilon)^{y(b)} \quad (11)$$

$$x(b) = 0.0926 - 0.033b \quad (12)$$

$$y(b) = 1.587b - 2.323 \quad (13)$$

$$\varepsilon = \sqrt{1 - \gamma^2} \quad (14)$$

$$Wisching\ and\ Lite\ damage, D_{WL} = \delta_{WL} * D_{NB} \quad (15)$$

x and y are the functions used in order to calculate Wisching and Lite correction factor.

2.3.4 Ortiz and Chen method

Ortiz and Chen developed the following correction factor by applying the generalized spectral bandwidth to the narrow-band distribution [12]. Correction factor of Ortiz and Chen is;

$$\delta_{OC} = \frac{{\beta_k}^b}{\gamma} \quad (16)$$

$$\beta_k = \sqrt{\frac{m_2 m_k}{m_0 m_{k+2}}},\ k=2/b \quad (17)$$

$$Ortiz\ and\ Chen\ damage, D_{OC} = \delta_{OC} * D_{NB} \quad (18)$$

β_k is variable to obtain Correction factor of Ortiz and Chen.

2.3.5 α 0.75 method

The second correction method, named α 0.75 (AL), was proposed by Benasciutti and Tovo in 2004 [12]. Corrtection factor of α 0.75 is;

$$\delta_{AL} = {\gamma_{0.75}}^2 \quad (19)$$

$$\gamma_{0.75} = \frac{m_{0.75}}{\sqrt{m_0 m_{1.5}}} \quad (20)$$

$$\alpha\ 0.75\ \text{damage}, D_{AL} = \delta_{AL} * D_{NB} \quad (21)$$

$\gamma_{0.75}$ is parameter of α 0.75 correction factor.

2.3.6 Benasciutti and Tovo methods

In 2002, Benasciutti and Tovo first proposed an approach where the fatigue life is calculated as a linear combination of the upper and lower fatigue-damage intensity limits [12]. The final expression for the estimated fatigue-damage value is;

$$\delta_{BT} = [z + (1 - z).{\gamma_2}^{b-1}].\gamma_2 \quad (22)$$

$$z = \frac{(\gamma_1 - \gamma_2)[1.112(1 + \gamma_1\gamma_2 - (\gamma_1 + \gamma_2))e^{(2.11.\gamma_2)} + (\gamma_1 - \gamma_2)]}{\gamma_2} \quad (23)$$

$$Benasciutti\ and\ Tovo\ damage, D_{BT} = \delta_{BT} * D_{NB} \quad (24)$$

z is a parameter related to Benasciutti and Tovo correction factor.

3. VIBRATION FATIGUE DAMAGE ESTIMATION

To achieve the aim of this study, notched test specimens were considered. Test specimens have been previously designed [4]. Two different materials, aluminum, and steel, with the same geometry were used. Material properties are specified in Table 1.

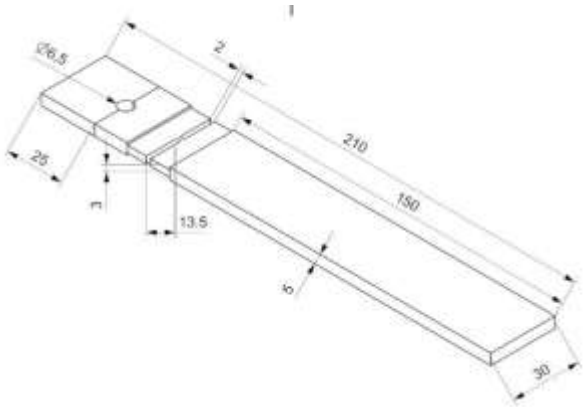

Figure 6. The geometry of test specimen [mm] [4]

Table 1. Material properties of test specimens [4]

Material Properties	Aluminum	Steel
Young Modulus [MPa]	68300	200000
Poisson's Ratio	0.33	0.27
Density [t/mm^3]	$2.71x10^{-9}$	$8x10^{-9}$
Ultimate tensile strength [MPa]	320.3	653.7

Modal analyses were performed to obtain the modal shapes and natural frequencies of the structure can be calculated in two ways which are numerical analysis and physical modal testing. Modal analysis is the most preferred method to validate the structure. The modal testing method was performed for these test specimens (Preferences from literate [4]). To assess the modal testing results, modal analyses were performed in HyperMesh software. Firstly, the specimens were have meshed in HyperMesh software. Second-order hexahedral elements were used. Besides, element density was increased forward the notched region in order to consider stress concentration.

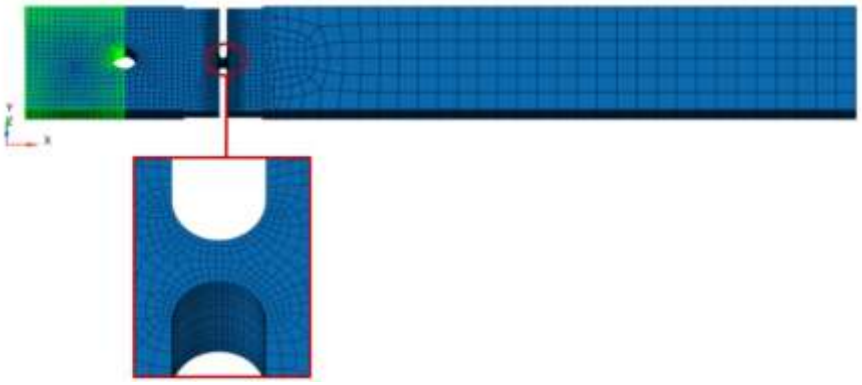

Figure 7. Finite element model of the test specimen

Modal analysis was performed up to 2000 Hz with fixed-fixed conditions. The modal participation factors (MPFs) and modal effective mass were requested as the outputs of the modal analysis. Modal effective mass value is expected to be between 80 and 90 percent for an accurate result in FEA. Also, MPF defines the orientation of modal shapes concerning the global axis.

Table 2. Modal Analysis Results (OptiStuct Solver in HyperMesh)

Material	Aluminum	Steel
Mod	Frequency (Hz)	Frequency (Hz)
1	2.352977E+01	2.325443E+01
2	3.934364E+01	3.922526E+01
3	3.343899E+02	3.367035E+02
4	6.616259E+02	6.591714E+02
5	1.898541E+03	1.892455E+03

Owing to MPFs from modal analysis, it's recorded that the 2nd, 4th and 5th modes are more dominant than the rest of the modes. Modal damping value can be calculated from the amplitude of natural frequencies by analytically. When performing vibration analysis, the modal damping ratio is applied to the relevant frequency range.

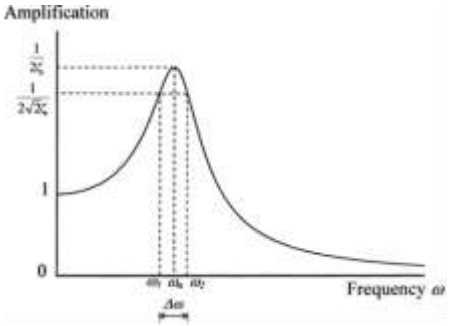

Figure 8. Frequency Amplitude of output [8]

Damping ratio (δ) can be calculated by equitation 7,

$$\delta = \frac{\omega_2 - \omega_1}{2\omega_n} \tag{25}$$

Table 3. Results of modal testing and modal damping ratio [4]

Material	Aluminum		Steel	
Modes	Frequency (Hz)	Modal Damping Ratio (δ) [%]	Frequency (Hz)	Modal Damping Ratio (δ) [%]
2	38.490	1.14	39.795	2.16
4	635.053	0.48	641.045	1.80
5	1762.752	0.46	1746.366	1.12

Vibration fatigue analyses were performed in two different finite element softwares and fatigue solvers (HyperLife – OptiStruct, Simcenter 3D – Falancs). For the calculation process of vibration fatigue damage in HyperLife, initially, random vibration analysis is performed in HyperMesh and then vibration fatigue damage is obtained in HyperLife by using PSD acceleration data and the results of random vibration analysis (PSD Stress) together. For the calculation process of vibration fatigue damage in Simcenter 3D, firstly modal analysis is performed in Simcenter 3D and then vibration fatigue damage is obtained in Simcenter 3D by using PSD acceleration data and the results of modal analysis (Modal stress and MPFs) simultaneously.

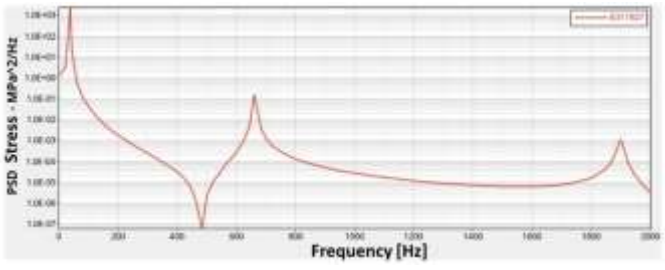

Figure 9. PSD Stress curve from random vibration analysis (HyperMesh-OptiStruct)

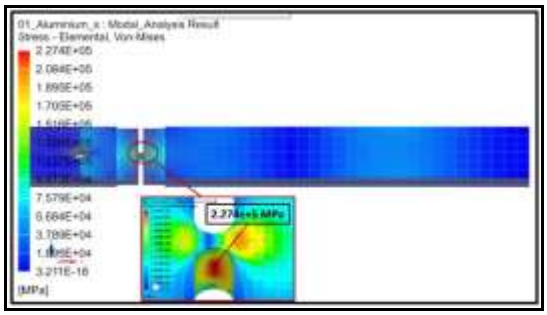

Figure 10. Example of modal stress result from modal analysis for one mode [Simcenter 3D – Simcenter Nastran]

The comparative results of the numerical and experimental [4] vibration fatigue damage values were summarized in table 4. Also, this table includes deviation ratios according to a physical test.

Table 4. Fatigue damage results from finite element solvers and physical test

	HyperLife OptiStruct Solver	Simcenter 3D Falancs Solver	Physical Test Shaker Table [5]
Material	Life – Deviation %	Life	Life
Aluminum	1059 (s) – 27.2	922.94 (s) – 10.8	832.5 (s)
Steel	768 (s) – 63.4	582 (s) – 23.8	470.3 (s)

Figure 11 shows the analytical calculation process for vibration fatigue damage. For this process, Python code was generated. To this end, vibration fatigue damage was obtained with the PSD Stress curve which was obtained from random vibration analyses of two different materials (aluminum and steel materials) in the present study.

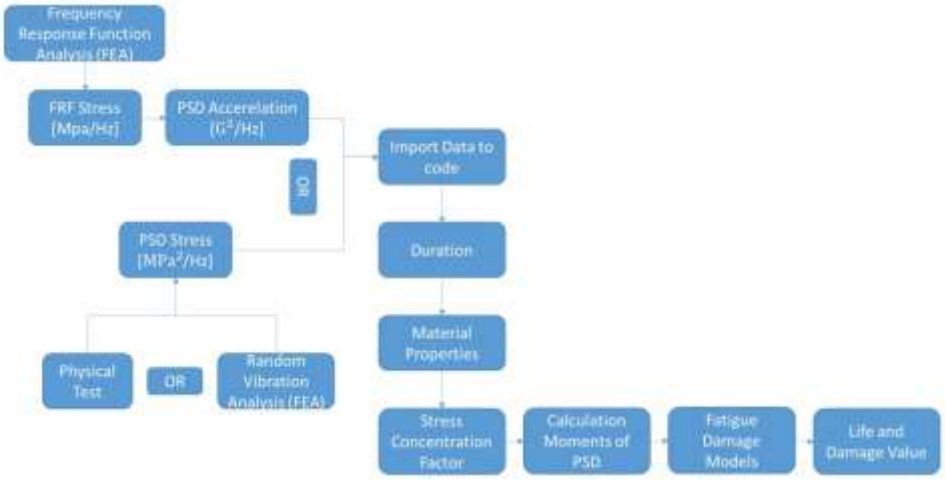

Figure 11. Analytical vibration fatigue damage calculation process in generated Python code

Analytical vibration fatigue damage results for aluminum and steel materials are listed in the table below.

Table 5. Analytical Fatigue damage results from generated script

	Dirlik Method (Form I)	Dirlik Method (Form II)	Narrow-Band Approach	Wirsching Light method	Ortiz and Chen method	α 0.75 method	Benasciutti and Tovo methods
Material	Damage	Damage	Damage	Damage	Damage	Damage	Damage
Aluminum	0.001405	0.0009784	0.001486	0.000708	0.001798	0.001455	0.001432
Steel	0.002343	0.0024038	0.002502	0.002004	0.002827	0.002455	0.00244

The estimated life values against the vibration fatigue damage results are listed in the table below.

Table 6. Estimated fatigue life results according to obtained damage values

	Dirlik Method (Form I)	Dirlik Method (Form II)	Narrow-Band Approach	Wirsching Light method	Ortiz and Chen method	α 0.75 method	Benasciutti and Tovo methods
Material	Life	Life	Life	Life	Life	Life	Life
Aluminum	711.6 (s)	1022 (s)	672.9 (s)	1412 (s)	556.3 (s)	687.5 (s)	698.3 (s)
Steel	426.7 (s)	416 (s)	399.7 (s)	499 (s)	353.7 (s)	407.4 (s)	409.9 (s)

Deviation ratios obtained according to physical tests are shown in the table below.

Table 7. Deviation ratios obtained according to physical tests

	Dirlik Method (Form I)	Dirlik Method (Form II)	Narrow-Band Approach	Wirsching Light method	Ortiz and Chen method	α 0.75 method	Benasciutti and Tovo methods
Material	Deviation ratios [%]	Deviation ratios [%]	Deviation ratios [%]	Deviation ratios [%]	Deviation ratios [%]	Deviation ratios [%]	Deviation ratios [%]
Aluminum	14.5	22.7	19.1	69.6	31.1	17.4	16.1
Steel	9.2	11.4	14.9	6.1	24.7	13.3	12.7

According to Table 7, Dirlik method form I, α 0.75 method and Benasciutti and Tovo methods are more stable than other methods.

4. CONCLUSIONS

In this study, the vibration fatigue process was performed numerically and analytically. For numerical analyses, HyperLife and Simcenter 3D finite element softwares were used. Python code was generated to obtain vibration fatigue damage and life for analytical calculation. Numerical and analytical results were compared with the physical test results [4]. In addition, different fatigue damage models were also evaluated. Fatigue damages were calculated from the power density function for the Dirlik method and the Narrow-Band approach. Fatigue damage was calculated by multiplying the damage value obtained with the narrow-band approach by the correction factor for the rest of the fatigue damage models. The results clearly showed that the Dirlik method form I was the most accurate one. If compare the softwares, Simcenter 3D gives more accurate results.

For fatigue damage estimation in Python code, calculated PSD Stress-frequency curve with a strain gauge in physical testing could be used. Owing to the PSD Stress curve obtains from the physical test, designers could be estimated fatigue damage without finite element analysis.

EGZOZ ISIL GERİ KAZANIM SİSTEMİNİN ARACA UYGULANMASI

Sinan KULA

TOFAŞ, Ar-Ge Direktörlüğü, Güç Sistemleri Müdürlüğü, Bursa, Türkiye
Sorumlu Yazar: Sina Kula, sinan.kula@tofas.com.tr

ÖZET

İçten yanmalı motor, yanma sonucu oluşan egzoz gazlarının çıkışı sebebiyle enerji kaybetmektedir. Bu çalışmadaki amaç, bu kaybolan ısının yani enerjinin geri kazanılmasını sağlamaktadır ve bu sayede motorun verimini arttırmaktır.

Özellikle soğuk havalarda ve motorun ilk çalıştırılması durumunda motor ideal çalışma rejimine geç girmektedir ve geç ısınmaktadır. Dolayısıyla, ideal çalışma sıcaklığına ne kadar erken girerse, yakıt tüketimi ve emisyonlar o denli azalacaktır. Yakıt tüketimi ve emisyonların yanı sıra, aracın ısıtma sisteminde geç devreye gireceği için bu durum yolcu konforunu da negatif yönde etkilemektedir.

Bu etkenleri azaltmak / ortadan kaldırmak için, motorun soğuk çalışma durumlarında egzoz gazlarının enerjisini kullanarak motorun ideal çalışma sıcaklığına daha hızlı getirilmesi hedeflenmektedir.

Anahtar Kelimeler: egzoz, atıl ısı, geri kazanım, ısınma

IMPLEMENTATION OF WASTE HEAT RECOVERY SYSTEM ON VEHICLE

ABSTRACT

Internal combustion engine is losing energy due to the exit of exhaust gases resulting from combustion. The purpose of this study is to recover this heat & energy loss, and thus increase the efficiency of the engine.

Especially in cold weather conditions and when the engine starts at first time, the engine reaches at the ideal operating regime late and as a consequence, warm up time is late. So as soon as the engine works at ideal operating temperature, the fuel consumption and emissions will be lower. In addition to fuel consumption and emissions, this situation effects negatively passenger comfort as the vehicle's heating system will be activated lately.

In order to reduce / eliminate these factors, it is aimed to bring the engine to the ideal operating temperature faster by using the energy of the exhaust gases in cold operating conditions of the engine.

Keywords: exhaust, waste heat, recovery, warm up

1. GİRİŞ

İçten yanmalı motora sahip araçlarda motorun çalışması için gerekli olan enerjiyi yakıttan alır. Yakıttan alınan bu enerjinin tümü efektif işe dönüşmez. Efektif işe dönüşen kısım yaklaşık %30 mertebesindedir ve %40 oranındaki kısım ise egzoz gazıyla, ısı olarak dışarıya atılır. Geriye kalan %30'luk kısım ise araç soğutma sistemi ile atılan ısı ve diğer yardımcı ekipmanların (klima kompresörü, mekanik kayıplar vb.) çektiği güç olarak tanımlanabilir.

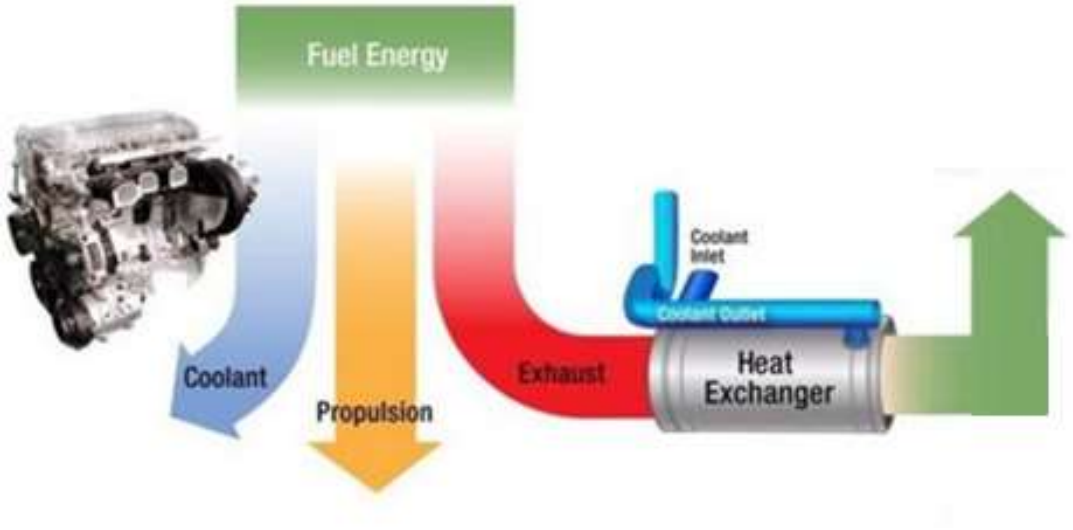
Bu çalışmanın amacı da egzoz gazı ile dışarıya atılan ısıyı kullanabilmektir. Bu açığa çıkan ısı enerjisini motor emisyonları azaltmak amacıyla kullanılacaktır. Şematik olarak Şekil1 'de gösterilen Sankey diagramında, egzoz gazından çıkan sıcak gazlar ile bir eşanjör yardımıyla motor suyu ısıtılacaktır.

İçten yanmalı motorlarda emisyonları arıttırıcı birçok farklı etken vardır, bunlardan bir tanesi de motorun soğuk çalışma durumu esnasındaki fazladan açığa çıkardığı emisyonlardır. Motor soğuk çalışma esnasında verimli çalışma rejiminde

olmadığı için, beklenenden çok daha fazla emisyon gazları açığa çıkarır. Motor ısınana kadar, yani normal çalışma şartlarına dönene kadar, yüksek miktarda yakıt tüketir ve bunun sonucunda da emisyon gazları daha fazla açığa çıkar.

Motorun ideal çalışma sıcaklığına ne kadar geç girilirse o kadar fazla yakıt tüketimi olur ve egzoz gazı emisyonları artığı meydana gelir. Özellikle soğuk havalarda motorun geç ısınması, yakıt ve emisyonu arttırdığı gibi yolcu konforunu da bozmaktadır.

Bu çalışmadaki amacımız, motoru soğuk rejiminde (ilk çalıştırmada, soğuk havalarda) egzoz gazını kullanarak ısıtmaktır. Motor çalışma sıcaklığına mevcut duruma kıyasla daha hızlı ulaşacaktır ve verimsiz çalıştığı zaman dilimi azaltılacaktır.



Şekil 1. Yanma sonrasındaki yakıtın enerji dağılımı

Literatüre baktığımızda buna benzer mantıkta kullanılan egzoz gazından çıkan atıl ısıyı kullanan sistemler mevcuttur. Bu sistemler, motor suyuna benzer bir mantıkta, motor yağının ısıtılmasını hedeflemektedir. Bu konuda yapılan araştırmalara bakıldığında, motor yağı belirlenen test çevrimlerinin sadece son kısmında, ideal çalışma sıcaklığına ulaşıyor [2]. Bu da, motorun soğuk yağ ile çalışma durumunda sürtünme ile kaybolan ısı enerjisini arttırarak, verimi düşük bir seviyede motor çalışma performansı ortaya koymaktadır.

Atıl egzoz gazı enerjisinin kullanıldığı bir diğer alan ise, kabin içi sıcaklık performansının arttırılmasıdır. Soğuk şartlarda kabin içine sıcak hava verilmesi için elektrikli PTC ısıtıcılar mevcuttur. Kullanılan bu elektrikli ısıtıcılar motordan ekstra bir yük çekmekte ve motor verimini dolayısıyla emisyon değerlerini kötüleştirmektedir. Bunu bertaraf etmek için, elektrikli ısıtıcı yerine, egzoz gazından açığa çıkan ısı bu tip yerlerdi ısıtma ihtiyacı için kullanılabilir [3].

2. DENEYSEL TASARIM VE TEST KOŞULLARI

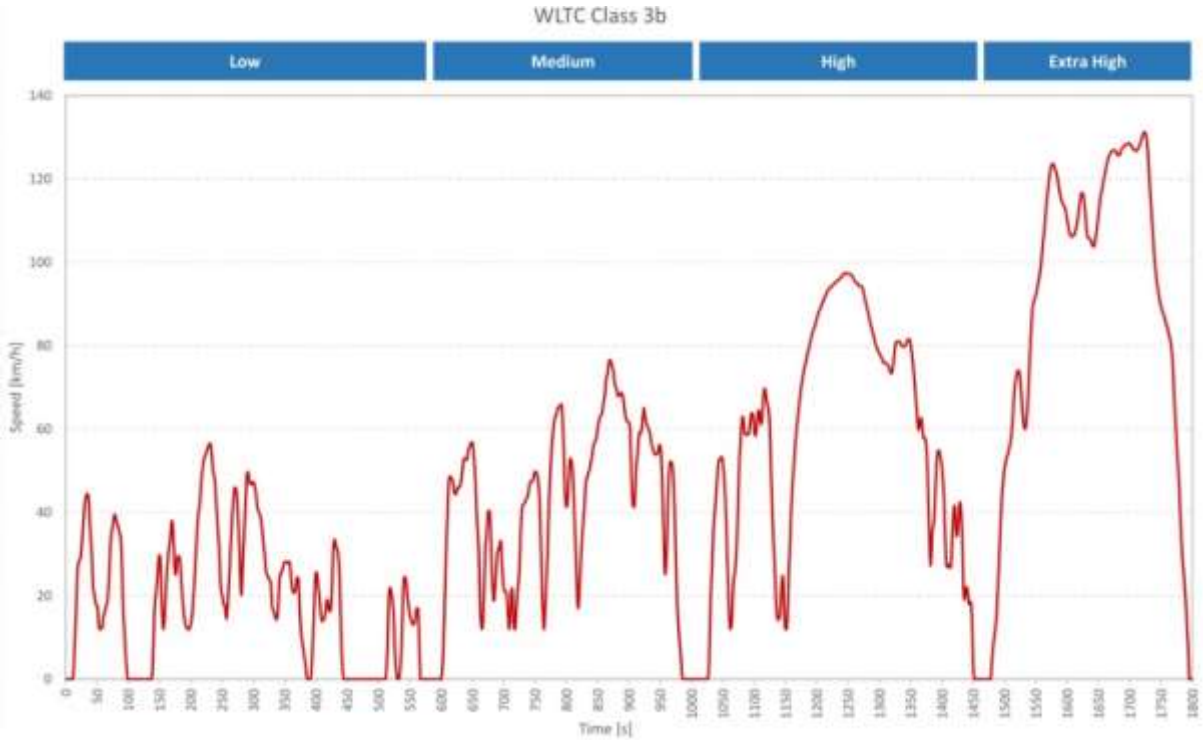
Bu çalışmada egzoz geri kazanım sistemi, bu sisteme özel oluşturulan soğutma suyu çevrimi, eşanjör ve ekipmanlarla birlikte araç üstü fiziksel emisyon testleri yapılarak incelendi.

Denemeler sırasında kullandığımız ekipmanların detaylı özellikleri aşağıda belirtilmiştir.

- Binek tip bir araç
- Dizel 1,6 litrelik bir motor
- Isı Değiştirici (Eşanjör)

- 2 Yollu Valfler
- Eşanjör ve radyatör arasındaki ek su hatları
- T tipi konnektörler

Emisyon testi yapılırken, Avrupa ile eş seviye olan WLTP çevrimi kullanılmıştır. Şekil 2'te [1] uygulanan WLTP çevrimin adımları detaylı olarak görülebilir.



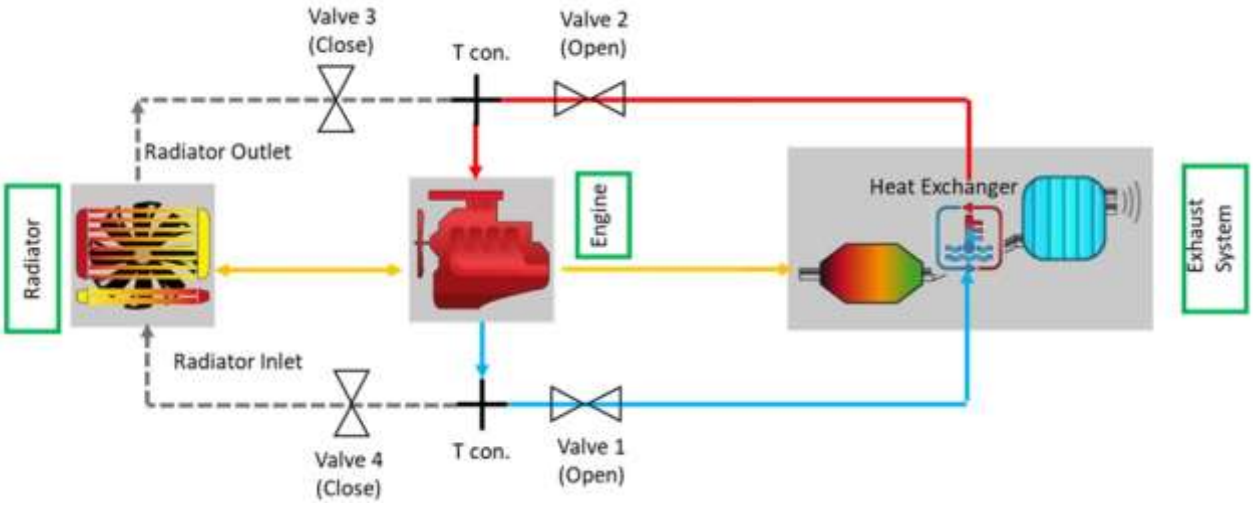
Şekil 2. Uygulanan WLTP emisyon çevirimi

WLTP çevrimi esnasında, motor ilk çalıştığında rejime girene kadar belli bir süre boyunca verimsiz çalışma bandında çalışacaktır. Egzoz ısıl geri kazanım sistemi, tam olarak bu faz içerisinde devreye girecektir.

Yani motorun çalışmaya başlamasından, rejime kadar geçen süre dilimi içerisinde sistem aktif olarak çalışacaktır. Egzoz gazından gelen ısı, motor soğutma suyunu ve dolayısıyla da motoru ısıtmak için kullanılacaktır.

Bu sistemin aktif halini şematik olarak Şekil 3'de görebiliriz. Kesikli çizgi ile görülen soğutma hattı devre dışıdır. Bu durumda sadece kırmızı ve mavi ile işaretli soğutma hattı aktif olacaktır. Bu hat üzerinde de eşanjör konumlandırılmıştır. Kullandığımız T konektör ve 2 yollu valfler yardımıyla soğutma hattı by-pass edilmiştir.

Şekil 3'deki durumda, egzoz gazından gelen sıcak ve basınçlı gaz eşanjöre ulaşıyor, aynı anda soğuk olan motor soğutma suyuda eşanjöre giriyor. Neticesinde, motor suyu bir miktar ısınarak motora tekrar geri dönüyor ve motorun normalden daha hızlı bir şekilde ısınmasını sağlıyor.

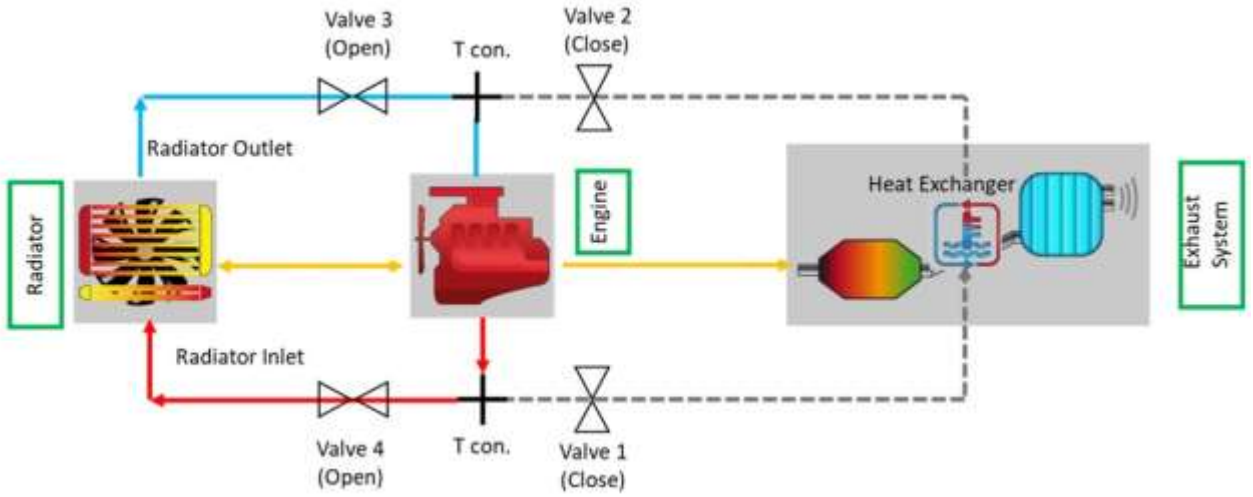


Şekil 3. Egzoz geri kazanım sisteminin soğuk motor durumundaki çalışma koşulu

Bu sistem ile motor normalden daha hızlı bir sürede rejim sıcaklığına gelecektir. Motor rejim sıcaklığına yaklaştığı anda, Şekil 4'te görüleceği gibi, kesitli hat devre dışında kalmaktadır. Yani egzoz gazından gelen ısıl enerjiyi soğuta suyunu ısıtmak için kullanılmamaktadır.

Bu esnada kırmızı ve mavi ile gözüken, radyatör ile su soğutma sistemi aktif hale gelmiştir. Bu noktadan sonra soğutma suyu ile sistem tamamen bilinen ve konvansiyonel soğutma sistemine geçişini yapmıştır. Bu geçişi yine T konektörler ve 2 yollu valfler vasıtasıyla tamamlanmaktadır.

2 yollu valfler elektromekaniktir ve harici olarak kontrol edilmektedir. Soğutma suyu hattı ve motor termostat bölgesinde bulunan sıcaklık sensörleri ile motorun soğuk / sıcak fazda olma durumunu algılayıp otonom bir şekilde motor soğutma veya egzoz ısı geri kazanım ile motor suyunu ısıtma seçeneğini gerçekleştirmektedir.

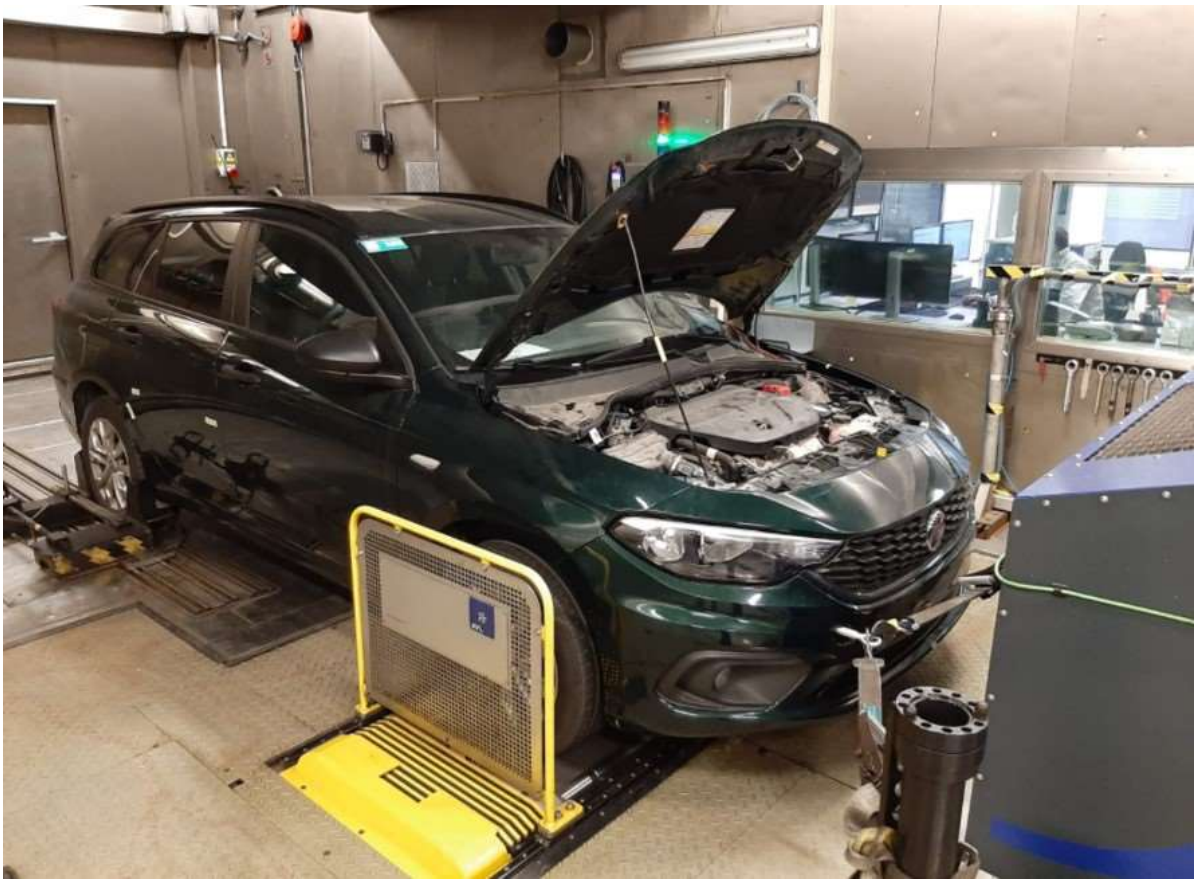


Şekil 4. Egzoz geri kazanım sisteminin sıcak motor durumundaki çalışma koşulu

Şekil 3 ve 4 'te bahsedilen sistemlerin araç altına uygulanmış halini, Şekil 5 üzerinde görülmektedir. Eşanjör, egzoz hattı üzerine konumlandırılmıştır. Eşanjör üzerinde sıcak ve soğuk suyun giriş yaptığı hatlara ayrı bir şekilde soğutma hattı sistemi tasarlanmıştır. Bu soğutma sistemi hattı üzerinde, 2 yollu valfler ve T konnektörler konumlandırılmış ve sistemin kontrolü otomatik olarak sağlanmaktadır.

Şekil 5. Araç üstü ısı değiştiricinin pozisyonu ve soğutma çevrimi hatları

Araç üzerine tüm sistemlerin yerleşiminin ardından, aşağıda Şekil 6'da görüleceği gibi araç emisyon laboratuvarında dinamoya bağlanıp, test gerçekleştirilmiştir.



Şekil 6. Emisyon laboratuvarında yapılan araç üstü testler

3. SONUÇ

Bu çalışmada egzoz gazından gelen ısıl enerji ile motorun soğuk fazlarda çalışma karakteristiğinin ne oranda iyileştireceğinin deneysel olarak karşılaştırması yapılmıştır.

	CO2 Emisyonları
	Total WLTP Çevrimi (gr/km)
Standart Araç	**100x**
Egzoz Isıl Geri Kazanım	**98,4x**

Tablo 1. Emisyon Değerleri

İçten yanmalı motorlardaki verim kayıplarının en önemli adımlarından birini soğukta çalıştırma karakteri ve performansı oluşturur. Soğukta çalışma sadece havanın soğuk olduğu zamanı değil, motorun rejim sıcaklığına ulaşmadığı tüm sıcaklık aralıklarını kapsar. Dış ortamın soğuması, motorun soğukta çalışma süresini daha da arttıracağı için verimi de düşürür. Yukarda detayları bahsedilen bu çalışma ile, motorun verimsiz olduğu bölgelerden biri olan soğukta çalışma performansını iyileştiren bir sistem incelenmiştir.

Yapılan deneysel çalışmada, egzoz sisteminden açığa çıkan ve atıl olan ısı , motorun soğuk rejimde olduğu zaman dilimi içinde kullanılması amaçlanmıştır. Bu yolla atıl olan ısı, motorun soğuk şartlarda ısıtılmasında kullanılmıştır. Egzoz gazı ile, motor soğutma suyundaki ısı geçişi de eşanjör vasıtasıyla sağlanmıştır. Bu eşanjör motor suyu soğutma sistemine entegre edilmiştir.

WLTP çeviriminde karşılaştırmalı olarak yapılan emisyon ölçümleri sonuçlarını Tablo 1'de görebiliriz. Egzoz gazının geri kazanımıyla elde edilen iyileştirme sayesinde, motor daha hızlı bir şekilde rejime ulaşmıştır. Bu iyileşmeyi egzoz gazlarının salınımında ve yakıt tüketimi üzerinde görmekteyiz.

30 dakika süren WLTP test çeviriminin , başlangıç kısımlarında motor suyu sıcaklığı rejime girene kadar, egzoz gazı, motor suyunu çevrime entegre edilen eşanjör vasıtasıyla ısıtmıştır. Motor bu sayede, standart durumdan daha hızlı biçimde ısınıp, rejim sıcaklığına yani verimli çalışma aralığına daha hızlı ulaşmıştır.

Motor suyu sıcaklığı standart durumdan daha hızlı ısındığı için, motorun verimli çalışma bölgesine daha hızlı geçmiştir ve bu çalışma sayesinde , egzoz gazı emisyonlarında yaklaşık olarak %1,6 'lık bir iyileşme meydana gelmiştir. Yakıt tüketimi olarak değerlendirecek olursak, yaklaşık %1,4 'lük bir iyileştirme elde edilmiştir.

ÖZET

Değişken supap zamanlaması (DSZ) aynı hacim ve devirde içten yanmalı motorların (İYM) gücünü artırmak için yapılan araştırmalarının merkezinde olan konulardan biridir. Bu bağlamda özellikle sürekli değişkenlik (SDSZ), dolgu miktarının motor devrine de bağlı olması bakımından son derece önemlidir. Bu çalışmada, literatürde ilk defa piezo uzaması deneysel olarak bir İYM'un emme supabının direkt olarak tahrik edilmesi için kullanılmıştır. Piezonun uzamasını supap kalkma miktarı mertebelerine çıkarmak için bir hidromekanik büyütücü kullanılmıştır. Amaç motor çalışırken motorun emme supabı için her devirdeki en yüksek dolgu miktarını (volumetrik verim-VV) veren açma ve kapanma zamanlarını kolay kontrol edilebilir bir sistemle bulmaktır. Böylece dolgu miktarını supapla kontrol ederek kelebeksiz motorun verim avantajından da istifade edilebilecektir.

Tasarımı yapılan sistemde 1000 V besleme gerilimi ile 22.000 N yük altında 100 µm uzayabilen 154 mm uzunluğunda ve 45 mm çapında bir piezo, en fazla 620 V gerilimle çalıştırılabilmiştir. Bu nedenle supabın maksimum kalkma (lift) miktarı olan 7,6 mm'ye ulaşılamamış ortalama 4 mm civarında bir değerde çalışılmıştır. Motorun sıcak çalışmadaki titreşimlerinin piezoya zarar vermemesi için İYM bir elektrik motoru ile tahrik edilerek soğuk çalıştırılmıştır. VV'deki iyileşmede motorun supabının soğuk çalışma ve 4 mm kalkma miktarında orijinal açma ve kapanma zamanları kriter alınmıştır. 389 cm^3 lük tek silindirli bir motorla yapılan deneyler sonucunda 1500 d/dak'dan 3000 d/dak'ya kadar değişen hızlarda VV'de %11,5 ile %19,6 arasında değişen "en iyi" değerleri sağlayan supap zamanlamaları tespit edilmiştir.

Anahtar kelimeler: Supap, piezo-eyleyici, içten yanmalı motor, volumetrik verim

EXPERIMENTAL DETERMINATION OF VOLUMETRIC EFFICIENCY INCREASE PROVIDED BY PIEZO-ACTUATED VALVE MECHANISM

ABSTRACT

Variable valve timing (VVT) is one of the topics at the center of research studies to increase the power of internal combustion engines (ICEs) at the same volume and speed. In this context, continuously variable valve timing (CVVT) is especially important for that volumetric efficiency (VE) also depends on the engine speed. In this study, for the first time in the literature, piezo elongation was experimentally used to drive intake valve of an engine directly. A hydro-mechanical magnifier was used to magnify the elongation of piezo to the order of valve lift. The aim is to have an easy-to-control system, while the engine is running, which vary the valve timing to obtain best VE at each engine speed. By this way it will be also possible to control amount of the charge with valve timing which avoids the throttling losses considerably and increase overall efficiency.

In the designed system a 154 mm long and φ45 mm piezo stack, which yields 100 µm elongation under 22,000 N load when derived at 1000 VDC, was derived at most 620 VDC. Therefore we couldn't obtain the original lift of the valve i.e. 7,6 mm, but only 4.0 mm. In order to avoid severe vibrations during the operation of the engine with combustion and not to damage the piezo, experiments were carried out with cold engine driven by an electric motor. Thus original opening and closing times of the engine's valve with cold operation and 4 mm lift were taken as criteria for evaluation of performance improvement. In the experiments with a single cylinder 389 cc gasoline engine, operated at speeds varied between 1500 rpm to 3000 rpm, we determined the "best-efficiency" valve timings which are yielding minimum 11.5%, maximum 19.4% improvement in VV.

Keywords: Valve, piezo-actuator, internal combustion engine, volumetric efficiency

1. GİRİŞ

İçten yanmalı motorlarda belli bir motor hacminden alınan güç motora problemsiz olarak verilebilen yakıt miktarı ile orantılıdır. Halbuki hem buji ateşlemeli motor hem de dizel motor uygulamalarında aynı hava miktarı ile karıştırılabilecek yakıt miktarının alt ve üst sınırları vardır. O halde motorun üst güç sınırını problemsiz artırabilmenin yolu önce hava miktarını artırabilmektir. Aynı hacimdeki motora daha fazla hava alabilmenin ölçütü volumetrik verimdir. Volumetrik verim emme ve egzoz supaplarının açma ve kapanma zamanları, maksimum kalkma miktarları ve supapları iten kam profilleri olmak üzere 8 parametreye bağlıdır. Dolayısıyla motorun dolgu verimini ve aynı devir için motordan alınacak gücü iyileştirmenin yolu bu parametreleri optimize etmektir. Bu, pratikte hem zor olacak hem de sadece belirli bir devir için geçerli olacaktır. Asıl önemli olan, aynı supap zamanlamasının farklı devirlerde çok farklı volumetrik verim ve dolayısıyla dolgu miktarı değerleri verebilmesidir. Yüksek devir değerlerinde volumetrik verimdeki düşüş çok radikal olabilmektedir. O zaman sabit supap parametreleri (emme ve açma supabı açma ve kapanma zamanları, kalkma miktarı ve kam profili) yetersiz kalmakta ve devir değişikliklerinde dahi emilen havanın miktarını, dolayısıyla motor momentini yüksek tutabilecek değişkenliğe ihtiyaç olmaktadır. O halde motorun her devri için bu 8 değeri farklı yapabilen sürekli (sınırsız) değişken supap hareketi sağlayan sistemler gerekir.

Supap mekanizması tasarımı ve volumetrik verime etkisi ile ilgili olarak son derece geniş bir literatür vardır. Bunlardan önde gelen bazıları aşağıda özetlenmiştir. Yapılan bu çalışmalar kamlı ve kamsız supap mekanizmaları olarak 2 ana kategoride incelenebilir;

Kamlı sistemler krank milinin hareketine bağlı olarak çalıştığından dolayı kamsız sistemlerin aksine yüksek doğruluğa, yinelenebilirliğe, sağlamlığa sahip olmakla birlikte oldukça sınırlı esnekliğe sahiptir ayrıca mekanizmanın çok kompleks olması, bu sistemlerin diğer bir dezavantajıdır.

Kam miline krank dönmesine kıyasla faz değiştiren (cam phaser), farklı kam profillerinin birinden diğerine geçiş (cam profile switching-kademeli kam profili), 3 boyutlu (sürekli değişken yüzeyli) kam mekanizması (three-dimensional cam mechanism), elektrohidrolik kayıp hareket (electro-hydrolic lost motion) günümüzde yaygın olarak kullanılan kamlı değişken supap zamanlamalı sistemlerindendir.

Kam miline krank dönmesine kıyasla faz değiştiren sistemler, supap zamanlaması için standart mekanizmadır. Bu mekanizma kullanılarak krank miline bağlı olarak açısal konumu böylece de supap açılıp kapanma hareketini eşzamanlı olarak değiştirmek mümkün olmaktadır ama bu sistemde toplam supap açıklığı ve açılma süresi sabit kalmaktadır (Schafer ve Balko, 2007).

Kademeli kam (Cam Profile Switching) tekniğinde supap hareketi 2 bazen 3 farklı kam lobu arasında değiştirilir. Düşük motor hızı boyunca küçük supap açıklığı sağlayacak yüzeye sahip kam supap koluna bağlıdır. Bir kamdan diğerine geçiş elektriksel ya da hidrolik bir sistem aracılığıyla gerçekleşir. Bu sistemde kam profilleri istenen çalışma şartları için 2 veya 3 motor hız aralığı boyunca dönüşümlü olarak birlikte çalışmaktadır (http://world.honda.com/automobile-technology/VTEC/, 2016).

Kam profile switching sisteminde supap hareketi kam kademesi sayısına bağlı olarak yalnızca belirli 2 veya 3 kam profili aralığında yapılabilmektedir. Ama 3 boyutlu kam mekanizması (three-dimensional cam mechanism) tekniği, motora supap zamanlaması ve açıklığını motorun geniş çalışma aralığı boyunca sürekli olarak değiştirmeye imkan vermektedir. Bu mekanizmada kam ekseni boyunca kam profili sürekli olarak değişmekte ve kam milinin izleyiciye göre eksenel hareketi supap açılma miktarında değişikliğe sebep olmaktadır. 3 boyutlu kam mekanizması Nagaya ve ark. tarafından da hem supap zamanlaması, hem de supap açıklığının bağımsız olarak kontrol edebilmesi için uygulanmıştır (Nagaya vd., 2005). Bu tekniğin Nagaya ve ark. uygulamasındaki gibi eğik değil de eğrisel yüzeyi olan ve böylece artan motor devrine göre sürekli aynı yönde eksenel hareketle her devirde maksimum volumetrik verim sağlayan bir başka uygulaması Sürmen ve ark. tarafından çalışılmıştır (Sürmen vd., 2017).

"Elektrohidrolik Kayıp Hareket (Electro-Hydrolic Lost Motion)" tekniğinde de temel prensip; kam hareketi kam-izleyici ikilisi ile eksenel konumdaki hidrolik pompaya aktarılır. Sonrasında yağ yüksek basınç hidrolik çizgisine ve normal olarak açık iki yollu selonoid valfe pompalanır. Selenoid valf kapandığında, supap kam hareketini izler. Ancak selonoid valf açıldığında yağ hidrolik silindir yerine, düşük basınç akümülatörüne sevk edilir ve böylece supap erken kapanır. Fiat bu tekniği kullanarak supap açma kapama zamanlamasını ve açılma süresini ayarlayabilmektedir (Bernard vd., 2003), ayrıca Hyundai, Jacobs Vehicle System and IVECO'da motorlarında bu tekniği kullanan üreticilerden

bazılarıdır (Lee vd., 1995; Hu vd.,1997; Fesser ve Genova, 2004). Ancak supap açıklığının supap açılış süresine bağlı olması ve selonoid tepki süresi bu sistemin başlıca eksiklikleridir.

Kamlı sistemler birçok araç üreticisi tarafından başarılı şekilde uygulanmıştır ancak başta motor hızına bağımlı olması ve diğer birçok sınırlamalar sebebiyle daha esnek supap sistemlerinin geliştirilmesi üzerinde çalışmalar devam etmektedir. Bu sebeple kamsız supap mekanizmaları araştırmacıların ilgi odağı durumundadır.

Kamsız İçten Yanmalı Motor fikri 1899'un başlarında ortaya çıkmıştır (Deokar, 2013). Kamsız sistemlerde krank mili ve supap mekanizması arasında mekanik bir bağlantı yoktur. Supap hareketinin ve supap zamanlamasının esnekliği bu sistemlerin en büyük avantajıdır. Elektro-mekanik, elektro-hidrolik, elektro-pnomatik supap mekanizması gibi bu kategori içerisinde değerlendirilebilecek sistemler en esnek supap tahrik mekanizmaları olmakla birlikte, yüksek maliyet, düşük güvenilirlik, yüksek güç tüketimi (>2.2kW - 16 supaplı motor ve 5000 rpm motor hızı için-), kompleks kontrol mekanizmaları gibi faktörler bu sistemlerin motor uygulamalarını kısıtlamaktadır.

Elektro-mekanik sistemler genelde 2 mıknatıs ve 2 adet denge yayından ibarettir. Elektromanyetik supabın hareketli parçaları supaba bağlanır. Mıknatıslar devre dışı iken, armatür denge yayları tarafından orta konumda tutulur.

Motor çalışmaya başladığında üstte iki elektromıknatıs aktif hale gelir, armatürü iter ve elde edilen potansiyel enerji tutma yayında depolanır (Giglio vd., 2002). Supabı açmak için üstteki elektro-mıknatıs pasif duruma getirilir ve depolanan enerji, kinetik enerjiye (armatürü altta yer alan elektro-mıknatısa taşıma görevi yapar) çevrilir. Alttaki mıknatıstan 1 mm den daha az bir uzaklıktaki hareketli kısım yakalanır ve tutulur. Supap kapanmasında da benzer durumlar tekrarlanır. Manyetik kuvvetin non-lineer karakteristiğe sahip olmasından dolayı yüksek iniş hızı (>0.5 m/s - 1500 dev/dak'da-), konvansiyonel sistemlere göre yüksek güç kaybı, güçlü geri besleme sistemlerine ihtiyaç duyulması gibi bir takım gereklilikler bu yöntemin ticarileşmesi önünde en önemli engellerdendir (Wang vd., 2002).

"Elektro-Pnomatik Tahrik Sistemlerinde" kullanılan hidrolik ve pnomatik mekanizmalar sıkıştırılmış hava akışından maksimum işi elde etmeye imkan tanır dolayısıyla düşük hava basıncı altında çalışılabilir (Trajkovic vd., 2007; Ma vd., 2007)

"Elektro-Hidrolik Tahrik Sistemlerinde" de elektro-mekanik supap sistemlerine benzer şekilde supap yuvasına oturma hızını (valve seating velocity), geçiş zamanı (transition time), çevrimsel kararsızlıklar (cyclic variability) düşürmek için bir kapalı devre elektronik kontrol gereklidir (Anderson vd., 1998). Servo-valf cevap süresi bu değişken supap zamanlaması sisteminin önemli problemlerindendir. Selonoid bobin indüktansı ve deplasman üzerindeki doğrusal olmayan (non-lineer) kuvvet için selenoidin maksimum çalışma sıklığı düşürülür, bunun sonucu olarak da sistem yüksek motor hızlarında çok düşük performans gösterir.

Piezo tetiklemeli supap tahrik sistemleri üzerine çalışmalar son çeyrek asırda oldukça yaygınlaşmıştır. (Giurgiutiu vd. 1995; Jalili vd., 2003; Anmelder, 2014; Gatecliff vd. 2004; Christoph vd., 2004; Brader,J.S. ve Rocheleau, 2004; Clifford vd., 2003)

Bu çalışmada ise bir piezoelektrik eyleyici, bir hidrolik modül ile entegre edilerek sıra dışı bir supap açma mekanizması geliştirilmiş ve motor uygulaması yapılmıştır. Bu sistemle motor devrine göre yukarıda sözü edilen 8 parametrenin özellikle çok etkin olan ilk dördünün (her iki supabın açma ve kapama zamanları) değişimi çok yüksek motor hızlarında bile istenildiği gibi problemsiz mümkün olabilmiştir.

2. MATERYAL VE YÖNTEM

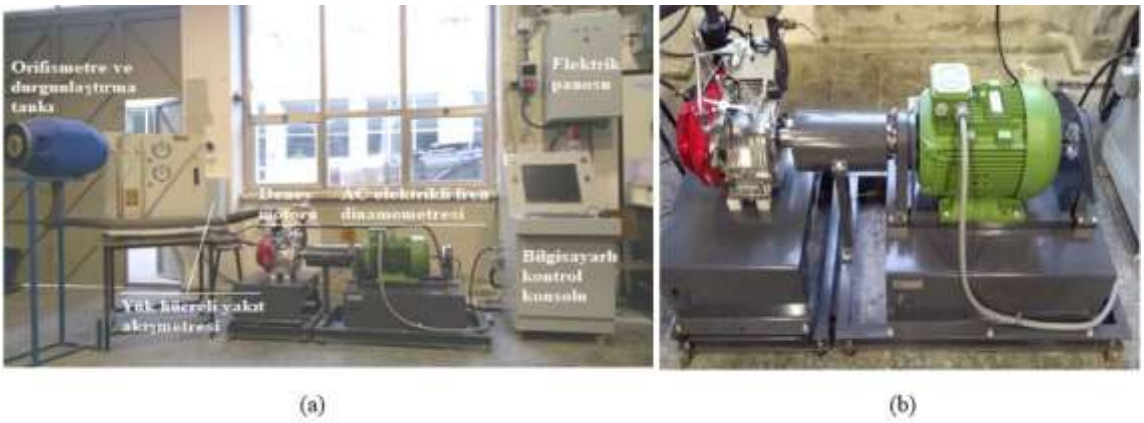
2.1. Deney Standı

Deneyler bilgisayar kontrollü ve girdap akımlarını kullanarak frenleme enerjisi üreten Netfren marka bir test ünitesi üzerinde gerçekleştirilmiştir. AC motorlu aktif dinamometre motorlu frenin teknik özellikleri de Tablo 1'de verilmiştir.

Tablo 1. Fren test ünitesinin teknik özellikleri.

Fren Tipi	AC motorlu aktif dinamometre
Çalışma devri	0-6000 dev/dak
Frenleme momenti	0-58 Nm ±1 Nm (0-3000 dev/dak arası)
Tork kolundaki frenleme kuvveti ölçümü	S tipi load cell
Motor devri ölçümü	Rotary encoder
AC motor soğutma tipi	Hava tip cebri soğutma
Yakıt debisi ölçüm sistemi	g/s ve g/HP biriminde ölçüm
Yük kontrolü	Bilgisayardan kontrollü

Şekil 2'de deney düzeneği ve deney motoru ile fren test ünitesinin elektrik motoru görülmektedir.



Şekil 2. (a) Deney düzeneği ekipmanlarının yerleşimi, (b) Deney motoru ile fren test ünitesi elektrik motoru

Fren test düzeneğinin çalışma prensibi; deney motoru çalışmak istenilen devire getirilir. Fren test düzeneği elektrik motoruna da bu devir sayısı girilerek devir sayıları eşitlenir. Daha sonra bilgisayar programı yardımıyla elektrik motorunun devir sayısı düşürülerek deney motoruna yükleme yapılır.

2.2. Deney Motorunun Belirlenmesi

Şekil 3'te projede kullanılan tek silindirli buji ateşlemeli (benzinli) motor görülmektedir. Bu motor literatürde üsten kamlı olarak geçmekle birlikte aslında gövdeden kamlı bir motordur. Gövdeden kamlı olması sadece emme supabını tek başına piezo eyleyici ile kontrol etme imkanı sağlamıştır. Aksi takdire üstten kamlı bir motor olsaydı bu avantajdan yararlanılamayacak egzoz supabı için de ayrı bir piezo eyleyici gerekecekti. Deney motorunun teknik özellikleri Tablo 2'de verilmiştir.

Şekil 3. Tek silindirli buji ateşlemeli Honda motoru

Tablo 2. Deney motorunun teknik özellikleri

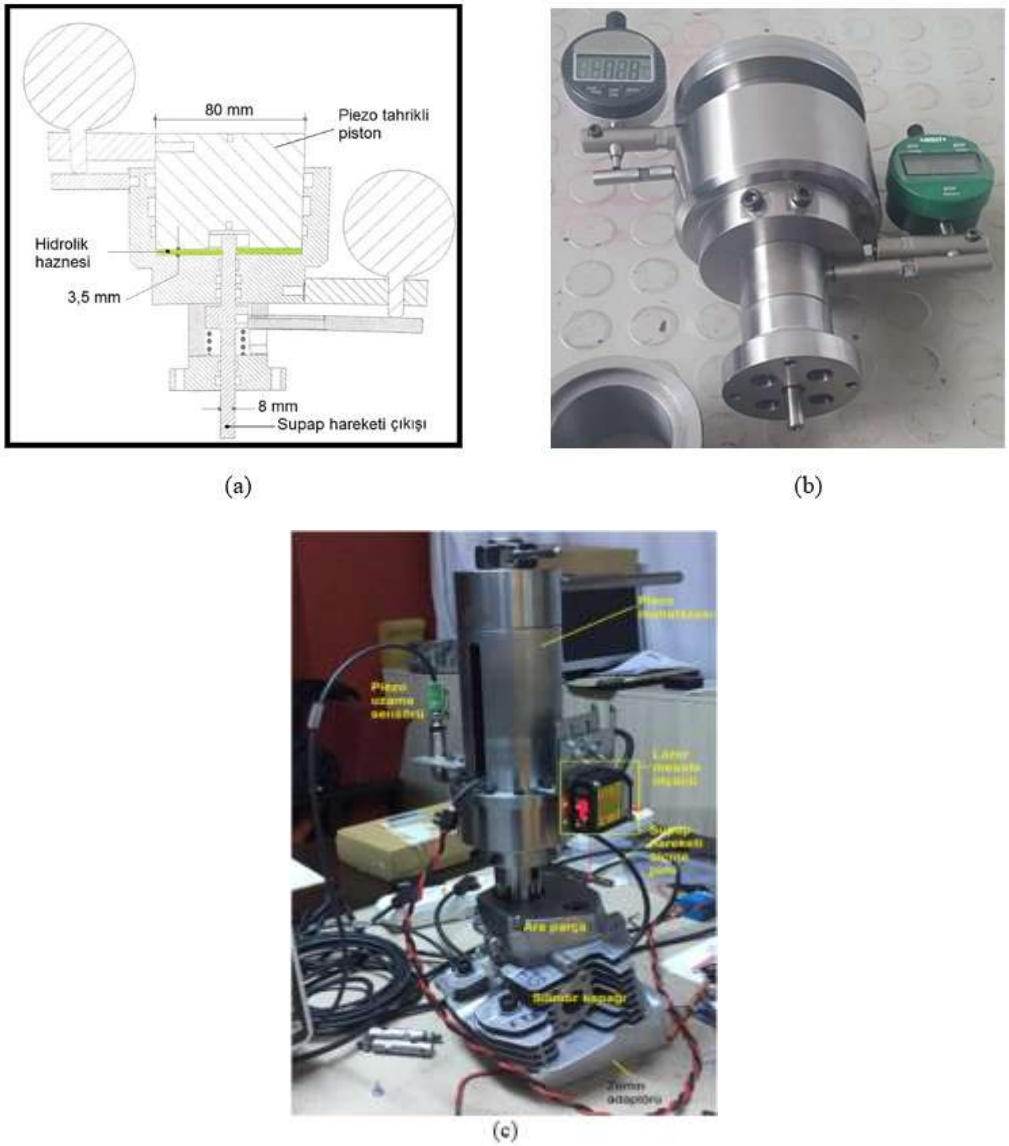
Motor Tipi	Honda GX390
Yakıt tipi	Benzin
Silindir Sayısı	1
Silindir çapı	88 mm
Silindir stroğu	64 mm
Silindir Hacmi	389 cc
Maksimum Motor Gücü	13 BG; 10 kW (3600 dev/dak)
Maksimum Motor Torku	27 Nm (2500 dev/dak)
Sıkıştırma Oranı	8:1
Soğutma Sistemi	Cebri Hava Soğutmalı
Ateşleme Sistemi	Manyetolu, Elektronik

2.3. Piezo Tahrik Sisteminin Tasarımı

Piezo tahrikçi ile kast edilen yapı temelde hidrolik büyütücü ve ona üsten monte edilmesi düşünülen silindirik metal piezo eyleyici muhafazasıdır. Sistem komplesinde bunun dışında piezo-aktüatörü, piezo eyleyici ve piezo eyleyici sürme devresi bulunmaktadır. Piezo eyleyiciyi sürmek için kullanılan sistemde emme supabı zamanlama eğrisine göre kontrol sinyalini üretecek olan elektronik kontrol ünitesi (EKÜ) ve piezo eyleyici sürecek güç kuvvetlendiricisi mevcuttur.

Seçilen motor için öncelikle emme supabı yay karakteristikleri tespit edilmiştir. Motorun emme supabı 77 N'luk bir ön gerilmeye sahiptir ve ÜON'dan 120º sonra maksimum açılma miktarı 7,6 mm'ye ulaşmaktadır. Bu noktada maksimum yay kuvveti ise 172 N'dur. Piezo elemanının seçimi için gaz kuvvetlerinin de bilinmesi gerekmektedir. (Yay kuvveti+gaz kuvveti)x(hidrolik aktüatörün büyütme faktörü) eşitliğinden piezo eyleyiciye gelecek kuvvet 16 kN olarak bulunmuştur. 7,6 mm'lik deplasmanın sağlanması için ise piezo deplasmanının 100 µm olması gerektiği belirlenmiştir. Bu doğrultuda 50000 N bloklama kuvveti ve 180 µm yüksüz deplasman değerlerine sahip olan PI System firmasının P-045.90 piezo eyleyicisi seçilmiştir. Piezo aktüatörünün seçimi ve pizeo eyleyici ile ilgili detaylı bilgilere ve hesaplamalara sırasıyla Sürmen ve ark. (2019) ve Dirim ve ark. (2019)'nın çalışmalarından ulaşılabilir.

Hidrolik büyütücü için iki farklı tasarım üzerinde çalışılmıştır. Başlangıçta çift kademeli bir tasarım (Sürmen ve ark. 2019) yapılmıştır. Bu tasarımda üst haznede 220-230 bar, alt haznede ise 25 bar basınç değerleri oluşmaktadır. Ancak bu tasarımın fonksiyonellik testleri beklentileri karşılamamıştır. Hidrolik büyütücüden 81 kat büyütme beklenirken sadece 9 kat civarında bir büyütme elde edilebilmiştir. Bunun sebepleri keçelerin oluşturduğu iç direnç, sıkıştırılabilme faktörü ve hava kabarcıklarıdır. Bu nedenle Şekil 4'te verilen tek kademeli bir başka tasarım yapılmıştır. 80 mm hidrolik hazne çapı ve 8 mm çıktı pimi çapına sahip olan yeni tasarımda hazne basıncı yaklaşık olarak 7,11 kat azaltılarak 43,8 bar basınç elde edilmiştir. Supap ve gaz kuvvetleri için gerekli kuvvet en fazla 16000 N olduğundan bunun supap için gerekli kısmı $16000/9{,}81/\ \pi\ (8)^2/4 = 32{,}5$ bardır. Bu yeni tasarımla hedef, piezo sınır değerleri olan maksimum 100 µm deplasman ve 2200 kg kuvvet ile en azından 5 mm gibi bir değerin altına düşmeyen bir supap deplasmanı elde etmektir. Yeni tasarım ile istenilen 100 kat büyütme 1 mm gibi makul seviyedeki bir hata ile elde edilebilmektedir.



Şekil 4. Tek kademeli hidrolik büyütücünün teknik resmi (a), gerçek fotoğrafı (b) ve Motor kafasına monte vaziyette hidrolik modül-piezo entegresi

2.4. Soğuk Motor Volumetrik Verim (VV) Deney Planı

Motorun mevcut konvansiyonel mekanik emme supabı kamının açma ve kapanma değerleri deneylere başlamadan önce belirlenmiştir; **emme supabı ÜÖN'dan 30º önce açılmakta ve AÖN'dan 100º sonra kapanmaktadır.** Motor üzerinde hiç kullanılmamış piezonun denenmemiş devirlerde ne problemler çıkarabileceği bilinmediğinden çok geniş bir açı değerleri matrisi (emme açılma (EA) x emme kapanma (EK)) ile çalışma tabii ki risktir. Ancak anlamlı ve çalışmanın hedefine ulaşmasına katkıda bulunacak zenginlikte bir matris olması da gerekir. Dolayısıyla birer tanesi orijinal değerler olmak üzere, açılma ve kapanma tarafında bu orijinal değerlerin erken ve geç taraflarına ikişer farklı açı daha ilave ederek bir matris oluşturulması kararlaştırılmıştır. Böylece deneylerin 5x6 açılık bir matris üzerinden gerçekleştirilmesi planlanmıştır. Bunlar;

Emmenin açılması ÜÖN'dan önce olmak üzere	50º, 40º, **30º**, 20º, 10º
Emmenin kapanması AÖN'dan sonra olmak üzere	120º, **100**º, 80º, 60º,40º,20º

olarak uygun görülmüştür. Altı çizili koyu yazılı olanlar motorun orijinal değerleridir. Bu değerler referans alınacağı için matrise dahil edilmek zorundadır. **Bu çalışmada iyileştirme kriteri bu iki açıda farklı devirlerde ve takriben 4,0 mm sabit kalkma miktarında elde edilecek volumetrik verim (VV) değerleri olacaktır.**

Motor sıcak çalıştırılmadığından elektrik motoru ile döndürülmüştür. Elektrik motoru 6000 d/dak'ya kadar çıkabilmektedir. Ancak motorun nominal devri olan 3600 d/dak'nın aşılmasının getirebileceği riskler tahmin edilemediğinden 1500, 2000, 2500 ve 3000 d/dak için deneyler gerçekleştirilmiştir.

Kontrol devresi emme supabının her alternatif açma-kapanma ve dolayısıyla açık kalma süresi için piezoya 100 µm genlikli bir sinüs dalgası şeklinde açılma komutu gönderecektir. Dolayısıyla bu sinüs fonksiyonunun şekli, komut olarak gönderilen genlik değeri hep aynı (100 µm) ama açık kalma süresi farklı olduğundan, her açı kombinasyonu için 1°'lik adımlarla belirlenmekte ve sisteme yüklenmektedir. Deneyler sırasında motoru durdurmadan yeni bir açı kombinasyonuna geçmek mümkün olacak şekilde tasarım ve denetim mekanizması oluşturulmuştur.

Deneylerde atmosfer sıcaklığı bir termometre ile kaydedilmiş, basınç için ise sürekli 100 kPa değeri kullanılmıştır. Hava debisi için bir durgunlaştırma tankının girişine konulmuş keskin kenarlı lüle (orifis) ve sıvısı su olan eğik manometre kullanılmıştır. Sonuçta okunan manometrik yükseklik mmH_2O olarak kaydedilmiştir ve basit bir excel programlama ile de volumetrik verimler hesaplanmıştır.

3. SONUÇLAR VE TARTIŞMA

Deneylerde elde edilen volumetrik verim değerleri Tablo 3'te sunulmuştur. 1500 ve 2000 d/dak değerlerinde istenilen açma ve kapanma değerlerinden az bir miktar sapma olurken 2500 ve 3000 d/dak'da daha büyük sapmalar gerçekleşmiştir. Bu durum günümüzde dizel araçlarda kullanılan piezo enjektörlerin karakteristiklerinde de daha hafif dozda benzer şekilde görülebilmektedir. Orada söz konusu olan kütleler daha küçük olduğundan sistem ataletleri ve gecikmeler daha küçüktür. Ancak burada söz konusu olan sistemde özellikle piezonun bastığı ana hidrolik pistonunun eksenel boyu, yan yüzeydeki sızdırmazlık elemanlarının gerektirdiğinden çok daha uzun tutulmuştur. Bu da ağırlığını artırmıştır. Bu nedenle de sistem yüksek hızlarda verilen sinyali takip edememektedir. Dolayısıyla önceden her açı çifti için hazırlanan sinüs eğrilerinin motorda birebir uygulaması mümkün olmamıştır. Böyle olunca verilen sinyalin aynısını beklemek yerine, beklenen açma-kapama açılarını veya onlara kabul edilebilir ölçüde yakın olan çıkış değerlerini sağlayan manipüle edilmiş sinyaller gönderme cihetine gidilmiştir. Tablo 3'te gerçekleşmesi beklenen Emme Açılma ve Emme Kapanma açılarına göre elde edilen VV değerleri verilmiştir.

Tablo 3. Farklı emme açma-kapanma açısı kombinasyonları için elde edilen VV değerleri

N=1500 d/dk						
		Emme Açılma				
		10	20	30	40	50

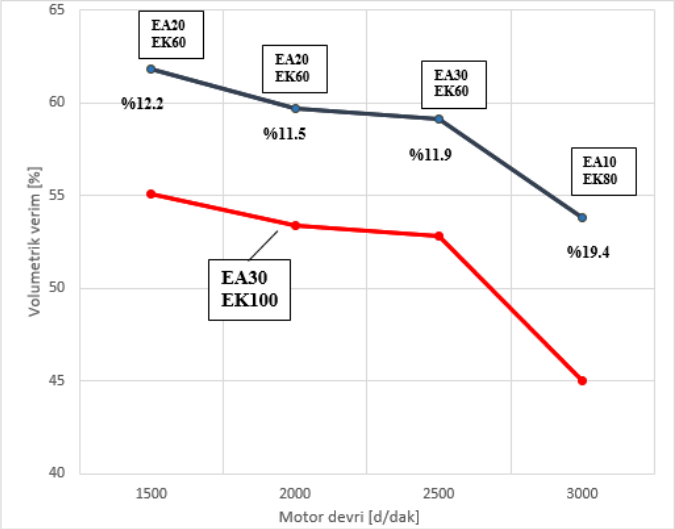
Çalışmanın ana hedefi her devirde en yüksek volumetrik verimi oluşturacak EA-EK kombinasyonlarını araştırmak ve tercihen bu değerlerin motorun orijinal değerlerinin üstünde olabileceğini göstermek idi. Tablo 3'te kırmızı kutucuklarla işaretlenen her motor devrinin en yüksek VV değerleri, yine her devirde motorun orijinal emme açma-kapanma değerleri olan 30º-100º kombinasyonlarındaki değerlerle karşılaştırılarak her devirde sağlanabilecek VV artış oranları belirlenmiştir. Her devirde en iyi değerler, oluştukları açı kombinasyonları, referans EA-EK değerlerindeki (30º-100º) değerler ve artış oranları rakamsal olarak Tablo 4'te verildiği gibidir:

Tablo 4. Referans şartlara göre volumetrik verimdeki iyileşme

	Referans vol. Ver. (**30º -100º**)	En iyi vol. Verimler ve gerçekleştikleri açılar	İyileşme yüzdesi
1500 d/dak	55.06 º	61.80 º (20 º-60 º)	(%12.2)
2000 d/dak	53.37 º	59.49º (20º-60º)	(%11.5)
2500 d/dak	52.84 º	59.12º (30º-60º)	(%11.9)
3000 d/dak	45.05 º	53.78º (10º-80º)	(%19.4)

Volumetrik verimde sağlanan bu radikal değişim grafik olarak da Şekil 5'de gösterilmiştir.



Şekil 5. Piezo tahrikli sürekli değişken supap zamanlaması ile VV'de sağlanabilecek iyileşme

Volumetrik verimde sağlanan ve %11,5 ile %19,4 arasında değişen değerler, motor için aynı oranda güç artışı demektir. Bu denli bir güç artışının aşırı doldurma hariç tek başına hiçbir teknoloji ile sağlanabilmesi mümkün değildir.

TEŞEKKÜR

Bu bildiriye esas olan çalışmaları 216M241 Nolu 1003 projesi kapsamında desteklediği için TÜBİTAK'a teşekkürlerimizi arz ederiz.

KISMİ ESNEK SİLECEK MEKANİZMASININ DİNAMİK PERFORMANSININ İNCELENMESİ

Mert Ali ÖZEL[1,2], Sevda TELLİ ÇETİN[1], Osman KOPMAZ[1]

[1,]Bursa Uludağ Üniversitesi Makine Mühendisliği, Bursa, Türkiye
[2] İletişim yazarı: Mert Ali ÖZEL, mertaliozel@uludag.edu.tr

ÖZET

Rijit uzuvlu mekanizmalar yerine eşlenikleri olan esnek mekanizmalar tercih edildiğinde, mekanizmalarda uzuv ve mafsal sayısının azaltılması neticesinde mekanizmanın ağırlığı, uzuvların montaj süreleri, mafsallardaki titreşimler ve sürtünmelerin azaltılması mümkün hale gelmektedir. Bu avantajlarının yanında esnek bağlantıların şekil değiştirme dirençlerinin sisteme etki etmesi nedeniyle, mekanizmanın dinamik performansında değişiklikler olmaktadır. Çalışma kapsamında, çift sileceğe sahip araç ön cam silecek mekanizmasının kısmi esnek bağlantılı eşleniğinin dinamik performansı incelenmiştir. Esnek mekanizmanın modellenmesinde, eşlenik rijit cisim modeli ve ayrık model kullanılmıştır. Çalışma sonucunda, kısmi esnek mekanizmanın tahrik motorunun güç ihtiyacı yaklaşık %7 oranında artmıştır. Mafsallardaki reaksiyon kuvvetlerinin ise 2.5 kat arttığı görülmüştür. Bunun yanında, eşlenik rijit cisim modeli sonucu ile ayrık model sonucu arasında yaklaşık %16 değerinde fark oluşmuştur. Bu hatanın temel sebebi, eşlenik rijit cisim modelinde esnek bağlantıların doğrusal burulma yayları ile temsil edilmiş olması ve uzama rijitliğinin modellenmemesinden kaynaklı olduğu görülmüştür.

Anahtar Kelimeler: Esnek mekanizma, Silecek mekanizması, Eşlenik rijit cisim modeli, Ayrık model.

DYNAMIC PERFORMANCE ANALYSIS OF SEMI-COMPLIANT WIPER MECHANISM

ABSTRACT

It is possible to reduce the weight of the mechanism when compliant mechanisms are preferred instead of rigid link mechanisms. Besides, the assembly time of the links, vibrations and friction in the joints are improved because of compliant mechanisms are decreased number of link and joints. Although, it causes changes in the dynamic performance of the mechanism due to the deformation stiffness of the compliant links affecting the system. In the scope of the study, the dynamic performance of the partial compliant double-wiper link windshield wiper mechanism was investigated. The equivalent rigid body model and the discrete model were used in the modeling of the compliant mechanism. As a result of the study, it increases the power requirement of the drive motor of the partial compliant mechanism by approximately 7%. Also, it has been observed that it enhances the reaction forces in the joints 2.5 times. Besides, there is a difference of approximately 16% between the equivalent rigid body model and the result of the discrete model. The main reason for this error was found to be due to the linear torsional spring modeling of the compliant links in the equivalent rigid body model and the non-modeling of the elongation stiffness.

Keywords: Compliant mechanism, Wiper mechanism, Pseudo model, Discrete model.

1. GİRİŞ

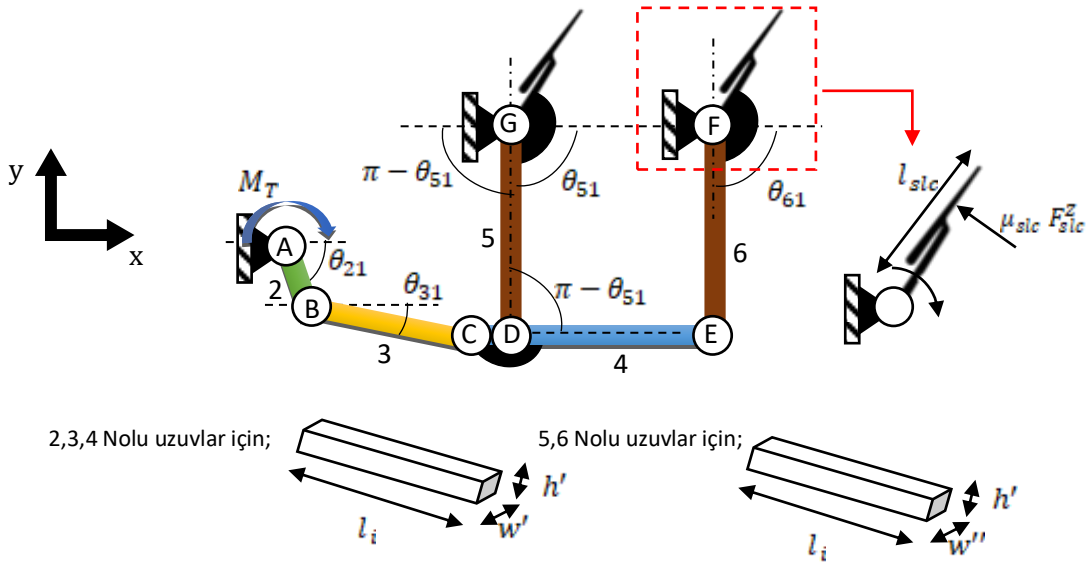
Mekanizmalar en genel tanımıyla hareketi, enerjiyi ve kuvveti aktarmak ya da dönüştürmek için kullanılan bir sistemdir, [1]. Literatürde yaygın olarak karşılaşılan geleneksel rijit gövde mekanizmaları, mafsal olarak tabir edilen hareketli bağlantılarla bağlanan rijit uzuvlardan oluşur. Eklemeli imalat teknolojisinin yaygınlaşması ile uygulama alanı artan esnek mekanizmalar ise, rijit mekanizmalar gibi hareket, kuvvet veya enerji iletiminde ya da dönüşümünde kullanılabilmektedir, [2]. Esnek mekanizmaların rijit uzuvlu mekanizmalardan temel farkı, hareketliliğini esnek elemanlarının şekil değişiminden sağlamalarıdır. Bu sayede, mafsal elemanlarına ihtiyaç duymamakta ve rijit uzuvlu mekanizmalara göre daha az parçadan oluşmaktadır. Bu avantajı dikkate alındığında, esnek mekanizmalarda mafsallarda meydana gelen sürtünmeler oluşmaz, yağlanmaya gereksinim duyulmaz, mafsallarda aşınma ve boşluklardan ötürü meydana gelen titreşim ve gürültü problemleri meydana gelmemektedir, [3,4,5,6]. Bu faydalı

özelliklerinin yanında, esnek mekanizmaların tasarımları ve modellenmesi rijit kol mekanizmalarına göre nispeten daha zordur. En önemlisi ise şekil değiştiren esnek elemanlarda yorulma problem meydana gelmektedir. Bu sebeple, son yıllarda yapılan çalışmalar özellikle esnek mekanizmalarının modellenmesini ve yorulma dayanımları üzerinde durulmuştur, [7,8,9,10]. Esnek mekanizmalar, tam esnek ve kısmi esnek mekanizmalar olarak iki kategoride sınıflandırılabilir. Özellikle mekanizmaların performanslarının iyileştirilmesi için rijit uzuvlu mekanizmaların kısmi esnek bağlantılı eşlenikleri tasarlanabilmektedir. Bu sayede, mekanizmanın parça sayısı azaltılabilir ve performansı iyileştirilebilmektedir, [11,12,13]. Tasarımı ve modellenmesi rijit uzuvlu mekanizmalara kıyasla daha zor olan esnek mekanizmaların, modellenme safhasında farklı teknikler kullanılabilmektedir, [14]. Eşlenik rijit cisim (pseudo) modeli, sonlu elemanlar analizi, elastika yöntemi ve ayrık model literatürde yaygın olarak kullanılmaktadır. Eşlenik rijit cisim modeli, mekanizmanın rijit uzuvlu olarak modellenmesi ve oynar bölgelerinin ise yay elemanları kullanılarak temsil edilmesiyle hızlı analize imkan tanımaktadır. Ayrık model ise, uzuvların kütle, yay ve sönüm olacak şekilde N adet parçaya bölünerek modellenmesidir. Ayrık model, düzlemsel hareket yapan esnek elemanların uzama ve eğilme hareketlerini modellemeye imkan tanımaktadır, [15].

Cam silecek mekanizmaları, araçlarda vazgeçilemeyen sistemlerden biridir. Bu sebeple bu sistemler üzerinde yapılacak ağırlık azaltmaları, maliyet indirimleri ve performans iyileştirmeleri üretici firmalara önemli kazanımlar sağlamaktadır. Karakuş ve Tanık [16], patentli kısmi esnek ve tek silecekli araç ön cam silecek mekanizmalarının tasarım ve modellenme süreçlerini detaylandırmışlardır. Sonlu elemanlar analizi ile yapmış oldukları yorulma analizi sonuçlarını, ürettikleri prototip üzerinde yaptıkları test sonuçları ile kıyaslamışlardır. Çalışma sonucunda, kısmi esnek mekanizmanın sonsuz ömre ulaştığı görülmüştür. Esnek mekanizmanın önemli kazançları olmasının yanında, esnek bağlantıların şekil değiştirme dirençlerinin sisteme etki etmesi sebebiyle mekanizmanın dinamik performansında değişikliklere sebebiyet vermektedir. Bu çalışmada, literatürde incelenmeyen çift silecekli araç ön cam silecek mekanizmasının kısmi esnek bağlantılı eşleniği modellenerek dinamik performansları kıyaslanmıştır. Kısmi esnek eşlenik mekanizmadaki esnek bağlantıların modellenmesinde eşlenik rijit cisim modelleri ve ayrık model kullanılarak her iki yöntemin sonuçları mukayese edilmiştir. Çalışmanın sonucunda, esnek mekanizmanın %7 oranında mekanizmanın güç ihtiyacını arttırdığı görülmüştür. Bunun yanında, esnek elemanların bağlandığı mafsal yataklarındaki reaksiyon kuvvetlerini 2,5 kat arttırdığı görülmüştür. Çalışma sonucunda ayrıca, eşlenik rijit cisim yöntemi ile ayrık modelin sonuçlarında yaklaşık %16 değerinde fark olduğu görülmüştür. Çalışmanın, gelecekte yapılacak yorulma analizi çalışmaları ve deneysel çalışmalara temel olacağı düşünülmektedir.

2. MATERYAL VE YÖNTEM

Çalışma kapsamında öncelikle, Şekil 1'de gösterilen çift sileceğe sahip ön cam silecek mekanizmasının geleneksel rijit uzuvlu modeli tanıtılmıştır. Burada tanımlanan mekanizmaya ait boyutlar, açılar ve noktalar eşlenik kısmi esnek modelle aynı olacak şekilde kullanılacaktır.



Şekil 1.

Rijit uzuvlu geleneksel çift silecekli ön cam silecek mekanizması

Referans alınan cam silecek mekanizması, sileceklerin 48,86 derecelik tarama açısını sağlayacak şekilde kol-sarkaç ve çift kol hareketini sağlayan iki adet dört çubuk mekanizmasının birleşimi şeklinde tasarlanmıştır. Mekanizmaya ait ölçüler Tablo 1'de paylaşılmıştır.

Tablo 1. Mekanizma özellikleri

l_2	AB uzvu uzunluğu	100 mm	$[\|AG\|_x \|AG\|_y]$	AG arası sabit uzvun yatay ve düşey mesafeleri	[150 400] mm
l_3	BC uzvu uzunluğu	400 mm	l_s	Silecek uzunluğu	500 mm
|DE|	DE arası uzunluk	400 mm	|GF|	GF arası sabit uzuv uzunluğu	400 mm
l_5	GD ve GC arası uzunluk	250 mm	l_6	FE uzvu uzunluğu	250 mm
h'	Uzuvlarının düşey kesiti	40 mm	w'	2,3 ve 4 nolu uzuvlarının yatay kesiti	10 mm
|CD|	CD arası uzunluk	20 mm	w''	GD ve FE uzuvlarının yatay kesiti	4,5 mm

Mekanizmanın konum analizi için, Denklem 1 ve Denklem 2'de tanımlanan kapalı çevrim denklemleri oluşturulmuştur.

$$\overrightarrow{AB} + \overrightarrow{BC} = \overrightarrow{GD} + \overrightarrow{DC} + \overrightarrow{AG} \tag{1}$$

$$\overrightarrow{GD} + \overrightarrow{DE} = \overrightarrow{GF} + \overrightarrow{FE} \tag{2}$$

Kapalı çevrim denklemlerini kullanarak oluşturulan kompleks sayılar yöntemiyle mekanizmanın konum analizi Denklem 3 ve Denklem 4'de verilmiştir. Bu iki denklemin zamana göre birinci türevleri hız analizinde, ikinci türevleri ise ivme analizinde kullanılacaktır.

$$l_2 e^{i\theta_{21}} + l_3 e^{i\theta_{31}} = l_5 e^{i\theta_{51}} + |DC| e^{i\theta_{41}} + |AG| e^{i\theta_{11}} \tag{3}$$

$$l_5 e^{i\theta_{51}} + |DE| e^{i\theta_{41}} = l_6 e^{i\theta_{61}} + |GF| e^{i\theta_{11}} \tag{4}$$

Geleneksel dört uzuvlu mekanizma ile eşleniği olan esnek mekanizmaların tork, açısal hız ve güç değerleri üzerinden kıyaslanabilmesi için ihtiyaç duyulan hareket denklemi Euler-Newton Hareket Denklemleri yöntemiyle elde edilecektir. Düzlemsel hareket için her bir uzuv için hesaplanacak olan toplam kuvvet, toplam moment ve atalet terimleri Denklem 5, Denklem 6 ve Denklem 7'de tanımlanmıştır.

$$\rightarrow + \sum \overrightarrow{F_x} = m_i \overrightarrow{a_{x_i}} \tag{5}$$

$$\uparrow + \sum \overrightarrow{F_y} = m_i \overrightarrow{a_{y_i}} \tag{6}$$

$$\circlearrowleft + \sum \overrightarrow{M_Z} = I_i \overrightarrow{\alpha_i} \tag{7}$$

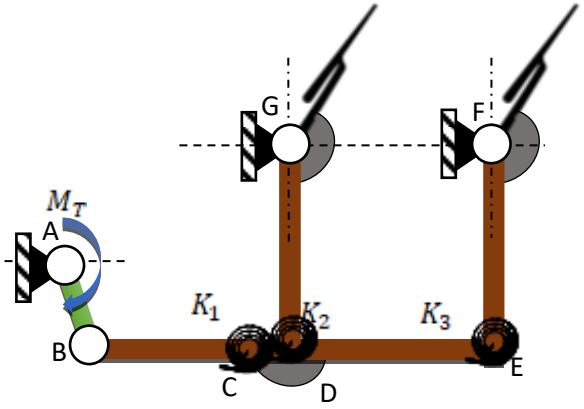
Mekanizmada, 5 adet hareketli uzuv olması sebebiyle toplamda 15 adet lineer bağımsız denklem elde edilebilmektedir. Denklem 8'de kapalı matris formunda verilen bu denklemler yardımıyla, sırasıyla tahrik momenti M_T ve mafsallardaki reaksiyon kuvvetleri $F_A^x, F_A^y, F_B^x, F_B^y, F_C^x, F_C^y, F_D^x, F_D^y, F_E^x, F_E^y, F_F^x, F_F^y, F_G^x, F_G^y$ olmak üzere toplamda 15 bilinmeyen bulunabilmektedir.

$$\underset{\sim}{[K]}_{15x15} \underset{\sim}{[x]}_{15x1} = \underset{\sim}{[b]}_{15x1} \tag{8}$$

Burada, $\underset{\sim}{K}$, $\underset{\sim}{x}$ ve $\underset{\sim}{b}$ sırasıyla; kuvvet ve momentlerin katsayılar matrisi, tahrik momenti ile 14 adet reaksiyon kuvvetini içeren bilinmeyen matrisi ve atalet terimlerini içeren sağ taraf matrisidir. Terimler, belirtilen yöntemle elde edilebildiğinden detayları burada ayrıca paylaşılmayacaktır. Mekanizmanın yatay pozisyonda çalışması sebebiyle ağırlık kuvvetleri düzlem dışından etki ettiğinden uzuv ağırlıkların etkisi ve döner mafsalların sürtünmeleri ihmal edilmiştir. Bunun yanında, silecek ile ön cam arasındaki sürtünmeler Şekil 1'de tanımlanmıştır. Ön cam ile silecek arasındaki sürtünmeden meydana gelen sürtünme kuvveti Denklem 9'da tanımlanmıştır.

$$F_s = \begin{cases} \mu_{slc} F_{slc}^{z}, & v_{slc} = 0 \\ c_{slc}\, v_{slc}, & v_{slc} \neq 0 \end{cases} \tag{9}$$

Burada, F_{slc}^{z} düzleme dik doğrultuda etki eden ve sileceğin cama temasını sağlayan kuvvet, μ_{slc} cam ile silecek arasındaki statik sürtünme katsayısı, c_{slc} cam ile silecek arasında oluşan su tabakasının viskoz sürtünme katsayısı ve v_{slc} sileceğin geometrik orta noktasının hızıdır. Sürtünme kuvvetinin sileceğin orta noktasından etki ettiği kabul edilmiştir. Şekil 2'de görüldüğü üzere, 5 uzuvlu ve 7 mafsallı rijit uzuvlu mekanizmanın, eşlenik kısmi esnek mekanizma modelinde hareketli uzuv sayısı 2'ye, mafsal sayısı ise 4'e düşürülmüştür.



Şekil 2.

Kısmi esnek bağlantılı silecek mekanizmasının burulma yayı modeli

Eşlenik rijit cisim modelinde, ilgili esnek bağlantılar burulma yayı olarak modellenecektir. C, D ve E noktalarındaki burulma yaylarının momentleri sırasıyla Denklem 10-12 arasında tanımlanmıştır.

$$M_C = K_1[(\theta_{31} - \theta_{41}) - \theta_{C0}] \tag{10}$$

$$M_D = K_2[(\theta_{51} - \theta_{41}) - \theta_{D0}] \tag{11}$$

$$M_E = K_3[(\theta_{61} - \theta_{41}) - \theta_{E0}] \tag{12}$$

Burada, θ_{C0}, θ_{D0} ve θ_{E0} sırasıyla C, D ve E noktalarındaki burulma yaylarının başlangıç açısal konumlarıdır. 4 numaralı uzuv, paralel kol mekanizması özelliği nedeniyle mekanizmanın hareketi boyunca açısal konumu θ_{41} sıfıra eşit olmaktadır. Burulma yayı modelleri, eşlenik rijit cisim modeli için Denklem 8'e dahil edilmektedir. Doğrusal olarak modellenen burulma yayı rijitlikleri Denklem 13 yardımıyla hesaplanmaktadır.

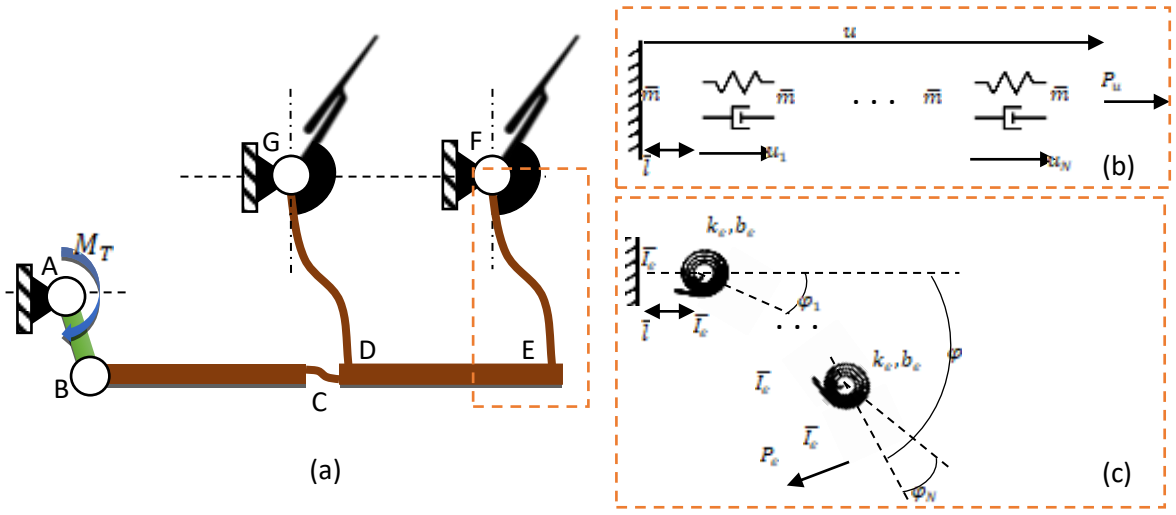
$$K_i = \frac{EI_i}{L_i} \quad i = 1,2,3 \tag{13}$$

Burada, E elastisite modülü, I_i ilgili noktanın atalet momenti ve L_i uzunluğudur. Şekil 3'te tanımlanan kısmi esnek mekanizmanın ayrık modeli, esnek davranış sergileyen 5 ve 6 nolu uzuvlar ile C noktasındaki esnek bağlantının uzama ve eğilme modellerini içermektedir. Geleneksel rijit uzuvlu silecek mekanizmalarında uzuvlar genel olarak çelik malzemeden üretilmektedir. Esnek mekanizmaların üretiminde ise plastik malzeme tercih edildiğinde geleneksel plastik enjeksiyon ile seri üretime uygun olarak üretilebilmektedir. Bunun yanında, üretim adedi az mekanizmalar için eklemeli imalat yöntemi de tercih edilmektedir. Bu sebeple her iki üretim yöntemine uygun olacak şekilde uzuvların malzemesi polipropilen tercih edilmiştir. Polipropilen malzemelerin akma dayanımı/elastisite oranlarının yüksek, uygun maliyetli,

işlemesi kolay ve yoğunluğunun düşük olması hasebiyle esnek mekanizmalar için uygundur. Mekanizmanın plastik malzemeyle üretimi neticesinde sistemin ağırlığını azaltmak mümkün hale gelmektedir. Tablo 2'de malzemelere ait özellikler paylaşılmıştır.

Tablo 2. Malzeme özellikleri

	St52	Polipropilen
Akma Dayanımı [MPa]	310	41
Elastisite Modülü [GPa]	210	1.325
Yoğunluk [kg/m^3]	7850	905



Şekil 3.

(a) Kısmi esnek bağlantılı silecek mekanizmasının ayrık modeli (b) Uzama modeli (c) Eğilme modeli

Uzama ve eğilme hareketleri ayrı olarak sırasıyla Denklem 14 ve Denklem 15'de tanımlanmıştır.

$$\underline{\bar{m}}\,\underline{\ddot{u}} + \underline{b}\,\underline{\dot{u}} + \underline{k}\,\underline{u} = \underline{P_u} \tag{14}$$

$$\underline{\bar{I}_e}\,\underline{\ddot{\varphi}} + \underline{b_e}\,\underline{\dot{\varphi}} + \underline{k_e}\,\underline{\varphi} = \underline{M_e} \tag{15}$$

Burada, $\underline{\bar{m}}$ birim kütle matrisi, N adet birim kütle $\bar{m} = m/N$, $\underline{\bar{I}_e}$ birim kütle atalet momenti, N adet birim kütle atalet momenti $\bar{I}_e = I_e/N$, uzama matrisi $\underline{u}$, eğilme matrisi $\underline{\varphi}$, uzamayı meydana getiren kuvvet matrisi $\underline{P_u}$ ve P_e kuvveti etkisinde meydana gelen eğilme momenti matrisi $\underline{M_e}$ olarak tanımlanmıştır. Burada N 20'ye eşittir. Uzama rijitliği k ve eğilme rijitliği k_e ifadeleri Denklem 16 ve Denklem 17 yardımıyla hesaplanabilmektedir.

$$k = \frac{EA}{\bar{l}_i} \tag{16}$$

$$k_e = \frac{EI_i}{\bar{l}_i} \tag{17}$$

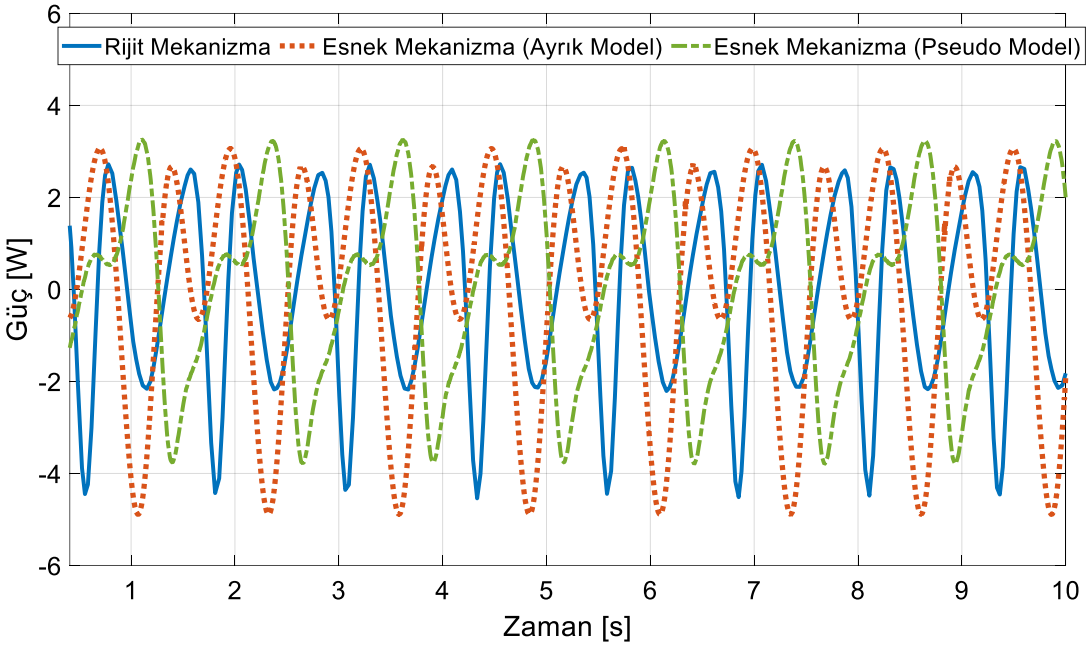
Burada, birim uzunluk $\bar{l}_i = l_i/N$ olarak tanımlanmaktadır. Birinci mertebeden yaklaşım için sönüm katsayıları b ve b_e rijitlik ile orantılı (α) tanımlanmıştır.

$$b = \alpha k \tag{18}$$

$$b_e = \alpha k_e \tag{19}$$

3. ARAŞTIRMA SONUÇLARI

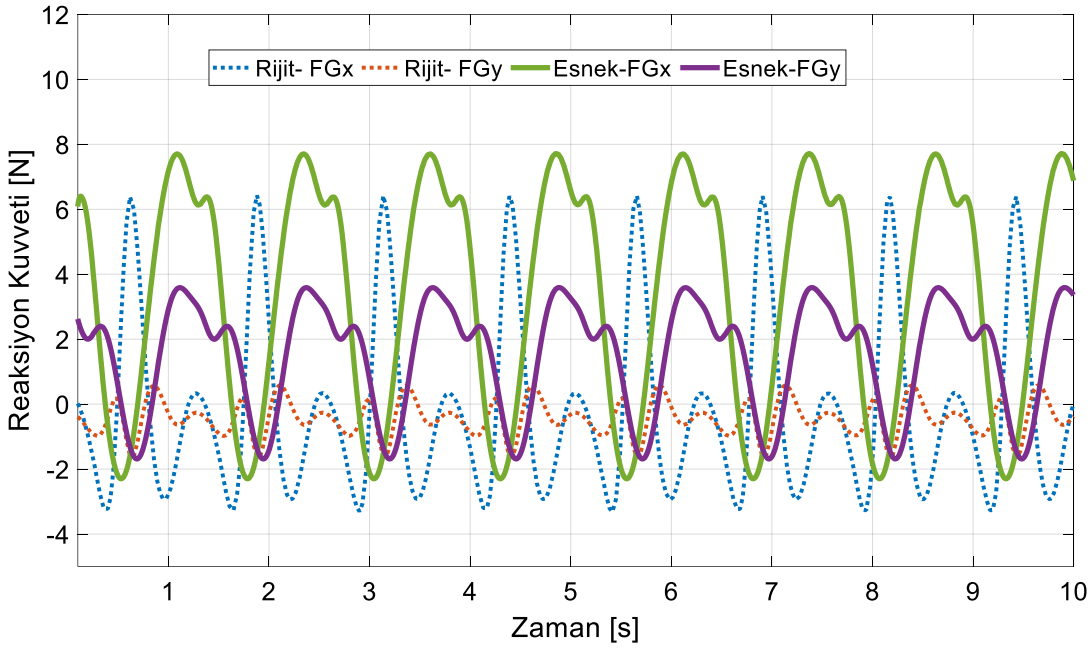
Bu bölümde, ikinci bölümde tanıtılan teorik modelin MATLAB SIMULINK programında Runge-Kutta yöntemiyle çözümünün sonuçları paylaşılacaktır. Mekanizmaların analizinde, A noktasına bağlı bulunan tahrik motorunun sabit 50 devir/dak açısal hızla döndüğü kabul edilmiştir. Modellenen mekanizmaların çözümü, 10 saniyelik simülasyon süresi içerisinde sileceklerin sekiz kez 48,86 derecelik tarama açısı hareketini sağlayacak şekilde yapılmıştır. Şekil 4'te, sabit açısal hız koşulu altında A noktasına bağlı tahrik motorunun güç profili her üç model için paylaşılmıştır. Buradan görüldüğü üzere, esnek mekanizmanın ayrık model için rijit uzuvlu mekanizmaya kıyasla güç ihtiyacını yaklaşık %7, eşlenik rijit cisim modeli için %2 arttırdığı görülmüştür. Bu doğrultuda, esnek bağlantıların şekil değiştirmeye olan direngenliğinin mekanizmanın güç ihtiyacını arttırdığı sonucuna varılmaktadır. Bunun yanında, eşlenik rijit cisim modeli ile ayrık model arasında yaklaşık %16 değerinde bir fark oluşmaktadır. Bunun temel sebebi, esnek bağlantıların 48,86 derecelik nispeten büyük yer değiştirmeleri hasebiyle doğrusal olmayan davranış meydana gelmesi ve eşlenik rijit cisim modelinde eksenel uzamanın etkisinin ihmal edilmesidir. Eşlenik rijit cisim modelinin sonucunun iyileştirilebilmesi için, burulma yayı rijitliklerinin doğrusal olmayan denklem olarak tanımlanması gerekmektedir.



Şekil 4.

Tahrik motorunun güç profili

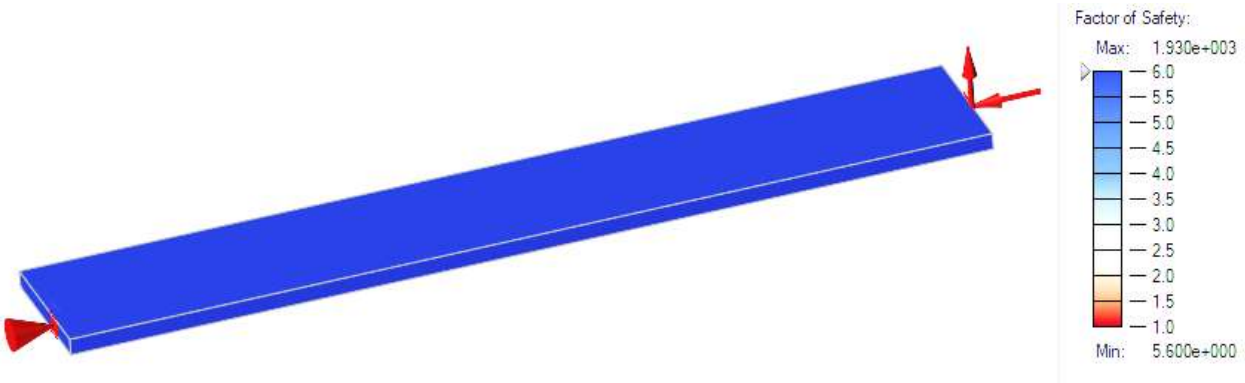
Şekil 5, esnek davranış gösteren 5 numaralı uzvun şekil değiştirmeye karşı direnç göstermesi sebebiyle bağlı bulunduğu mafsalda meydana gelen reaksiyon kuvvetlerini x doğrultusunda 1,2 kat, y doğrultusunda ise yaklaşık 2,5 kat arttırdığını göstermektedir. Bu nedenle, esnek mekanizma için mafsal yataklarında daha erken hasar meydana gelmesi muhtemeldir. Yatak kuvvetlerinde en fazla artışın G mafsalında oluşmakla birlikte, benzer artışların A ve F yataklarında da olduğu görülmüştür.



Şekil 5.

G mafsalına etki eden düzlemsel reaksiyon kuvvetleri

Esnek mekanizmalarda dikkat edilmesi gereken en önemli hususlardan birisi de, esnek bağlantıların yorulma dayanımıdır. Oluşturulan model yardımıyla, esnek elemanlara gelen maksimum kuvvet uzuv doğrultusunda 3.5 N ve uzuva dik doğrultuda ise 7.7 N olduğu görülmüştür. Bu kuvvetlerin etkisi de yapılan yapısal analiz sonucunda, polipropilen malzemeye sahip esnek uzvun 5.6 kat emniyetle çalışabildiği görülmektedir. Ayrıca bu kuvvetler etkisi altında, uzvun yorulma analizinin yapılması ve testlerle doğrulanması önerilmektedir.



Şekil 6.

5 numaralı esnek uzvun yapısal analizi

4. SONUÇLAR

Çalışma kapsamında, çift silecekli araç ön cam mekanizmasının kısmi esnek bağlantılı eşleniğinin dinamik performansı incelenmiştir. Eşlenik kısmi esnek mekanizma sayesinde, 5 uzuvlu ve 7 mafsallı rijit uzuvlu mekanizmanın uzuv sayısı 2'ye, mafsal sayısı ise 4'e düşürülmüştür. Bu sayede, mekanizmanın parça sayısı, montaj süresi, bakım ihtiyacı ve mafsallarda meydana gelebilecek titreşim problemleri azaltılmış olmaktadır.

Çalışmada, esnek mekanizmanın dinamik performansının eşleniği olan geleneksel rijit uzuvlu mekanizma ile kıyaslanabilmesi için teorik model oluşturulmuştur. Bu modelde, rijit uzuvlu mekanizmanın hareket denklemi Euler-Newton hareket denklemleri ile elde edilmiştir. Esnek mekanizmanın modelinde ise iki yöntem incelenmiştir. Modellenmesi nispeten daha kolay olan eşlenik rijit cisim modelinde, esnek bağlantıların şekil değiştirme direngenlikleri doğrusal burulma yayları ile tanımlanmıştır. İkinci yöntem olan ayrık modelde ise, esnek bağlantıların eğilme ve eksenel uzama modelleri oluşturulmuştur.

Oluşturulan teorik modellerin Runge –Kutta yöntemiyle çözümü neticesinde, eşlenik rijit cisim modelinin sonucu ile ayrık modelinin sonucu arasında yaklaşık %16'ya yakın hata saptanmıştır. Bunun temel sebebi, burulma yaylarının doğrusal modellenmesi sebebiyle 48,86 derecelik eğilme hareketi neticesinde esnek bağlantıların doğrusal olmayan şekil değiştirme direngenlikleridir. Bunun yanında, eşlenik rijit cisim modelinde eksenel uzamanın ihmal edilmesi hatayı arttıran bir başka etkendir. Burulma yaylarının doğrusal olmayan denklemler ile modellenmesiyle bu hata değerinin azaltılabileceği düşünülmektedir.

10 saniyelik çözüm sonucunda, esnek mekanizmanın tahrik uzvunun gücünü yaklaşık %7 arttırdığı görülmüştür. Bu artışın temel sebebinin, esnek elemanların şekil değişimine harcanan gücün sisteme dahil olmasından kaynaklıdır. Ayrıca yaylanma direnci oluşturan esnek bağlantıların, mekanizmanın düzgünsüzlük değerini de arttırması mümkündür. Bunun yanında, esnek mekanizmanın bağlı bulundukları döner mafsallarda meydana gelen reaksiyon kuvvetlerini yaklaşık 2,5 kat arttırdığı görülmüştür. Güç ihtiyacının ve reaksiyon kuvvetlerinin şiddetlerinin azaltılabilmesi için mekanizmanın tasarımında optimizasyon çalışmaları yapılması önerilmektedir.

Çalışmada ayrıca, esnek davranış gösteren uzuvların emniyetli olarak çalıştığı yapılan sonlu elemanlar analizi ile doğrulanmıştır. Uzuvların yaklaşık 5,6 kat emniyetle çalışmasına rağmen, uzuvlarda meydana gelecek yorulma probleminin incelenmesi gerekmektedir. Gelecek çalışmalarda, mekanizmanın üretilecek prototipi ile deneysel olarak yorulma dayanımının incelenmesi amaçlanmaktadır.

ÖZET

Bu çalışma kapsamında, değişken manyetik alan DMA özelliğine sahip tekerlek içi elektrik motoru mimarisi ile sürekli değişken güç aktarma organına SDA (CVT) sahip araç şasesi içerisine konumlandırılan elektrik motoru mimarisinin WLTC sınıf 2 sürüş çevrimi ile enerji tüketim değerleri kıyaslanmıştır. Sürekli değişken güç aktarma organı, motorun çalışma noktalarını sahip olduğu yüksek verimli bölgelerde çalışacak şekilde kontrol ederek enerji tüketimini azaltmayı hedeflemektedir. Değişken manyetik alanlı elektrik motoru mimarisi ise, operasyonel çalışma noktalarını kontrol etmek yerine, motorun verim haritasını kontrol ederek talep edilen tork ve açısal hız değerinin yüksek verimli bölgede karşılanmasını sağlamaktadır. Matematik modelin çıktıları neticesinde DMA mimarisinin, SDA sisteminin 2. vites profiline göre yaklaşık %3 daha az ve 1. vites profiline göre yaklaşık %1.6 daha fazla enerji tükettiği görülmüştür. Bu çalışma, gelecekte yapılacak optimizasyon ve deneysel çalışmalara temel olacağı düşünülmektedir.

Anahtar kelimeler: Tekerlek içi elektrik motoru, Sürekli değişken aktarma, Enerji tüketimi, Değişken manyetik alan.

COMPARISON OF ENERGY CONSUMPTIONS OF VARIABLE MAGNETIC FIELD IN-WHEEL ELECTRIC MOTOR AND CONTINUOUSLY VARIABLE TRANSMISSION ARCHITECTURE FOR ELECTRIC VEHICLES

ABSTRACT

In the current study, energy consumptions of two different vehicle architectures were compared; one is the continuously variable transmission (CVT) system and the other one is the variable magnetic field (VMF) in-wheel electric motor. The continuously variable powertrain aims to reduce energy consumption by controlling the operating points of electric motors to operate in high-efficiency areas. On the other hand, VMF in-wheel electric motor architecture ensures that the demanded torque and angular speed values are operated in the high-efficiency region by controlling the efficiency map of the motor. It has been observed that the energy consumption of the VMF in-wheel layout is consumed less than 2nd shifting profile of the CVT architecture approximately 3% but it is consumed more than 1st shifting profile of the CVT almost 1.6%. This study is thought to be the basis for future optimization and experimental studies.

Keywords: In-wheel electric motor, Continuously variable powertrain, Energy consumption, Variable magnetic field.

1. GİRİŞ

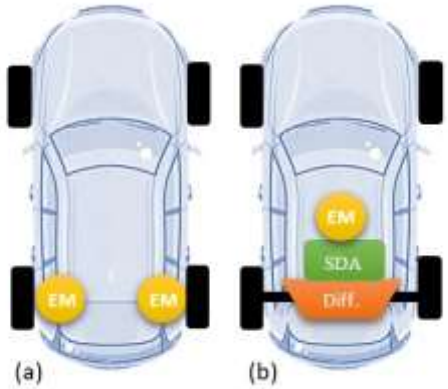
İçten yanmalı araçlardan elektrikli araçlara geçişin hızla arttığı günümüzde, yüksek enerji verimliliği sağlayan araç mimarilerinin tasarımı giderek daha önemli hale gelmiştir. Farklı araç mimarileri ve araç performansı üzerinden elde edilecek enerji tüketimi değerleri, aracın matematik modelleri yardımıyla farklı koşullar altında optimize edilmeye çalışılmaktadır. Bataryalı elektrikli araçlar, hibrit elektrikli araçlar ve hidrojen yakıt hücreli elektrikli araçlar çevreye olumlu etkileri nedeniyle sıfır emisyonlu sürüş için ana çözümler olarak nitelendirilmektedirler. Özellikle, bataryalı elektrikli araçlara kıyasla şarj dolum hızı daha yüksek olması nedeniyle hidrojen enerjili araçların yaygınlaşması artmıştır, [1-6]. Bu avantajının yanında, hidrojen enerjili araçların toplam maliyeti ve hidrojen yakıtının üretim maliyeti nispeten yüksektir, [7-9]. Ancak konu ile ilgili olarak yapılan birçok araştırma neticesinde, hidrojen enerjili araçların ana bileşenlerinin maliyetinin düşürülmesi ve güneş, rüzgar vb. yenilenebilir enerji sektörlerinin hidrojen yakıtı üretimine yaptığı yatırımlar sayesinde, hidrojen yakıtının toplam maliyetinin gelecek yıllarda düşeceği tahmin edilmektedir, [10-12]. Bu olumlu gelişmelere rağmen, hidrojen enerjili araçların genel verimliliği bataryalı elektrikli araçlara göre daha düşüktür. Bu nedenle enerji verimliliği, hidrojen enerjili araçlar için hayati bir durumdur. Literatürde

karşılaşılan farklı tipteki güç aktarma mimarileri, elektrik motoru özelliklerinde değişiklik yapma imkanı sunmaktadır. Bu imkanın sağladığı en önemli esneklik ise elektrik motorunun rotor ve stator geometrisinin boyutunun küçültülmesidir. Bu nedenle, daha verimli, daha hafif, daha ucuz ve düşük hacimli elektrik motoru tasarlamak mümkündür. Son zamanlarda, farklı araç mimarilerinin enerji tüketimi değerlerinin karşılaştırılması hakkında farklı araştırmalar bulunmaktadır, [13,14]. Bottiglione ve ark. [13], tek aşamalı (1G) ve iki aşamalı (2G) dişli sistemleri, yarı ve tam toroidal sürekli değişken şanzımanları (SDA'lar) ve iki farklı sonsuz değişken şanzımanı (IVT'ler) karşılaştırmak için bir elektrikli aracın enerji tüketim modelini incelemişlerdir. Elektrikli motorların enerji verimliliklerini ve elektrikli araçlar için altı farklı şanzıman türünün performansını hesaplamayı başarmışlardır. Sluis ve ark. [14], tek döngü setli SDA kayışının tek kademeli, çift kademeli otomatik ve çift kaademeli çift kavramalı şanzımana kıyasla avantajlarını, ebatları küçültülmüş (downsized) elektrik motoruna göre enerji tüketimi, maliyet ve performansa dayalı olarak incelemiştirler. SDA sistemleri sonsuz çevrim oranına sahip olması hasabiyle, motordan talep edilen çalışma noktalarını yüksek verimli bölgelere taşıyabilmektedirler, [15,16,17]. Yaygın olarak tercih edilen zincir (kayış) tipi SDA, toroidal SDA sistemine göre daha hafif ve düşük maliyetli olması sebebiyle otomotivde tercih edilmektedir, [18,19,20]. Bir diğer mimari olan tekerlek grubu içerisine taşınan elektrik motoru, gerekli performansı sağlaması durumunda aktarma organına gereksinim duymamaktadır. Bu özellik sayesinde, aktarma organının sahip olduğu ağırlık ve aktarma organlarında meydana gelen enerji kayıpları ortadan kalkmaktadır. Dört tekerden (4x4) çekişe sahip elektrikli araçlarda, tekerlek içi elektrik motorlarının birbirinden bağımsız olması hasabiyle, araç stabilite, araç çekiş kontrolü ve sürüş dinamiğinde iyileşmeler gözlemlenmektedir, [21]. Bu avantajlarının yanında, elektrik motorunun tekerlek grubunun kütlesini arttırması sebebiyle yaysız kütledeki artış sürüş konforunu olumsuz etkilemektedir. Tekerlek grubundaki artış, askı sistemindeki elemanlarının yorulma dayanımlarını da düşürmektedir, [22]. Yıldız ve Özel [23], tekerlek içi mimarisi ve sürekli değişken güç aktarma organı mimarilerini de içeren altı farklı hidrojen enerjili elektrikli araç mimarisinin enerji tüketim ve geri kazanım değerlerini karşılaştırmışlardır. İncelenen bu çalışmada, özellikle tekerlek içi elektrik motor mimarisi sayesinde aracın stabilite kontrolünün rejeneratif frenleme ile yapılmasıyla aracın enerji geri kazanım/tüketim oranın iyileştirildiği görülmüştür.

Bu çalışma kapsamında, referans alınan çalışmada [23] incelenmeyen değişken manyetik alan özelliğine sahip tekerlek içi elektrik motoruna sahip mimarinin enerji tüketim değerleri incelenecektir. Değişken manyetik alanlı elektrik motoru mimarisinin, sürekli değişken aktarma mimarisi gibi operasyonel çalışma noktalarını kontrol etmek yerine, motorun verim haritasını kontrol ederek talep edilen tork ve açısal hız değerinin yüksek verimli bölgede karşılanmasını sağlamaktadır. Matematik modelin çözümü sonucunda, her iki mimarinin enerji tüketim değerleri yakın çıkmakla birlikte, farklı tipte vites profilleriyle ve optimizasyon çalışmalarıyla her iki mimarininde enerji tüketim değerlerinin iyileştirebileceği görülmüştür.

2. TEORİK MODEL

Bu bölümde, geliştirilen simülasyon modelinin detayları sunulmuştur. Şekil 1'de gösterilen değişken manyetik alanlı (DMA) tekerlek içi motor mimarisi ve sürekli değişken aktarma (SDA) şase içi motor mimarilerine bağlı olarak matematik formülasyonlar geliştirilmiştir. Model; sürüş çevrimlerini, taşıt hareket denklemlerini, güç aktarma organı modeli, elektrik motorları modelleri, verim haritaları modelleri ile yakıt pili modellerini içermektedir.



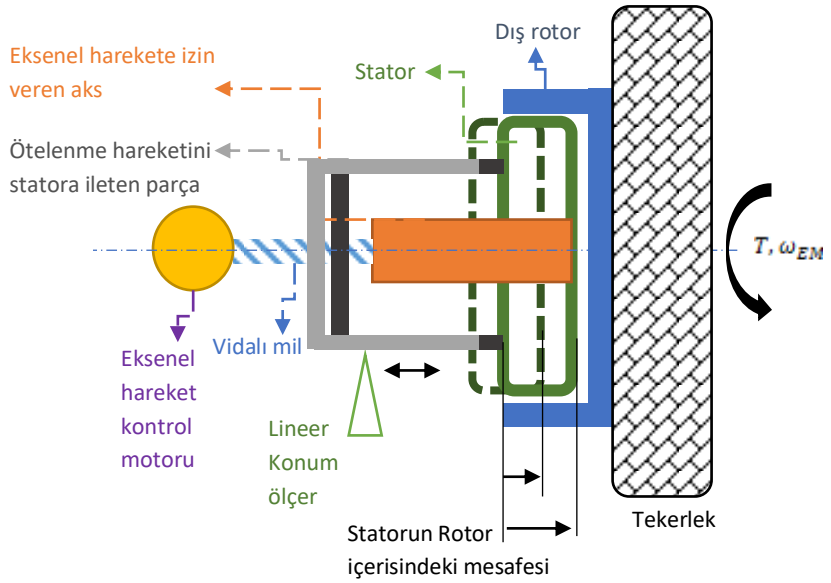
Şekil 1.

(a) DMA Tekerlek İçi Mimari (b) SDA Şase İçi Motor Mimarisi

Her iki mimari için kullanılacak taşıt direnç kuvveti F_d Denklem 1'de paylaşılmıştır.

$$F_d = m_t \frac{dv}{dt} + \rho c_d A_f \frac{v^2}{2} + m_t g \sin(\beta) + m_t g(f_0 + f_1 v^2) \quad (1)$$

Burada, m_t araç toplam kütlesi, v araç hızı, ρ hava yoğunluğu, g yerçekimi ivmesi, β yol eğimi ve diğer değerler Tablo 1'de paylaşılmıştır. Şekil 2'de detay üst görünümü paylaşılan tekerlek içi motor mimarisi için motordan talep edilen açısal hız ω_{EM} ve tork T değerleri Denklem 2'de sunulmuştur.



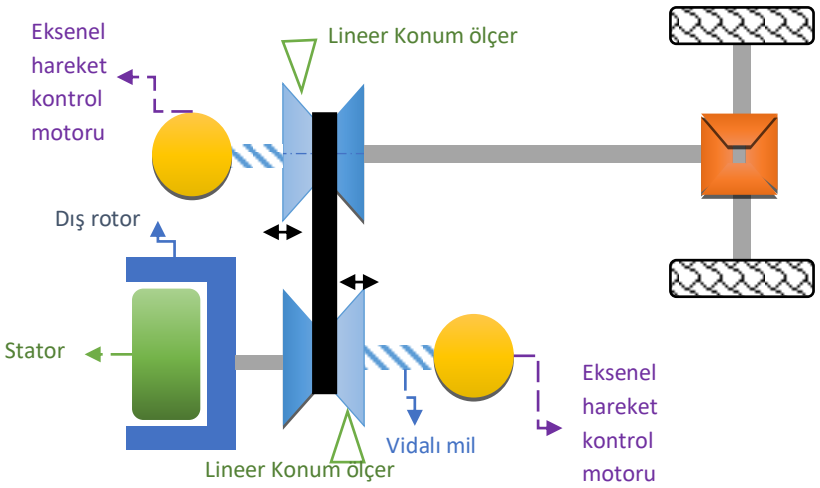
$$\omega_{EM} = \frac{v}{R_t}$$
$$T = \frac{F_d R_t}{2} \quad (2)$$

Şekil 2. DMA Tekerlek İçi Motor Mimari Detay Üst Görünümü

Denklem 3'de görüldüğü üzere, SDA mimarisinde diferansiyel ve SDA çevrim oranlarına bağlı olarak motordan talep edilen açısal hız ve tork değerleri değişkenlik göstermektedir.

$$\omega_{EM} = \tau_{SDA} \tau_{dif} \frac{v}{R_t}$$
$$T = \frac{F_d R_t}{\tau_{SDA} \tau_{dif}} \quad (3)$$

Şekil 3'de SDA sisteminin detay üst görünümü paylaşılmıştır. SDA sistemin iki serbestlik dereceli olması, DMA sistemine kıyasla maliyetlerinin arttırılması ve vites kontrollerini nispeten zorlaştırmaktadır. Bu sebeple, DMA sisteminin mimarisi nispeten daha basittir.



Şekil 3. SDA Şase İçi Motor Mimari Detay Üst Görünümü

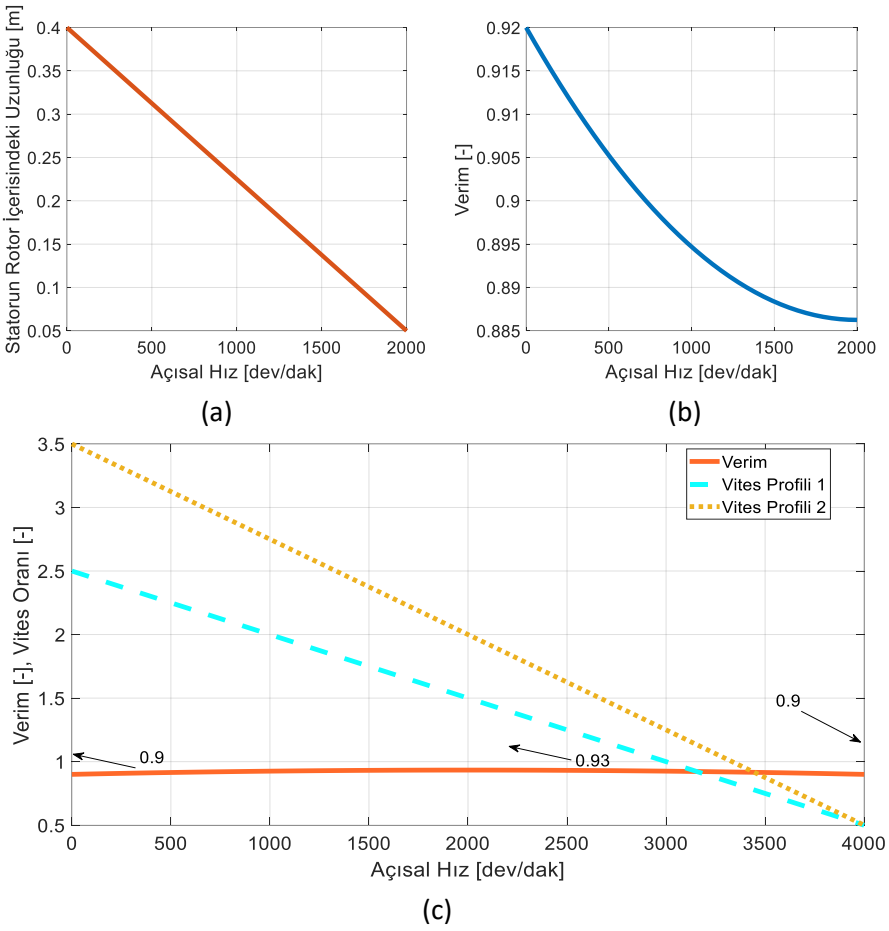
Taşıt hareket denklemleri yardımıyla her iki mimari için hesaplanan açısal hız ve tork değerleri motorun özelliklerine bağlı olarak ilgili verim μ_m değerinde karşılanmaktadır. Denklem 4, motorun özellikleri ile açısal hız ve tork değerlerine bağlı olarak motor verim değerini μ_m hesaplamaktadır. Her iki mimari için fırçasız DC motor tercih edilmiş olup karakteristik değerleri 36 kutup 27 slot motor mimarisi üzerine hesaplanmıştır.

$$\mu_m = \% \frac{T\omega_{EM}}{T\omega_{EM} + P_0 + k_e T^2 + k_w \omega_{EM}{}^2} 100 \tag{4}$$

Güç aktarma sistemine bağlı olarak her iki mimari için motor tarafından talep edilen akım değerler Denklem 5'te sunulan eşitlikler yardımıyla hesaplanmaktadır.

$$I = \frac{T\omega_{EM}}{\mu_m \mu_{dma} V_{yp}} \quad ,DMA$$
$$I = \frac{T\omega_{EM}}{\mu_m \mu_{SDA} \mu_{diff} V_{yp}} \quad ,SDA \tag{5}$$

DMA sisteminin vites profili ve verimi μ_{dma} ile SDA sisteminin çevrim oranı τ_{SDA} değerleri ve μ_{SDA} verim değerleri Şekil 4'de paylaşılmıştır.



Şekil 4. (a) DMA için statorun konum değişimi (b) DMA için verim grafiği (c) SDA vites profilleri ve verim grafiği

Çalışma kapsamında, hidrojen yakıt piline sahip elektrikli araç modeli üzerinden hareket edilmiştir. Yakıt pili gerilimi V_{yp} değerinin hesabında Denklem 6'da görüldüğü üzere, Nernst geriliminin V_{Nernst} aktivasyon gerilimi V_{akt}, konsantrasyon gerilimi V_{kon} ve omik gerilimin V_{ohm} farkı olarak hesaplanabilmektedir. Burada, N yakıt pilinin hücre sayısıdır ve 255 adettir. Bu değerlerin hesabında referans alınan [23] çalışmadaki model kullanılmıştır. Hidrojen yakıt tüketimi HC hesabı için Denklem 7 kullanılacaktır.

$$V_{yp} = [V_{Nernst} - V_{akt} - V_{kon} - V_{ohm}]N \tag{6}$$

$$HC = k_{yp} V_{yp} I \tag{7}$$

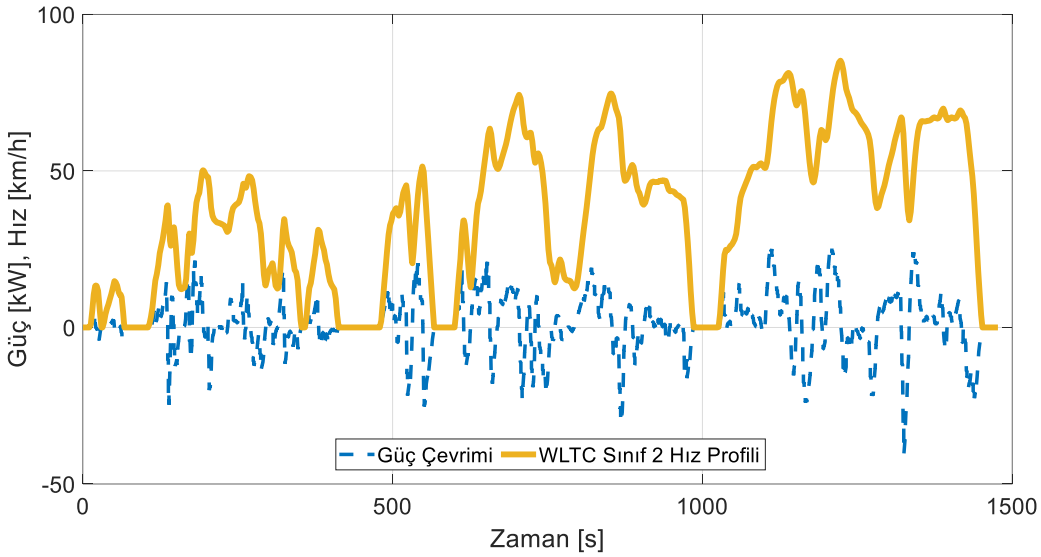
İki farklı araç mimarilerin enerji tüketim performansları WLTC sürüş çevrimine göre hesaplanacaktır. Üç farklı sınıfı bulunan sürüş çevriminde, araç ağırlığı dikkate alındığında WLTC Sınıf 2 hız profili kullanılacaktır. 1477 saniye simülasyon süresi ve 14,664 km mesafelik güzergahta elektrikli araç maksimum 85.2 km/h hızla hareket edecektir. WLTC hız ve güç profilleri Şekil 5'te paylaşılmıştır.

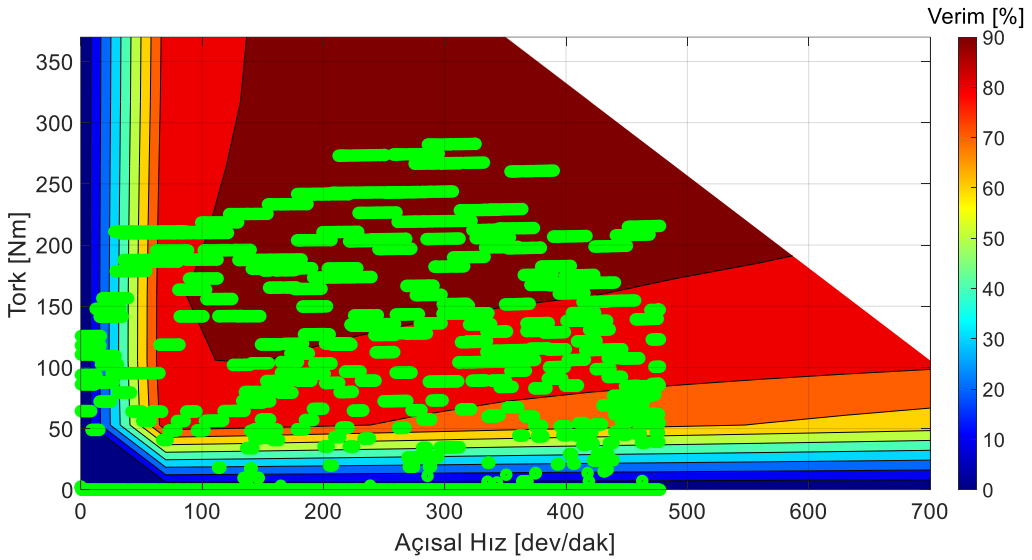


Şekil 5. WLTC sürüş çevrimi

Oluşturulan model, çalışma kapsamında dikkate alınan iki farklı mimarinin enerji tüketim değerlerinin hesaplanmasında ve aynı zamanda çalışma noktalarının verim haritası üzerindeki dağılımının incelenmesinde kullanılacaktır. Seçilen vites profilleri, motorun açısal hızına bağlı oransal değişmektedir ve PID tabanlı bir kontrole sahiptir. Oluşturulan kontrol modeli 0,02 saniye cevap hızına ve maksimum 0.05 hataya sahiptir.

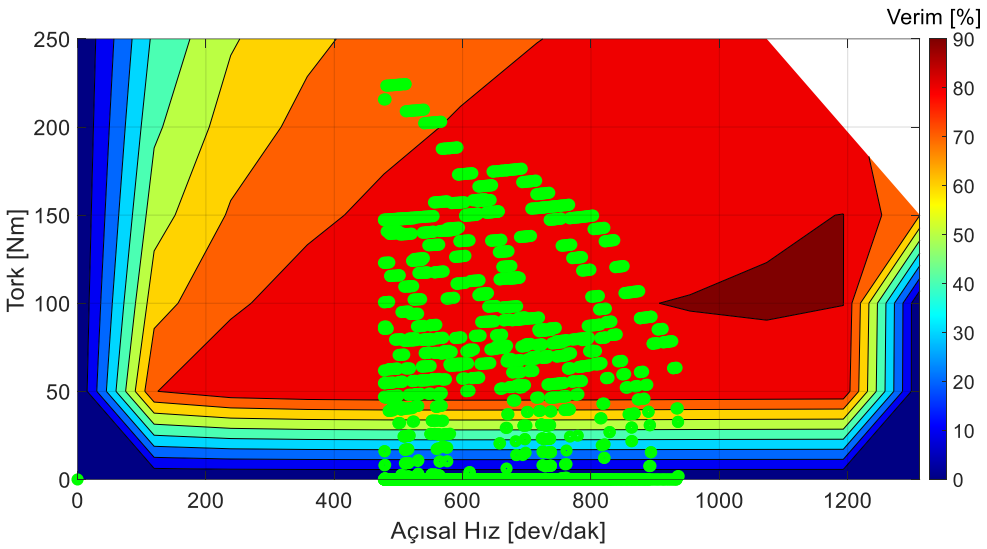
3. ARAŞTIRMA SONUÇLARI

Bu çalışma kapsamında, değişken manyetik alan özelliğine sahip tekerlek içi motor mimarisi ve şase içerisine yerleştirilen ve sürekli değişken güç aktarma ünitesine sahip hidrojen enerjili elektrikli araçların enerji tüketim modelleri gerçekleştirilmiştir. Değişken manyetik alanlı tekerlek içi elektrik motorunda, stator konumunun değiştirilmesi suretiyle verim haritasında değişikliklere neden olmaktadır. Statorun konumu, motordan talep edilen açısal hıza göre kontrol edildiğinde talep edilen tork ve açısal hız değerini olabilecek en verimli noktada karşılaması sağlanabilmektedir. Statorun rotor içerisindeki kalan uzunluğu 0.05 metre ila 0.4 metre arasında vidalı milin imkan verdiği tüm değerlerde olabilmektedir. Bu sayede, sürekli değişken bir verim haritası elde edilebilmektedir. DMA sisteminin sonuçlarının kolay incelenebilmesi için, statorun sadece iki farklı konumunun sonuçları paylaşılacaktır. Şekil 6'da, statorun 0.4 metre pozisyonundaki verim haritası ve çalışma noktaları sunulmuştur.



Şekil 6. DMA tekerlek içi elektrik motorunun statorun 0.4 m pozisyonundaki verim haritası ve çalışma noktaları

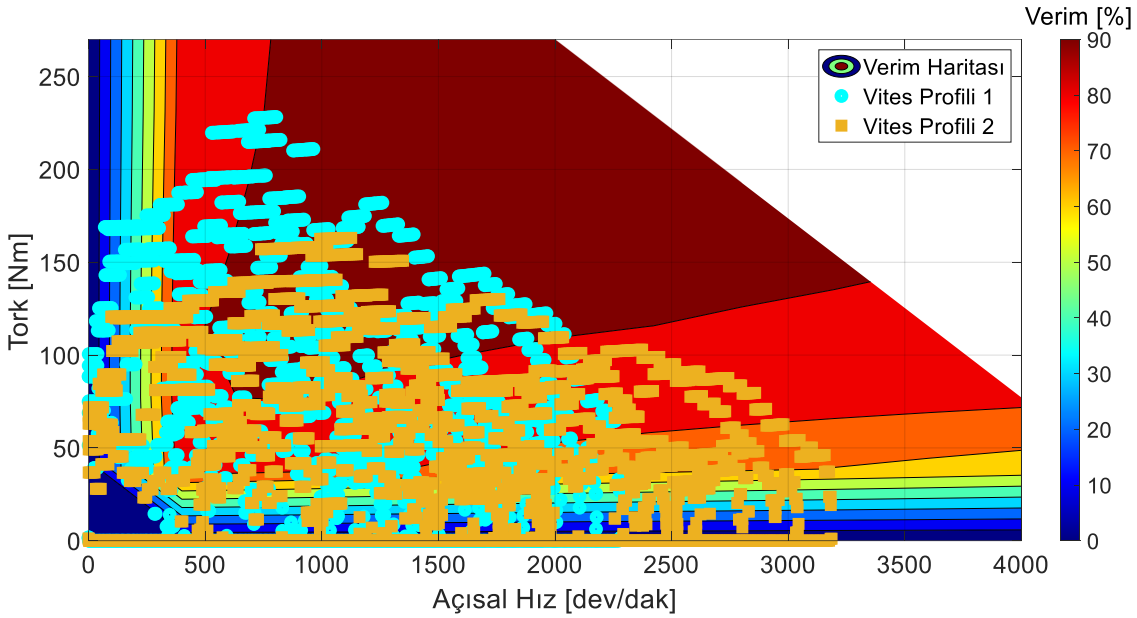
Şekil 6'da sunulan tekerlek içi motorun başlangıç konumunda (0.4 metre) sahip olduğu verim haritasında görüldüğü üzere, motorun maksimum açısal hızı yaklaşık 700 dev/dak'dır. WLTC sürüş çevriminden hareketle, tekerlek içi elektrik motorunun en fazla yaklaşık 960 dev/dak hız değerine ulaşması gerekmektedir. DMA özelliği sayesinde, statorun rotor içerisindeki uzunluğunun azaltılmasıyla motorun zıt elektromotor gerilimi değeri düşmekte ve neticede motorun açısal hızı artmaktadır. Bunun yanında, statorun rotor içerisindeki uzunluğunun azalmasıyla motorun maksimum tork değeri ise azalmaktadır. Sürüş profiline bağlı olarak bu özellik kullanılabilir hale gelmektedir. Şekil 7'de görüldüğü üzere, motorun açısal hızı yaklaşık 480 dev/dak olduğunda, stator konumu 0.32 metre değerine getirilmektedir. Bu nedenle, motorun açısal hız değeri artarken, motorun tork değerinin azaldığı görülmektedir. En önemlisi, sürüş çevrimine bağlı olarak motordan talep edilen çalışma noktaların çoğunlukla yüksek verimli bölgede karşılanması sağlanabilmektedir. Bu sayede, DMA özelliğine sahip tekerlek içi elektrik motoru mimarisinin enerji tüketim değeri azaltılabilmektedir.



Şekil 7. DMA tekerlek içi elektrik motorunun statorun 0.32 m pozisyonundaki verim haritası ve çalışma noktaları

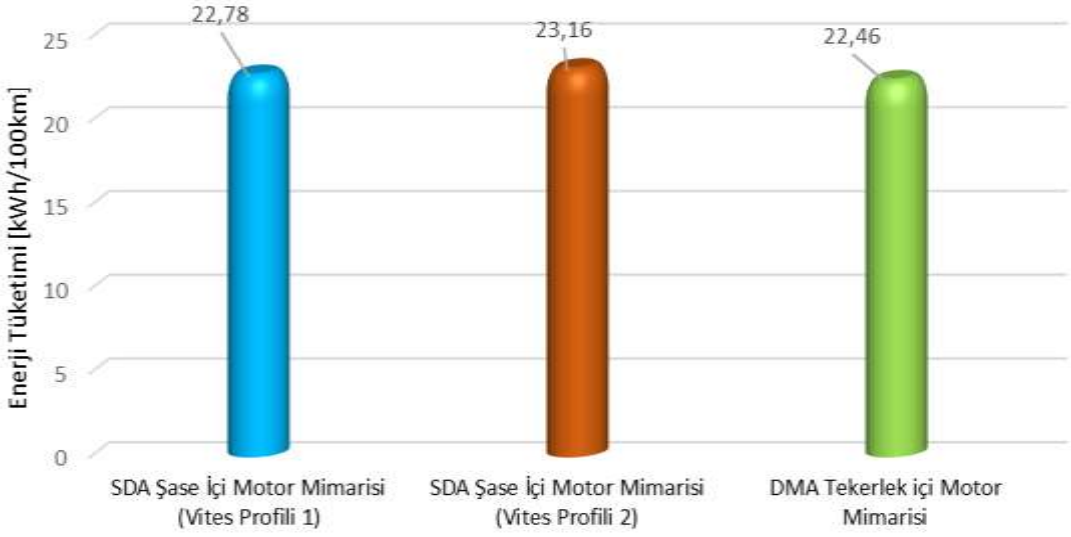
SDA sistemi motordan talep edilen açısal hız ve tork değerlerini yüksek verimli bölgelerde karşılaması için DMA sistemine göre farklı bir ilke uygulamaktadır. SDA sistemi, DMA mimari gibi motorun verim haritasını değiştirmek

yerine çevrim oranını değiştirerek tork ve açısal hızdan oluşan çalışma noktalarını verimli noktalara taşımaktadır. Çevrim oranın uygun bir şekilde değiştirilmesi için literatürde farklı optimizasyon ve kontrol algoritmaları kullanılmıştır. Bu çalışmada, açısal hıza bağlı olarak çevrim oranının değişimini kontrol eden iki adet doğrusal vites profili tercih edilmiştir. Şekil 8'de bu iki kontrol neticesinde çalışma noktalarının verim haritası üzerinde dağılımı görülmektedir. Buradan görüldüğü üzere, doğrusal modelde eğimin değişmesine bağlı olarak çalışma noktalarının verim haritası üzerindeki dağılımı değiştirilebilmektedir. Aynı değişimi, DMA mimarisinde de görmek mümkündür. Şekil 8'de özellikle 1. vites profilinin daha fazla sayıda yüksek verimli bölgede bulunan çalışma noktasına sahip olduğu görülmektedir. Neticede, ilk profilin motorun enerji tüketimini azaltması muhtemeldir.



Şekil 8. SDA sistemine sahip şase içi elektrik motorunun verim haritası ve çalışma noktaları

Motordan talep edilen çalışma noktalarının yüksek verimli bölgelerde karşılanması için incelenen iki farklı stratejinin enerji tüketim değerleri Şekil 9'da paylaşılmıştır. DMA tekerlek içi motorun SDA sisteminin 2. vites tipine göre %3 daha az, 1. vites oranına göre %1.6 daha fazla enerji tüketmiştir. Bu değer hesaplanırken, DMA sisteminde stator konum kontrolü ve SDA sisteminde kasnakların konum kontrolleri için harcanan enerjiler hesaba katılmamıştır. Bunun yanında, stator konum kontrolü ve SDA sisteminin kasnak konum kontrolü için farklı algoritmalar ve yapılacak optimizasyon çalışmaları neticesinde bu değerlerin iyileştirilebileceği düşünülmektedir.



Şekil 9. İki farklı mimarinin enerji tüketim değerlerinin kıyaslanması

4. TARTIŞMA

Bu çalışma kapsamında, DMA özelliğine sahip tekerlek içi elektrik motoru mimarisi ile SDA sistemine sahip şase içi elektrik motoru mimarisinin enerji tüketimleri karşılaştırılmıştır. Enerji tüketimlerinin hesaplanması için araç tahrik modeli, elektrik motoru verim modeli, güç aktarma sistemi modeli ve yakıt pili modeli oluşturulmuştur. Enerji tüketim değerlerinin hesabında WLTC sınıf 2 sürüş çevrimi kullanılmıştır.

DMA özelliğine sahip mimarinin temel çalışma ilkesi olan statorun rotor içerisindeki konumu değiştirilmesi suretiyle verim haritasının değişimi, elde edilen simülasyon çıktılarında sunulmuştur. DMA özelliği sayesinde, değişken güç aktarma organına gereksinim duyulmadan, motorun çalışma noktaları verimli bölgelerde karşılanabileceği görülmüştür.

SDA sisteminin temel çalışma ilkesi ise, çevrim oranını değiştirmek suretiyle motorun çalışma noktalarını verim haritasındaki yüksek verimli bölgelerde olacak şekilde konumlandırılabilmektedir. DMA sisteminin aksine, motor verim haritasını değiştirmeden çalışma noktalarını mümkün en yüksek verimli bölgelere taşınabilmesine olanak sağlamaktadır.

Matematik modelin çıktıları neticesinde, DMA sisteminin, SDA sisteminin 2. vites profiline göre yaklaşık %3 daha az ve 1. vites profiline göre yaklaşık %1.6 daha fazla enerji tükettiği görülmüştür. Bu değerin hesaplanmasında, stator konum kontrolüne ve SDA sisteminin çevrim oranı kontrolüne harcanan enerjiler dikkate alınmamıştır. Gelecek çalışmalarda, kontrole harcanan enerjinin hesaba katılmasıyla modelin iyileştirilmesi hedeflenmektedir. Aynı zamanda, yapılacak deneysel çalışmalarda, oluşturulan modelin doğrulanması hedeflenmektedir.

Bu çalışmada oluşturulan model, ilgili konu üzerinde yapılacak gelecek çalışmalara referans olacağı düşünülmektedir. Çalışmada, stator konum kontrolü ve SDA sisteminin kasnaklarının konum kontrolünde motorun açısal hızına göre doğrusal bir ilişki içeren algoritma kullanılmıştır. Gelecek çalışmalarda, konum kontrolünde izlenen stratejinin iyileştirilmesiyle her iki sistem için enerji tüketim değerlerinin azaltılacağı öngörülmektedir. Bunun yanında yazarlar, algortima ve sistemin tasarımında yapılacak optimizasyon çalışmalarıyla performanslarının iyileştirileceğini düşünmektedirler.

ABSTRACT

Noise source localization or source identification is an important phase during the diagnosis activities of an NVH problem. It is basically the detection of an unknown noise source. It can become very cumbersome when the noise comes from a crowded environment containing lots of noise sources. Such efforts may require special tools and/or methods as well as new experiment or test designs because standardized tests do not provide sufficient information for some cases. In this paper, the diagnosis phase of a high-order / high-frequency noise problem arising from the eccentric (camshaft) cover of a diesel engine is summarized. The tests designed and the maneuvers chosen for spotlighting the issue, frequency range determination, noise localization methods and swap analysis activities are explained. It is also stressed how the use of acoustic holography technique supported the diagnosis activities and validates the outcomes from the other NVH analyses as well as the swap studies.

Keywords: Noise source localization, noise source identification, acoustic holography, eccentric camshaft noise, NVH diagnosis, swap analysis

1. INTRODUCTION

Localizing the source of a noise problem is a major concern in NVH area. Since there are lots of noise sources on a vehicle, this may not always be an easy task. Various methods and specialized equipments have been developed to be utilized in noise source localization activities. Some of the noise mapping methods are sound intensity mapping, acoustic holography and beam forming [1]. Acoustic holography is probably the most preferred one among these methods. It is especially useful for the sound source localization issues having mid-to-high frequency content.

2. INVESTIGATION OF THE NOISE

2.1. Characterization of the Noise

In this study, a noise issue having a high-order / high-frequency content emitted from the engine compartment of a diesel internal combustion engine is investigated. The noise is audible from inside the vehicle cabin during acceleration and deceleration maneuvers in low gears. It can also be heard while cruising at constant speed with low rpm.

The characteristic of the noise is a turbo-whoosh-like high frequency sound. In order to find out the frequency range of the noise, two vehicles which were subjectively evaluated as noisy and quiet were arranged. After a preliminary measurement from the driver ear location, the analyses of the data collected pointed out that the noise lies within 2000-3000 Hz interval. Figure 1 shows the difference in the noise levels of the two cars in comparison. In this figure, the color maps in the upper row belong to the quiet car while the ones in the lower row represent the noisy car. The left-hand side pair depicts the data collected during a constant speed drive in first gear. And the right-hand side pair shows the measurement results performed during a constant speed drive in second gear. As seen in the figure, the noisy car has a dirtier content in the color maps between 2000-3000 Hz for both of the maneuvers. Using these data, a listening and filtering study was also executed. By bandstop and bandpass filtering the data between 2-3 kHz and listening the filtered data, the frequency interval of the noise was validated.

2.2. Noise Source Localization Studies

2.2.1. Microphone Array Measurements

To investigate the noise further, the top cover of the engine was removed and a measurement setup having an array of 12 microphones over the engine was prepared. This array consists of four rows and three columns. The microphones were positioned in paralel to the engine block top surface at a height of 5 cm from the top level of the engine (Figure 2).

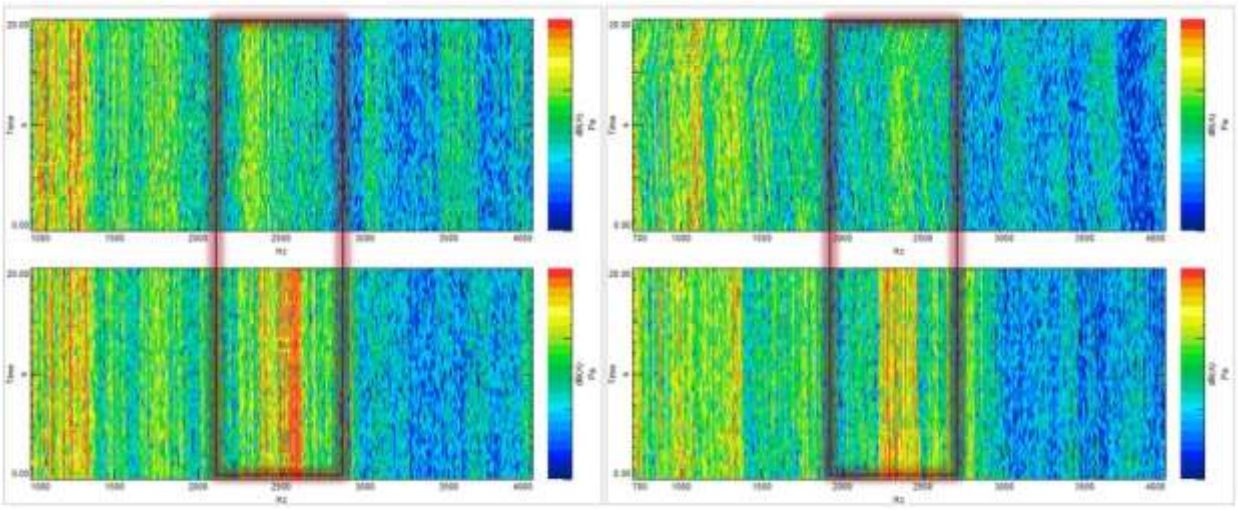

Figure 1. Frequency interval of the noise.

Figure 2. Microphone array

The measurements were carried out on the chassis dynamometer in a semi-anechoic chamber. To constitute a standard for the measurement activities, two maneuvers on the chassis dyno were determined. These maneuvers were cruising at the constant speed of 10 kph (1300 rpm) in first gear and at the constant speed of 18 kph (1250 rpm) in second gear. At the same time, the noise levels inside the cabin at the driver ear positions were also measured. The results of the measurements performed on the two vehicles were compared. The frequency spectrum graphs were plotted after taking the average of the data from left and right ear positions (Figure 3). The graphs in Figure 3 show that the noisy car has more than 3 dB higher noise level than the quiet car in the 2-3 kHz interval for both maneuvers.

The result of the microphone array measurement was mapped by color to provide some visualization (Figure 4). In this map, the red color represents the areas with a sound pressure level of more than 82 dB and at the same time having a difference of more than 4 dB in SPL with respect to the quiet vehicle. The yellow color represents the areas with a sound pressure level of more than 82 dB and at the same time having a difference of less than 4 dB in SPL with respect to quiet vehicle. And the green color represents the areas with a sound pressure level of less than 82 dB and at the same

time having a difference of more than 4 dB in SPL with respect to quiet vehicle. As seen in the map, the center area of the engine with a U-shape painted in red color seemed to be critical regarding the issue.

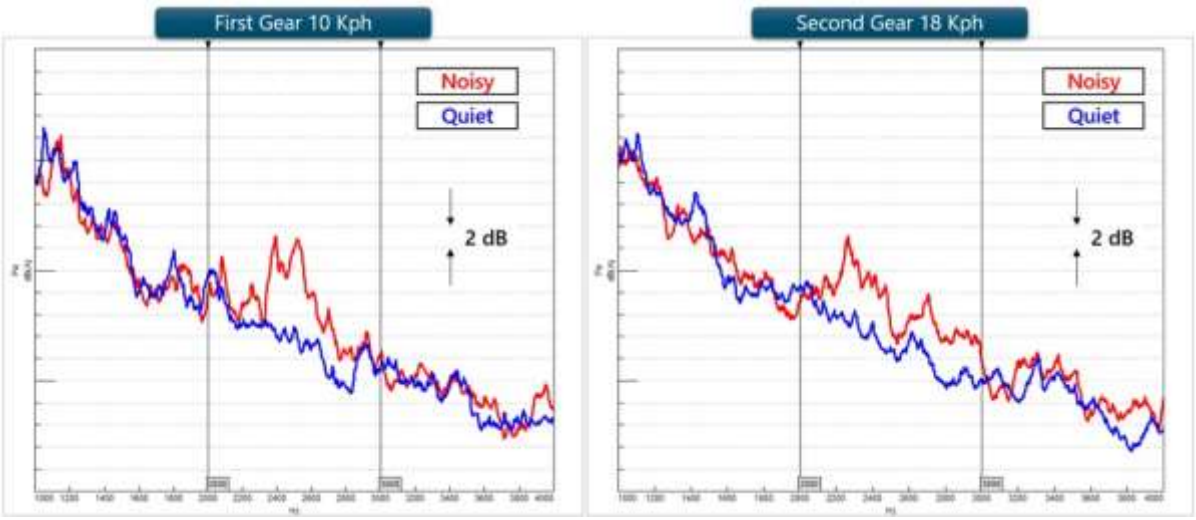

Figure 3. Comparison of the noise levels at driver ears for the noisy and the quiet vehicles

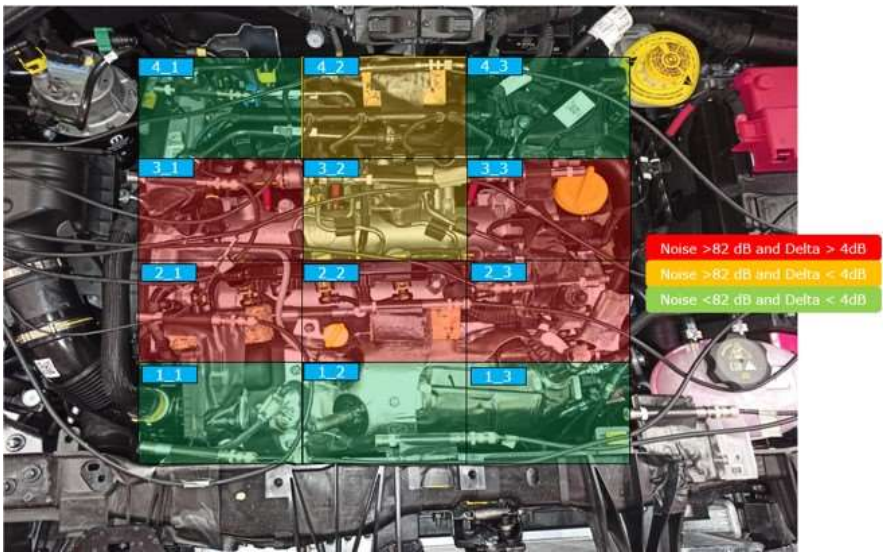

Figure 4. Result of the microphone array measurement

2.2.2. Acoustic Holography Analyses

Since this map is somewhat blurred and does not finely localize the noise source, acoustic holography method was also applied. For this purpose, a special acoustic holography instrument operating on a beamforming method called Head Visor was utilized. It is a powerful tool for visualization of the sound sources. It has an array of 56 microphones arranged in a spiral shape and logarithmic distribution (Figure 5). It has its own data collection hardware and a specialized software [2]. The software has the ability to create holographic images for a selected range of frequency. Also, it provides a tool called 'Virtual Microphone' to specifically show the noise level at a desired spot on the holographic image. Also, with its so-called 'Stepping' function, the primary source can be eliminated from the analysis and this way, the next most important noise source in the absense of the primary source can be spotted.

There are also other types of sound source localization techniques such as mapping by sound intensity [3], or Near-Field Acoustic Holography [4]. But for the case under investigation, only the beamforming method was utilized.

Figure 5. Head Visor acoustic holography instrument

The same maneuvers were repeated for the noisy and the quiet vehicles with the Head Visor. The results of the acoustic holography analyses for the two maneuvers are given in Figure 6 and Figure 7. The same two spots appear as the noise source for both of the maneuvers. The one on the right-hand side with a higher noise level is around at the center of the eccentric top cover (exhaust camshaft) while the one on the left-hand side with a lower noise level points out the eccentric cogwheel of the exhaust camshaft. There is a difference of around 5 dB in the noise levels of these two sources. From these results, it can be concluded that the primary source of the noise is the exhaust camshaft and the secondary one is the exhaust camshaft cogwheel. For the noisy car, the noise levels measured at these points are 6 to 8 dB higher than those of the quiet car. Since the holographic images are 2D planar views, they do not provide information about the depth of the area of interest. This means that the noise sources marked the picture may be beneath the spotted area.

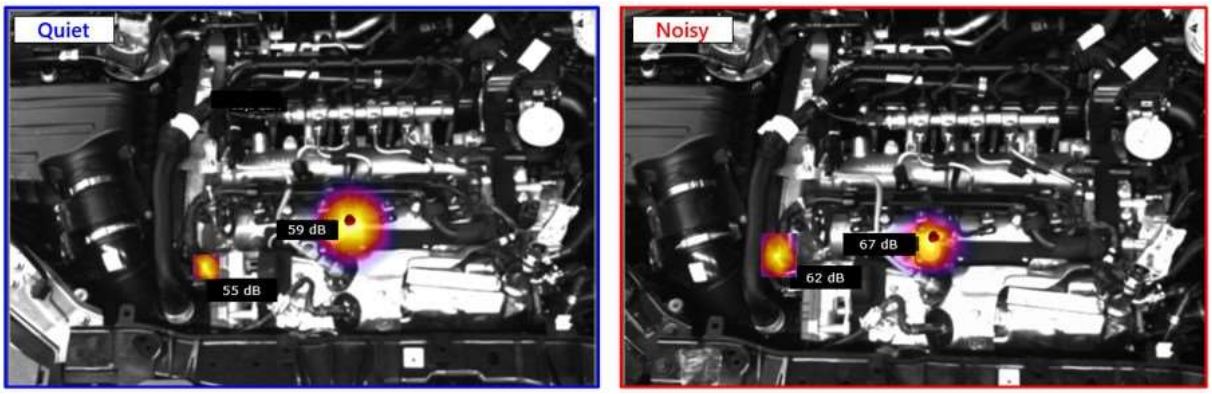

Figure 6. Acoustic holography 2-3 kHz result for the first maneuver (10 kph - 1300 rpm in 1st gear)

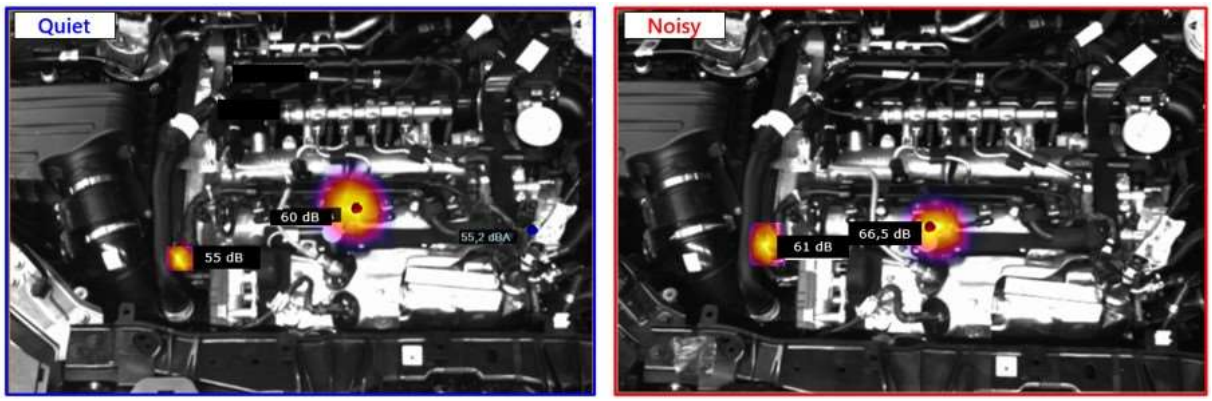

Figure 7. Acoustic holography 2-3 kHz result for the second maneuver (18 kph - 1250 rpm in 2nd gear)

2.3. Non-Stationary Measurements

Since the noise pitch changes with the changing engine speed, to see the situation in non-stationary (transient) conditions, it was also executed acoustic measurements with the same microphone array during run-up/run-down maneuvers in first and second gears with the noisy and the quiet vehicles. Again, these maneuvers were held on chassis dyno. The frequency of the noise was changing with increasing or decreasing engine speed.

The results of the acceleration and deceleration maneuvers in second gear are given in Figure 8. These are the color map graphs plotted from the measurement data of the microphone designated as 3_1 in Figure 2. It can be seen in Figure 8 that the noise follows the 110th order both for run-up and run-down maneuvers. There is a distinct trace line at 110th order for the noisy car. The situation was similar for the first gear maneuvers as well.

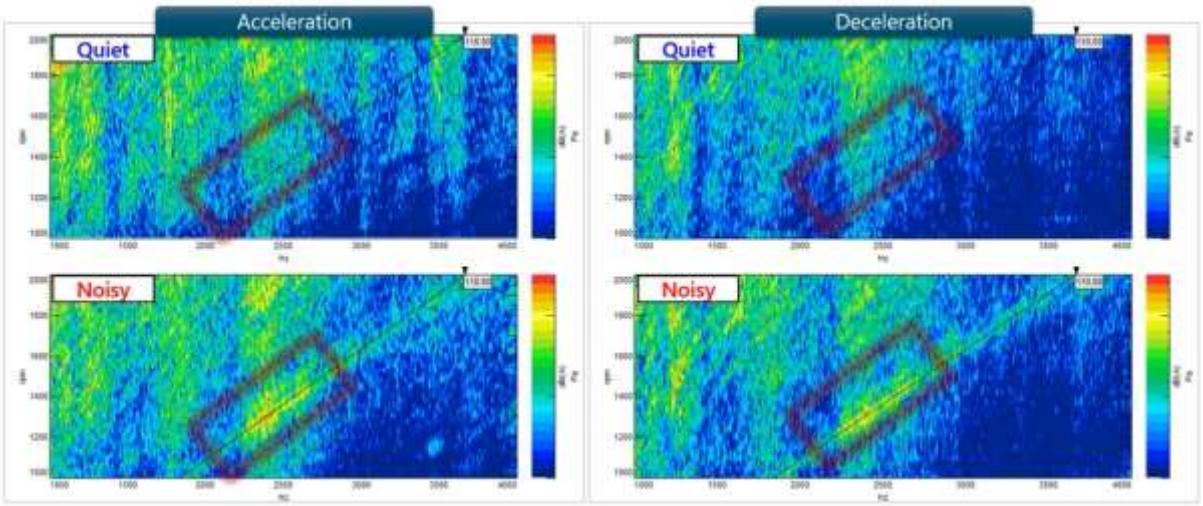

Figure 8. Measurement results in run-up /run-down maneuvers

To obtain additional information and to understand if there exist a modulation between the rotating parts, a vibration measurement setup was organized (Figure 9). In this setup, four accelerometers were attached onto the camshaft casing. Three of them were on the exhaust camshaft side and one accelerometer was on the intake camshaft side. These are tri-axial vibration sensors and vector sum of the vibration data collected from these sensors were analyzed. Again, the measurements were executed on the two vehicles with the same setup and maneuvers on the chassis dyno.

Figure 9. Vibration measurement setup

The result of the vibration measurements pointed out the 110th order again. The highest level of vibration among the measurement points was observed at Point 2. No modulation or no side bands/orders were detected in the analyses. All maneuvers gave the similar results. As an example, the color map graphs for the vibrations measured during the second gear acceleration maneuver are given in Figure 10.

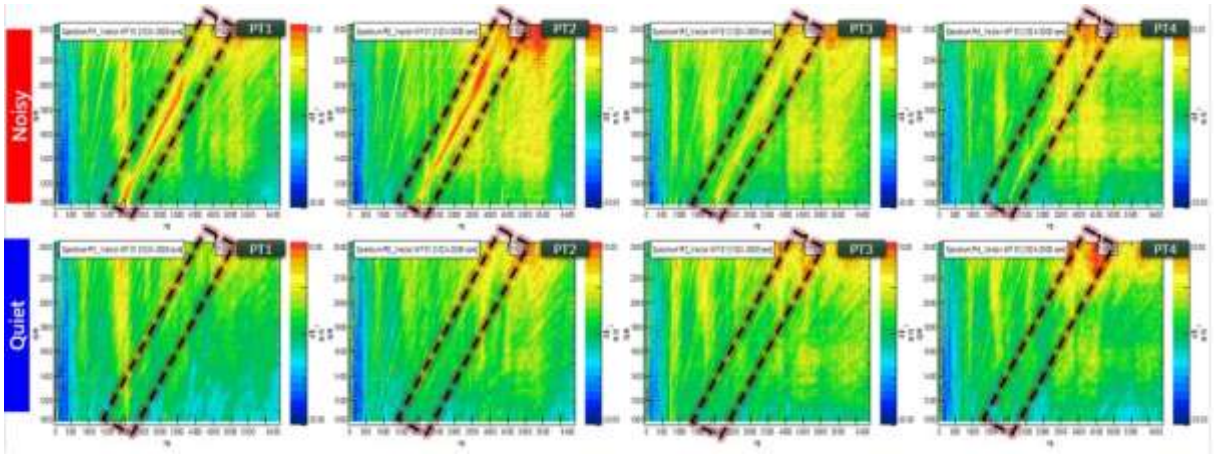

Figure 10. Results of the vibration measurements for the acceleration in second gear

The type of camshaft system of the engine under study is classified as an overhead valve train camshaft system in which each cam or lobe opens the valve directly with a bucket [5]. Since there are two camshafts on this camshaft system, it is named as a dual overhead camshaft system [6]. They are covered by one single housing (top cover). One of the camshafts is responsible for the intake valve timing and the other one manages the timing of exhaust valves. The camshafts are driven by the crankshaft. There is a small-diameter pulley attached to the back of the crankshaft pulley. The timing belt transmits the torque from the crankshaft via this small pulley to the camshaft pulley (cogwheel). The camshaft pulley drives the exhaust camshaft. The intake camshaft is driven by the pair of camshaft gears. This way, the lobes on the camshafts perform the push-pull action of the corresponding valves which is crucial for valve timing to provide synchronization for the famous four-cycle process of an internal combustion engine. The 110th order comes from these rotating powertrain elements.

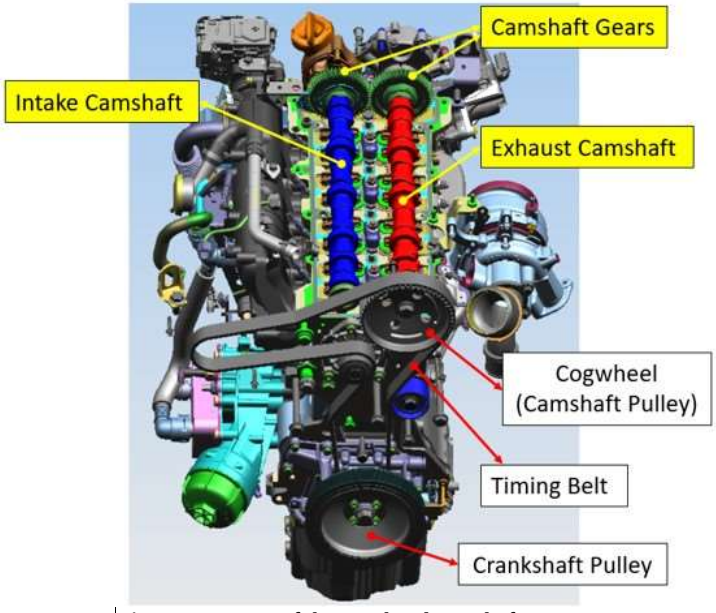

Figure 11. Parts of the overhead camshaft system

2.4. Swap and Trial-Error Analyses with Physical Parts on Vehicles

In parallel with the acoustic measurements, a swap and trial-error analysis plan with physical part replacements on vehicles was executed. First, the V-belt driving the engine accessory parts like the air conditioner compressor was disassembled from the noisy car. The noise continued to exist in this condition. After that, timing belt tension was checked and validated. Next, the vacuum pump and the turbo oil inlet pipe were replaced with new ones on the noisy vehicle. These trials did not change the noise.

Then, parts swapping activities between the noisy and the quiet vehicles were started. Since the characteristic of the noise gave the sense of turbo-noise similarity, first the turbo compressors of the two cars were swapped. After this intervention, the noisy vehicle was still noisy and the quiet vehicle was still quiet.

Next, the complete camshaft assembly with the camshafts and gears was swapped between the two vehicles. With this modification, the noisy car became quiet and the quiet car became noisy. In other words, the noise was carried from the noisy car to the quiet car. In order to validate these results, the same parts were re-swapped to their original conditions. After re-swap, the noise was transferred again to the car which was noisy at the beginning. Also, the originally quiet car became quiet again after the reswap. Hence, the outcome was validated and it was understood that the noise source is inside the complete camshaft assembly.

To investigate further the issue, this time only the housing (cover) of the camshafts assembly was swapped between the two vehicles. With this attempt, the noise did not transferred to the quiet car. So, the housing was acquited.

Next, the camshaft pulleys (cogwheel) driving the camshafts through the timing belt were interchanged between the two cars. This intervention did not change the noise conditions of the noisy and the quiet vehicles.

The next attempt was to swap the camshaft gears between the two vehicles. After this swap trial, again, the noisy vehicle was still noisy and the other one was still quiet. This means the problem does not arise from these gears.

When the exhaust camshafts were swapped between the two vehicles as the next step, the quiet car became noisy and the noisy car became quiet. This indicated that the source of the noise is the exhaust camshaft of the vehicle which had been subjectively evaluated as noisy. The trials and the swap activities were summarized in Table 1.

Table 1. Summary of Swap and Trial-Error Activities with Physical Parts on Vehicles

Swap No	Activity	Noisy Vehicle	Quiet Vehicle
0	Original condition	Noisy	Quiet
0	The V belt was canceled on Noisy Vehicle	Noisy	X
0	Engine timing belt tension checked on Noisy Vehicle	Noisy	X
0	Vacuum pump changed on Noisy Vehicle	Noisy	X
0	Turbo oil intake pipe changed on Noisy Vehicle	Noisy	X
1	Turbo	Noisy	Quiet
2	Complete Camshaft Assembly (cover, camshafts, cogwheel, camshaft gears) was swapped	Quiet	Noisy
3	Complete Camshaft Assembly (cover, camshafts, cogwheel, camshaft gears) was re-swapped	Noisy	Quiet
3.a	Camshaft Housing (Cover)	Noisy	Quiet
3.b	The Cogwheels (Camshaft Pulley) were swapped	Noisy	Quiet
3.c	The camshaft gears were swapped	Noisy	Quiet
3.d	**Exhaust Cam Shafts were swapped**	Quiet	Noisy

3. CONCLUSION

The outcome of all of the analyses indicated that the source of the noise is the exhaust camshaft. Both the intake camshaft and the exhaust camshaft each have eight lobes on them corresponding to the timing valves of the engine. These lobes push the valves and pull back or release them as they rotate synchronously with the crankshaft. This action provides the precious valve opening/closing cycles with a perfect timing which is a key operation principle for an internal combustion engine.

After the detailed examinations and inspections on the camshaft, it was found out that the root cause is a chattering phenomenon on the camshaft lobe surface finish with an order of magnitude of nanometer levels. The chatter phenomenon is a known fact that can create different noise issues [7]. The inspection and examination details on the issue are beyond the scope of this article. However, it is seen from the studies explained that the sound source localization techniques together with the conventional NVH measurements and analyses lead to the right direction and provide valuable information for the solution progress of a noise problem. Knowing that on which point to focus and attack, the right corrective or improving action can be organized more easily.

ABSTRACT

The increase in the search for comfort in vehicles puts pressure on the automotive OEMs and their suppliers to work on these issues. These pressures are the driving force for the development of each element that makes up the vehicle at a level that will increase the interior comfort quality of the vehicle. In addition, the customer expectation is that this comfort continues for a long time. In this study, it includes the analysis of the acoustic performances of the vehicle door sealing elements, which are one of the important elements of the interior cabin comfort, with the weathering & permanent set effect. In line with the study, the acoustic performances of two types of door sealing elements used in passenger cars were examined before and after weathering and permanent set. While the weathering cabinets of the weathering tests and the test conditions suitable for the main industry were determined, the acoustic cabin was used for the acoustic tests by the experimental method. As a result of the interpretation of the experimental test results, it has been observed that the weathering tests have effects on the acoustic performance on the level of frequency and sound transmission loss, but the weathering simulation existing test procedures are not sufficient to observe the effect of aging on acoustic performance. This study is of critical in terms of the importance of reconsidering the acoustic perspective on weathering & permanent set test processes in the sealing systems of the OEM and sub-industry companies' perfectives.

Keywords: Sound transmission loss, vehicle sealing profiles, thermoplastic elastomer, acoustic analysis, weathering

1. INTRODUCTION AND MAIN SECTIONS

Vehicle noise and vibration performance is an important vehicle design validation criterion since it significantly affects the overall image of a vehicle. Noise and vibration degrade the driver's and passengers' comfort and induce stress, fatigue and feelings of insecurity. Modern vehicle development requires noise and vibration refinement to deliver the proper level of customer satisfaction and acceptance. It is common for a customer's perception of vehicle quality to relate closely to the noise and vibration characteristics of the vehicle. Globalization combined with increased competition in the marketplace requires a vehicle's noise and vibration characteristics to be well optimized. The sound present in the interior of a vehicle consists mainly of powertrain noise, road noise and wind noise. The disturbing noise sources of a vehicle and the disturbing acoustic design parameters that determine the comfort quality can be summarized as the following visual.

Table 1. Vehicle acoustics: minimization.[1].

Exterior noise	Pass-by	Disturbing noise
	Idle	
Interior noise	Squeak/rattle	
	Resonance effect	
	Road noise	
	Auxiliaries

Wind noise is one of the most important sources of noise in vehicles. It creates disturbance for customers in terms of noise and harmony in the cabin and is expected to improve. It is an important requirement for companies to be able to respond to this need by conducting R & D processes for automotive manufacturers. Since the improvements in noise source are limited by criteria such as ergonomics, performance and cost, the most efficient way is to prevent high frequency wind noise in the transmission path, that is, acoustic insulation of the cabin. The sealing profiles used for the purpose of the isolation of all environmental factors in the vehicles are also one of the most important parts for the prevention of wind noise. A well-designed seal should have high sound transmission loss (STL) [1].

Weather-strips are essential parts to control noise levels in the vehicle interior. Elastically properties of the rubber parts are utilized to reduce aeroacoustics noise around the vehicle emitting via an airborne transfer path. Even there not any air leakage through the interior cabin, Sealing systems are required to have a good insulation performance to prevent mid and high-frequency noise ingress.

TPE sealing materials, which are an effective solution in the topics such as weight and cost reduction, one of the trends of the century in automotive sector, have been the subject of many academic and industrial researches . EPDM materials, on the other hand, still remain an important raw material in the sealing systems industry. These two materials fulfill the performance characteristics that expected of a sealing system within their dynamic, mechanical properties. These two materials, which have different behaviors as chemical and physical properties, naturally exhibit different performances[2].

Sealing element studies take place in the literature with R&D studies on more than one subject. While the studies of EPDM materials, which form the raw material of the sealing element, are evaluated under the title of chemistry, acoustic studies, one of the performance criteria expected from the components, are examined under the title of noise, vibration and hardness (NVH). Past studies have been analyzed under both titles following the subject of this study. When the past NVH studies are examined, Gur and Norman performed FEM (Finite Element Method) calculations for single layer elastomer parts for door sealing and presented their findings along with vehicle-level test results[3]. Andro et al. presented numerical FEM results with a comparison of the measurements, and they provided the effect of compression on the STL (Sound Transmission Loss) curve [4]. Zhao et al. experimentally conducted a study examining the aging process of EPDM material [5].

Automotive components are critical parts for their long-term performance in terms of operating conditions and time. What is expected from a sealing system is that it can insulate the interior of the vehicle from water, dust and sound by preserving its long-term geometry. Due to the fact that the sealing systems are made of polymer-based raw materials, they may experience performance changes over time by being affected by external factors. In this direction, weathering & permanent set tests are carried out in order to simulate long-term aging and shape changes on the sealing elements under laboratory conditions. In these tests, the changes after the sealing elements are exposed to certain weather conditions are examined. This study investigated the effect of these weathering & permanent set tests on the acoustic performance of the seals. Acoustic performance is one of the important characteristics of sealing elements. They are of critical importance in providing vehicle interior comfort.

In this study, the effect of weathering and permanent set applications on the acoustic performance of the sealing elements, which are one of the important insulation materials of the vehicles, was analyzed. In the study, a door sealing element and body sealing element made of EPDM materials used in passenger cars were tested. The test set was created in this way in order to observe the effect on each sealing element and the effects of different materials.

In the study, weathering conditions were carried out in weathering cabinets in the laboratory. Two main variables were selected in the weathering conditions and weathering was performed in different situations, temperature and time. Test groups were tested under two different climatic temperature and time conditions. This situation is designed to analyze the effect of each test parameter.

Then, test samples, whose weathering and permanent set tests were completed, were subjected to experimental acoustic performance tests. Acoustic tests were carried out using an acoustic cabinet under laboratory conditions. By evaluating the results obtained with the outputs of the acoustic tests, changes were observed in the acoustic performance of both the frequency band and the STL levels after the weathering and permanent set applications of the sealing elements.

2. MATERIALS AND METHOD

Material and method details used in the study are specified under two main subheadings. While the first of these is the grouping and material details of the sealing elements that make up the test set, the second includes the details of the methods of test and verification studies used in the study.

2.1. Test Parts & Materials

Sealing elements used in the automotive industry are manufactured from raw materials in polymer class. Polymer-based materials differ from materials such as metals and ceramics due to their atomic structures and bonds. The molecular structures and molecular chains that determine the physical characteristics of polymers have different configurations due to their random kinks and coils.
These configurations are determinative for many characteristic properties of polymer-based materials, from mechanical behavior to temperature sensitivity. These characteristic molecular structures give polymers viscoelastic properties. Thanks to its viscoelastic feature, polymer-based materials show viscous characteristics at high temperature values, while they can display rubbery solid characteristics at medium temperature values and glassy characteristics at low temperature levels. Thanks to their viscoelastic properties, polymer-based materials have both viscous and elastic properties [6].

Energy lost as heat. It is the viscoelastic behavior characteristics that affect many performance of polymer materials such as dynamic, mechanical and acoustic. Viscoelastic parameters of polymer materials are expressed with elastic and viscous modules. Elastic module measures the elasticity ability of the material and shows its ability to store energy, while viscous module the ability of the material to dissipate energy, the energy lost as heat. The tan delta value obtained from the proportional value of these two values represents the dumping capability of the material [7].

$$E' = \frac{\sigma'}{\varepsilon} = E \cos \delta \quad (1)$$

$$E'' = \frac{\sigma''}{\varepsilon} = E \sin \delta \quad (2)$$

$$\tan\delta = E''/E' \quad (3)$$

where:
E: Young's or Tensile Modulus,
E': Stored energy representing the Storage Modulus - elastic part,
E": Energy dissipated as heat representing the Loss Modulus - viscous part,
δ : The phase angle or phase shift, between the deformation and response is measured,
tan δ: tan delta loss modulus / storage modulus.

EPDM material continues to be the most commonly used raw material of sealing vehicle sealing systems, due to its suitability for mass production and the characteristics required for the sealing element. In order to become the raw material of EPDM sealing element, which is a polymer-based material, it must chemically interact with many chemical components. This chemical process creates two different classes of raw materials used in sealants, sponge and compact. Sponge raw materials represent low density materials, while compact raw materials represent materials with higher density and hardness values.

In this study, a test group was formed from sealing elements with EPDM raw material. Sealing elements are grouped in two main classes according to the conditions of use. Static sealing elements are the name given for glass sealing systems, while other door, body and dust sealing systems are called dynamic sealing elements. Test group was determined as door sealing element. Material density and hardness values used in sealing elements in each group are the same. Geometry factor was not included in the study, since this study aims to determine the basic level analysis of the relationship between weathering and permanent set and acoustic performance. This study will form the basis for future

studies that will investigate the effect of geometric parameters on weathering and permanent set and acoustic performance.

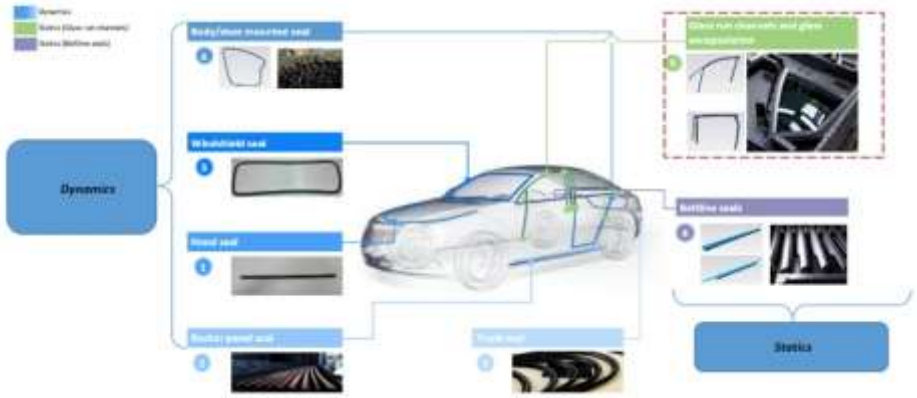

Figure 1. Sealing elements in a vehicle.

Each sample in the test group has been prepared according to the method conditions of the study, according to the weathering and permanent set tests. In Figure 2, the images of the sealing elements to be used in the study are shared (Sample 1, Sample 2). The test group consists of a door seal that is mounted on the vehicle chassis with tape or clip, a body seal mounted with a metal carrier in the vehicle chassis,

Figure 2. Test sealing elements, door, body seals

2.2. Test Methods

Weathering is the adverse response of a product to climate, often causing unwanted and premature product failures and also projection of the long term performance. The weathering test is created by considering the worst conditions of the usage conditions of the part where the test will be applied. Weathering tests are usually carried out using weathering cabinets. In these cabinets, the behavior of the materials is analyzed by exposing the test samples to solar radiation, temperature or water.

The temperature of materials exposed to solar radiation influences the effect of the radiation. Photochemical reactions usually accelerated at elevated temperatures. Besides, temperature determines the rate of subsequent reaction steps. The period is another critical parameter of the weathering tests. In this study, the temperature and period effects of the weathering were selected as test variables, for a better understanding of the effects of each parameter.

Permanent set is the ability of a polymer to maintain its original shape after an applied force. It is also defined as the ratio of elastic to viscous components for polymer-based materials[8].This parameter is measured as the rate of dimensional change after the forces the materials are exposed to for a certain period of time. This force application can also be called compression set under conditions where it is applied as compression. In this study, samples in the test group were subjected to 25% compression test apparatus. Each test group has been tested using the same test apparatus at the same compression rate. Compression set ratio has been determined by examining OEM test standards and literature studies.

Permanent set test results are analyzed in two different ways in sealing elements. The first of these is the proportional change of geometry with the help of measuring devices. In this measurement method, the first and last measurements of the dimensional change of the element of the sealing element are evaluated proportionally Another measurement

technique is the measurement of the instantaneous compression load deflection values (Force-Deflection Analysis) of the samples with computer-connected force gauge test machines. In this study, the first method was chosen as it will provide convenience in proportional comparison. In this study, while the measurement area was determined as the bulb height for the body and door seal. Permanent set calculation equations and sample test apparatus drawing is given below.

$$\text{Permanent set} = \frac{\text{Initial length} - \text{Final length}}{\text{Initial length}} \times 100 \quad (4)$$

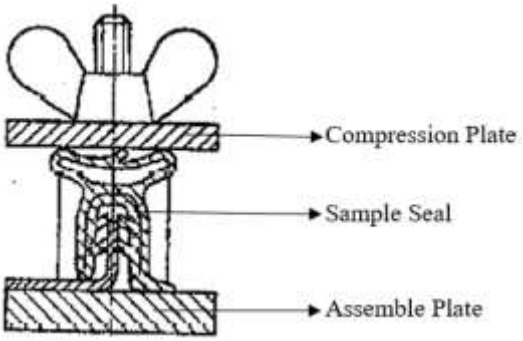

Figure 3. Test apparatus of permanent set

In this study, each sealing element weathering was tested in four different weathering test setups. Each test set contains different scenario details. These test parameters are determined in order to observe the effect of each parameter. Test settings are as below table.

Table 3. Test set parameters.

Test Sets	Temperature (°C)	Time (Hour)
Set 1	100	72
Set 2	100	168
Set 3	70	72
Set 4	70	168

Two different experimental acoustic test systems were used as test systems in the study. The first of these is the acoustic test cabin where the sound transmission loss of the sealing elements is measured before and after the weathering and permanent set tests.

In order to determine the performance of the parts in the acoustic cabinet tests, the profile section was taken as a basis and the standard sample size to simulate this section was used. Thus, the acoustic performance of the geometric and material properties of the part has been tested. In addition, the door openings in the mounting position on the vehicle were taken into account and all test samples were tested on the same door and frame type sections. A suitable apparatus has been manufactured in order to ensure the tight assembly of the part between the source and the receiving side.

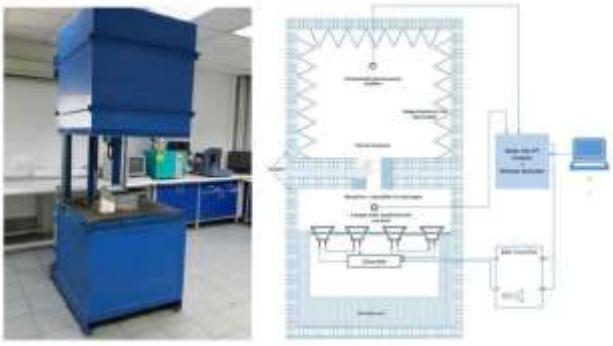

Figure 4. Acoustic cabinet measuring hardware images

The measuring equipment mainly consists of a source chamber representing the scattered area and an anechoic receiver room representing the free space. Between these two rooms, there is a separator partition and mounting fixture that

allows the sound transmission to occur only through the part to be measured. The visual of the acoustic cabinet and the schematic image of the measurement system is given in Figure 4.

Noise between 250 - 10k Hz was generated by using the white noise signal on the source side. The noise levels measured on the source and receiver side are shown in 1/3 octave bands. The generated noise level was obtained by averaging the sound pressure level of 3 points on the receiver side. Absorbent materials and reflective structures used on the receiver side were tried to create a free space effect as much as possible, and a dispersed area effect as possible with the diffusers on the source side. The results obtained are shown in a linear scale in 1/3 Octave band between 500 - 5 kHz. Sound transmission loss (STL) is a theoretical performance metric that determines the sound transmission character. Measurements have been made within the framework of the formulations below and the results are graphed in 1/3 octave band.

$$STL = 10 \log_{10} \frac{I_t}{I_i} \quad (5)$$

where:

I_t :Radiated acoustic energy

I_i :Radiated acoustic energy

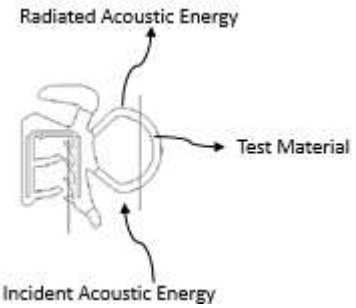

Figure 5. Acoustic Cabin Test Model

In order to verify the effect of elasticity loss of materials on acoustics, a comparative validation study of impedance tube results with finite element analysis software was conducted. Verification studies were carried out in order to verify that the sealing elements lost their elasticity after air conditioning applications.

The impedance tube Test kits consist of precision testing tubes that are equipped with microphones and sound sources. Material samples are inserted into the tube. A loudspeaker in the tube then emits precisely quantified sound, and the microphones measure the sound pressure level at specific locations along the length of the tube. The software then calculates the normal incident acoustic properties of the material based on frequency response functions measured between the various measurement locations.These tests were performed under the test conditions specified in ASTM E2611 standard. In line with impedance tube theory, a sound source is mounted at one end of the impedance tube, and a sample of the material is placed in a holder. The loudspeaker generates broadband, stationary random sound waves that propagate as plane waves. The plane waves hit the sample in the holder with part of the waves reflected back into the source tube, part absorbed by the material and part passing through the material to the receiving tube. The portion of the plane waves that pass through the material then encounter the end of the receiving tube where some of the waves are reflected and some exit the tube. By measuring the sound pressure at four fixed locations (two in the source tube and two in the receiving tube) and calculating the complex transfer function using a four-channel digital frequency analyzer, it is possible to determine the transmission loss of the material [9].

MSC Actran is used as the analysis program based on finite element method. The geometry of the apparatus used in impedance tube tests was taken as a reference in the program. In two-dimensional modeling, the acoustic airports and the boundary conditions of the profile are determined by taking the cabin test as a reference. The acoustic performances of the sealing profiles of MSC Actran analyzes are determined by the sound transmission loss measured under the diffuse sound field and calculated by numerical methods. In this study, sound transmission loss analyzes for sealing profiles were performed under numerically generated diffuse sound field excitation. Finite and infinite acoustic spaces are modeled. Acoustic analyzes were theoretically carried out by making free field and dispersed field theoretical assumptions [7]

3. RESULTS & DISCUSSION

The materials in the experiment set were first placed in the weathering cabinets and tested under the same permanent deformation pressure at different test temperatures and times. At this stage, the effect of different temperature and time on the products was examined. Test outputs are shared as in the table below. In line with the obtained test results, it has been observed in all products that temperature is a more dominant parameter than time under air conditioning conditions.

Table 4. Test results of weathering & permanent set

Test Sets	Temperature (℃)	Time (Hour)	Sample 1	Sample 2
Set 1	100	72	38,00%	40,00%
Set 2	100	168	48,00%	52,00%
Set 3	70	72	28,00%	28,00%
Set 4	70	168	33,00%	34,00%

Acoustic cabin tests were conducted before and after weathering tests for each profile. Set 2 samples, in which the highest dimensional difference was observed for each sample, were used for the evaluation of acoustic cabinet tests. Thus, these set samples were preferred in order to analyze the differences before and after the test more clearly.

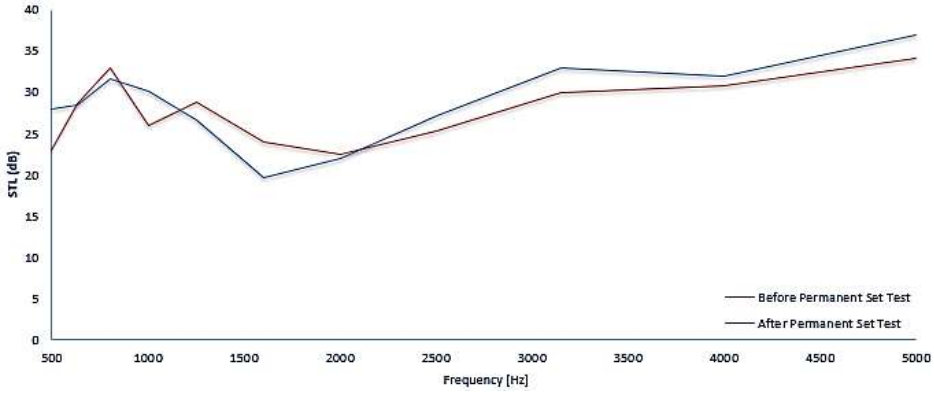

Figure 6. Test sealing elements, door, body seals

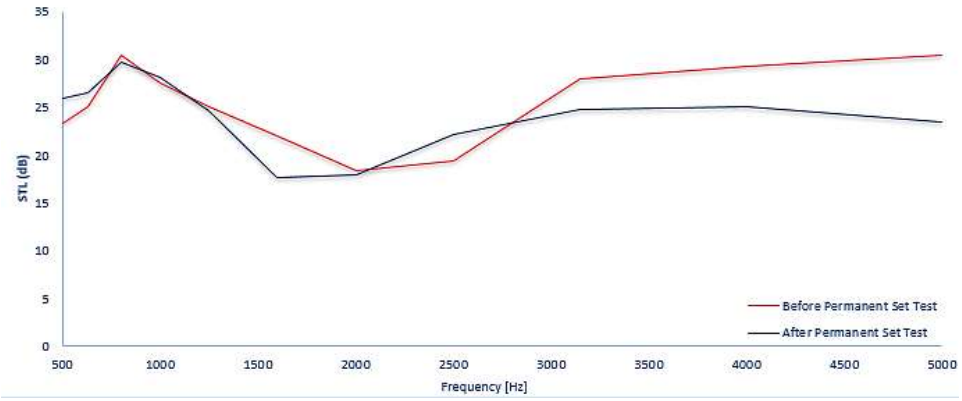

Figure 7. Test sealing elements, door, body seals

When the obtained results are evaluated, a frequency shift is observed at the first resonance points in the STL graphs within two samples. In addition, a decrease in STL capabilities has been observed. It is predicted that the reason for the slip of this resonance point is due to the loss of elasticity in the materials after being exposed to the climatic conditions. In order to verify this prediction, the decrease in elasticity of the materials was analyzed using the experimentally validated FEM model to analyze the decrease in elasticity. In this way, it was observed that the materials lost their elasticity with air conditioning and permanent set tests and the effect of this loss of elasticity on acoustic performance was also observed numerically. Accordingly, a sample set with known mechanical properties was subjected to a sound

transmission loss test in the impedance tube. Afterwards, the same test system was modeled in the FEM software MSC Actran and the results were shared as follows.

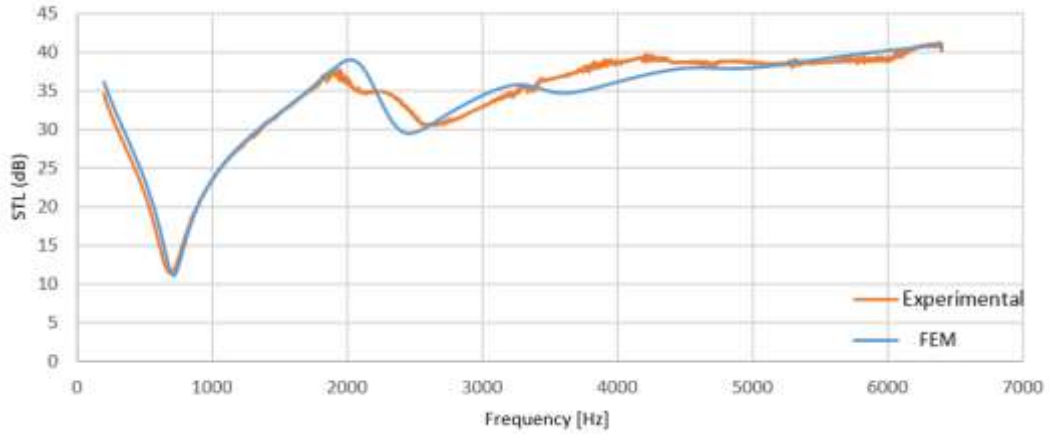

Figure 8. FEM & impedance test results

When the results obtained from the tests of circular samples, independent of the geometries of the sealing elements, were compared experimentally and FEM, it was observed that the model was successful in modeling the bottom frequency. After that, the frequency and STL behavior were analyzed when the material loses its elasticity by decreasing the elasticity value of the same model. The results obtained are plotted on the graph below.

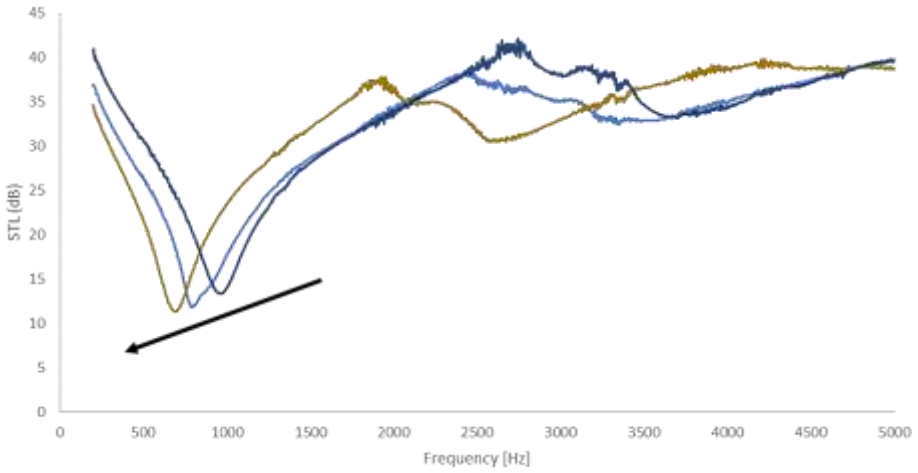

Figure 9. STL curves of FEM model (Elasticity reduction effect is mentioned).

4. CONCLUSION

In this study, the effect of the weathering & permanent set tests used in aging simulations of the sealing elements used in vehicles on the acoustic performance of the sealing elements was investigated. The outputs of the acoustic tests performed before and after the weathering & permanent set test of the door and vehicle casing sealing elements selected for the test group are respectively given below:

- It has been determined that the temperature parameter is more dominant on the deformation of the products than the duration parameter.
- When the results of the acoustic cabinet tests were examined, it was observed that the weathering & permanent set tests effect on the sealing elements as acoustic performance. It has been determined that these tests affect the dip frequency values, which are critical in the acoustic performance of the samples, both in the STL and the frequency band.
- It has been determined by FEM analysis that the effect on acoustic performance is caused by the loss of elasticity in the material. When the results obtained by reducing the elasticity of the material in

FEM analyzes with the validated material model were compared with the acoustic cabinet tests, it was determined that similar behaviors were displayed.

- This study yielded key results aimed at determining whether the weathering & permanent set tests affect the acoustic performance of the sealing elements. The information that will serve as a basis for future studies has been obtained, where the material and geometric factors of the sealing elements can be examined.

ÖZET

Günümüzde motorlu taşıt sayısı ve buna bağlı olarak hava kirliliği oranı her geçen gün artmaktadır. Egzoz gazlarının doğaya ve insan sağlığına olan zararlarını en aza indirmek için 1992 yılında Euro1 emisyon limitleri ile başlayan kısıtlamalar günümüzde çeşitli sistemler ile geliştirilmiş ve Euro7 sistemlerinin kullanımına kadar gelmiştir. Ancak karbon salınım değerlerinde genel olarak istenilen seviyelere ulaşılamadığından, araç üreticileri fosil yakıtlı sistemlere alternatif olarak farklı enerji kaynaklarının kullanımını içeren teknolojileri araştırma ve geliştirmeye yönelip çevreye daha duyarlı olan hibrit (HEV), şarj edilebilir hibrit (PHEV), tam elektrikli (BEV) ve sıkıştırılmış hidrojen yakıtlarla (FCEV) çalışan araçlar geliştirmeye başlamışlardır. Start stop uygulamalarını içeren hafif hibrid ve 48 volt batarya teknolojilerini içeren hibrid teknolojilerinden kısmen etkilenen araç mimarisi, tam elektrikli araçlarda kullanılan batarya paketleri, yüksek voltaj kablolar ve elektrikli motorların araçlara entegrasyonuyla birlikte daha ciddi bir oranda etkilenmektedir. Bu yeni komponentlerin kullanımıyla birlikte araç ölçüleri ve mimarisinde önemli değişiklikler oluşabilmektedir.

Bu çalışmada elektrikli araç geliştirmeleriyle birlikte gelen komponentlerin araç üzerine entegrasyonu ile birlikte geleneksel araç mimarisine etkileri incelenmiş, içten yanmalı araç mimarisi ve yeni nesil tam elektrikli araç mimari yapıları geometrik entegrasyon açısından karşılaştırılmıştır. Geleneksel araç platformuna sahip bir proje aracında yük kolları ve gövde yapılarında yapılan değişiklikler ile tam elektrikli araç geometrik isterlerini sağlayan, entegre edilebilecek batarya modülü sayısının geleneksel mimari üzerine yapılacak bir yerleşime kıyasla iki kat artıralabildiği ve içten yanmalı motor mimarisi kullanımına uygun olan bir hibrit araç platformu geliştirilmiştir.

Anahtar kelimeler: Tam elektrikli araç, araç mimarisi, batarya paketi, batarya entegrasyonu

EFFECTS OF BATTERY ELECTRICAL VEHICLES ON VEHICLE ARCHITECTURE

ABSTRACT

Today, the amount of motor vehicles and rate of air pollution increases with each passing day. In order to minimize the harm of exhaust gases to nature and human health, the restrictions that started with Euro1 emission limits in 1992 have been developed various systems and have reached the use of Euro7. However, since the automotive manufacturers could not reach to desired levels of carbon emission values they started developing more environmentally vehicles such as hybrid electric vehicle (HEV), plug-in hybrid (PHEV), battery electric vehicles (BEV) and full cell electric vehicle (FCEV). Vehicle architecture, which is partially effected by hybrid technologies, including light hybrid and 48-volt battery technologies with start-stop applications, is highly effected with BEV by the integration requirements of battery packs. Using of these components there can be significant changes in vehicle dimensions and architecture.

In this study, the integration of the new spesific components of BEV developments and their effects on conventional vehicle architecture are examined and internal combustion vehicle architecture & new generation battery electric vehicle architecture structures are compared in terms of geometric integration. Additionally, hybrid vehicle platform has been developed that meets the geometric requirements of battery electic vehicle with the modifications on the load arms and body structure in a project vehicle with a conventional vehicle platform and it is seen that the number of battery modules that can be integrated on conventional arhitecture can be doubled with this new developed hybrid vehicle platform which is also compatible with internal combustion engine architecture.

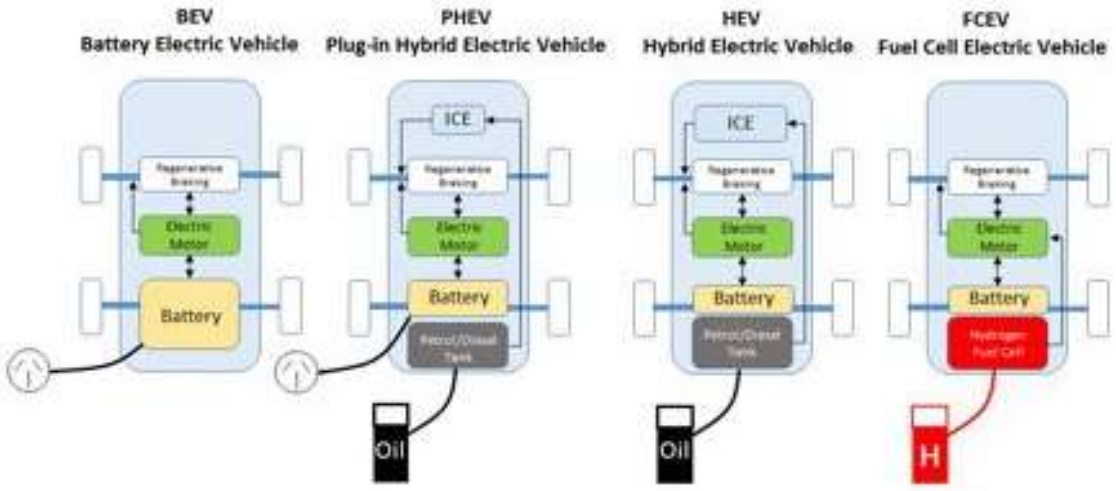
1. GİRİŞ

1.1.Emisyon Kısıtlamaları ve Otomobillerde Emisyon Azaltma Çalışmaları

Bu sayıya paralel olarak yine TAYSAD (Taşıt Araçları Tedarik Sanayicileri Derneği) tarafından açıklanan verilere göre 2018 yılından itibaren dünya üzerinde dolaşımda 1,3 milyar üzerinde araç olduğu öngörülmektedir (URL1). Artan araç sayısı ve bu araçlardan çıkan zararlı egzoz gazları ve partiküller çevre ve insan sağlığı açısından önemli bir tehdit oluşturmaktadır. Bu nedenle Avrupa Birliği (AB) komiteleri 1992 yılından itibaren egzoz salınımın değerlerini kontrol altında tutmak için emisyon limitleri belirlemişlerdir. 1992 yılında Euro1 limitleri ile başlayan kısıtlamalar günümüzde Euro6 kurallarıyla birlikte iyice düşürülmüş ve otomobil üreticilerinin çeşitli tedbirler geliştirilmesine neden olmuştur (Kaya, 2016). Ayrıca AB'nin 2019 yılında yayınlamış olduğu 2019/631 sayılı regülasyona istinaden binek ve ticari araçların karbondioksit salınım performansı için de 2020 yılı itibari ile sınırlamalar arttırılmıştır. Buna göre binek araçlar için 95 g/km, ticari araçlar için ise 147 g/km gibi zorlu bir karbondioksit emisyon oranı hedefi belirlemiştir (URL2). AB bu kısıtlamalar ile yetinmeyip binek araçlarda 2025 yılından itibaren 2019/631 regülasyon hedeflerine kıyasla emisyon limitlerini %15 oranında, 2030 yılından itibaren ise %37.5 oranında azaltacak limitler koymayı planlamaktadır (URL3). Bu zorlayıcı hedefler otomobil üreticilerini fosil yakıt teknolojisi yerine elektrik enerjisi destekli veya tamamen elektrik enerjisi ile araç hareketini sağlayabilecek teknolojiler ile ilgili çalışmalara yöneltmiştir. Bu yeni konsept, elektrikli araç teknolojisi olarak tanımlanabilmektedir.

Elektrikli araçlarda güç aktarımının elektrifikasyonu ile ilgili pazarda şu anda 4 ana konsept trendi mevcuttur. Bu konseptler BEV, HEV, PHEV ve FCEV tiplerinden oluşmaktadır (Şekil 1).



Şekil 1. Elektrikli Araç Tipleri ve Mimari Yapıları (URL3), (URL5)

Tam elektrikli araç olarak adlandırılan BEV, içten yanmalı motorun bulunmadığı, araç hareketinin tamamiyle 60-120 KW arasında değişen güçlere sahip elektrik motorları ile sağlandığı bir konsept iken HEV ise içerisinde hem içten yanmalı motor hem de batarya bulunan elektrikli araçlara verilen isimdir. HEV konsepti içerisinde en popüler uygulama ise MHEV olarak adlandırılan hafif hibrit uygulamasıdır.

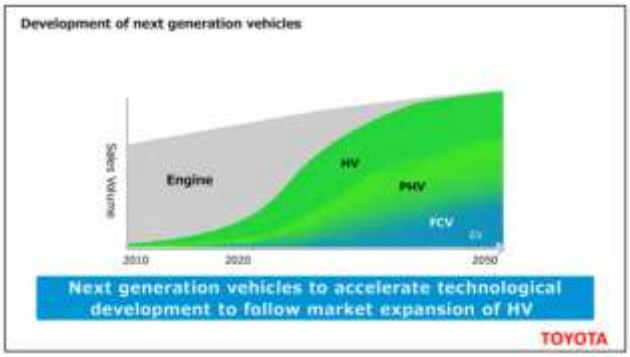
MHEV uygulaması yakıt tüketimi optimizasyonu için içten yanmalı motora destek verilmesi amacıyla ortaya çıkan, 12V veya 48V batarya kullanımıyla elektrik motoruna güç aktarımının sağlandığı, şarjını motor veya fren enerji geri kazanımından elde eden, elektrik motoru konumu itibariyle, P0-P5 arasında değişen 6 mimari tanımlamaya sahip bir hibrit teknolojisidir.

Kablolu hibrit veya plug-in hybrid olarak adlandırılan PHEV ise, MHEV'e kıyasla daha büyük bir batarya enerji kapasitesine sahip, kısa süreli sürüşlerde içten yanmalı motorun devre dışı kalarak güç aktarımının tamamiyle yaklaşık 100 KW gücündeki bir elektrik motoru ile sağlanabildiği, şarj edilebilir bir hibrit teknolojisidir.

Yakıt hücreli elektrikli araç olarak adlandırılan FCEV ise elektrik motorunu çalıştırmak için bir yakıt hücresi kullanan veya bir akü veya süper kapasitörle birlikte kullanan bir elektrikli otomobil türüdür. Araçlardaki yakıt hücreleri, genellikle havadan oksijen ve sıkıştırılmış hidrojen kullanarak motora güç vermek için elektrik üretir. Ancak bu teknoloji 2021 yılı itibariyle halen diğer uygulamalara kıyasla daha maliyetli olduğundan henüz yaygınlaşmamıştır.

1.2 Elektrikli Araçlarda Zararlı Gaz Salınımı ve Maliyet Faktörleri

Tam elektrikli araçlar dışındaki tüm elektrikli araç tipleri içten yanmalı motora sahiptir. Bu elektrikli araç tiplerinde özel durumlarda devreye girecek şekilde bir batarya tarafından sağlanan elektrik enerjisi ve elektrik motoru yardımıyla içten yanmalı motor bir süre devre dışı bırakılabilir veya sistem içten yanmalı motora bir süre destek sağlar. Ancak bu özel durumlar dışında araç hareket enerjisini tamamen veya kısmen içten yanmalı motor dolayısıyla fosil yakıt kullanımı vasıtası ile sağlamaktadır. Bu nedenle bu tip elekrikli araçlar doğaya salınan sera gazları veya NOX gibi insan sağlığı ve çevre açısından zarar oluşturan gaz miktarını azaltsa da içten yanmalı motor ve fosil yakıt kullanımı nedeniyle emisyon oranlarını sıfıra indirememektedir. HEV için sadece içten yanmalı motora sahip bir araca göre tahmini emisyon azaltım oranı ancak %20'ye ulaşırken, PHEV için bu değer %20'nin üzerinde olmasına rağmen gaz emisyon miktarı sıfırlanamamaktadır (URL4) .Mimari yapısında herhangi bir içten yanmalı motor bulunmayan tam elektrikli araçlar, hareket enerjisinin tamamını, diğer elektrikli araç tiplerine göre daha büyük güçler üretebilen bataryaların oluşturduğu elektrik akımı vasıtasıyla elektrik motoru ile sağlaması nedeniyle herhangi bir zararlı gaz salınımı gerçekleştirmemektedir. Dolayısıyla tam elektrikli araçlar sıfır emisyon miktarı ile en çevreci elektrikli araç tipi olarak tanımlanabilir. Buna rağmen 2021 yılı itibari ile halen HEV ve PHEV üretim ve satış hacimleri BEV'e kıyasla daha fazladır (Şekil 2). Bunun en önemli nedenleri ise BEV tipinde kullanılan güçlü bataryaların oluşturduğu maliyet yükleri dışında araç üzerine entegre edilen yüksek hacimli bataryanın ve batarya ile ilişkili diğer sistem ve komponentlerin araç mimari yapısı ve ölçülerine etkileridir.



Şekil 2. Elektrikli Araç Tipi ve Satış Hacmi Kıyaslamaları (URL 6)

2. TAM ELEKTRİKLİ ARAÇLAR İLE BİRLİKTE ARAÇ MİMARİSİNE EKLENEN YENİ KOMPONENTLER

Bu bölümde tam elektrikli araçlarda sisteme dahil olan temel komponentler ile ilgili bilgi verilmiştir.

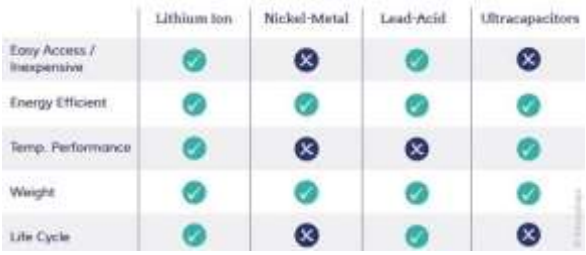
2.1. Traksiyoner Batarya

Traksiyoner batarya, kimyasal enerjiyi depo edebilen ve ihtiyaç durumunda kimyasal enerjiyi elektrik enerjisine çevirerek araç hareketine yardımcı olan sistemlere iletiminde kaynak olarak görev yapan bir komponenttir (şekil 3). BEV araçlar için genel olarak kullanılan bataryalar lityum-iyon bataryalardır (Kampker, Vallée, Schnettler, 2018). Bir lityum iyon pil, üreticiye bağlı olarak hücre boyutları (uzunluk, genişlik ve yükseklik) ve şekli (prizmatik ve silindirik) ile birbirine bağlı hücrelerden oluşmaktadır. Otomobil üreticileri araç mimarilerine uygun olarak farklı tiplerde batarya sistemleri kullanmaktadırlar (Schmuch, Wagner, Hörpel, Placke, 2018)

.

Şekil 3. Traksiyoner Batarya (Kampker, Vallée, Schnettler, 2018).

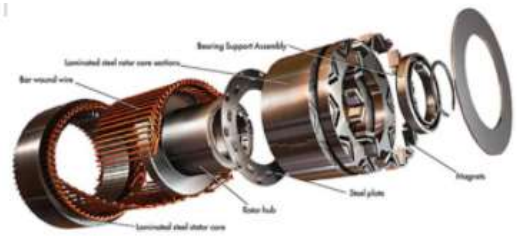
Araçlarda kullanılan günümüz bataryalarının büyük çoğunluğu maliyet, ağırlık, sıcaklık performansı, enerji verimi, kolay erişim ve ürün ömrü gibi faktörler açısından en avantajlı konumdaki Lityum-İyon olarak genelleştirilen kimyasal yapıya sahip olan batarya tiplerinden oluşmaktadır. Lityum-İyon dışında kullanılabilen alternatifler ise Nikel-Metal, kurşun asitli ve ultrakapasitörlü batarya tipleridir (şekil 4).



Şekil 4. Batarya tipleri ve Kıyaslamaları (URL 7)

2.2. Elektrik Motoru

Elektrik motoru, bataryadan alınan elektrik enerjisi mekanik enerjiye çevirerek araç tekerlerine iletilmesini vasıtasıyla aracın hareket etmesine yardımcı olan bir komponenttir. Genellikle alternatif akım ile çalışmaktadır (şekil 5).



Şekil 5. Elektrik Motoru ve Alt Parçaları

2.3. Güç İnvertörü

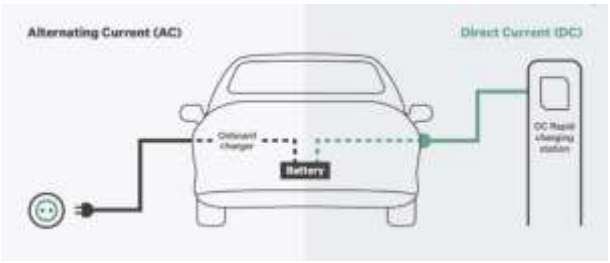
Bataryadan çıkan doğru akımı alternatif akıma çevirir ve alternatif akım ile çalışan elektrik motoruna iletilmesini sağlar. Aynı zamanda rejeneratif frenleme sayesinde depolanan enerjinin bataryanın şarj edilmesi amacıyla kullanımı sürecinde alternatif akımın doğru akıma çevirebilmesini sağlayan bir komponenttir.

2.4. Konvertisör

Bataryadan çıkan yüksek voltajı, 12 volt veya 48 volta düşürerek, aracın daha düşük voltaj ile çalışabilen diğer elektronik komponentlerine iletilebilmesine yardımcı olan voltaj çevirici bir komponenttir. Elektrikli araçlarda genel olarak doğru akımdan yine doğru akıma olan geçişlerde kullanılır.

2.5. Yerleşik Şarj Cihazı

Şebekeden aktarılan alternatif akımı, bataryanın çalışabileceği akım çeşidi olan doğru akıma çevirir ve bu şekilde traksiyon bataryasının sarj olabilmesine olanak sağlar. Doğru akım ile gerçekleştirilen şarj işlemlerinde ise devreden çıkarak akımın direkt olarak bataryaya iletilmesine izin verir (şekil 6).



Şekil 6. Elektrikli Araç Alternatif ve Doğru Akım Şarj Çevrimi (URL7)

2.6. Şarj Portu

Dış güç sağlayacısından gelen akımı araç sistemine transferini gerçekleştirerek bataryanın şarj olmasına yardımcı olan bir komponenttir. Bölge, ülke ve akım tipine göre çeşitli tipleri mevcuttur (şekil 7).

Şekil 7: Bölge, Ülke ve Akım Tipine Göre Şarj Portu Tipleri (URL8), (URL9)

2.7. Elektrikli Şanzıman Sistemi

Elektrikli şanzıman, elektrik motorundan alınan mekanik enerjinin tekerleklere iletilmesine yardımcı olan bir komponenttir.

2.8. Soğutma Sistemi ve Çevrimi

Soğutma sistemi, elektrik motoru, batarya, elektronik üniteler ve benzer komponentlerin çalışma sıcaklık aralıklarında kalabilmesi için kullanılan klima ve radyatör sistemine verilen isimdir. Özellikle tam elektrikli araçlarda, soğutulması gereken komponent sayısının fazlalığı ve bu komponentlerin belli bir bölgede yoğunlaşacak şekilde paketlenememesi nedeniyle özellikle içten yanmalı motor ile çalışan araçlara kıyasla oldukça kompleks bir bağlantı çevrimi mevcuttur (şekil 8).

Şekil 8. Tam Elektrikli Araçlarda Soğutma Çevrimi

2.9. Yüksek Gerilim Kabloları

Elektrikli araçlarda elektrik motorunun aracı hareket ettirebilmesi için büyük bir enerji ihtiyacı oluşmaktadır. Bu nedenle bataryaya giren veya çıkan akım gerilim değerleri 800 volta kadar ulaşabilmektedir. Yüksek gerilime sahip bu elektrik akımını ilgili komponentlere iletebilecek teknik özelliklere sahip bakır kablolar kullanılmaktadır. Bu kablolara yüksek gerilim veya yüksek voltaj kabloları denilmektedir ve özellikle tam elektrikli araçlarda komponent kullanımına bağlı olarak araç üzerindeki yoğunlukları oldukça artmıştır (şekil 9).

Doğru akımda 60 volt değerinin üzerindeki gerilim değerleri yüksek voltaj olarak tanımlanmaktadır. İnsan hayatı için tehlikeli olan bu gerilim değerlerine sahip olan bakır kablolarda kullanılan kaplamalar genellikle turuncu renk koduyla tanımlanmıştır. Bu sayede ilgili kişiye kabloların yüksek voltaja sahip olduğu uyarısı verilmektedir.

3. PLATFORMLAR ÜZERİNDE TAM ELEKTRİKLİ ARAÇ KOMPONENT YERLEŞİMLERİNİN İNCELENMESİ

Bu bölümde tam elektrikli araç mimarileri ele alınmış ve otomobil üreticilerinin tam elektrikli araçlar için mimari çözümleri incelenmiştir. Elektrikli araçlar için mimariyi belirleyen en önemli komponent, batarya ve batarya paketlerinin araç üzerinde konum ve yerleşimleridir. Batarya hücrelerinin bağlantı yöntemleri ve adetleri aracın

menzilini etkilediği için araç üzerinde batarya paketi yerleşimi için ayrılan hacim çok önemlidir. Nadiren farklı çözümler olmakla birlikte genel itibari ile 2 farklı mimari çözüm olduğu görülmektedir.

İlk mimari çözüm (A tipi) geleneksel içten yanmalı araç platformu üzerine gerçekleştirilen tam elektrikli araç komponent yerleşim uygulamaları içermektedir. Bu yerleşim tipinde, içten yanmalı motorlarda bulunan egzoz borularının geçişleri için kullanılan tünel bölgesindeki boşluk, ikinci sıra yolcu koltuğu altında kalan, genel olarak yakıt ve SCR deposu yerleşimlerinde kullanılan bölge ve nadiren bagaj bölgesinde yedek lastik veya tamir kiti yerleşiminin gerçekleştirildiği yedek lastik havuzu, batarya modülü entegrasyonu için kullanılmaktadır.

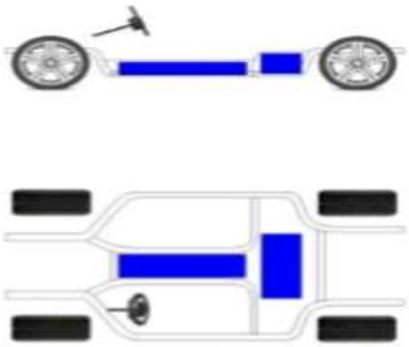
İkinci (B tipi) mimari çözümde ise araç mimarisinde majör değişiklikleri içeren bir uygulamadır. Bu platform içten yanmalı araçlar için uygun olmayan, sadece tam elektrikli araçlar için kullanımı öngörülen, batarya yerleşiminin A tipi mimari çözümden farklı olarak düz bir alt gövde yapısı üzerine gerçekleştirildiği bir çözümdür. Düz gövde yapısı veya düz bir batarya karkas yapısı sayesinde araca daha fazla batarya yerleşimi yapılabilmektedir.

Tablo 1. Batarya Yerleşim Çözümleri

TIP	UYGULAMA	BATARYA PAKETI YERLEŞİMİ
A	Geleneksel İçten Yanmalı Araç Platformu	Tünel Bölgesi, Taban altı ve Bagaj bölgesi
B	Yeni Tam Elektrikli Araç Platformu	Düz Alt Gövde Altı ve Karkas Yapı İçin

3.1. A Tipi Geleneksel Araç Mimarisi Üzerine Tam Elektrikli Araç Komponentlerinin Yerleşimi

Geleneksel otomobil mimarisi içten yanmalı motorlar ve içten yanmalı motorlarda kullanılan mekanik sistemlere uygun olarak oluşturulmuştur. Farklı uygulamalar olmakla birlikte genel olarak içten yanmalı motor, motor boşluğu olarak da isimlendirilen araç ön tarafında yer alan boşluğa, motoru soğutmak için kullanılan radyatör modülü, motor ve ön tampon arasına, yakıt deposu ise taban altında aracın ikinci sıra koltuk altında kalan boşluk alana konumlandırılırlar. Yakıt, soğutma ve hava emiş borusunun araç üzerine yerleşimleri, yakıt deposu ve radyatör modülünün araç üzerindeki konumuna göre belirlenmektedir. Egzoz sistemi içerisinde yer egzoz boruları ise diğer mekanik sistemlerle termal hedeflerin sağlanması için alt gövde tabanında yer alan tünel sacı olarak isimlendirilen dairesel gövde yapısı içerisinde konumlandırılırlar.Geleneksel platforma sahip araçlara tam elektrikli araç uygulamasında, araç mimari yapısında içten yanmalı araçlarda bulunan motor, yakıt deposu ve egzoz borusu gibi komponentler yer almadığı için motor boşluğu bölgesine elektrikli motor, voltaj düzenleyici üniteler, güç invertörü ve şanzıman, alt gövde taban altına ise batarya modüllerinin yerleşimi gerçekleştirilmektedir. (şekil 9)



Şekil 9. A tipi geleneksel araç mimarisi üzerine batarya yerleşimi

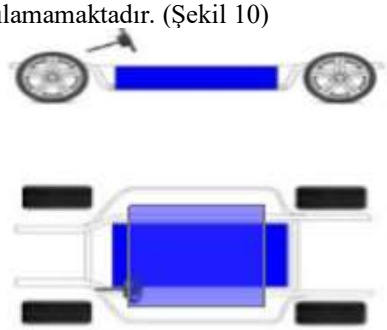
Güç Sistemleri: Elektrik motorunun yerleşimi için İçten yanmalı araç mimarisinde motor ve şanzımanın bulunduğu ön burundaki motor boşluğu kullanılır. Elektrik motoruyla birlikte voltaj düzenleyeceği üniteler ve güç invertörü de bu alanda yer almaktadır.

Süspansiyon Sistemi: Geleneksel mimaride motor ve şanzıman taşıyıcı takozlar yerine elektrik motoru çevreleyen karkas motor takozu ve gövdesi yer almaktadır. Bu yapı genel olarak süspansiyon sistemi içerisinde yer almakta ve tam elektrikli araç uygulamasında süspansiyon sistemi için majör bir yenilik olarak yer almaktadır. Bu karkas yapı aynı zamanda araç gövdesi üzerine bağlandığı için araç gövdesinde de değişiklikler yapılması gerekmektedir.

Enerji Sistemi: Batarya modülleri ve paketlerinin yerleşimi içten yanmalı motorlarda yakıt deposu ve egzost borularının yer aldığı taban altı ve tünel bölgesi kullanılmaktadır. Nadiren de olsa bagaj bölgesinde yer alan ve yedek lastik ve tamir kiti yerleşiminde kullanılan boşluk batarya paketi yerleşimi için kullanıldığı görülmektedir. Taban altı ve tünel bölgesinde kısıtlı bir hacim olması batarya yerleşimi için en önemli kritikliği oluşturmaktadır. Bu bölgelerde yer alan kısıtlı alanları kullanmak için farklı batarya yerleşim çözümleri yapılması gerekmektedir. Bu durum aynı otomobil firmasının her bir model için spesifik bir batarya paketi oluşturmasına neden olmakta, ortak ve modüler kullanım zorlaşmaktadır. Batarya sayısına bağlı olarak araç menzili de düşük olduğu görülmektedir. Enerji sistemi içerisinde yer alan yüksek voltaj kablolar e motor, güç dağıtıcı ünite ve bataryalar arasında güç transferi için kullanılmaktadır. Dolasıyla elektrik motor ve batarya paketi arasında yüksek voltaj kablo yerleşimi yapılması gerekmektedir. Geleneksel mimariye yapılan uygulama batarya paketlerinin yerleşimi farklı alanlara ve karmaşık olarak yapıldığı için yüksek voltaj kablo yerleşimi de karmaşık ve daha uzun olabilmektedir. Bu durumda kablo geçişleri için çeşitli kablo kanalları kullanılacağı için araç maliyetini ve yerleşimini yüksek oranda etkilemektedir.
Soğutma Sistemi: İçten yanmalı motorlardan farklı olarak tam elektrikli araçlarda bataryalarında soğutulması gerektiği için soğutma sistemi ve bu sistemi oluşturan hortum, boru ve su pompası gibi komponentlerin sayısı içten yanmalı motorlara göre oldukça fazladır. Batarya yerleşimi tünel bölgesi, taban altı ve bagaj bölgesi gibi farklı bölgelere yapıldığı için soğutma sistemi ve iletim hatları çok karmaşıktır. Bu durum aracın kalite hedefleri ve maliyet hedeflerini doğrudan etkileyebilmektedir.

3.2. Yeni Nesil Elektrikli Araç Mimarisi Üzerine Tam Elektrikli Araç Komponentlerinin Yerleşimi

Geleneksel araç mimarisi üzerine entegre edilen hibrid ve tam elektrikli araç teknolojileri araç platformunun bu teknolojilerin entegrasyonu için uygun hacmi sağlamaması nedeniyle kısıtlı batarya modülü yerleşimi yapılabilmektedir. Bu durum üretilen araçların düşük menzile sahip olmasına neden olmaktadır. Bu yüzden dünya üzerinde satış hacmi yüksek olan birçok üretici geleneksel mimari yerine yeni nesil tam elektrikli araç platformu geliştirmeye yönelmişlerdir. Bu yeni nesil araç platformu geleneksel araç mimarisinde bulunan alt gövde tamamen ortadan kaldırılmakta, alt gövde yerine batarya modüllerinin içine konulduğu, koltuk ve konsolun bağlandığı karkas bir yapı içermektedir. Bu sayede daha fazla batarya yerleşimi yapılabilmekte, araçlar daha fazla menzile sahip olabilmektedir. Bu platformların diğer özelliği ise modüler olarak batarya paketlerinin yerleşimlerinin yapılabilmesi ve aynı üreticinin birçok modelinde kullanılabilmesidir. Fakat bu platform sadece tam elektrikli araçlar için uygundur ve içten yanmalı motorlar bu platformda kullanılamamaktadır. (Şekil 10)



Şekil 10. Yeni nesil araç mimarisi üzerine batarya yerleşimi

Enerji sistemini oluşturan batarya paketleri için yeni nesil tam elektrikli araç platformu oldukça önemlidir. Bu yeni platform yapısında batarya modülleri araç tabanını da oluşturan düz bir karkas yapı içerisine yerleştirilir. Karkas yapı batarya modülleri yerleşimi için düzgün bir geometrik yapı ve hacme sahip olduğu için bataryalar karkas yapı içerisinde düzenli bir şekilde seri olarak bağlanabilmektedir. Bu durum aynı karkas yapının ve batarya paketinin bir çok modelde ortak kullanım sağlayacaktır. Böylece araç menzili artırılarak dolum sıklığı düşürülebilmektedir. Aynı zamanda ilgili modelin ihtiyacına göre karkas yapı içerisinde batarya modülleri ekleme ve çıkarma yapılarak modüler şekilde kullanılabilmektedir. Yüksek voltaj kablo tesisatları bataryaların düzenli yerleşimi nedeniyle daha düzenli ve basit bir yerleşime sahiptir. Bu durum özellikle yüksek maliyetli olan kabloların daha ekonomik olarak araçta kullanımını sağlamaktadır.

Soğutma sistemi oluşturan radyatör modülü geleneksel mimari de olduğu gibi araç üzerine pozisyonlabilmektedir. Batarya yerleşiminin karkas yapı içerisinde düzenli olması ve tüm modülleri aynı yerde yer alması nedeniyle soğutma sistemi çevriminde kullanılan boru ve hortum yerleşimleri oldukça düzenli ve mimariye sahiptir.

3.3. Geleneksel Mimari ve Yeni Elektrikli Araç Mimarisini Karşılaştırılması

Geneneksel araç mimarisi ve Yeni Nesil Tam elektrikli araç mimarilerinde batarya yerleşimi karşılaştırıldığında Geneneksel araç mimarisinde batarya yerleşimi için 2. Sıra koltuk altında kalan boşluk alan, tünel bölgesi ve nadiren bagaj yükleme batarya yerleşimi için kullanılabilmektedir. Dolayısla bu bölgelerde kalan hacme düşük sayıda batarya modülü yerleşimi yapılabilmektedir. Yeni nesil elektrikli araç mimarisinde tünel sacı olmadığı, alt gövde yerine batarya modüllerinin içine konulduğu, koltuk ve konsolun bağlandığı karkas bir yapı bulunduğu için batarya yerleşimi için daha fazla hacim sağlanmaktadır. Bu sayede daha fazla batarya yerleşimi yapılabilmekte, araçlar daha fazla menzile sahip olabilmektedir. Bu durum daha düşük sıklıkla müşterinin bataryayı şarj etmesini sağlamaktadır. (Tablo 2)

Tablo 2. Batarya Konumları ve Menzile Etkilerinin Karşılaştırılması

TIP	UYGULAMA	BATARYA YERLEŞIMI	MENZIL	ŞARJ SIKLIĞI
A	Geleneksel İçten Yanmalı Araç Platformu	Düşük	Düşük	Yüksek
B	Yeni Nesil Tam Elektrikli Araç Platformu	Yüksek	Yüksek	Düşük

Geneneksel araç mimarisi ve Yeni Nesil Tam elektrikli araç platform çözümleri araç mimarisine etki, batarya yerleşimi, ortak batarya kullanımı ve maliyet açısından karşılaştırılmıştır. Buna göre geleneksel araç platformu hali hazırda içten yanmalı motor içinde kullandığı için tam elektrkli araç uygulamasında gövde ve diğer mevcut komponentlerine üzerinden yapılması gereken değişiklikler sınırlıdır. Bu yüzden bu uygulamada araç mimarisi üzerinde majör bir değişiklik beklentisi düşüktür. Yeni nesil elektrikli araç mimarisinde ise araç mimarisi köklü olarak değişmektedir. Geleneksel alt gövde sacı yerine karkas yapı kulllanılmakta, batarya modüllerin yerleşimler, yüksek voktaj kablo geçişleri, koltuk ve konsol bağlantıları bu platform üzerine yapılabilmektedir. Geleneksel araç mimarisine batarya yerleşimi düzenli olmadığı için batarya yerleşmi aynı üreticinin farklı modelleri için bile spesifik olmaktadır. Bu yüzden ortak batarya ve modüler kullanım olcukça düşüktür. Yeni nesil araç platformunda batarya yerleşimi düz yapılı karkas yapı içerisine düzenli bir şekilde yapılmakta, aynı karkas gövde içerisine farklı modellerin ihtiyaçlarına göre faklı sayıda batarya modülü yerleşimi yapılarak yüksek oranda modüler kullanım sağlanmaktadır. Fakat yeni nesil bir araç platformu geliştirmek araç mimarisi, araç ölçülerini, kullanıcı ergonomisi, üretim şartları ve üretim hatlarını önemli şekilde etkilemektedir. Sadece elektrikli araçların kullanabileceği bir platform olması nedeniyle yüksek yatırım maliyeti gerektirmektedir (Tablo 3).

Tablo 3. Uygulama tiplerinin araç mimarisine, ortak batarya kullanımı ve maliyete etkisi

TIP	UYGULAMA	MIMARIYE ETKISI	MALIYET	ORTAK BATARYA PAKETI KULLANIMI	MODÜLER KULLANIM
A	Geleneksel İçten Yanmalı Araç Platformu	Düşük	Düşük	Düşük	Düşük
B	Yeni Nesil Tam Elektrikli Araç Platformu	Yüksek	Yüksek	Yüksek	Yüksek

3.4. Hibrit Tipi Araç Mimarisi Üzerine Tam Elektrikli Araç Komponentlerinin Yerleşimi

Geleneksel araç mimarisinin tam elektrikli araçların batarya yerleşimi için kısıtlı hacim sağlaması ve dolayısıyla düşük menzile sahip olması, yeni nesil tam elektrkli araç mimarisinin ise gerekli batarya hacmi ve menzili sağlamasına rağmen günümüz teknolojileri için oldukça maliyetli olması ve bu yeni platformun içten yanmalı motorlar için kullanılamıyor olması ile birlikte müşteri için radikal çözümler içermesi nedeniyle otomobil üreticileri geleneksel araç platformunda bazı değişiklikler yaparak daha fazla batarya yerleşimini gerçekleştirmeyi amaçlıyorlar (Şekil 11). Bu amaçla özellikle araç alt gövdesinde aracın yapısal dayanımını da düşürmeyecek şekilde bazı değişiklikler yapmışlardır. Bu ara çözümde özellikle alt tabanda yer alan yük kollarında ve taban altı traversler üzerinde değişiklikler yapılarak daha fazla batarya yerleşimi yapılması sağlanmaktadır.

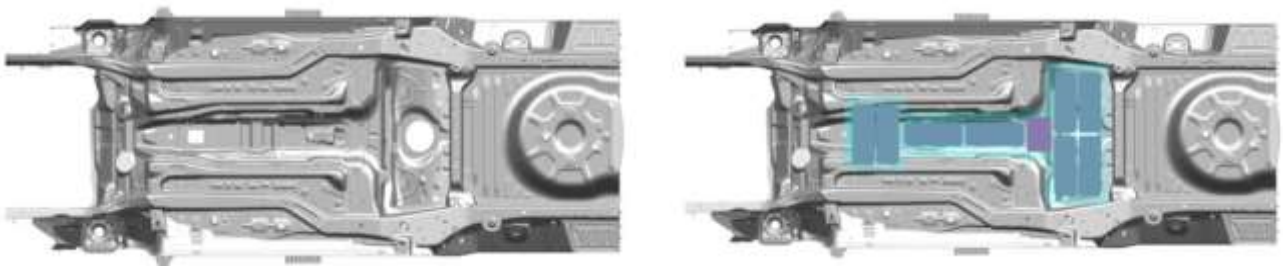
Şekil 11. Otomobil üreticilerinin araç segmenti bazında kullandıkları platformlar

TOFAŞ Ar-Ge bünyesinde yapılan bir tam elektrkli araç geliştirme projesinde geleneksel araç mimarisi ve geneneksel araç mimarisine değişiklik yapılarak oluşturulan hibrit tip üzerine batarya yerleşim çalışmaları gerçekleştirilmiştir. Projede geleneksel içten yanmalı mevcut araç platfortmu üzerine alt tabanda yer alan yük kolları ve traversler üzerinde değişiklik yapılarak batarya yerleşimi üzerine çalışılmıştır. Geliştirilen mimari yapı aynı zamanda içten yanmalı araçların mimari yerleşimi için de uygun olması hedeflenmiştir.

Gerçekleştirilen çalışma öncesinde A tipi geleneksel araç alt gövdesi üzerine 9 adet batarya modülü yerleşimi yapılabilmektedir (Şekil 12). Gövde üzerinde yük kolları ve traversler üzerinden yapılan değişiklik ile alt tabanda batarya yerleşimi için hacim artırılmış ve ilave olarak 9 adet daha batarya modülü yerleşimi yapılarak toplam 18 adet batarya modülü yerleşimi gerçekleştirilebilmiştir (Şekil 13). Proje hedefine uygun olarak yapılan değişiklikler araç kabin içinde herhangi bir hacim veya parça değişikliğine neden olmamıştır. Ayrıca yapılan değişiklikler aracın güvenlik performanslarında herhangi bir değişikliğe neden olmadan hem içten yanmalı hem de tam elektrik araç platformu hedef ve beklentilerinin karşılanması sağlanmıştır (Tablo 4).

Tablo 4. Proje aracı değişiklik öncesi ve sonarsı durum

ÇALIŞMA ARACI		
PARAMETRE	**A TIPI ICTEN YANMALI ARAÇ PLATFORMU**	**HIBRIT ARAÇ PLATFORMU**
MENZIL	167 km	334 km
ALT GOVDE	Geneneksel içten yanmalı	Hibrit
AKS MESAFESI	2636 mm	2636 mm
ARAÇ AĞIRLIĞI	1535 kg	1535 kg
BATARYA MODULU	9 adet	18 adet
BATARYA	21,3 KWh	42,6 KWh
BATARYA UZUNLUĞU (L)	1180 mm	1470 mm
BATARYA GENİŞLİĞİ (W)	900 mm	900 mm
BATARYA AĞIRLIĞI	180 kg	330 kg
MOTOR GÜCÜ	105 kW	105 kW



Şekil 12. A tipi geleneksel araç mimarisi üzerine batarya yerleşim çalışma örneği

Şekil 13. Hibrit tip araç mimarisi üzerine batarya yerleşim çalışma örneğ

4. SONUÇ

Bu çalışmada tam elektrikli araçlarla kullanılmaya başlanılan komponentlerin araç mekanik mimarisine etkileri ve araç platformları incelenmiştir. Geleneksel araç platformu ve yeni nesil elektrikli araç platformu üzerine tam elektrikli araç uygulamaları karşılaştırılmış. Otomobil üreticilerinin optimum mimari yerleşim çözümlere ulaşmak için uyguladıkları stratejiler değerlendirilmiştir.

Geleneksel araç mimarisi üzerine tam elektrikli araç uygulaması durumunda araç mimarisinde değişiklik düşük olmakla birlikte yerleştirilen batarya modülü sayısı ve buna bağlı olarak araç menzilin de düşüktür. Ayrıca spesifik batarya kullanımı yüksektir. Yeni nesil elektrikli araç platformunda ise batarya yerleşimi, menzil, ortak ve modüler kullanım yüksek olduğu için optimum mimari çözümleri içermektedir. Fakat bu platformun sadece elektrikli araçlar için özel olarak geliştirilmesi dolayısıyla yüksek maliyetli olması ve içten yanmalı motorlara uygun olmaması nedeniyle otomotiv üreticilerinin maliyet açısından beklentilerini karşılamamaktadır. Bu nedenle TOFAŞ Ar-Ge bünyesinde yapılan bir çalışmada, hem içten yanmalı araçların mimari yapısına, hem de tam elektrikli araç mimarisine uygun olacak hibrit bir platform çalışması yapılmıştır.

Geleneksel araç platformu üzerinde yapılan değişiklikler ile platform hem içten yanmalı hem de günümüz tam elektrikli araç mimarisi ve müşteri beklentilerine uygun hale getirilmiştir. Yapılan çalışma öncesinde mevcut araç gövdesine 9 adet batarya modülü yerleşimi yapılabilmektedir. Gövde üzerinde yük kolları ve traversler üzerinden yapılan değişiklik ile alt tabanda batarya yerleşimi için kullanılabilecek hacim artırılmış ve ilave olarak 9 adet batarya modülü daha yerleşimi yapılarak toplam 18 adet batarya modülü yerleşimi gerçekleştirilebilmiştir. Böylece araç menzili de yaklaşık olarak %100 oranında artırılmıştır. Proje hedefine uygun olarak yapılan değişiklikler ile araç kabin içinde müşteri memnuniyetsizliği oluşturabilecek hacim ve güvenlik performansları negatif yönde etkilyecek herhangi bir değişikliğe neden olmadan hem içten yanmalı hem de tam elektrik araç platformu hedef ve beklentilerinin karşılayan hibrit bir araç platformu geliştirilmesi sağlanmıştır

BASINÇSIZ DÖKÜM YÖNTEMİNİN SUSUZ BORAKS KATKILI ALÜMİNYUM ALAŞIMLI KOMPOZİT MALZEMENİN MEKANİK ÖZELLİKLERİNE ETKİSİNİN İNCELENMESİ

Şenol Şahin[1], Ayşegül Bodur Yılmaz[2]
[1,2] Kocaeli Üniversitesi, Mühendislik Fakültesi, Makina Mühendisliği, Kocaeli, Türkiye
[2] Sorumlu Yazar: Ayşegül Bodur Yılmaz, aysegul.bodur@kocaeli.edu.tr

ÖZET

Bu çalışmada, susuz boraks (SB) maddesinin Etial 150 (EA150) alüminyum alaşımının mekanik özelliklerine etkisi ve aynı zamanda kompozit malzeme üretim yönteminin mekanik özellikler üzerindeki etkileri araştırılmıştır. Bu kapsamda nihai ürüne (EA150/SB kompozit malzemesine) farklı mekanik özellikler kazandırmak üzere, hacimce %1 ve %5 oranında susuz boraks ($Na_2B_4O_7$) işlem uygulanmadan EA150 alüminyum alaşımıyla birlikte (yerinde reaksiyon yöntemi kullanılarak) aynı potada ergitilmiştir. Ayrıca SB ve EA150 alüminyum alaşımı ayrı ayrı ergitilmelerinin akabinde karıştırılarak mekanik özelliklere farklı üretim yöntemlerinin etkisi de araştırılmıştır. 800ºC ve 1000ºC ergitme sıcaklığı, 40 dak ve 60 dak ergime sıcaklığında tutma süresi olacak şekilde farklı üretim parametreleri kullanılarak basınçsız döküm yöntemi ile metal matrisli kompozit malzemeler imal edilmiştir. Deney numunelerine sertlik ve üç nokta eğme testleri uygulanarak kompozit malzemelerin eğme akma gerilmesi, eğme akma uzaması ve Brinell sertlik değerleri belirlenmiştir. Ayrıca, kırılma yüzeylerindeki mikroyapı taramalı elektron mikroskobu (TEM) ile incelenmiştir. Üretilen kompozit malzemelerin eğme akma gerilmesi, eğme akma uzaması ve sertlik değerleri üzerinde olumlu ve/veya olumsuz yönde tüm parametrelerin etkili olduğu görülürken, üretim yönteminin mekanik özellikler üzerindeki en etkili parametre olduğu açık bir şekilde tespit edilmiştir.

INVESTIGATION OF THE EFFECT OF THE NON-PRESSURE CASTING METHOD ON THE MECHANICAL PROPERTIES OF ANHYDROUS BORAX ADDITIVE ALUMINUM ALLOY MATERIAL

ABSTRACT

In this study, the effect of anhydrous borax (SB) on the mechanical properties of Etial 150 (EA150) aluminum alloy and also the effects of the composite material production method on the mechanical properties were investigated. In this context, EA150 was melted in the same crucible together at the rate of 1% and 5% by volume anhydrous borax ($Na_2B_4O_7$) in order to give different mechanical properties to the final product (EA150 / SB composite material). In addition, SB and EA150 aluminum alloys were mixed after being melted separately and the effect of different production methods on mechanical properties was also investigated. Metal matrix composite materials were produced by using different production parameters like melting temperature of 800ºC and 1000ºC, a holding time at a melting temperature of 40 minutes and 60 minutes, using the non-pressure casting method. By applying hardness and three-point bending tests to the test specimens, the flexural yield stress, flexural yield extension, and Brinell hardness values of the composite materials were determined. In addition, the microstructure of the fracture surfaces was examined by scanning electron microscopy (SEM). While all parameters were effective (positive and/or negative) on the bending yield stress, bending yield strain, and hardness values of the composite materials produced, it was determined that the production method was the most effective parameter on the mechanical properties.

Key words: Aluminum, Metal Matrix Composite, Anhydrous Borax, Mechanical Properties, AlB_2

1. GİRİŞ

Alüminyumun hafiflik, dayanıklılık ve fonksiyonel olması özellikleri onu günümüzde kullanılan önemli bir mühendislik malzemesi haline getirmektedir. Yaşadığımız evlerde, tüm ulaşım araçlarında, kullandığımız cihazlarda, kablolarda, mutfak gereçlerinde ve ilaç, kimya hatta gıda gibi birçok sektörde kullanılmaktadır [1].

Hafif malzeme seçimi yakıt tasarrufu için önemli bir nokta olduğundan dolayı özellikle otomotiv sektöründe hafif yapı metallerinin, alüminyum, magnezyum, titanyum gibi, kullanım alanı oldukça geniştir. Hızlı bir gelişime sahip olan otomotiv endüstrisinde alüminyumun işlenebilirlik, maliyet, geri dönüşüm, korozyon direnci yönünden avantajlara sahip olması nedeniyle kullanımının her geçen yıl daha da artmasına neden olmaktadır. Yolcu güveliği araç tasarımdaki en önemli hususdur ve alüminyum da çarpma sırasında ortaya çıkan enerjiyi çok iyi absorbe edebildiği için kullanım açısından en uygun element haline gelmektedir. Tercih nedenlerine bakıldığında hem güvenlik önlemlerini iyileştirmek için hem de taşıt ağırlığını azaltmak için çok uygun bir element olduğu görülmektedir [2]. Ayrıca alüminyumu çelikle kıyasladığımızda sahip olduğu yoğunluk ve mukavemet nedeniyle önemli avantajları mevcuttur. Çelikle alüminyum spesifik mukavemet (mukavemet/yoğunluk) açısından karşılaştırıldığında alüminyum çok önemli bir avantaja sahiptir. Bu da aynı miktardaki yükü, aynı ağırlığa sahip çelik ve alüminyum üretilmiş bileşenin taşıyabileceği anlamına gelmektedir [3].

Çalışmanın bir diğer önemli malzemesi olan susuz boraks incelendiğinde; fiziksel işlemlerle zenginleştirilerek konsantre bor haline getirilip kimyasal süreçlerden sonra rafine bor ürünlerine dönüştürülerek kullanımı yaygındır. Sektörde borun nihai kullanımı rafine bor ürünleri olarak ve aynı zamanda konsantre bor şeklinde de doğrudan tüketilebilmektedir [4]. Tüketim alanlarında bor ürünleri ana bileşen değil, karışım içinde diğer endüstriyel minerallerle birlikte prosese beslenerek malzemeye farklı özellikler kazandırarak nihai ürünün içerisinde %0,01 ile %20 arasında değişen oranlarda kullanımıyla alüminyum nihai ürünlerinin bünyesine girmektedir [4].

Çalışmada yerinde reaksiyonla üretim (in-situ) yöntemi kullanılarak Al/AlB_2 kompozit üretimi amaçlanmıştır. Yerinde reaksiyon üretim yöntemi ile dışarıdan takviyeli üretim yöntemi arasındaki en temel fark, güçlendiricilerin sonradan ilavesi yerine güçlendiricilerin matris alaşımı içerisinde kendiliğinden oluşmasıdır [5,6]. Güçlendirici fazlar metal matrisli kompozitlerin üretimi aşamasında element ve bileşiklerin ekzotermik reaksiyonları sonucunda kendiliğinden oluşmaktadır. Ekzotermik reaksiyonlar sonucunda kendiliğinden oluşan güçlendiriciler matris içerisinde termodinamik olarak kararlı, homojen dağılımlı ve kuvvetli ara yüzey bağı gibi özellikler sergilemektedir. Yerinde reaksiyonla üretim yönteminde matris alaşımları alüminyum, titanyum, bakır, nikel, demir ve bunların alaşımlarından oluşur iken takviye elemanları ise matris alaşımı içerisinde kendiliğinden oluşan borür, karbür, oksit, nitrür ve bunların karışımlarından oluşmaktadır [7,8].

Yerinde reaksiyonla elde edilmesi amaçlanan AlB_2 parçacıklarının, alüminyum diborid takviyeli alüminyum matris kompozitlerinin mekanik özelliklerinde iyileştirme sağladığı bilinmektedir. Fonksiyonel olarak derecelendirilmiş Al/AlB_2 kompozitleri için yaygın hammaddeler elementel alüminyum ve bordur. Ancak elementel borun fiyatı son derece yüksektir [9]. Bu nedenle bu çalışmada toz haldeki SB ($Na_2B_4O_7$) maddesine işlem uygulanmaksızın, düşük maliyetli Al/AlB_2 kompozitlerinin üretimi amaçlanmıştır.

2. MALZEME VE YÖNTEM

2.1. Alüminyum Alaşımı (Etial 150)

Çalışmada metal enjeksiyon yöntemiyle mamul ve/veya yarı mamul üretiminde tercih edilen ve ticari ismi ETİAL 150 (EA 150) olan alüminyum alaşımı kullanılmıştır. Bu alaşımın kullanılma gerekçesi ise tedarik edilen Aksu Elektrikli Ev Aletleri San.ve Tic. A.Ş'nin ve Akım Metal San.ve Tic. A.Ş'nin mamul ve/veya yarı mamul seri üretimlerinde kullandığı alüminyum alaşımı olmasıdır. Üretici firma (Eti Alüminyum) tarafından yüksek mukavemetli basınçlı dökümlerde kullanılması önerilen ETİAL 150'nin üretici tarafından belirtilen fiziksel ve kimyasal özelikleri Tablo 1'de bir araya getirilmiştir.

Tablo 1. EA150 Alaşımlı külçelerin fiziksel ve kimyasal özellikleri [13]

Fiziksel Özellikleri									
Özgül Ağırlık (g/cm^3)		Ergime Aralığı (°C)		Korozyon Dayanımı	Dökülebilirlik		İşlenebilme	Anodik Oksidasyon	
2,67		525-580		Orta	Mükemmel		İyi	Sadece yüzey korumada	
Kimyasal Bileşim Limitleri (%Ağırlık)									
Fe	Si	Cu	Mn	Mg	Zn	Ni	Ti	Pb	Sn
1	11,00-13,00	1,75-2,50	0,5	0,4	0,7	0,3	0,15	0,1	0,1

2.2. Susuz Boraks (Etibor-68)

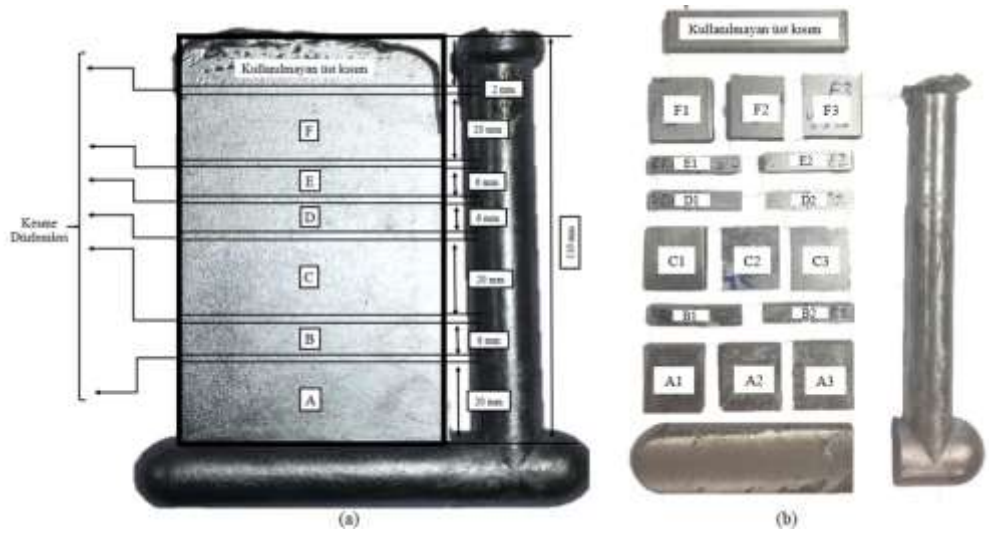
Kompozit malzemelerin üretimi için katkı ve/veya dolgu malzemesi olarak, Eti Maden A.Ş.'den 1 mm tane boyutunda temin edilen, yoğunluğu 2,37 g/cm^3 ve ergime sıcaklığı 742,5°C olan ticari ismi Etibor-68 ($Na_2B_4O_7$) minerali öğütülerek, elek altı 71 µm ve elek üstü 56 µm partikül boyutlarında kullanıldı. Bazı kimyasal bileşimlerinin içeriği B_2O_3 için %68,30 ila 69,4 arasında, Na_2O için %30,41 ila 30,90 arasında SO_4 için maksimum 200 ppm, Cl için maksimum 150 ppm ve Fe için maksimum 150 ppm'dir [10].

2.3. Numune Üretimi

Kompozit malzeme üretiminde Bentrup TC 60/8 model ve 1280°C maksimum ısıtma kapasitesine sahip sıcaklık kontrollü, önden yüklemeli fırın kullanıldı. Kompozit üretiminde ürünün sanayide kullanımı hedeflendiğinden, düşük maliyetli üretimin sağlanabilirliğini görmek ve susuz boraksın ergime sıcaklığını aşarak alüminyum ile reaksiyona girebilmesi için 800°C ve literatür araştırması sonucu [11] iyi mekanik özelliklere sahip kompozitin elde edilebildiği 1000°C ergitme sıcaklık (T_e) değerleri seçildi. Ayrıca düşük aspekt oranlı ve kompleks şekle sahip AlB_{12} kristallerinin oda sıcaklığında kararsız ve gevrek bir özelliğe sahip olduğu bildirildiğinden [7,12] ve üretilmesi hedeflenen kompozitin iç yapısında AlB_{12} kristallerinin bulunması mekanik özelliklerini olumsuz yönde etkileyebileceğinden, basınçsız döküm işleminin akabinde kalıp (içindeki eriyik haldeki kompozit) 20°C sıcaklıktaki çeşme suyu havuzuna daldırılarak hızlı soğuması sağlanarak gevrek AlB_{12} yapısının oluşması engellendi.

Kompozit malzemeler; hacimce %1 ve %5 oranlarında susuz boraksın direkt olarak toz halinde ETİAL 150 alüminyum alaşımı külçesinden kesilen numune parçalarıyla üstü açık seramik potalar içinde birlikte ergitilmesiyle elde edildi. Farklı oranların birbirini etkilememesi için her bir SB katkı oranına özel ayrı bir pota kullanıldı. Seri üretim koşullarında kullanılan üretim yöntemi incelendiğinde ilk ürün ile son ürünün elde edilmesi arasında belirli bir bekleme süresi bulunduğundan, hem seri üretime benzer koşullar oluşturulması hem de potalarda farklı bekleme (ergitme sıcaklığında tutma) sürelerinin kompozit malzeme üzerindeki etkisinin belirlenmesi amacıyla 40 dak ve 60 dak ergitme sıcaklığında tutma süreleri tercih edilerek kompozit malzeme üretimleri gerçekleştirildi. Homojen karışım elde edilebilmesi amacıyla pota içindeki kompozit eriyik, bekleme süresi boyunca ilk 5. dak ve son 5. dak bor nitrür kaplı demir çubuklarla karıştırıldı.

Ergitme işleminin ardından, kompozit eriyikler önceden ısıtılan (ergitme sıcaklığından 400°C daha düşük olan sıcaklıktaki) kalıpların kalıp boşluğuna dökülerek soğuma işlemine tabi tutuldu. Şekil 1'de kalıptan (kalıp boşluğundan) çıkarılan basınçsız döküm ürünün görüntüsü ve deneylerde kullanılacak numune bölgelerin hazırlanmış hali bulunmaktadır.



Şekil 1. Kalıptan çıkan ürün ve deney numunesi hazırlama bölgeleri

Üretim yönteminin etkisini görmek amacıyla iki farklı yöntem daha kullanılarak yeni üretimler gerçekleştirildi. Susuz boraksın toz olarak alüminyum ile birlikte ergitilmesi sırasında susuz boraksın yoğunluğunun daha az olmasından dolayı potanın üst kısmında fazla miktarda cüruf oluşmakta ve Şekil 2'de görüleceği üzere döküm esnasında eriyiğin içine karışarak kötü bir ara yüzey oluşturup dayanımı azaltmaktaydı.

Şekil 2. Numunenin içine karışan cüruf

Standart üretim yöntemine uygun şekilde (alüminyum ve susuz boraks aynı potada birlikte ergitilerek) 1005D isimli kompozit malzeme üretimi gerçekleştirilirken, homojen karışım elde etmek için yapılan karıştırma işlemi ilk üretimden farklı olarak eriyiğin üst yüzeyinde bulunan cürufun asgari oranda, bor nitrür ile kaplanmış tel kaşık yardımıyla, eriyik üzerinden alınarak gerçekleştirildi. Ayrıca kalıp sıcaklığının etkisinin olabileceği düşüncesiyle de kalıp sıcaklığını 400°C de sabit tutarak, 40 dak tutma süresi, 1000°C ergitme sıcaklığı, %5 SB katkı oranı parametreleri kullanılarak üretim gerçekleştirildi.

Alüminyum ve susuz boraks ayrı ayrı potalarda ergitilip sonradan karıştırılıp kullanılarak susuz boraksın içinde bulunan Na ve O atomlarını mümkün olduğunca alüminyum ile etkileşime girmeden uzaklaştırmak, kompozit eriyik yüzeyinde oluşan cürufu azaltmak ve kompozit malzeme içinde oluşan dayanımı azaltan boşlukları gidermek amacıyla, 40 dak tutma süresi (ayrı ayrı ergitilen malzemeler karıştırıldıktan hemen sonra bekletildi), 1000°C ergitme sıcaklığı ve %5 SB katkı oranı parametreleri kullanılarak 1005E isimli kompozit malzeme elde edildi. Daha sonra bu iki kompozit malzeme için de Brinell sertlik ölçümü ve üç nokta eğme deneyi gerçekleştirildi.

Tablo 2. Kompozit Malzeme Üretim Adımları

Adımlar			Numune adı					
			801	805	1001	1005	1005	
							D	E
1	Fırının ön ısıtma sıcaklığı (°C)		500	500	700	700	700	700
2	EA150 alaşımı ile SB katkısının birlikte içinde bulunduğu potanın ön ısıtma sıcaklığındaki fırına yerleştirilmesi		X	X	X	X	X	
3	EA150 alaşımı ile SB katkısının ayrı ayrı içinde bulundukları potaların ön ısıtma sıcaklığındaki fırına yerleştirilmesi							X
4	Alaşım ve katkı dolu potaların 10°C/dak ısıtma hızında ergitme sıcaklığına yükseltilmesi (ısıtılması)		X	X	X	X	X	X
5	Fırın ve potalar ergitme sıcaklığına ulaştığı an ayrı pota içinde bulunan SB katkısının ayrı potada bulunan EA150 alaşımına ilave edilmesi (bir potada birleştirme)							X
6	Kompozit eriyiklerin ergitme sıcaklığında tutulması (dak)		40	60	60	40	40	40
7	Ergitme sıcaklığında tutma süresinin	4. dakikasında eriyik üzerinde oluşan cürufun temizlenmesi					X	X
		5. dakikasında eriyiğin 10 s karıştırılması	X	X	X	X	X	X
		son 6. dakikasında eriyik üzerinde oluşan cürufun temizlenmesi					X	X
		son 5. dakikasında eriyiğin 10 s karıştırılması	X	X	X	X	X	X

2.3.1. Metalografik Zımparalama

Üç nokta eğme deneyi için kesilen numunelerin testere ile temas eden tüm yüzeyleri METKON Forcipal 2V markalı modüler zımparada sırasıyla 180, 320, 600, 1200 ve 2500 gridli SiC zımparalar ile çentik etkisini yok etmek için 2 dak sürecince zımparalama işlemine tabi tutuldu. Diğer taraftan sertlik deneyi için kesilen numunelerin testere ile temas eden tüm yüzeyleri ise 100 grid ve 400 gridli SiC zımparalar ile, her bir sertlik numunesi için aynı ve/veya benzer pürüzlülük değerine sahip yüzeyler elde etmek amacıyla, 2 dak sürecince zımparalama işlemine tabi tutuldu.

2.3.2. Üç Nokta Eğme Numunesi ve Deneyi

Üç nokta eğme deneyi için yatay şerit testere ile kesilen 29 mm ± 1 mm x 6 mm ± 0,5 mm x 6,5 mm ± 0,5 mm boyutlarındaki Şekil 1 de gösterilen B, D ve E bölgeleri kullanıldı. Testler 30kN kapasiteli ve bir bilgisayar destekli Bluehill yazılımı bulunan INSTRON Universal çekme basma test cihazında, eğme hızı 0,5 mm/dak ve destekler arası açıklık 15 mm olan sabit parametrelerde gerçekleştirildi. Testlerin tamamı sıcaklığı 25±1°C, nemi %50±10 ortam koşullarında gerçekleştirdi. Her bir ortalama deneysel değer için en az 5'er adet deney numunesi kullanıldı. İlgili deneysel verilerin en yüksek ve en düşük sonuçları çıkarılarak istatistiksel olarak değerlendirildi.

2.3.3. Brinell Sertlik Numunesi ve Deneyi

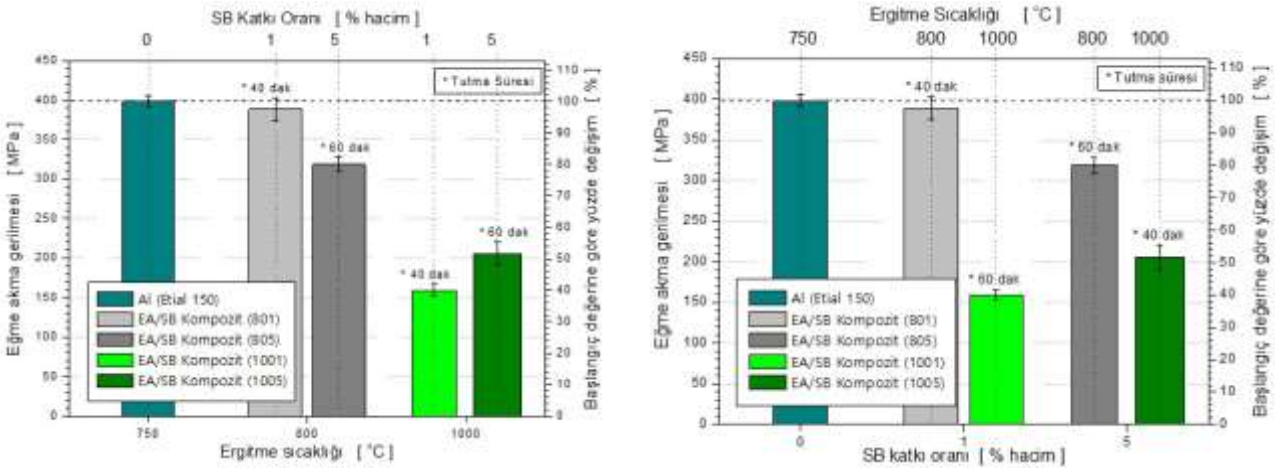
Sertlik deneyi için yatay şerit testere ile kesilen 18,6 mm ± 1 mm x 18,6 mm ± 1 mm x 6,5 mm ± 0,5 mm boyutlarındaki Şekil 1'de gösterilen A, C ve F bölgeleri kullanıldı. Sertlik ölçümleri WOLPERT marka Universal sertlik ölçme test cihazında, TS EN ISO 6506-1 standardına uygun olarak 27 ± 2 °C ortam sıcaklığında, 15 saniye süreli 31,25 kg yük etkisindeki test parametrelerinde gerçekleştirildi. Her bir ortalama deneysel değer için en az 5'er adet deney numunesi kullanıldı. İlgili deneysel verilerin en yüksek ve en düşük sonuçları çıkarılarak istatistiksel olarak değerlendirildi.

3. DENEY SONUÇLARI

3.1. Eğme Akma Gerilmesi

Üç nokta eğme testi ile elde edilen katkısız (saf) EA150 numunenin eğme akma gerilmesi değerleri ile EA150/SB kompozit malzemelerin eğme akma gerilmesi değerleri karşılaştırmalı olarak Şekil 3'te grafikleştirilmiştir. Şekil 3

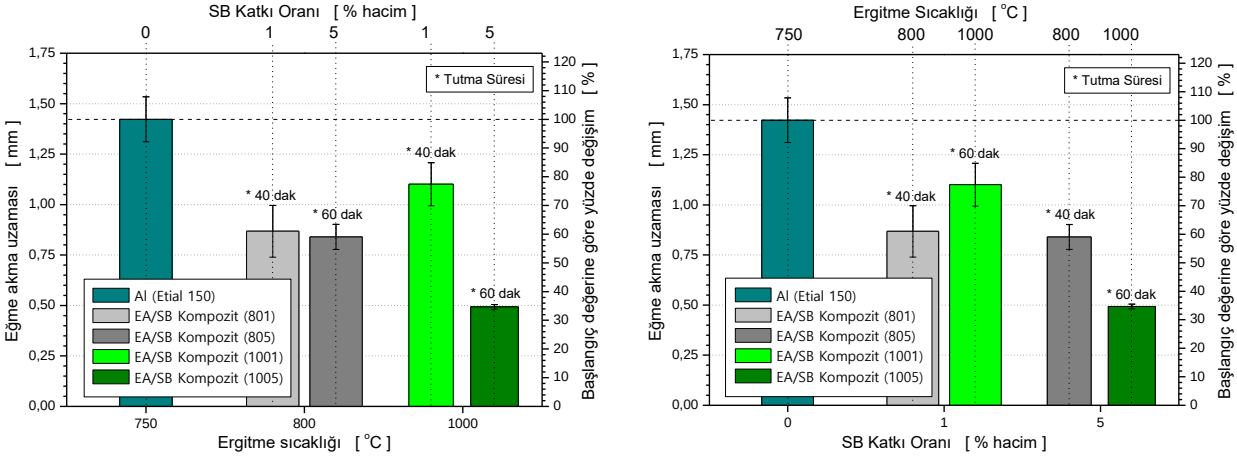
incelendiğinde sonuç üzerinde en etkili parametrenin ergitme sıcaklığının olduğu görülürken ondan sonra en etkili parametrenin tutma süresi olduğu tespit edildi. Bunun yanı sıra SB katkı oranının kayda değer bir etkisi olmadığı belirlendi. %1 ve %5 katkılı, 800º C ergitme sıcaklığında üretilen numunelerin eğme akma gerilmesi değerlerinin sırasıyla saf malzemeye oranla %2,42 ve %19,95 azaldığı, 1000ºC ergitme sıcaklığında üretilen %1 ve %5 katkılı numunelerin eğme akma gerilmesi değerlerinin ise sırasıyla saf malzemeye oranla %60,04 ve %50,23 azaldığı görüldü. Bekleme süresinin artması 800ºC ergitme sıcaklığında numunenin eğme akma gerilmesi değerlerini azalttığı tespit edilirken 1000ºC ergitme sıcaklığında eğme akma gerilmesi değerlerinin yaklaşık %10'luk artış sağladığı görüldü.



Şekil 3. SB katkılı kompozit malzemenin eğme akma gerilmesinin imalat parametrelerine göre değişimi

3.2. Eğme Akma Uzaması

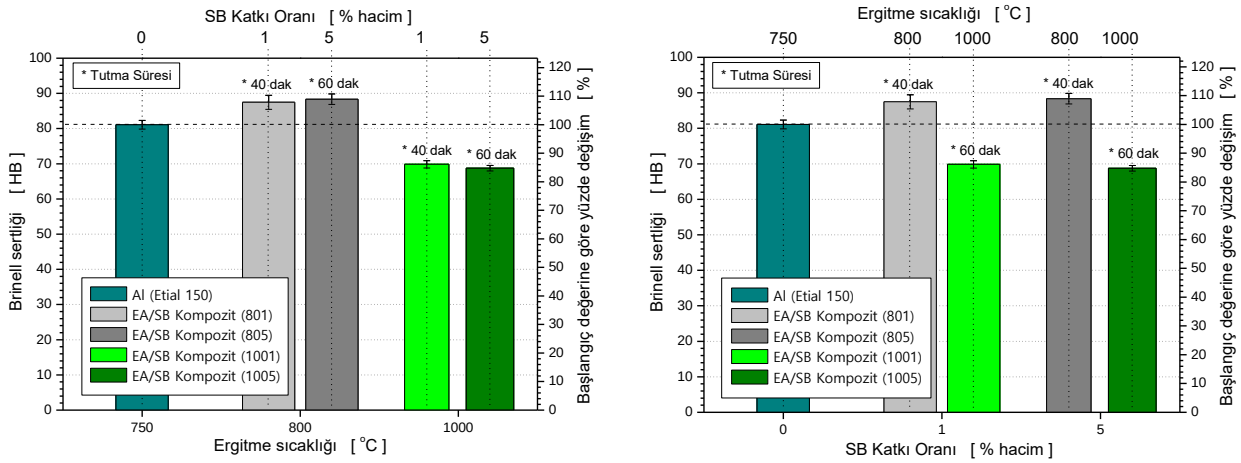
Üç nokta eğme testi ile elde edilen katkısız (saf) EA150 numunenin eğme akma uzaması değerleri ile EA150/SB kompozit malzemelerin eğme akma uzaması değerleri karşılaştırmalı olarak Şekil 4'te grafikleştirilmiştir. Şekil 4 incelendiğinde sonuç üzerinde en etkili parametrenin SB katkı oranının olduğu görülürken ondan sonra en etkili parametrenin tutma süresi olduğu tespit edildi. %1 ve %5 katkılı, 800º C ergitme sıcaklığında üretilen numunelerin eğme akma uzaması değerlerinin saf malzemeye oranla yaklaşık %40 azaldığı, 1000ºC ergitme sıcaklığında üretilen %1 ve %5 katkılı numunelerin eğme akma uzaması değerlerinin ise sırasıyla saf malzemeye oranla %22,62 ve %65,34 azaldığı görüldü. Bekleme süresinin artmasının; 800ºC ergitme sıcaklığında kısmen etkisiz olduğu tespit edilirken 1000ºC ergitme sıcaklığında eğme akma uzaması değerini yaklaşık %40 azalttığı görüldü.



Şekil 4. SB katkılı kompozit malzemenin eğme akma uzamasının imalat parametrelerine göre değişimi

3.3. Brinell Sertlik

Brinell sertlik deneyi ile elde edilen katkısız (saf) EA150 numunenin sertlik değerleri ile EA150/SB kompozit malzemelerin sertlik değerleri karşılaştırmalı olarak Şekil 5'te grafikleştirilmiştir. Şekil 5 incelendiğinde sonuç üzerinde en etkili parametrenin ergitme sıcaklığı olduğu görülürken SB katkı oranının ve tutma süresinin kayda değer bir etki göstermediği tespit edildi. %1 ve %5 katkılı, 800º C ergitme sıcaklığında üretilen numunelerin sertlik değerlerinin sırasıyla saf malzemeye oranla %7,85 ve %8,94 arttığı görülürken 1000ºC ergitme sıcaklığında üretilen %1 ve %5 katkılı numunelerin sertlik değerlerinin ise sırasıyla saf malzemeye oranla %13,86 ve %15,24 azaldığı görüldü.

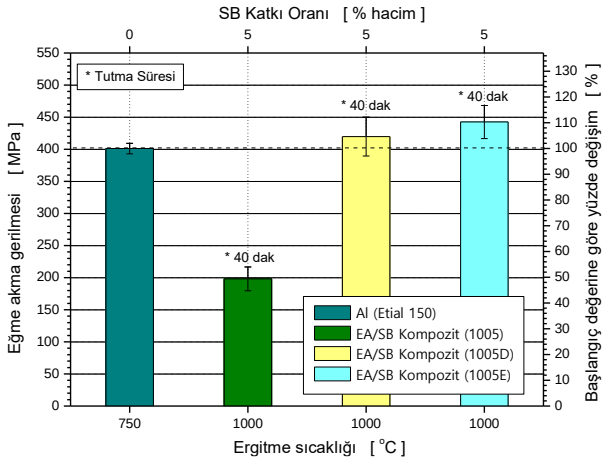


Şekil 5. SB katkılı kompozit malzemenin Brinell sertliğinin imalat parametrelerine göre değişimi

3.4. Üretim Yönteminin Mekanik Özelliklere Etkisi

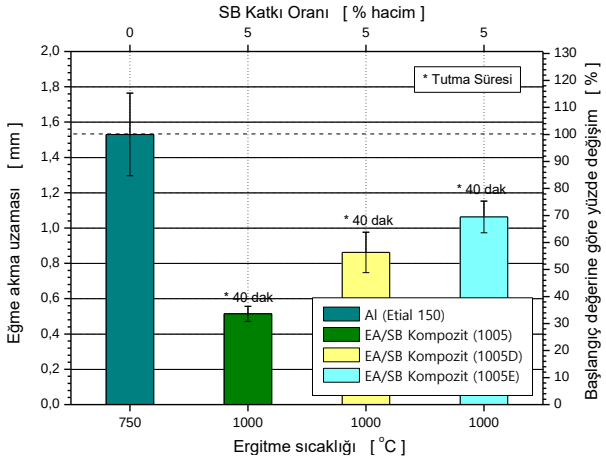
Üretim yönteminin EA150/SB kompozit malzemesinin mekanik özellikleri üzerinde güçlü bir etkiye sahip olduğu yapılan deneyler sonrası açıkça görülmektedir. SB ve EA150 alaşımı yoğunluk farkından ve alüminyumun oksijenle temasından dolayı eriyik yüzeyinde oluşan cürufun numune içine karışarak dayanımı azalttığı daha önce belirtilmiştir. Bu etki ortadan kaldırıldığında EA150/SB kompozit malzemelerin mekanik özelliklerindeki değişimin olumlu yönde olduğu tespit edildi.

Eğme akma gerilmesi değerlerinin üretim yöntemine göre değişimi Şekil 6'da grafikleştirilmiştir. Şekil 6 incelendiğinde; hem kalıp sıcaklığı 400ºC 'ye düşürülerek hem de kompozit eriyik üstünde oluşan curüf asgari ölçüde temizlenerek basınçsız döküm yapıldığında EA150/SB kompozit malzemenin (1005D) eğme akma gerilmesinin değeri ilk üretime (1005) göre %55,69 artarken saf malzemeye kıyasla da %5,41 arttığı tespit edildi. Ayrı ayrı potalarda ergitilip sonradan bir potada birleştirilerek (ve karıştırılarak) üretilen EA150/SB kompozit malzemenin (1005E) ise ilk üretime kıyasla eğme akma gerilmesinin değeri yaklaşık %61,33 arttığı, saf malzemeye kıyasla ise yaklaşık %11,10 artarak en iyi sonucu verdiği tespit edilmiştir.



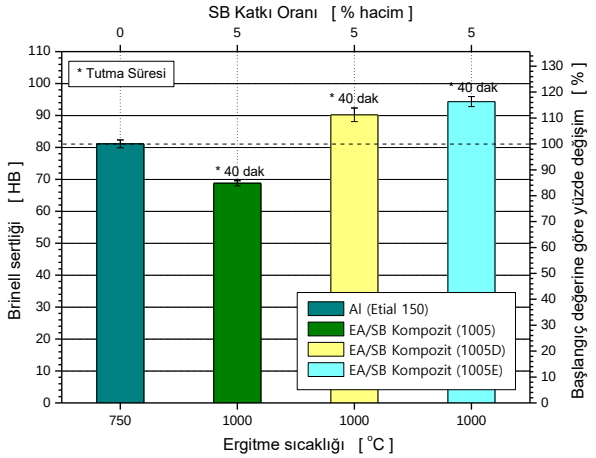
Şekil 6. %5 SB katkılı kompozit malzemenin eğme akma gerilmesinin imalat yöntemine göre değişimi

Eğme akma uzaması değerlerinin üretim yöntemine göre değişimi Şekil 7'de grafikleştirilmiştir. Şekil 7 incelendiğinde 1005D isimli numunenin eğme akma uzaması değeri ilk üretime göre %24,45 artarken saf malzemeye kıyasla %39,41 azaldığı tespit edildi. 1005E isimli numunenin ise ilk üretime kıyasla eğme akma uzaması değerinin %38,58 arttığı, saf malzemeye kıyasla ise %25,28 azaldığı tespit edilmiştir.



Şekil 7. %5 SB katkılı kompozit malzemenin eğme akma uzamasının imalat yöntemine göre değişimi

Üretim yöntemine göre Brinell sertlik değerinin değişiminin verildiği Şekil 8 incelendiğinde 1005D isimli numunenin Brinell sertlik değeri ilk üretime göre %26,48 artarken saf malzemeye kıyasla %11,24 arttığı tespit edildi. 1005E isimli numunenin ise ilk üretime kıyasla Brinell sertliği değerinin yaklaşık % 31,57 arttığı, saf malzemeye kıyasla ise %16,33 artarak en iyi sonucu verdiği tespit edilmiştir.



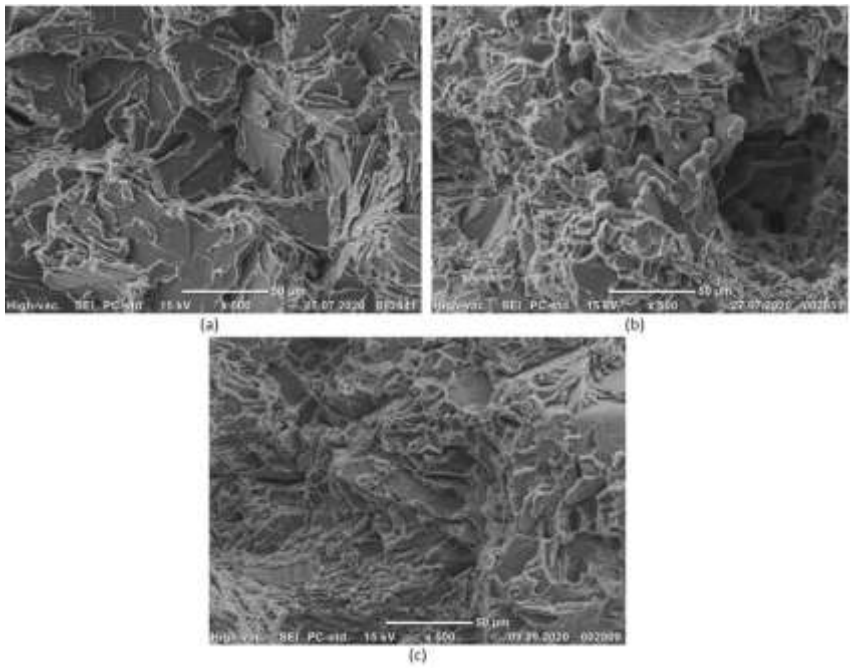
Şekil 8. %5 SB katkılı kompozit malzemenin Brinell sertliğinin imalat yöntemine göre değişimi

Elde edilen deney verileri incelendiğinde tüm mekanik özelliklerde artış olduğu tespit edilirken en iyi mekanik özelliklerin elde edildiği 1005E isimli kompozit malzemenin, ayrı potalarda ergitildikten sonra SB ve EA150 karıştırıldığında susuz boraksın alüminyum alaşımı ile daha homojen karıştığı ve ayrıca yoğunluk farkından dolayı kompozit eriyik üstünde kalarak cüruf haline gelen susuz boraksın miktarı bu yöntemle azaltıldığından en iyi sonucu verdiği düşünülmektedir.

3.3. TEM Görüntüleri

İlk üretimde elde edilen numunelerin kırılma yüzeylerinin Şekil 9'da verilen TEM görüntüleri incelendiğinde oluşması istenen AlB_2 yapısının net olarak elde edilemediği belirlendi. Ayrıca, kırılma yüzeylerinden basınçsız döküm numunelerinin boşluklar ihtiva ettiği ve SB katkılı numunelerde oluşan yüzey yapısının katkısız numuneye kıyasla

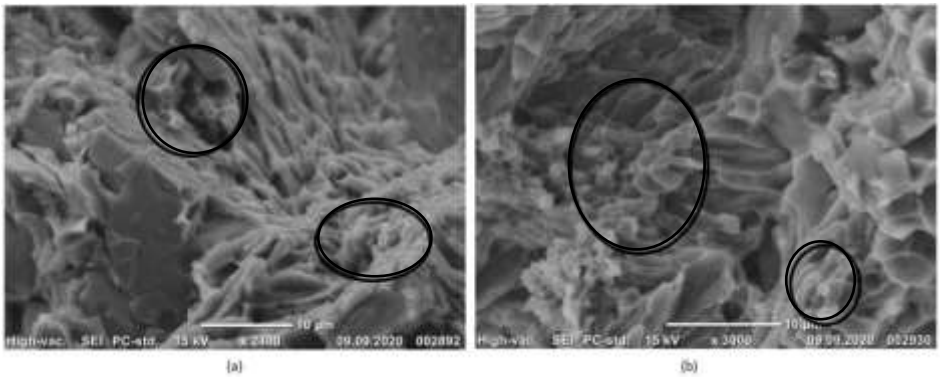
farklılaşmasının belirlenebilmesi, susuz boraksın karıştığına dair bir tespit elde edilmesini sağlarken, halihazırda hangi oranda ve/veya oranlarda karışım elde edildiği tespit edilememiştir.



Şekil 9. Kırılma yüzeyleri SEM görüntüleri (a) Naturel (b) 800ºC %1 SB katkılı (c) 1000ºC %5 SB katkılı

Kompozit numunelerin üretim sıcaklıklarına bağlı olarak sıcaklığın artmasıyla birlikte susuz boraks içinde bulunan elementlerin ve/veya EA150 alaşımı içinde bulunan elementlerin kompozit numune içinde kaynayarak boşluklara sebep olduğu düşünülürken aynı zamanda kırılma esnasında oluşan yapıların (tane dışı ayrılma sonucu) koparak yüzeyden ayrıldığı düşünülmektedir.

Farklı üretim yöntemleri ile üretilen numunelerin eğme akma gerilmesi, eğme akma uzaması ve Brinell sertlik değerlerinde artış olduğu tespit edilmiştir. Numunelerin kırılma yüzeylerinin Şekil 10'da verilen TEM görüntüleri incelendiğinde ise mekanik özelliklerde artışa neden olan olumlu etkinin, üretilen kompozit malzemelerin iç yapısında oluşan mekanik özelliği artırıcı etkiye sahip AlB_2 yapısının olduğu tespit edilmiştir.



Şekil 10. Kırılma yüzeyleri SEM görüntüleri (a) 1000ºC %5 SB katkılı-1005D (b) 1000ºC %5 SB katkılı-1005E

4. SONUÇ VE ÖNERİLER

Yapılan deneysel incelemeler yardımıyla bu çalışmadan elde edilen sonuçlar;

- Üretim yönteminin farklılığının numunenin mekanik özelliklerine etkisi incelendiğinde; genel sonuç olarak kalıp sıcaklığının etkili bir parametre olduğu düşünülürken, SB ve EA150 alaşımının ayrı ayrı potalarda ergitilip sonradan karıştırılmasıyla gerçekleştirilen üretimin numune özelliklerine homojen karışma sağladığı ve daha az cüruf oluştuğu için olumlu etki ettiği tespit edildi.
- Eriyik yüzeyinde oluşan cürufun döküm esnasında numune içine karışmasıyla malzeme iç yapısında matris malzeme ile kötü ara yüzey oluşturduğundan kusurlara sebep olduğu tespit edildi.
- Uygun üretim yöntemiyle numunelerin eğme akma gerilmesi, eğme akma uzaması ve sertlik değerlerinde artış olduğu tespit edildi. Numunelerin kırılma yüzeylerinin TEM görüntülerinin incelenmesinden ise mekanik özelliklerde artışa neden olan olumlu etkinin, üretilen kompozit malzemelerin iç yapısında oluşan mekanik özelliği artırıcı etkiye sahip AlB_2 yapısından dolayı olduğu tespit edildi.

Devamında yapılacak olan çalışmalar için öneriler;

- Susuz boraks partikül boyunun azaltılması/artırılması ve SB katkı oranlarının azaltılması/artırılması,
- Farklı üretim parametrelerinin (ergitme sıcaklığı, ergitme sıcaklığında tutma süresi, kalıp soğutma sıcaklığı) kullanılması,
- Yoğunluk farkından dolayı zor olan homojen karışımın daha iyi sağlanabilmesi için gerekli karıştırma sistemi oluşturularak susuz boraks ve alüminyum alaşımının daha iyi karışmasının sağlanması,
- Dökme hızının uygun, standart bir hale getirilmesi,
- Üzeri açık seramik potalarda gerçekleştirilen kompozit üretiminin oksijenle temasının minimum düzeyde olacağı bir sistemle gerçekleştirilmesi,
- Bu çalışmanın başlangıç noktası olan basınçlı döküm yöntemiyle üretim gerçekleştirilerek sanayide kullanımının uygunluğunun incelenmesi önerilmektedir.

TEŞEKKÜR

Bu çalışma Kocaeli Üniversitesi, Fen bilimleri Enstitütsü, Makine Mühendisliği Anabilim Dalı, Yükseköğretim Kurulu (YÖK) 651227 tez numaralı, “Susuz Boraks Maddesinin Basınçsız Döküm İle Üretilen Alüminyum Malzemesinin Reolojik Ve Mekanik Özelliklerine Etkisinin Deneysel Tasarım Yöntemi İle Eniyilenmesi” isimli yüksek lisans tezi kapsamında hazırlanmıştır.

ÖZET

Günümüz otomotiv sektöründe plastik malzemelerin kullanımı oldukça fazladır. Plastiklerin diğer malzeme çeşitlerine göre hafif olması, otomotiv üreticilerinin hedeflediği maliyet indirimi, ağırlık azaltmaları ve buna paralel olarak sürekli zorlaşan yeni emisyon hedef salınım değerlerine uyum sağlanması kullanımlarında büyük bir olanak sağlamaktadır. Plastiklerin bu doğrultuda doğru kullanılabilmesi için ciddi bir mühendislik bilgi birikimiyle yapılan tasarımların sanal ve fiziki olarak kontrol edilmesi ile gerekmektedir. Bu çalışmada, bir otomobil su genleşme deposunun geliştirme aşamalarında istenen değerlerin sağlanması adına yapılan çalışmalardan bahsedilmiştir. Tasarım sürecinde gelen kaba stilin araç çevre parçaları da dikkate alınarak kalıplanabilirlik ve fonksiyonellik durumları göz önünde bulundurularak ilerletilmiştir. Ayrıca ürün tasarımında belirlenen maksimum hedef ağırlıkta ve istenilen minimum iç hacim değerleri de bu çalışmaların sınır koşullarını oluşturan etmenlerdir. Yapılan tasarım çalışmalarının ANSYS yazılımı ile basınç analizi yapılmıştır. Çıkan sonuçlarda genleşme deposunun deformasyonu, kaynak kordonunun basıncı incelenmiştir. Final durumda elde edilen uygun basınç değerleri ile tasarım aşamaları tamamlanmış olup bu 3D Cad modele göre kalıp tasarım aşamaları başlatılmıştır.

Anahtar Kelimeler: Plastik, Genleşme Deposu, Dayanım, ANSYS.

GEOMETRIC STRENGTH EXAMINATION OF WATER EXPANSION TANK OF A HEAVY VEHICLE

ABSTRACT

The importance and use of plastic materials in today's automotive industry is quite high. The fact that plastics are more lightweight than other types of materials provides great benefits in the cost reduction and weight reduction targeted by automotive manufacturers and in parallel with the efforts to adapt to the new emission target emission values that are constantly getting harder. In order for the plastics to be used correctly in this direction, it is provided by virtual and physical control of the designs made with a serious engineering knowledge. In this study, the studies carried out in order to provide the desired values during the development stages of an automobile water expansion tank are mentioned. The design process has been progressed by considering the incoming rough style and the vehicle peripheral parts, taking into account the mouldability and functionality. In addition, the maximum target weight determined in the product design and the desired minimum internal volume values are the factors that constitute the boundary conditions of these studies. An analysis of the work under pressure was made with the ANSYS software. The design stages have been completed with the appropriate pressure values obtained in the final state, and the mold design stages have been initiated according to this 3D Cad model.

Key words : Plastic , Expansion Tank , Strenght , ANSYS .

1. GİRİŞ

Otomotiv sektöründe kullanılan malzemelerin yaklaşık üçte ikisini şekillendirilmiş metaller olmasına rağmen yeni gelen emisyon zorunluluklarına uyum sağlanması adına ağırlık ve yakıt tasarrufunun sağlanması için plastik malzemelerin önemi artmaktadır. Plastik kullanımının optimum verimlilikte kullanılması amacıyla ciddi bir mühendislik alt yapısının oluşturulması zorunluluğu doğmuştur.

Klasik tanımıyla plastik malzemelerin üretim prosesi, hammaddenin belirli bir ısı ve basınç altında kalıp içinde sürtünmeye maruz kalarak malzemenin kalıp içinde dağıldıktan sonra soğutulup alınmasıyla gerçekleşir

Bu prosesin sağladığı en önemli avantajlarından biri, kalıp boşluğuna dağılan ham maddenin tek prosesle istenilen şekilde kalıplanması ve bu kalıplama neticesinde imal edilen üründe, ikinci bir işleme gerek duyulmamasıdır (Yurci,1998) [1]. Kalıptan istenilen ürünün elde edilmesi için ürün geliştirme aşamaları çok dikkatli bir şekilde mühendislik yazılımlarının desteği ile gerçekleştirilmektedir. Çünkü ürünün herhangi bir fonksiyonelliği konusunda bir sıkıntı yaşanması durumunda kalıpta istenilen modifikasyonun yapılması mümkün olmayabilir. Hatta kalıbın tekrar tasarlanıp en baştan işlenilmesi gerekebilir.

2. LİTERATÜR ARAŞTIRMASI

İnce cidarlı kaplarda olan mekanik gerilmeler ile farklı bilimsel çalışmalar yapılmıştır. Eruslu (2007) [2] ilgili çalışmasında ince cidarlı basınçlı tüplerde ASTM standartlarında belirtilen iki farklı çelik için basınç etkisi altında gerilme analizi yapmıştır. İki boyutlu ve üç boyutlu sonlu elemanlar modelleri Ansys 9.0 yardımıyla oluşturulmuş, üç boyutlu model tasarım yönünden iki farklı şekilde incelemiştir . Bu çalışmada ince cidarlı basınçlı tüplerin üzerine uygulanan yüklere karşı göstermiş olduğu direnç ve tüpün mukavemet artışı incelenmiştir. İncelemede hem deneysel hem de sayısal metodlar kullanılmıştır

Çayıroğlu ve ark.(2017) [3] çalışmasında ince cidarlı basınçlı kapların dış yükler altında mekanik davranışlarını deneysel ve sayısal olarak incelemiştir. İlgili çalışmada ince cidarlı basınçlı kapların dış yükler altındaki yük taşıma, enerji absorbe etme gibi alanlarda kullanılıp kullanılmayacağına yönelik yeni bir değerlendirme ele alınmıştır. İnce cidarlı basınçlı tüplerin üzerine uygulanan yüklere karşı göstermiş olduğu direnç ve tüpün mukavemet artışı incelenmiştir.

3. PLASTİK ÜRÜN TASARIM İLKELERİ

Başarılı bir plastik ürün tasarımına aşağıdaki dört temel unsur etki etmektedir : (Akyüz, 1999) [4]

1. Ürünün Tasarımı.
2. Ürüne en uygun plastik malzeme seçimi.
3. Üretim için gerekli alet ve takımların (makine, kalıp tasarımı) bir araya getirilmesi.
4. Malzemelerin kalıplanması.

Bir parçanın tasarım aşamasından önce mutlaka hata türleri ve etkileri analizinin yapılması gereklidir. Bu çalışma, ürünün fonksiyonelliği, müşteri özel istekleri ve yasal zorunluluklar dikkate alınarak yapılmalıdır. Mühendislik cad ve simülasyon programları bu aşamalarda ürünün kontrol edilebilirliği konularında büyük katkı sağlamaktadırlar.

4. MATERYAL VE YÖNTEM

Bu çalışmada, ağır vasıta su genleşme deposunun istenilen basınç değerlerinde çalışabilmesi adına plastik tasarım kuralları ve analizleri dikkate alınıp tasarımı yapılmıştır

Bu çalışma sürecinde aşağıdaki destek ekipmanlarından faydalanılmıştır:

A. Su genleşme deposu CAD modeli.

B. PP (Polipropilen) ham maddesi.

C. ANSYS simülasyon yazılımı

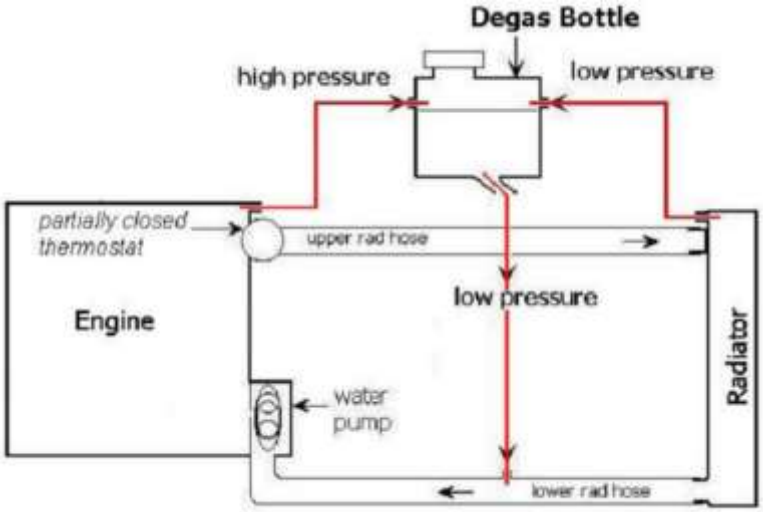
4.1. Parça Geometrisi ve Çalışma Prensipleri

Günümüzde üretilen otomobillerde motor ve radyatördeki ısı transferinin sağlanması için soğutma sıvısı kullanılmaktadır. Su, motor ve radyatördeki yüksek sıcaklık sebebiyle genleşir. Genleşen su yüksek basınç meydana getirir. Meydana gelen basınç ve ilave hacim de sisteme zarar verebilmektedir. Olası bir hasarı önlemek için dolaşan

soğutma suyu sistemden geri çekilir. Geri alınan su tekrar sisteme kazandırılır. Bu işlem için su genleşme depoları kullanılır.

Otomotivde kullanılan su genleşme depolarının geometrik sınırlarıyla ilgili herhangi bir regülasyon yoktur. Bu hacimleri belirleyen sınırlar müşterilerin kendi belirlediği kriterlerdir. Ancak, regülatif olarak bu parçaların hammaddelerinin yanmaz olması istenmektedir.

Seçilecek malzemelerin ısıl dayanımı ortam koşullarına uygun olmalıdır. Özellikle kaput altı parçası olması sebebiyle sıcaklık bu seçimde önemli bir etkendir. Bu alanlardaki uygulamalar için özel olarak geliştirilmiş malzemeler kullanılmalıdır. PP hammaddesi sahip olduğu fiziksel özellikleri sayesinde depolarda en çok kullanılan malzeme özelliğini taşımaktadır.

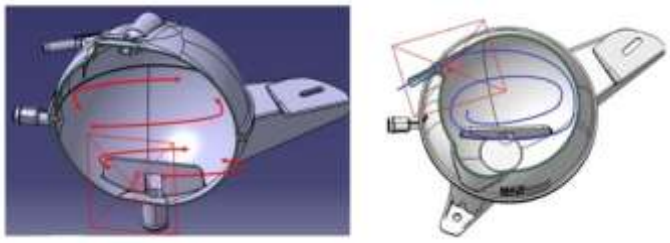


Şekil 1. Su deposu çalışma prensibi

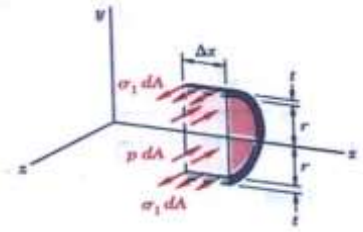
Yukarıdaki şemadan görüldüğü üzere; motor ve radyatörde bulunan yüksek basınçlı su depoya gönderilir ve depodan da şebekeye tekrar geri gönderilir. Depoda radyatör hattı ve motor hattı olmak üzere iki noktadan giriş bulunmaktadır. Radyatör hattı üzerinde herhangi bir pompa bulunmaması sebebiyle düşük basınçlı bir dolaşım vardır. Motor hattı, üzerinde bulunan pompa (Debiyi yükselterek dolaşımı ve motordan yayılan ısı transferini hızlandırmak için kullanılır .) sebebiyle yüksek basınçlı su taşımaktadır (Feka Automotive) [5]

Hattın besleme suyu, su soğutma deposunun tabanından çıkmaktadır. Çünkü çıkış, giriş seviyesinden daha düşük tutularak sistemde yükseklikten oluşan basınç farkını akış yönünde kullanır . Ayrıca deponun dolumu esnasında su, önce giriş hattına dolacaktır.

Su depolarında motor bloğundan gelen su yüksek basınca sahiptir. Yüksek basınçlı suyun, depo dış duvarlarını deforme etmesini önlemek için basıncın sönümlenmesi gerekmektedir. Bu basıncın sönümlenmesi için iç hacimde bir girdap hareketi oluşturulmalıdır. Oluşturulacak bu girdabın temel konsepti şekil 2'de tanımlanmıştır. Girdap oluşturabilmek için giriş kısmı, depo dış yüzeyine teğet olarak tasarlanmalıdır.



Şekil 2 . Örnek girdap hareketi

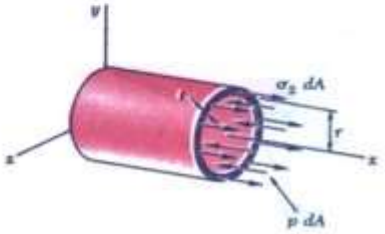


Şekil 3 . Silindir kap kesit profili

Şekil 3'te gösterilen iç yarıçapı r ve cidar kalınlığı t olan ve içersinde basınçlı bir akışkan bulunan silindirik bir basınçlı kapta silindir eksenine paralel ve dik gerilmeler meydana gelir .Bu kaplarda içindeki akışkan silindir eksenine göre simetrik olması nedeniyle kayma gerilmelerinin tesir edilmeyeceği ortaya çıkmaktadır . Parçada radyal ve eksenel gerilmeler bulunmaktadır . Radyal gerilme(σ_{radyal}) için 1 nolu denklem ifadesi girilerek 2 nolu denklemde belirtilen radyal gerilme denklemi elde edilir ,

$$\sum F_{radyal} = 0, \qquad \sigma_{radyal}(2t\Delta x) - p(2r\Delta x) = 0 \tag{1}$$

$$\sigma_{radyal} = \frac{pr}{t} \tag{2}$$



Şekil 4 . Eksenel kesit profili

Eksenel gerilmeyi tayin etmek için şekil 4'te gösterildiği gibi x eksenine dik bir kesit incelendiğinde kesitte oluşan eksenel gerilme ($\sigma_{eksenel}$) altta belirtilen denklemlerle tanımlanmaktadır ;

$$\sum F_{eksenel} = 0, \qquad \sigma_{eksenel}(2\pi rt) - p(\pi r^2) = 0 \tag{3}$$

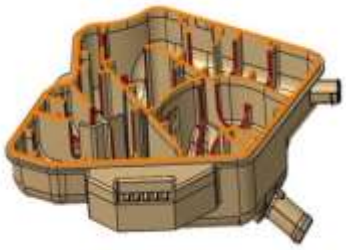
$$\sigma_{eksenel} = \frac{pr}{2t} \tag{4}$$

Bu ifadelerden anlaşılacağı üzere 5 nolu denklem alttaki gibi tanımlanmaktadır . ;

$$\sigma_{radyal} = 2\sigma_{eksenel} \quad (5)$$

Şekil 6'da gösterildiği gibi parçalar alt ve üst grubun birbirine vibrasyon kaynak yöntemiyle montajlanması ile oluşur .

$$F=P_{ic} * A_{basınç} = P_{kaynak} * A_{kaynak\ kordonu} \quad (6)$$



Şekil 5. Kaynak kordonu tasarımı

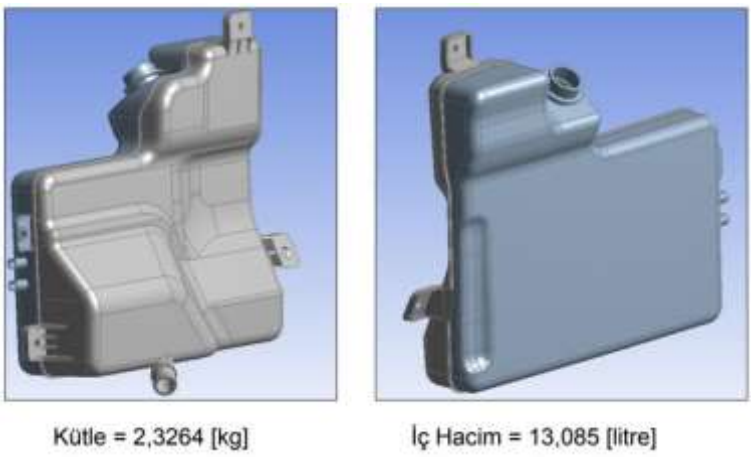
Şekil 6. Vibrasyon kaynak yöntemi

Şekil 5'te gösterilen kaynak kordon alanını arttırmak için federler de kalıp yüzeyi olarak kullanılmıştır. Kaynak kordonunun güvenli kabul edilebilmesi için seçilen ham maddenin (depo çalışma sıcaklığındaki) akma gerilmesinin %20 altında olması uygun kabul edilir. Örneğin: Bu çalışmada kullanılan Hostalen PPH1850 hammaddesinin 120°C derecedeki akma gerilmesi 8 MPa'dır. Kaynak kordonu 6 MPa'lık basınç değerini aşmamalıdır.

Gerilmelerin yüksek görüldüğü bölgelere ilave federler oluşturularak dış yüzeyde oluşan gerilme yığılması federlere taşınmaktadır. Aynı mantıkla iç kısımda oluşacak olan yüklenmeler eklenecek olan federlere aktarımı yapılır .

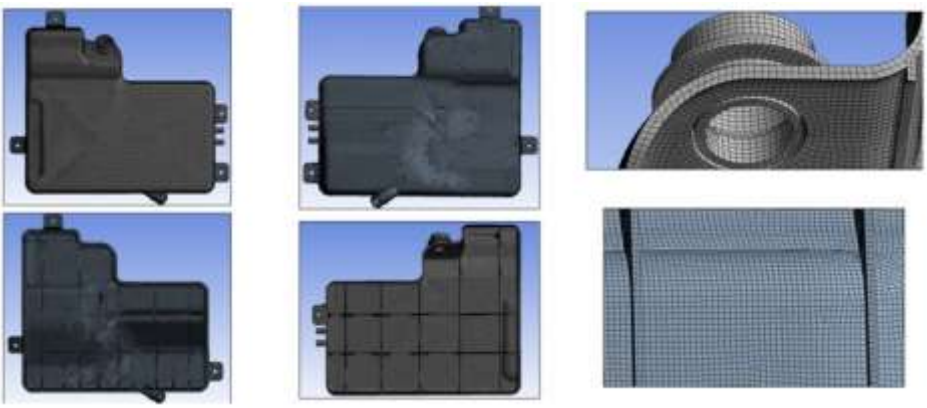
4.2. Analiz Çalışmaları

Çalışmada kullanılan su genleşme deposunun bazı fiziksel özellikleri şekil 7'de tanımlanmıştır. İlk tasarım çalışmalarında oluşturulan model görünümü alttaki gibidir. Basınç testlerinin sonuçlarının görülmesi amacıyla ilk analizler bu model üzerinden yapılmıştır.



Şekil 7. Su deposu 3D Cad data görseli

Şekil 8'de gösterilen analiz çalışmalarında ise ikinci derece Hexa elemanlar kullanılarak oluşturulmuş ve et kalınlığında en az iki sıra eleman olmasına dikkat edilmiştir. Node sayısı 1.527.108 iken elaman sayısı ise 393.741 olarak tanımlıdır.

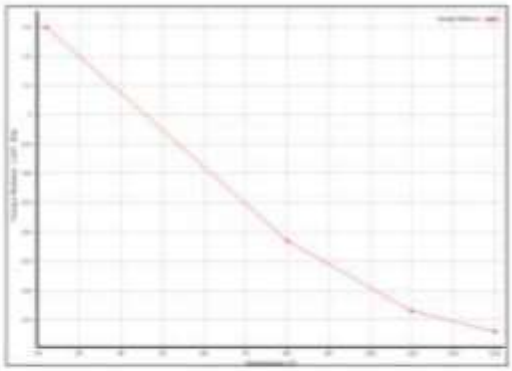


Şekil 8. Mesh çalışmaları

Elastik modülünün sıcaklığa bağlı eğrisi ANSYS programında tablo-1 ve şekil 9'da ki gibi tanımlanmıştır.

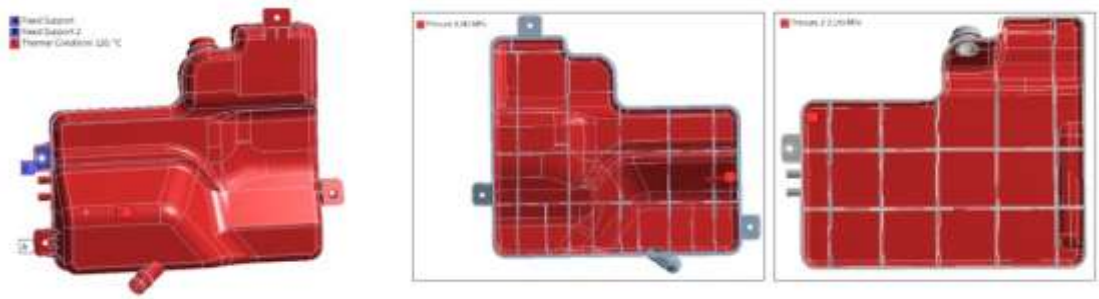
Tablo 1. Malzeme Özellikleri

Malzeme	PP H1850
Elastik Modül	1300 [MPA]
Poisson oranı	0.42
Yoğunluk	910 [kg/m^3]



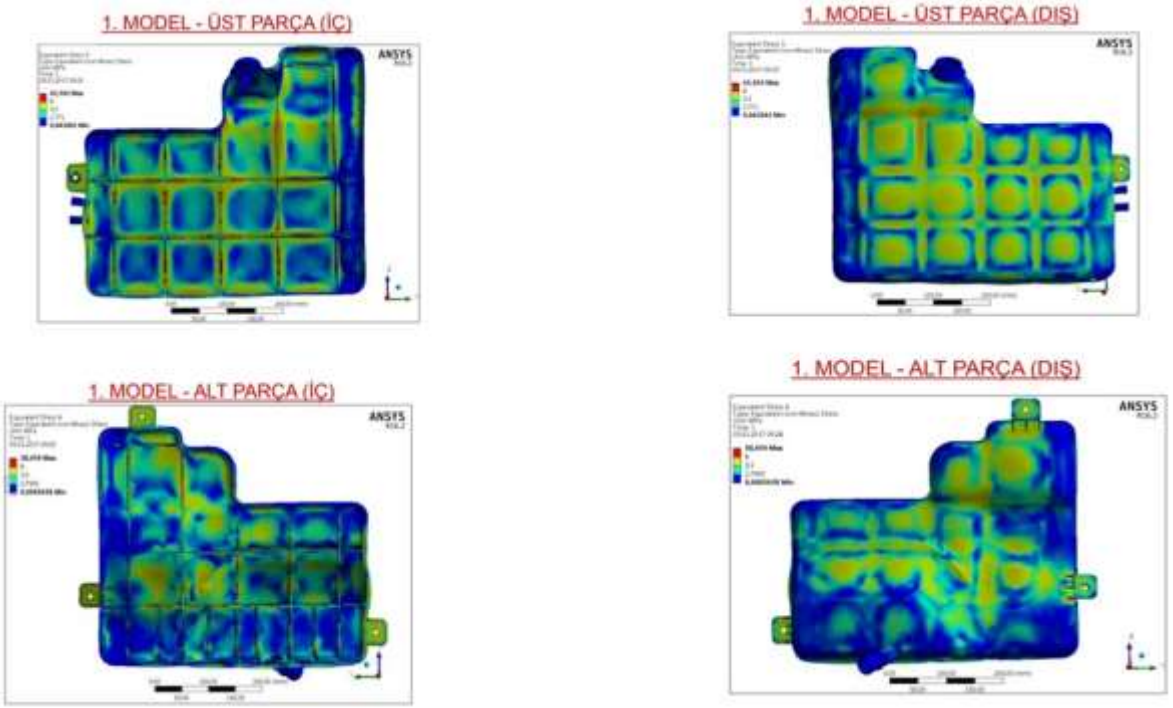
Şekil 9. Elastisite Modülü – Sıcaklık Eğrisi

Depo, Şekil 10'da gösterildiği gibi 3 adet alt parçadan ve 1 adet üst parçadan olmak üzere toplam 4 adet braket bölgelerinden sabitlenmiştir. Sıcaklığı 120 ° C olan su ve 0.145MPa basınç depoya uygulanmıştır.



Şekil 10. Sınır Koşulları

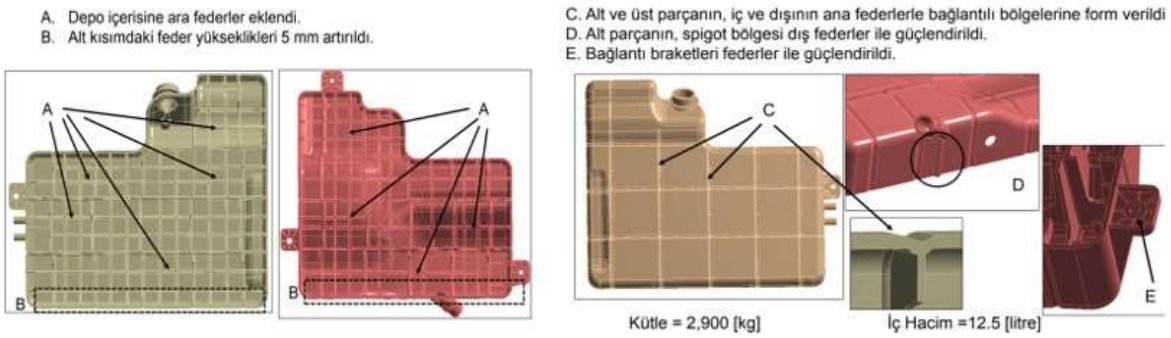
Depo malzemesi PP H1850'nin oda sıcaklığındaki akma gerilmesi 33 MPa'dır. Ancak deponun çalışma sıcaklığının 120°C olması durumu göz önüne alındığında malzemenin akma gerilmesi 8 MPa olmaktadır. Parçada nominal et kalınlığı (3 mm) üzerinde olduğu durumlarda 5-6 MPa gerilme değeri aşılmamalıdır. (Feka Automotive) [6].Şekil 11'de görüldüğü gibi birinci modele ait sonuçlar incelendiğinde çıkan değerler bu limitleri aştığı için riskler ortaya çıkmıştır. Kaynak bölgesi için de izin verilen maksimum gerilme 5-6 MPa olarak alınmıştır. Sonuçlar incelendiğinde, kaynak bölgesinin alanın artırılması uygun olacaktır.



Şekil 11. İlk Analiz Sonuçları

4. İYİLEŞTİRME ADIMLARI

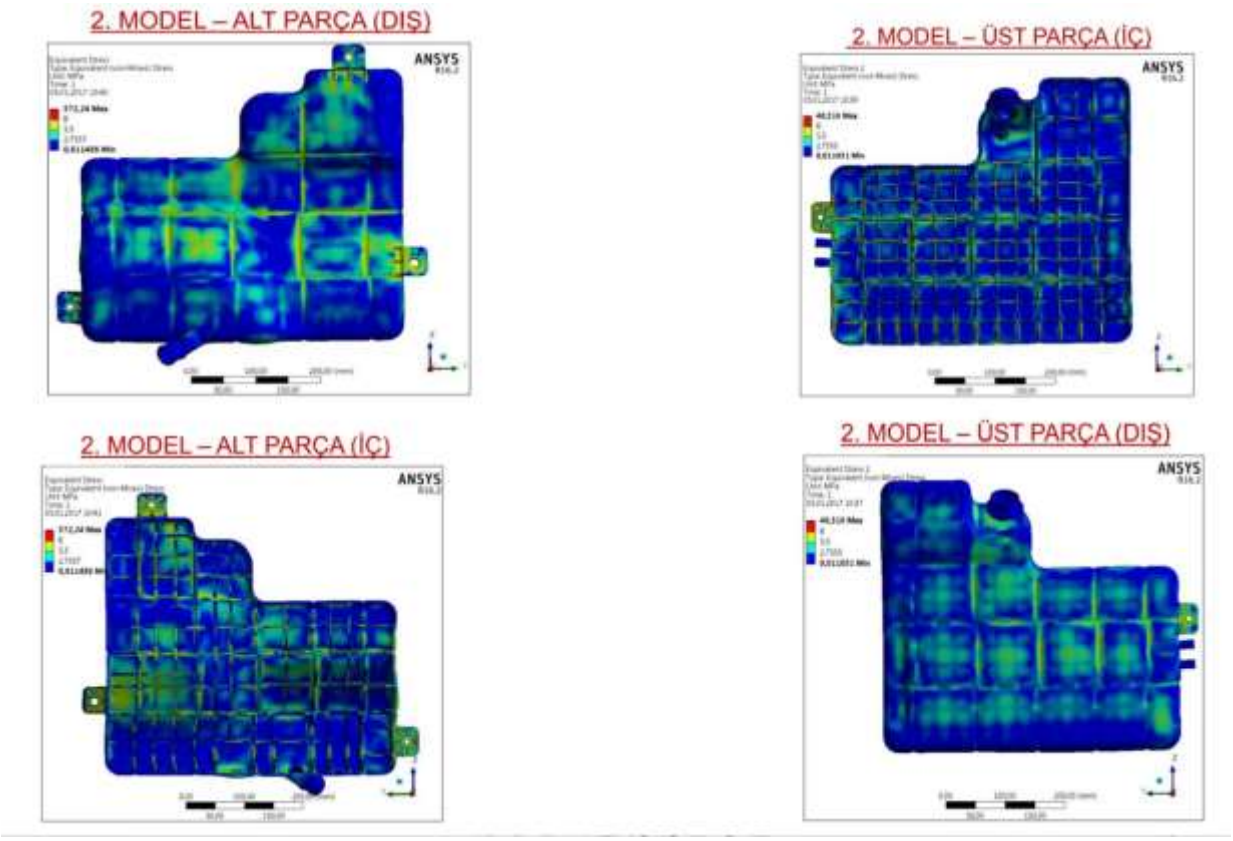
Yapılan ilk analiz sonuçlarına göre bazı deforme görülen bölgelere göre iyileştirmelerin yapılması planlanmıştır. Bunlar; A bölgesi ile tanımlı olan oklarla belirtilen yönlere ara federlerin eklenmesi ve B ile gösterilen alt kısımda bulunan tüm federlerin yüksekliklerinin 5 mm arttırılması şeklindedir. Ayrıca C,D ve E bölgelerinde güçlendirme çalışmaları yapılmıştır .



Şekil 12. İyileştirme çalışmaları

Yapılan iyileştirme çalışmalarına bağlı olarak aynı mesh çalışmaları yapılarak analiz tekrarlanmıştır. Şekil-13'deki gibi

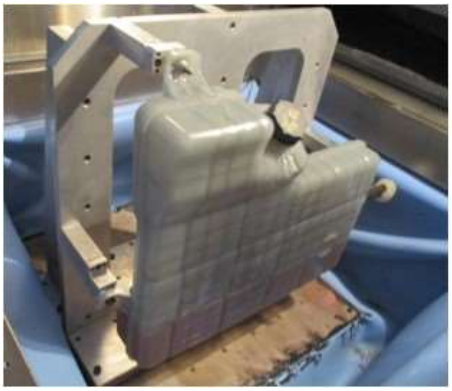
analiz sonuçlarında çıkan gerilme değerleri malzemenin akma değerinden düşük olduğu görülmüştür.



Şekil 13. İkinci Analiz Sonuçları

5.SONUÇLAR

Feder yüksekliklerinin arttırılması, iç ara federler eklenmesi, ana feder bağlantılarının iç ve dış bölgelerine form verilmesiyle ve lokal güçlendirmelerle gerilme değerleri hedeflenen mertebelere düşmüştür. 2.modelde 1.modele göre deponun kütlesi 574 [gr] artmış ve iç hacimde 0.5 [lt] azalma gerçekleşmiştir. Bu sonuçlar hedeflenen değerler içerisindedir. İlk yapılan çalışmalarda depo iç basınç değerleri 8 MPa malzeme gerilmesinin üstünde çıktığından dolayı yapılan iyileştirmeler ile birlikte 8 MPa altında sonuçlar elde edilmiştir. Bu değerler Şekil 14'te gösterildiği üzere fiziksel testler üzerinden de kontrol edilmiştir ve herhangi deformasyon görülmemiştir



Şekil 14. Fiziksel Test Koşulları

ABSTRACT

Electric vehicles (EV) are becoming more popular than internal combustion engine (ICE) vehicles. In addition to this, the structure of the vehicle body is changing. Body-in-white (BIW) which is the base of vehicle, is the most important factor influencing the stiffness of the full vehicle. Stiffness determine characteristics of vehicle dynamics, comfort and reliability.
In electric vehicles, the battery adds considerable rigidity and mass to the overall vehicle. In this study, modal and stiffness analysis of an electric sedan vehicle was performed using the finite element method over two computational models which are BIW with battery and BIW without battery. Thus, the effect of the battery on global torsion frequency, global bending frequency, torsional stiffness and vertical bending stiffness of electric sedan vehicle with a Li-Ion battery pack which is housed along the chassis in a skateboard configuration under the body was investigated.

Keywords: electric vehicle, BIW global stiffness, modal frequency, Optistruct FEM analysis, battery pack

1. INTRODUCTION

It is a known fact that the global automotive industry has been working mainly on electric vehicles in recent years. In this direction, it is inevitable to update and change the structure of the vehicles. While there is competition among manufacturers on the one hand, customers' expectations for NVH, reliability and vehicle dynamics are increasing on the other.
Designing a vehicle to have superior NVH performance is a task that should start very early in the development process, with careful analysis of the main sources of noise and vibration as well as many possible propagation paths. At this point, CAE (Computer Aided Engineering) programs help reduce both development cost and time and play an important role in establishing numerical models of vehicles or components and evaluating their behavior in areas such as noise, vibration and harshness. Two of the design features of a vehicle body that have the greatest impact on NVH performance are stiffness and BIW global natural frequencies and vibration modes.
Battery packs, which are quite heavy and stiff in electric vehicles, have become one of the basic parts of the body. This study is about how the battery influences torsion natural frequency, bending natural frequency, torsional stiffness and bending stiffness on the electric sedan vehicle body. In order to examine the effect of the battery, two models have been prepared, with and without battery. Optistruct was used as a solver for modal analysis and static stiffness analysis. Modal and global static stiffness analysis were run for both models and BIW global bending and torsion stiffness, modal frequency results were compared.

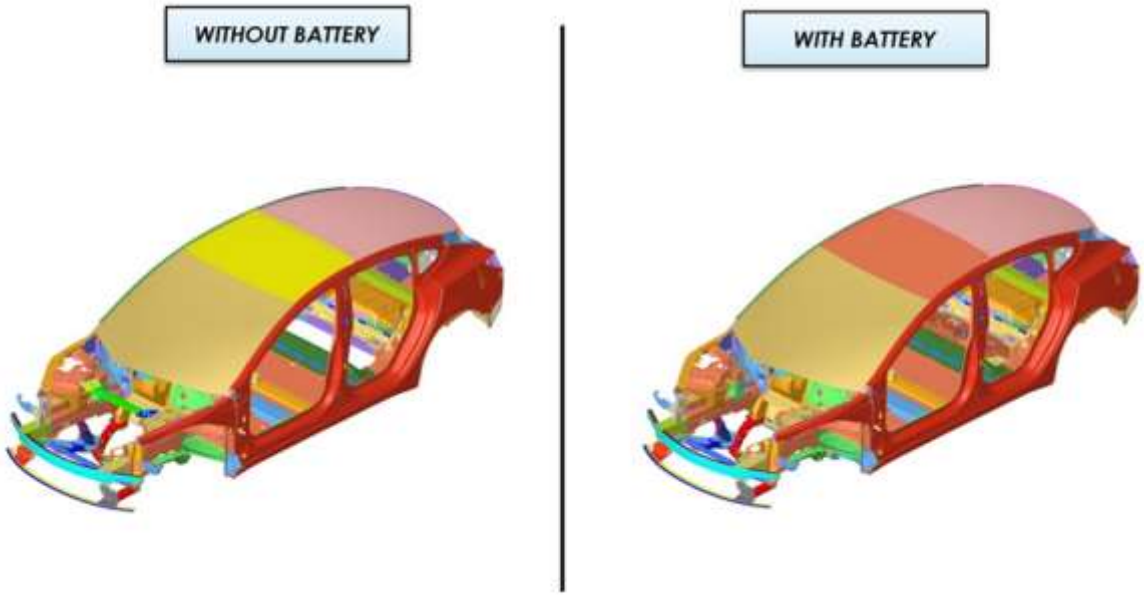

Figure 1. FEM model of sedan EV

The electric sedan vehicle FEM model used in this study is shown in figure 1 and includes windshield, front crash management system and front subframe in addition to the BIW. With these add-ons, the integrity of the vehicle has been ensured and the modal shapes have become easier to examine. Since the information of the battery cells is not available, they have been added to the model in mass. For component connections, spots and rivets are simulated as RB3 spot ACM (shell gap), adhesives as RBE3 hexa adhesive (shell gap) and bolts are simulated as beams. The information data of the fem model is given in table 1, and the information about the element type is given in table 2.

Table 1. FEM model data information

Data Type	BIW without Battery	BIW with Battery
Total # of Grids (Structural)	1603697	1922661
Total # of Elements	1385110	1685413
Total # of Rigid Elements	301102	322770
Total # of Rigid Element Constraints	1490556	1776822
Total # of Degrees of Freedom	9207462	11095398
Total # of Non-zero Stiffness Terms	260305719	312397137

Table 2. FEM model element type information

Element Type	BIW without Battery	BIW with Battery
CBEAM	632	909
CHEXA	109028	117335
CPENTA	880	912
CONM2	0	4
CQUAD4	1231289	1515245
CTRIA3	43281	51008

2. STIFFNESS ANALYSIS

2.1 Basic theory of Torsional Stiffness

When both sides of the car are landed with different loads, body will twist. For example, when driving on uneven roads, the effects of the bumps and pits will be transmitted to the suspension through the tires on both sides, and then transmitted to the body by the suspension. Currently, the body also is subject to torsional deformation. Only when the torsional stiffness of the body is sufficient, the torsional deformation will be within the limits of NVH requirements. When an asymmetrical vertical load is acting on the body, i.e there is a reversed load on both sides, the body is under torsion, and these asymmetrical loads will cause torsional deformation. The calculation diagram of torsional stiffness of body-in-white is shown in Figure 2 and the torsional stiffness can be calculated using equation 3.[1]

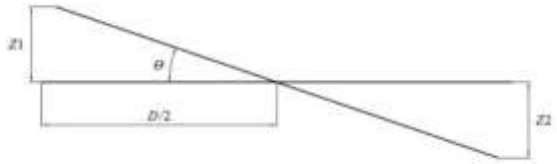

Figure 2. Simplified schematic diagram of torsional stiffness [1]

$$GJ = \frac{FD}{\theta} \tag{1}$$

Torsion angle calculation formula is as follow,

$$\theta = arctan\left(\frac{Z1-Z2}{D}\right) \tag{2}$$

Where Z1 and Z2 are the relative deformation of the left and right, longitudinal beams, D is the distance between the left and right measuring points.

2.2 Basic theory of Bending Stiffness

In order to calculate the bending stiffness of the body, the vertical force is applied on it, and thus the front and rear suspension mounts are constrained. This way, they can be considered a beam structure in simple terms.
The bending load acting on the body is also considered a point load for ease of calculation and understanding shown in figure 3. This point load is acting on the simple supported beam. By conducting the equilibrium equation and combining the boundary conditions and continuous conditions, the formula for the bending stiffness of the body and maximum vertical deflection can be obtained. [1]

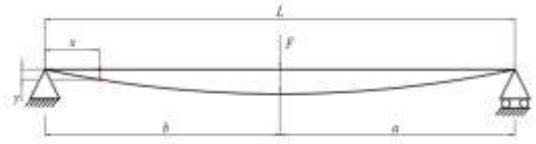

Figure 3. Simplified schematic diagram of bending stiffness [1]

$$EI = \frac{Fax(L^2-x^2-a^2)}{6Ly} \tag{3}$$

However, calculating the bending stiffness via tha above formula is fairly complicated. So, generaly, in order to simplify things, the stiffness value of the bending condition can be obtained via the following equation.

$$EI = \frac{\Sigma F}{\delta_{max}} \tag{4}$$

Where ΣF is total bending load (N) and δ_{max} is the maximum deformation of bending condition.

2.3 Torsional Stiffness Analysis

In torsional stiffness analysis, a load of 3000 Nm is applied to the front shock mount on the body. 3106N is applied in the z-dirction on the left, and 3106N is applied in the -z-direction on the right side, and the boundary conditions are shown

in figure 4. Degree of freedom of the right rear shock mount is constrained in the x,y,z direction, the left rear shock mount is constrained in the x,z direction, , and the lower middle of body is constrained in the z direction.[2]

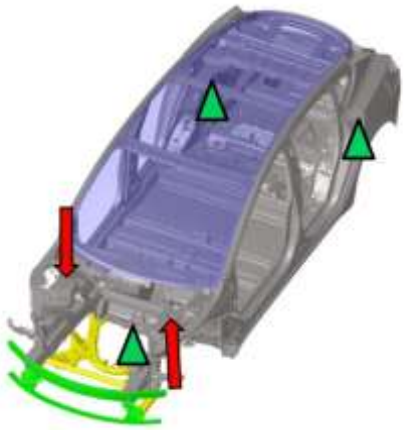

Figure 4. Torsional stiffness constrains

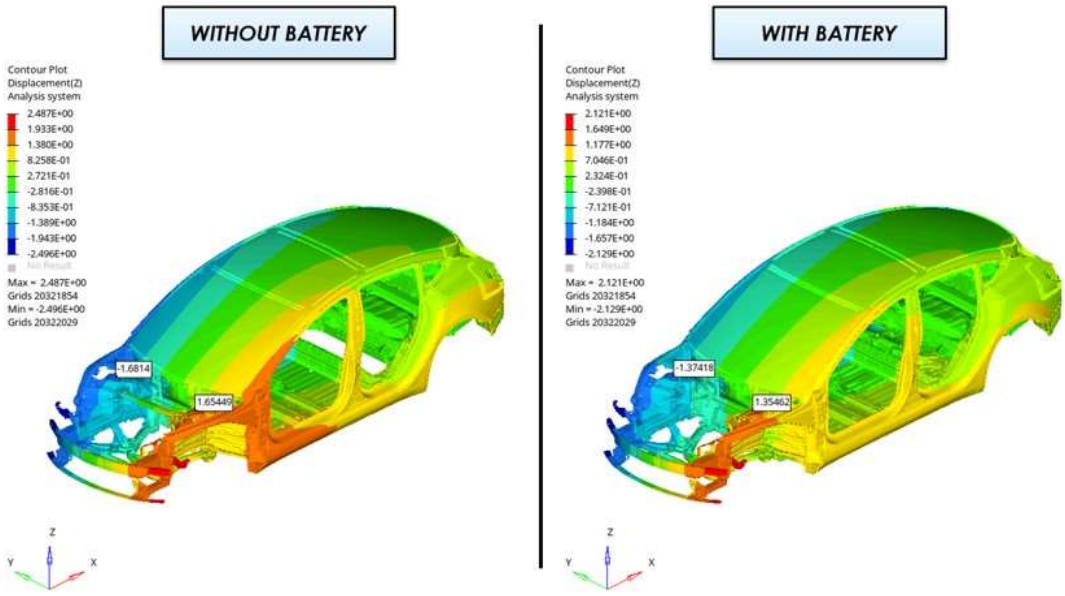

Figure 5. Torsional stiffness analysis result

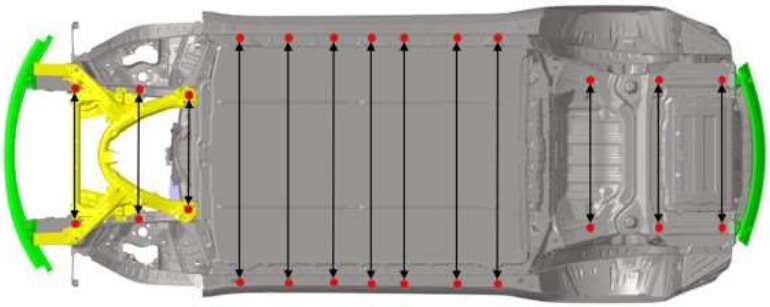

Figure 6. Points for calculating torsion angle

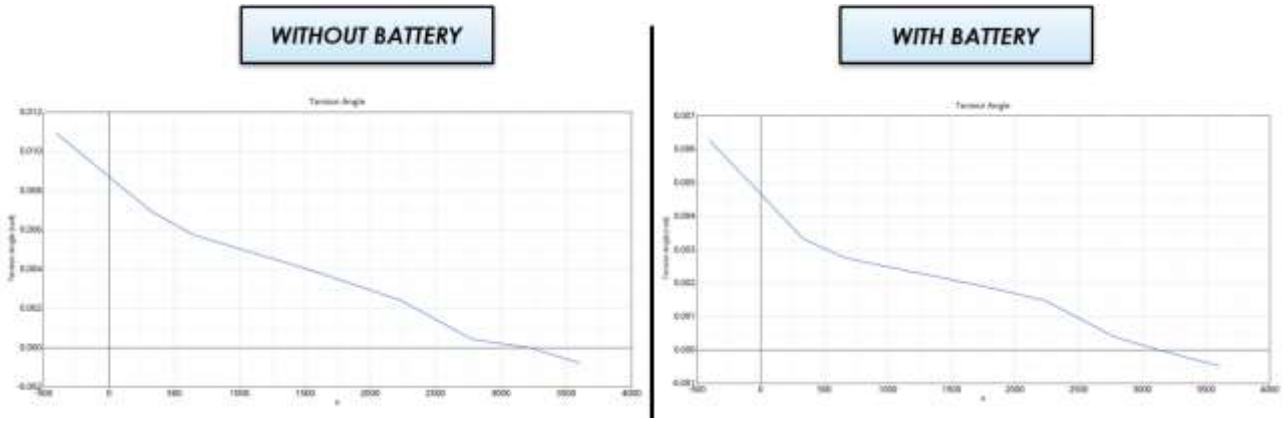

Figure 7. Torsion angle vs longitudinal x-axis graph

The torsional stiffness Z-displacement contour of body was calculated. Figure 5 shows the torsional rigidity Z-displacement contour of body. Figure 6 shows the locations of the measuring points for calculating torsion angle. Figure 7 shows the torsion angle of without battery and with battery model. Relative torsion angle of body along the longitudinal axis is 0.62 deg. for without battery model and 0.35 deg. for with battery model. When we compare the two models, torsion angle is decreased by 77 percent with the addition of the battery. Torsional rigidity of without battery is 868.8 kNm/rad for with battery model is 1062.2 kNm/rad. As the result show, with battery model 22. percent higher torsional stiffness than without battery model.

2.4 Bending Stiffness Analysis

In bending stiffness analysis, the load is applied as 1000N to each seat position and 4000N in total, and the boundary conditions are shown in figure 8. Degree of freedom of the right rear shock mount is constrained in the x,y,z direction, the left rear shock mount is constrained in the x,z direction, the right front shock mount is constrained in the y,z direction, and the left front shock mount is constrained in the z direction.[2]

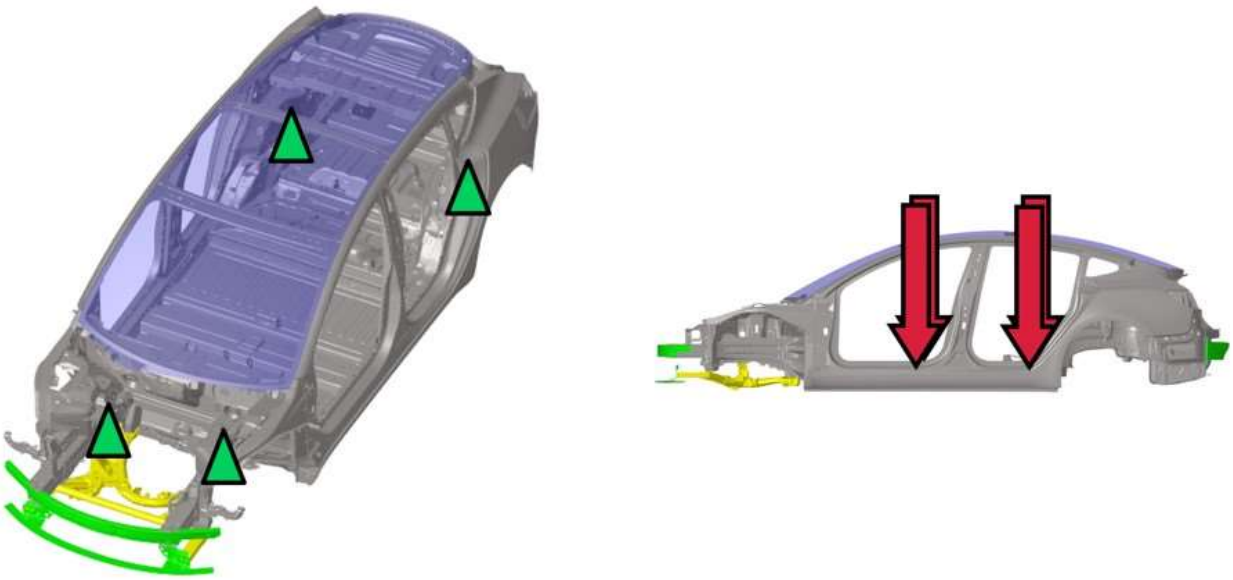

Figure 8. Bending stiffness constrains

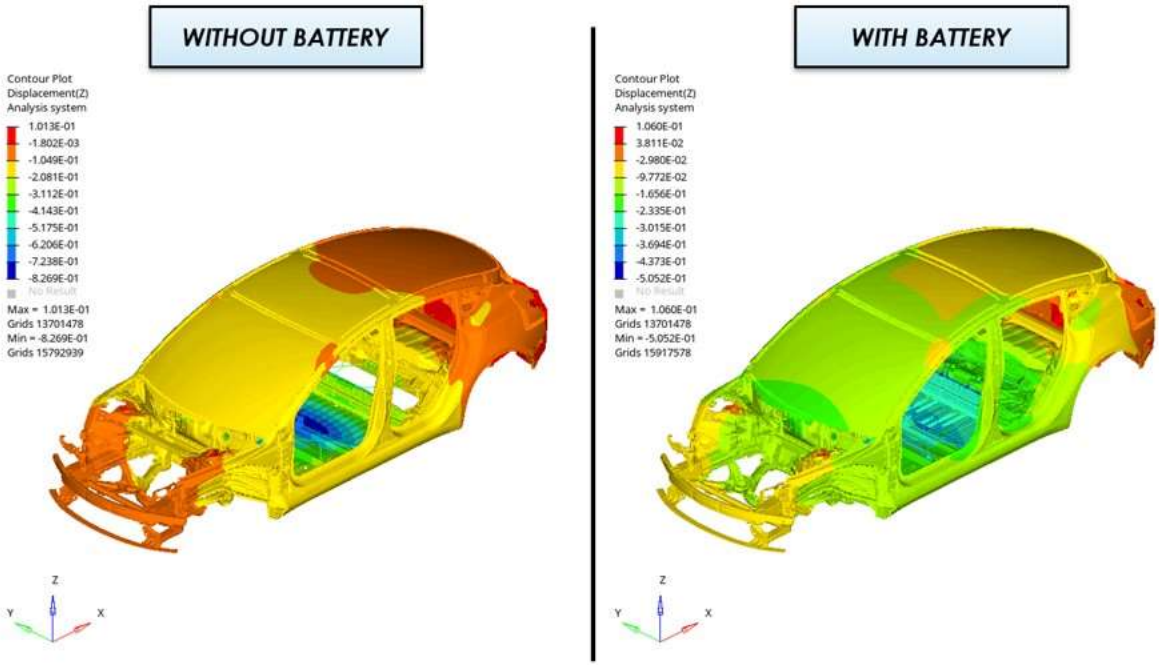

Figure 9. bending displacement contour of body

Bending stiffness of body was calculated. Figure 9 shows the bending in Z-displacement contour of body. In the figure 10, the maximum Z-displacement of the rocker side in the bending condition was given. The maximum z-direction displacement was taken rocker side of driver and its 0.224 mm, and the bending stiffness was calculated 17.8 kN/mm for without battery model. For the with battery model, the maximum z-direction displacement was taken as 0.179 mm on the rocker side of the driver, and the bending stiffness was calculated as 22 kN/mm for the model without battery. When we compare the two models, bending stiffness increased by 23 percent with the addition of the battery. Summary of the static stiffness analysis results are given in table 3.

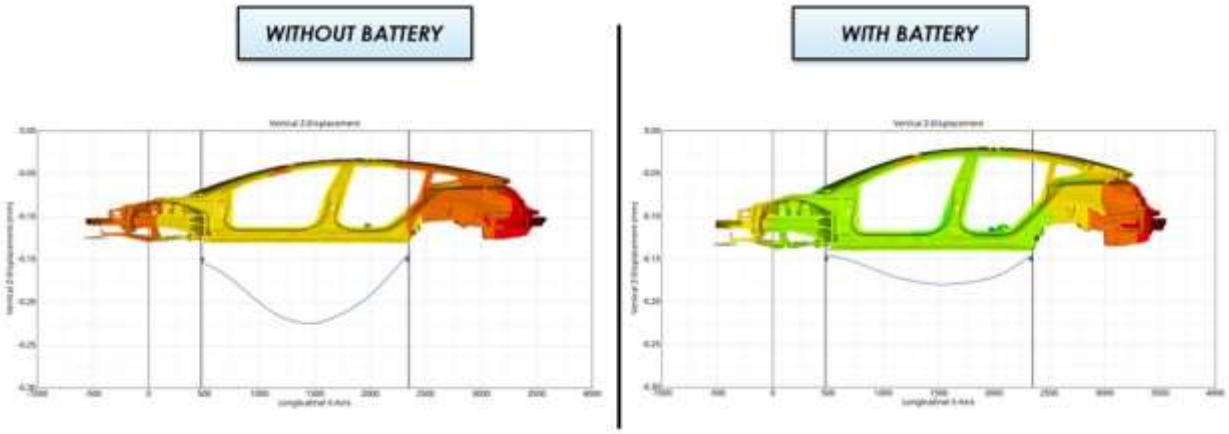

Figure 10. Maximum Z-displacement of body

Table 3. Static stiffness analysis results

Load Case Name	without Battery	with Battery	Change [%]
Torsional Stiffness [kNm/rad]	**868,8**	**1062,1**	**22**
Bending Stiffness [kN/mm]	**17,8**	**22**	**23**

3. MODAL ANALYSIS

3.1 Theory of Finite Element Modal Analysis

Modal analysis is the method of determining the dynamic characteristics of a structure, which contain many components connected by non-mass and rigid links. Each structure has its own vibration frequency, and this is called resonance frequency. When a structure's resonance frequency is triggered, it generates a vibration mod. The objective of modal analysis is to identify the modal parameters of the system, providing a foundation for dynamic characteristics. In the finite element modal analysis process, the computational model is created, and then numerical analysis is performed. For a vibration system with one degree of freedom, the differential equation of motion is

$$[M]\{\ddot{x}\} + [C]\{\dot{x}\} + [K]\{x\} = \{f\} \quad (5)$$

Where $[M]$ is system matrix, $[C]$ is damping matrix and $[K]$ is stiffness matrix.[3] For modal analysis the damping matrix is usually ignored. Damping is often neglected for modal calculations at FE methods, as the damping inside the body is very small and the contribution of the damping to the modal frequencies and shapes of the body is negligible.[4] When we arrange the equation according to free vibration and harmonic motion, we obtain:

$$([K] - \omega_i^2[M])\{x_i\} = \{0\} \quad (6)$$

Where ω_i^2 is eigenvalues, $\{x_i\}$ is eigen vectors and i shows the value between 1 and degrees of freedom. Furthermore, the square root of the eigenvalues gives the natural circular frequencies. Eigenvectors refer to the mode shape. Lanczos method was developed for diagonalizing matrices. After the coefficient matrix is diagonalized, the eigenvalues and eigenvectors can be calculated effectively. [5]

3.1.1 Natural Frequency of Cantilever Beam

When given an excitation and left to vibrate on its own, the frequency at which a cantilever beam will oscillate is its natural frequency. This condition is called Free vibration. The value of natural frequency depends only on system parameters of mass and stiffness. When a real system is approximated to a simple cantilever beam, some assumptions are made for modelling and analysis (Important assumptions for undamped system are given below):

- The mass (mm) of the whole system is considered to be lumped at the free end of the beam

- No energy consuming element (damping) is present in the system i.e. undamped vibration
- The complex cross section and type of material of the real system has been simplified to equate to a Cantilever beam[6]

The governing equation for such a system (spring mass system without damping under free vibration) is as below:

$$M\ddot{x} + Kx = 0 \tag{7}$$

$$\ddot{x} + \omega_n^2 x = 0 \tag{8}$$

$$\omega_n = \sqrt{\frac{k}{m}} \tag{9}$$

k , the stiffness of the system is a property which depends on the length (l), moment of inertia (I) and Young's Modulus (E) of the material of the beam and for a cantilever beam is given by:

$$k = \frac{3EI}{l^3} \tag{10}$$

3.2 Modal Analysis Results

Finite element model was solved free-free condition on Optistruct for both models which are with battery pack and without battery pack. The effect of the battery on the global torsion and global bending frequencies was examined.Global torsional frequency results are shown in figure 11 and global bending frequency results are shown in figure 12.

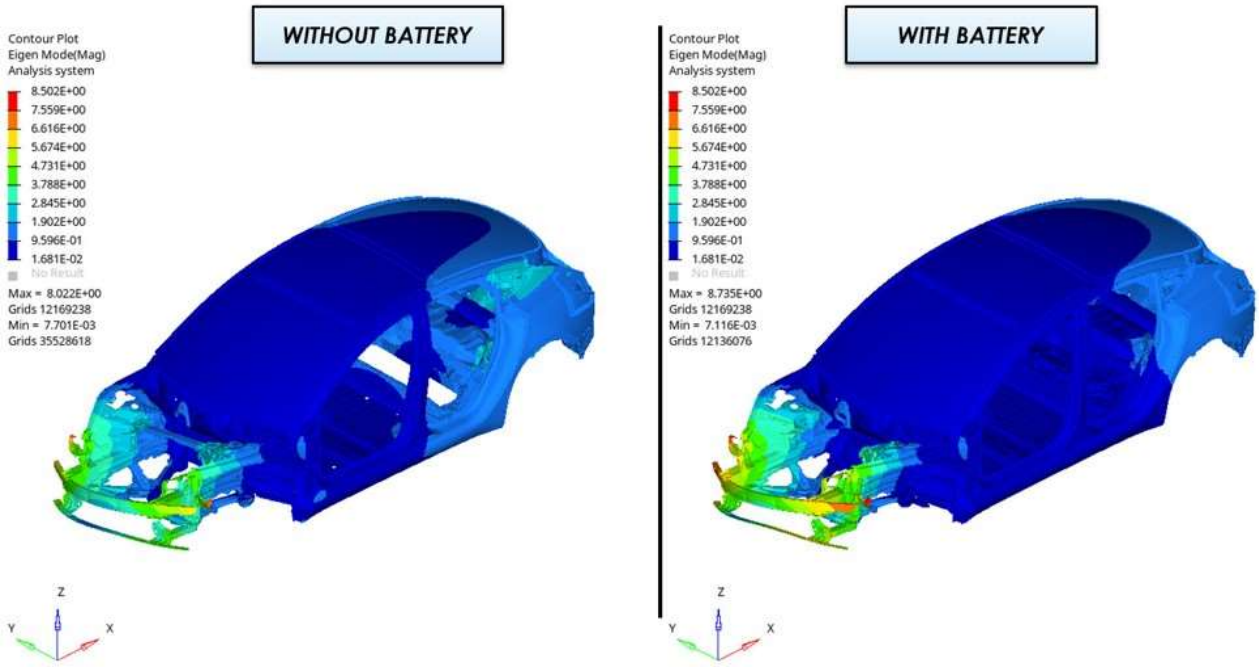

Figure 11. Global torsional frequency of sedan EV

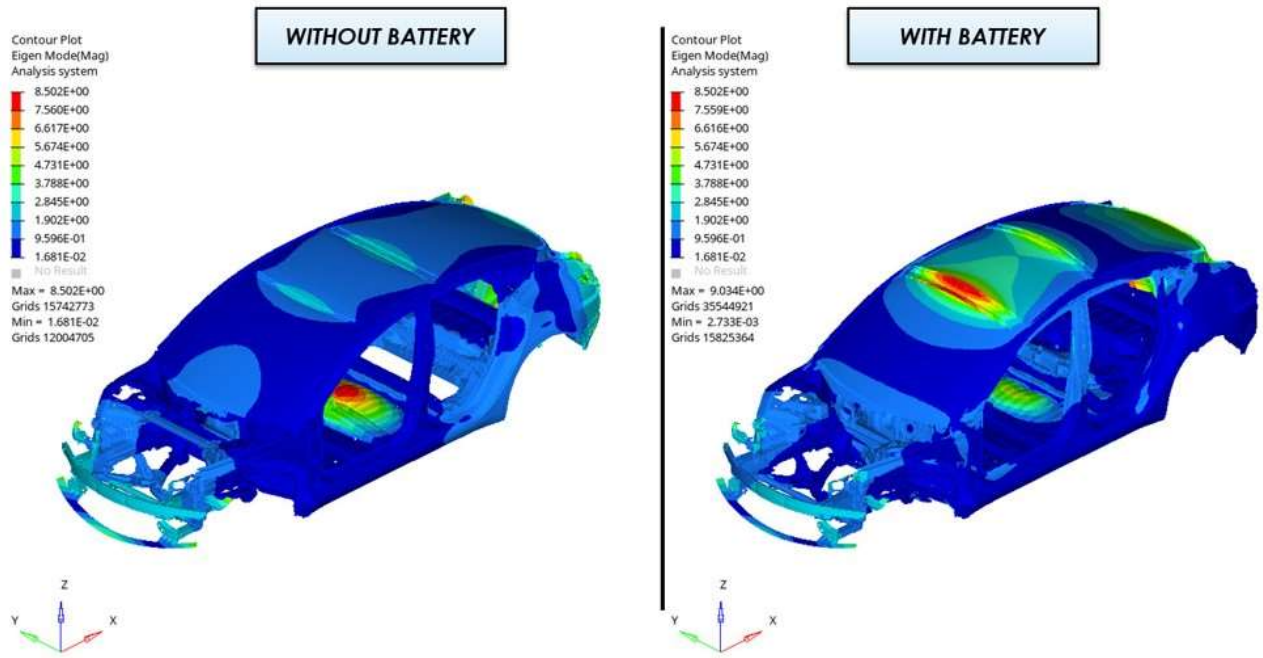

Figure 12. Global bending frequency of sedan EV

Table 4. Modal analysis results

Load Case Name	*without Battery*	*with Battery*	*Change [%]*
Global Torsional Mode Shape	**40,36 Hz**	**39,91 Hz**	**1**
Global Bending Mode Shape	**65,45 Hz**	**75,66 Hz**	**16**

The modal analysis results are shown in Table 4. Effect of mass and frequency change with respect to model without battery cancel each other and final global BIW torsional frequency does not change considerably in a modal with battery. Bending stiffness of a model with battery increases 23 percent with respect to model without battery. Combination of mass and stiffness increase results in 16 percent increase in total for global BIW bending frequency.

4.CONCLUSION

In conclusion, Hypermesh was used to create the finite element model of the sedan EV and Optistruct was used as a solver. Modal and static stiffness analyzes were performed and the effect of the battery was examined. As a result of modal analysis, the battery has almost no effect on the global BIW torsional frequency but 16 percent increase on the global BIW bending frequency. As a result of the static stiffness analysis, it has been determined that the effect of the battery pack on the torsional stiffness is more than the effect on the bending stiffness. While the battery pack provided a 22 percent increase in torsional stiffness compared to the model without battery, bending stiffness also provided an increase of approximately 23 percent. Finally, battery pack indicates dominant effect in global BIW torsional and bending stiffness, bending frequency, on the other hand there is no considerable effect of battery pack in global BIW torsional frequency compare to model without battery.

ÖZET

Günümüzde dizel motorların en büyük sorunlarından biri yüksek egzoz emisyonlarıdır. Egzoz emisyonları azaltılması adına birçok çalışma yapılmaktadır. Bu çalışmaların başında biyodizel yakıtların dizel motorlara ilavesi gelmektedir. Biyodizel yakıtlar petrol ürünlerine olan bağımlılığı azaltmak için bir fırsat olarak görülmektedir. Biyodizel kullanımının olumlu etkileri olduğu kadar olumsuz etkileri de bulunmaktadır. Bu olumsuz etkiler biyodizel kullanım oranlarının arttırılmasını engellemektedir. Biyodizel kullanımı ile termik verim azalmakta, özgül yakıt tüketimi artmaktadır. Emisyonlar özelinde incelendiğinde biyodizel kullanımı ile NOx emisyonu ve is emisyonlarında artış görülmektedir. Motor performans ve emisyonlarında ortaya çıkan bu olumsuz etkilerin giderilmesi için dizel-biyodizel karışımlarına ilave katkı maddeleri eklenerek deneyler yapılmaktadır. Bu katkı maddelerinin başında nanopartikül maddeler gelmektedir. Nanopartikül katkı maddeleri, geliştirilmiş yüzey alanı/hacim oranı, atomizasyonu arttırması ve daha kısa tutuşma gecikmesi süresini sağlaması gibi özelliklerinden dolayı yakıt özelliklerini geliştirmek amacıyla ideal bir katalizör görevi görmektedir. Bu çalışma, Dizel-Biyodizel karışımlarına ilave edilen nanopartikül maddelerin motor performansına ve emisyonlarına olan etkisi üzerine yapılan çalışmaların derlenmesiyle oluşturulmuştur. Bu derleme çalışmasında farklı oranlarda dizel-biyodizel yakıt karışımlarına eklenen çeşitli nanopartikül katkı maddelerinin motor performans ve emisyonlarına etkisi incelenmiştir.

Anahtar Kelime: Biyodizel, Nanopartikül Katkı Maddeleri, Dizel Motor Performansı, Dizel Motor Emisyonları

EFFECT OF NANO-PARTICLE SUBSTANCES ADDED TO BIODIESEL FUELS ON ENGINE PERFORMANCE AND EMISSIONS

ABSTRACT

Today, one of the biggest problems of diesel engines is high exhaust emissions. Many studies are carried out to reduce exhaust emissions. The most important of these studies is the addition of biodiesel fuels to diesel engine fuel. Biodiesel fuels are seen as an opportunity to reduce delendense on petroleum products. The use of biodiesel has not only positive effects but also negative effects. These negative effects prevent the increase in the rate of biodiesel use. With the use of biodiesel, brake thermal efficiency decreases and specific fuel consumption increases. When the emission characteristics are examined, it is seen that NOx emissions and soot emissions increase with the use of biodiesel. Additional additives can be added to diesel-biodiesel blends to eliminate these negative effects on engine performance and emissions. Nanoparticle substances come first among these additives. Nanoparticle additives act as an ideal catalyst to improve fuel properties due to their properties such as improved surface area / volume ratio, good atomization and shorter ignition delay time. This study was created by compiling the studies on the effect of nanoparticle substances added to Diesel-Biodiesel blends on engine performance and emissions. In this review, the effects of various nanoparticle additives added to diesel-biodiesel fuel mixtures on engine performance and emissions were investigated.

Keywords: Biodiesel, Nanoparticle Additives, Diesel Engine Performance, Diesel Engine Emissions

1.GİRİŞ

Alternatif bir yakıt seçeneği olan biyodizel, motorlar kaynaklı ortaya çıkan zararlı emisyonları azaltma potansiyeline sahip olması ve içten yanmalı motorlarda kullanılması nedeniyle diğer kaynaklar arasında en çok tercih edilen yakıtlardan biridir. Ekonomik ve çevre dostu olan biyodizel, petrol bazlı yakıtlar için önemli bir alternatiftir (Ganesan vd. 2020). Biyodizel kullanımı, Dizel motorlara belirli oranlarda eklendiğinde emisyonları azaltıcı etki göstermektedir. Ek olarak, yapılan çalışmalar gösteriyor ki biyodizel kullanımının, motor performansını olumsuz yönde etkilediği ve yakıt tüketiminde artışlara neden olduğu belirtilmiştir. Biyodizel kullanımının içeriğinde bulunan yüksek oksijen oranı nedeniyle NOx emisyonlarını arttırdığı literatürde belirtilmiştir. Olumlu etkilerinin yanında sıralanan bu olumsuz etkilerin giderilmesi adına dizel-biyodizel karışımlarına ilave katkılar katılarak deneysel çalışmalar gerçekleştirilmektedir. Bu katkılardan biri yakıtlara su ilavesidir ki bu ilave NOx emisyonlarının azaltılmasında önemli rol oynarken su kullanımı yanma odasında yanma sıcaklığını azalttığından dolayı tutuşma gecikmesi süresinde uzamalara neden olabileceği belirtilmiştir (Sezer vd. 2018). Biyodizel ile ilgili sıralanan olumsuz etkenlerin üstesinden gelmek adına organik ve inorganik metallerden elde edilen yakıt katkıları gibi kimyasal maddeler deneylerde kullanılmıştır. Kullanılan yakıt katkılarının genel amacı yanma verimini arttırmak ve kirliliği azaltmaktır. Hidrokarbon yakıtlar için yanma katalizörü olarak yardımcı olan katkı maddeleri demir, bakır, manganez, baryum, kalsiyum ve platin gibi metalik esaslı bileşiklerdir. Nanoteknolojideki gelişmeler, nano enerjik malzemelerin üretimine, kontrolüne ve karakterizasyonuna izin vermektedir. Nano-parçacıklar daha yüksek yüzey/hacim oranına sahiptir ve daha yüksek yüzey alanı, kütle formlarına kıyasla katalitik reaktivite ve geliştirilmiş manyetik özellikler için daha önemlidir. Gelişmiş nano malzemeler, daha yüksek yüzey alanı nedeniyle metalik tabanlı malzemelere göre daha etkilidir. Nano partikülün bir diğer önemli yararlarından biri de boyutudur, mikron boyutundaki partiküllerde olduğu gibi filtre tıkanması ve yakıt enjektörü tıkama olasılığı bulunmamaktadır. Bu bağlamda dize-biyodizel yakıt karışımlarına nano partikül maddelerin ilave edilmesi ile ilgili yapılan çalışmaların bir araya getirilerek değerlendirilmesi, daha sonra yapılacak olan motor performans iyileştirme ve emisyon azaltma çalışmalarına ışık tutacaktır (Ganesan vd. 2020). Dizel-biyodizel yakıtlara nano partiküllerin eklenmesi konusunda literatürde birçok çalışma yapılmıştır. Bu çalışmada, metal, metal oksit, manyetik, karbon nano tüp, nano organik katkı maddeleri ve karışık nano katkı maddeleri gibi çeşitli nano katkı maddelerinin motor performansı ve emisyonları üzerindeki etkilerine ilişkin literatür taraması yapılarak raporlanması yapılmıştır.

2. NANOPARTİKÜL MADDELER

Nanopartikül Maddeler, boyutları 1–100 nm arasında değişmekte olup yakıt katkısı olarak nano materyaller arasında Al, Ag, Cu, Mg, Ni, Ti, Zn gibi metaller, bor gibi yarı metaller ve Al_2O_3, CeO_2, TiO_2, Fe_2O_3 Fe_3O_4 CuO, MnO, MgO gibi metal oksit nano akışkanlar sıralanabilir (Sezer vd. 2018). Nanopartikül katkı maddeleri, uluslararası yakıt standartlarının karşılanmasında ve biyodizel ile ilgili sorunların aşılmasında çok önemli bir rol oynamaktadır. Nanopartikül katkı maddeleri yardımıyla egzoz emisyonlarınının azalması sağlanırken aynı zamanda motor performansını arttıran dizel-biyodizel yakıt karışımları oluşturulabilir (Madiwale, Karthikeyan, ve Bhojwani 2017). Nanopartikül katkı maddeleri, geliştirilmiş yüzey alanı/hacim oranı, ani buharlaşma ve daha kısa tutuşma gecikmesi süresi gibi özelliklerinden dolayı yakıt özelliklerini geliştirmek amacıyla ideal bir katalizör olarak düşünülmektedir (Sezer vd. 2018).

3. NANOPARTİKÜL MADDELERİN MOTOR PERFORMANS VE EMİSYONLARINA ETKİSİ

3.1 Termik Verim

Silindire girmiş olan karışımın yanması ile oluşan enerjiye karşılı, motorun bu enerjiyi faydalı işe çevirme oranına denir. Termik verim, motor performansının önemli bir ölçütüdür. Termik verim, yakıtların yanma kabiliyetini yansıtır. Başka bir deyişle, enerjinin ne kadar verimli bir şekilde mekanik işlere dönüştürüldüğünü gösterir (Özdamar ve Yelken 1986).

$$Termik\ Verim = \frac{Pex3600}{bexHu} \qquad Fren\ Gücü = \frac{Mexn}{9549} \qquad Moment = F \times L \times Df$$

Hu: Alt Isıl Değer(kj/kg)
Be: Özgül Yakıt Tüketimi(gr/kWh)
Pe: Efektif Motor Gücü (kW)
Me: Motor Momenti
N: Motor Devri (Devir/dk.)
F: Dinamometre Kuvvet Değeri
L: Dinamometre Kol Uzunluğu
Df: Moment Düzeltme Faktörü

Sanjeevarao ve ark., yapmış oldukları çalışmada dizel yakıtını, farklı oranlarda pamuk yağı (%20 ve %50) ve farklı oranlarda Al_2O_3 (50 ve 100 ppm) karıştırıp deneyler yaparak motor performans ve emisyonlarını incelemişlerdir.

Sonuçlar, 100 ppm Al_2O_3 nano katkılı biyodizel karışımı B20'nin, eklenen alümina Nano katkı maddeleri sayesinde maksimum yüklerde D100'e kıyasla daha yüksek termik verim sağladığını göstermektedir. Bu Al_2O_3 nanopartiküllerinin, yakıt ve yanma özelliklerini iyileştirmesinden kaynaklandığı belirtilmiştir (Sanjeevarao vd. 2020). Kumar ve ark., dizel yakıtına farklı oranlarda (%20, %30, %40) atık yemek yağı biyodizeli ilavesine ek olarak hacimce %2 dietil eter ve 80 ppm CeO_2 ilavesi yapılarak çalışmalarda bulunmuştur. Genel olarak katkılı yakıtların katkı ilavesiz yakıtlara göre daha yüksek verimlilik gösterdiği görülmektedir. Oksijenli yakıt DEE ve CeO_2 nanopartiküllerinin birleşik etkisi termik verimde ki bu artışa katkıda bulunduğu belirtilmiştir. Yüksek uçuculuk, daha yüksek setan sayısı ile DEE, CeO_2 nanopartikülleri tarafından desteklenen tutuşma gecikmesi azaltılmasına yardımcı olmuştur. B30'un yoğunluğu B20 harmanına göre daha yüksek olmasına rağmen, nanopartiküllerin eklenmesi ile hava ile biyodizel arasında daha iyi ısı transferi meydana geldiği ve bunun da tutuşma gecikme süresinin azaltılmasının nedeni olduğu belirtilmiştir (Kumar vd. 2020). Kumar ve ark., dizel yakıtına %20 oranında pamuk yağı biyodizeli eklemiş ve bu karışımlara ek olarak farklı oranlarda (40, 80, 120 ppm) ZnO ekleyerek motor performans ve emisyon özelliklerini incelemişlerdir. ZnO ile harmanlanmış yakıtların termik verimi daha yüksek yüklerde artmıştır ve nanopartiküllerin ppm seviyesindeki artışı ile verimin arttığı görülmüştür. Bu durumun, daha iyi yüzey alanı/hacim oranına sahip nanopartiküllerin daha iyi yanma özelliklerine bağlanabileceği belirtilmiştir (Deepak Kumar, Hussain, ve Ramesha 2019). Dharmaprabhakaran ve ark., B20 biyodizel karışımına farklı miktarlarda (25, 50, 75 ve 100 ppm) CuO_2 ilave ederek bu karışımların motor performanslarını incelemişlerdir. CuO_2 nanopartikülleri içeren ve içermeyen biyodizel ve dizel karışımı, BBAME içinde yüksek oksijen içeriği sağlayarak mükemmel bir yanma nedeniyle B20'ye kıyasla çok daha iyi termik verim sergilemiştir. B20+100 ppm, atomizasyonunda kullanılan nanopartikülün yüzey/hacim oranının daha yüksek olması yanma verimini arttırdığından B20 ile kıyaslandığında daha yüksek termik verim ile sonuçlandırdığı görülmüştür (Dharmaprabhakaran vd. 2020). Abdallah ve ark., artık yemek yağı biyodizelini %30 dizel yakıta ilave edip MgO, ZnO ve Al_2O_3 nano katkıları kullanarak deneyler gerçekleştirmiş ve motor performans ve emisyonlarını incelemiştir. Saf dizele kıyasla, metal oksit nanopartiküllerin kullanılması termik verimi arttırmıştır. Metal oksitler nanopartiküller, yakıt tasarrufu ve termik verim artışı sağlamak için yanma işlemine oksijen sağlamak üzere bir katalizör görevi gördüğü belirtilmiştir (Abdallah, Abdel-Rahman, ve Elwardany 2020). Gad ve Jayaraj, dizel yakıtına %20 Jatropha bitki yağı biyodizeline ek olarak TiO_2 (25, 50 ve 100 mg), CNT (25, 50 ve 100 mg), Al_2O_3 (25, 50 ve 100 mg) nano katkı maddeleri ilave ederek motor performans ve emisyonlarını incelemiştir. Nano biyodizel katkı maddeleri için termik verim, saf dizel yakıta kıyasla artmıştır. Nanopartiküllerin eklenmesi, iyileştirilmiş yanmayı ve yakıtın faydalı işe etkili enerji dönüşümünü sağlamıştır. Bu güç artışının ana nedeni, nanopartiküllerin yüzey/hacim oranını artırarak silindir içinde üretilen ek enerjiye bağlanabilir ve böylece ısı transferini arttırabileceği belirtilmiştir. Nano katkı maddeleri, yakıtın tutuşma gecikmesini ve yanma süresini azaltır, bu da daha yüksek silindir basıncına ve daha hızlı ısı yayılım oranına yol açar. Nanopartiküllerin varlığı nedeniyle yakıt havası karıştırma ve yanma özelliklerinde gelişmeler gösterildiği belirtilmiştir (Gad ve Jayaraj 2020). Rastogi ve ark., yaptıkları çalışmada, dizel yakıtına farklı yüzdelerde (25,50,75 ve 100 ppm) CuO nanopartiküllerinin jojoba biyodizel yakıt karışımına (JB20) eklenerek bu karışımların dizel motor performansı, emisyon ve yanma özellikleri üzerindeki etkisini incelemişlerdir. JB20 biyodizel karışımı CuO nanopartiküller ile birleştirildiğinde, yanma özellikleri ve yakıt ile hava karışımındaki iyileşme nedeniyle JB20 yakıtına kıyasla termik verimin artmasıyla sonuçlanır. CuO nanopartiküllerinin yüksek yüzey hacmi oranı nedeniyle artan yanma özellikleri, üstün yakıt oksidasyonu sağlar. Nanopartiküller, oksijen tamponuna benzer şekilde hareket eder, dolayısıyla yakıtın daha iyi yanmasına neden olan A/F'nin karışım oranını artırır. CuO nanopartiküllerinin miktarının artmasıyla termik verimin arttığı ve bunun yanma işlemi sırasında daha hızlı ısı açığa çıkmasına bağlı olduğu görülmüştür (Rastogi, Sharma, ve Kumar 2021). Thirugnanam ve ark., dizel yakıtına, %20 oranında palmiye tohumu yağı biyodizel karıştırarak, bu karışıma ilave 25, 50, 75, 100 ppm NiO eklenerek motor performansını ve emisyon özelliklerini incelemişlerdir. Motorun termik verimliliği, nano katkı maddelerinin ısı transferi hızı ve ısıl iletkenlik üzerindeki olumlu etkisi ile artırılmıştır. Nano katkılı harmanlanmış yakıtların termik verimin, tüm yük koşullarında daha yüksek ısı yayılım oranı nedeniyle B20'ninkinden daha yüksek olduğu görülmüştür (Thirugnanam vd. 2021).

Yapılan çalışmalar incelendiğinde çeşitli nanopartikül maddelerinin farklı konsantrasyonlarda ilavelerinin termik verimi iyileştirdiği gözlemlenmiştir. Nanopartikül madde ilaveleri ile atomizasyon artmış, daha iyi buharlaşma gerçekleşmiş ve bu da iyi yanmayı destekleyerek termik verimin artmasında önemli rol oynamıştır. Artan oksijen yoğunluğu iyi yanma iyileşmiş ve termik verimin artmasında önemli rol oynamıştır. Nanopartikül madde ilavesi ile artan yüzey/hacim oranı sayesinde yanmanın iyileştiği ve termik verimin arttığı gözlemlenmiştir. Nanopartikül maddelerin ilavesi tutuşma gecikmesini azaltarak daha yüksek silindir basınçları oluşturur ve bu durum termik verimin iyileşmesinde önemli rol oynamaktadır. Nanopartikül maddeler potansiyel bir katalizör görevi görerek reaktiviteye yardımcı olur, bu da daha iyi karışım ve yanmak demektir. Bu da termik verimde ki artışta önemli rol oynamaktadır.

3.2 Fren Özgül Yakıt Tüketimi (FÖYT)

Fren özgül yakıt tüketimi (FÖYT), içten yanmalı bir motorun tüketmiş olduğu yakıta karşılık krank mili üzerinde ürettiği gücün verimini ifade etmektedir. Özgül yakıt tüketiminin "fren" kelimesi ile kullanılmasının temel nedeni iste, dinamometre üzerinde içten yanmalı bir motorun karakteristik özelliklerinin belirleyen parametreler belirlenirken

frenleme gücünün kullanılmasıdır. İçten yanmalı bir motor güç üretebilmesi için havaya ve yakıta ihtiyaç duymaktadır. Motorun ne kadar yakıt harcadığı genellikte dinamometre üzerinde kütle debisi olarak ölçülmektedir. Fakat bu değer motorun verimini saptamak için yeterli değildir. Çünkü harcanan yakıttan ne kadar mekanik güç elde edildiği belli değildir. Bu nedenle anlık olarak tüketilen yakıt miktarı [kg/s], motor çıkışında elde edilen güce [W] bölünür ve böylelikle fren özgül yakıt tüketimi [kg/J] elde edilmiş olur (URL 1).

$$FÖYT = \frac{Be \times 10^3}{Pe}$$

.

Be [kg/s] – Yakıt Kütle Debisi [Motor Dinamometresi üzerinde ölçülen]
Pe [W] – Motor Çıkış Gücü
FÖYT [kg/J] – Fren Özgül Yakıt Tüketimi

Sanjeevarao ve ark., yapmış oldukları çalışmada dizel yakıtını, farklı oranlarda pamuk yağı (%20 ve %50) ve farklı oranlarda Al_2O_3 (50 ve 100 ppm) karıştırıp deneyler yaparak motor performans ve emisyonlarını incelemişlerdir. Sonuçlar, nano katkı numunelerinin FÖYT'sinin, alümina nanopartiküllerin eklenmesi nedeniyle daha yüksek yüklerle azaldığını göstermektedir. Bunun nedeni nanopartiküllerin yakıtı yakmak için yeterli oksijen içeriğini sağladığı gösterilmiştir (Sanjeevarao vd. 2020). Ağbulut ve ark., dizel yakıtı içerisine ilave edilen çeşitli metal oksit bazlı nanopartiküller ve biyodizel karışımlarının motor performans ve emisyonlarına etkisini incelemiştir. Test yakıtlarından $B10Al_2O_3$, en yüksek ısıtma değerine sahip olduğu için her motor yükü için en düşük FÖYT değerine sahip yakıt türüdür. Bununla birlikte, nanopartiküllerin eklenmesi, biyodizel-nanopartikül karışımlarının ısıtma değerini artırmıştır. Bu durum, FÖYT 'nin azaltılmasında bir avantaj sağlamıştır (Ağbulut vd. 2020). Kalaimurugan ve ark., B20 biyodizel karışımına farklı miktarlarda (25, 50, 75 ve 100 ppm) CeO_2 ekleyerek bu karışımların motor performanslarını incelemiştir. CeO_2 nanopartiküllerinin eklenen yakıt karışımlarının FÖYT'si B20'ye kıyasla düştüğü gözlemlenmiştir. Bunun nedeni, B20 yakıtının daha düşük ısıl değeridir. CeO_2 nanopartikül katkısı, gelişmiş atomizasyonun yanı sıra gelişmiş yanmayı da etkilemiştir ve bu nedenle güç artırılırken yakıt tüketimi azalmıştır (Kalaimurugan vd. 2020). Kumar ve ark., dizel yakıtına %20 oranında pamuk yağı biyodizeli eklemiş ve bu karışımlara ek olarak farklı oranlarda (40, 80, 120 ppm) ZnO ekleyerek motor performans ve emisyon özelliklerini incelemişlerdir. ZnO, yanma sürecini hızlandıran ve yüzey/hacim oranını iyileştiren ve FÖYT 'yi azaltan bir oksitleyici katalizör görevi görür. Çinko oksitin neden olduğu kısa tutuşma gecikmesi daha iyi yanmaya yol açar ve böylece aynı miktarda yakıt ile daha fazla iş elde edilir, böylece FÖYT, ZnO karışımlarında azalır (Deepak Kumar, Hussain, ve Ramesha 2019). Abdallah ve ark., artık yemek yağı biyodizelini %30 dizel yakıta ilave edip MgO, ZnO ve Al_2O_3 nano katkıları kullanarak deneyler gerçekleştirmiş ve motor performans ve emisyonlarını incelemiştir. Metal oksit nanopartiküllerin kullanılması, saf dizele göre fren özgül yakıt tüketimini azaltır ve yanmayı iyileştirir. Nanopartiküller, yanma sürecini iyileştiren bu katalitik etkinin nedeni olabileceği belirtilmiştir (Abdallah, Abdel-Rahman, ve Elwardany 2020). Gad ve Jayaraj, dizel yakıtına %20 Jatropha bitki yağı biyodizeline ek olarak TiO_2 (25, 50 ve 100 mg), CNT (25, 50 ve 100 mg), Al_2O_3 (25, 50 ve 100 mg) nano katkı maddeleri ilave ederek motor performans ve emisyonlarını incelemiştir. Bir dizi yük boyunca nano konsantrasyonlar için fren özgül yakıt tüketimleri, Jatropha biyodizel karışımı (J20) ve saf dizelden daha düşüktür. Fren özgül yakıt tüketimindeki azalma, muhtemelen nanopartiküllerin yakıtın fiziksel özellikleri üzerindeki etkisine ve bunun sonucunda tutuşma gecikme süresinin azalmasına bağlanabilir. Nanopartiküllerin varlığı nedeniyle yakıt havası karıştırma ve yanma özelliklerinde gelişme göstermiştir. Nano boyutlu parçacıklar, potansiyel bir katalizör olarak reaktiviteye yardımcı olan reaktif yüzeylere sahiptir. Biyodizel karışımlarında nanopartiküllerin varlığı, daha iyi katalitik etki ve daha iyi yanma için yüzey alanı hacim oranını artırarak daha az yakıt tüketimine yol açmıştır. Nanopartiküllerin dozlama seviyesinin artması ile özgül yakıt tüketimleri azalmıştır (Gad ve Jayaraj 2020). Gad ve ark., dizel yakıtına %20 oranında atık yemek yağı biyodizel ilave etmiş, bu karışıma ayrı ayrı 25, 50, 100 mg CNT ve CNS katarak bu karışımların motor performansını, emisyonları üzerine etkilerini incelemişlerdir. Biyodizel karışımına karıştırılan nanopartiküllerin buharlaşma ısısı, yakıt-hava karışımını, katalitik aktiviteyi ve ısı transfer katsayısını iyileştirmiştir. Yakıt molekülleri arasındaki momentum değişimi ve ısı transferindeki gelişme, baz yakıta kıyasla daha düşük FÖYT ile sonuçlanmıştır. Nano katkı maddelerinin ısı transfer hızı ve ısıl iletkenlik üzerindeki olumlu etkisi, motorun termik verimini arttırmıştır (Gad, Kamel, ve Anjum Badruddin 2021). Thirugnanam ve ark., dizel yakıtına, %20 oranında palmiye tohumu yağı biyodizel karıştırarak, bu karışıma ilave 25, 50, 75, 100 ppm Nikel oksit eklenerek motor performansını ve emisyon özelliklerini incelemişlerdir. Nanopartikül yakıt karışımları minimum FÖYT'ye sahipken, B20 maksimum FÖYT'ye sahiptir. Bunun nedeni biyodizelin daha düşük ısıtma değeridir. Bu durumda, aynı güç üretimi için daha fazla miktarda yakıt kullanılır. Maksimum güç üretimi, en düşük FÖYT ile sonuçlanan NiO yakıt karışımlarıyla ilgilidir. Genel olarak, Biyodizel NiO eklemek gücü arttırır ve yanmayı iyileştirdiği belirtilmiştir (Thirugnanam vd. 2021).

Yapılan çalışmalar incelendiğinde çeşitli nanopartikül maddelerinin farklı konsantrasyonlarda ilavelerinin FÖYT'yi düşürdüğü gözlemlenmiştir. Nanopartikül madde ilaveleri ile karışım içerisindeki oksijen miktarı artmış ve yanma özellikleri iyileşmesi ile FÖYT azalmıştır. Nanopartikül maddelerin ilavesi ile karışımların ısıl değerleri artmış ve

FÖYT azalmasında bu durum önemli rol oynamıştır. Nanopartikül madde ilavesi ile yakıt kalitesi iyileşir, tutuşma gecikmesi azalır ve ısı yayılım oranı artar. Bu da aynı miktarda yakıttan daha fazla enerji edileceği anlamına gelir ve FÖYT düşmesinde bu sebepler önemli rol oynamıştır. Nanopartikül maddelerin ilavesi ile reaksiyon yüzey alanı iyileşir, yanma süreci hızlanır ve bu durum FÖYT düşürmede önemli rol oynamıştır. Nanopartikül maddelerin ilavesi ile daha iyi atomizasyon, yüksek ısıl değer, azaltılmış yanma süreleri ve yüksek buharlaşma oranı FÖYT düşmesini sağlamaktadır. Nanopartikül maddeler, potansiyel bir katalizör görevi görür reaktiviteye yardımcı olan reaktif yüzeylere sahiptirler. Bu da yanmayı iyileştireceğinden FÖYT azaltıcı rol oynamıştır.

3.3 CO (Karbon Monoksit) Emisyonu

Kokusuz, renksiz bir gaz olan CO çok zehirlidir. Kandaki oksijen taşıma yeteneği hemoglobine göre 200 kat daha fazladır. Bu da CO olan bir ortamda hava soluyan bir insanın boğulmasına ve zehirlenmesine yol açar. Yanma ürünleri arasında CO olmasının ana nedeni oksijenin yetersiz olmasıdır. 1 kg benzin ya da dizel yakıtının tam yanması için 14,5 kg havaya ihtiyacı vardır. Eğer hava fazlalık katsayısı 1'den küçükse yanma yetersiz oksijen ortamı içinde olacaktır ve CO, CO_2'ye dönüşemeyerek CO olarak kalacaktır. Karbon monoksit, yanmanın yan ürünlerinden biridir ve yanma odasındaki daha yüksek sıcaklık, zengin hava-yakıt oranı, yakıtın özellikleri ve yüksek hızda yanma için oksijen bulunmaması nedeniyle karbon monoksit yüzdesi artar (Kalaimurugan vd. 2020). Dizel motorlardan kaynaklanan CO emisyonu seviyesi, yanmanın eksiksiz/eksik olduğunun bir göstergesidir. Egzoz yanma gazındaki yüksek CO konsantrasyonu, sadece yakıtın eksik yanmasının bir işareti olmakla kalmaz, aynı zamanda yanma odasına sağlanan kimyasal enerji kaybını da ortaya çıkarır (Behçet 2011). Sanjeevarao ve ark., yapmış oldukları çalışmada dizel yakıtını, farklı oranlarda pamuk yağı (%20 ve %50) ve farklı oranlarda Al_2O_3 (50 ve 100 ppm) karıştırıp deneyler yaparak motor performans ve emisyonlarını incelemişlerdir. Biyodizel kullanımı ve Al_2O_3 kullanımı ile artan oksijen yoğunluğu yanmayı iyileştirerek CO emisyonlarında azalmaya neden olmuştur (Sanjeevarao vd. 2020). Shaisundaram ve ark., dizel yakıt içerisine farklı karpuz çekirdeği yağı biyodizeli oranları ile (%10, %20, %30) 20 ppm seryum oksit ilave ederek motor performans ve emisyon özelliklerini incelemiştir. CO emisyonları, CeO_2 katkı maddeleri ekleyen B10, B20 ve B30 karışımı için daha düşük değerler göstermiştir. Bu, CeO_2 eklenmesi nedeniyle yanmanın iyileştirmesi olarak belirtilmiştir (Shaisundaram ve Chandrasekaran 2020). Ağbulut ve ark., dizel yakıtı içerisine ilave edilen çeşitli metal oksit bazlı nanopartiküller ve biyodizel karışımlarının motor performans ve emisyonlarına etkisini incelemiştir. Çalışmalarda 100 ppm Al_2O_3, 100 ppm TiO_2 ve 100 ppm SiO_2 kullanılmıştır. Karışımlara ek olarak hacimce %10 metil ester eklemişlerdir. Nanopartikül ilave edilmiş atık yemek yağı biyodizel yakıtı için CO emisyonunun oranı dizel yakıtına kıyasla biraz azalmıştır. Ayrıca metal oksit bazlı nanopartiküllerin eklenmesi CO emisyonunun azaltılmasını sağlamıştır. Bu, karışımlardaki metal bazlı oksit nanopartiküllerin artan oksijen içeriğine ve nanopartiküllerin yüksek katalitik aktiviteye (nanopartiküllerin daha yüksek yüzey alanı/hacim oranına bağlı olarak) neden olan gelişmiş yanma özelliklerine bağlanmıştır (Ağbulut vd. 2020). Hoseini ve ark., 3 farklı meyve yağı biyodizel yakıtlarını farklı oranlarda (%10, %20, %30) dizel yakıtına ilave etmiş, bu karışımlara ek olarak B20 ilavesine de 60 ppm Graphane (GO) oksit ekleyerek tüm bu karışımların motor performansı ve emisyonları üzerine etkilerini araştırmışlardır. GO'nun dizel-biyodizel karışımı ile kullanılmasıyla CO emisyonu azalmaktadır. GO'nun geniş yüzey alanı kimyasal reaktiviteyi yükseltir, bunun sonucunda tutuşma gecikmesi azalır. Tutuşma gecikmesini kısaltarak yanmayı iyileştirir ve sonuç olarak, karbon monoksit (CO) emisyonu azalır (Hoseini vd. 2020). Kumar ve ark., dizel yakıtına %20 oranında pamuk yağı biyodizeli eklemiş ve bu karışımlara ek olarak farklı oranlarda (40, 80, 120 ppm) ZnO ekleyerek motor performans ve emisyon özelliklerini incelemişlerdir. Çinko oksit kullanılması ile CO emisyon oranının azaldığı gözlemlenmiştir. Çinko oksit, iyileştirilmiş ısıl değer nedeniyle yanma odasının ortalama sıcaklığını arttırır, bu da karışımda daha fazla oksijenin reaksiyona girmesine neden olarak daha düşük CO ile sonuçlanır. ZnO ayrıca oksijen veren bir katalizör görevi görür ve CO oksidasyonu için oksijen sağlar (Deepak Kumar, Hussain, ve Ramesha 2019). Gad ve Jayaraj, dizel yakıtına %20 Jatropha bitki yağı biyodizeline ek olarak TiO_2 (25, 50 ve 100 mg), CNT (25, 50 ve 100 mg), Al_2O_3 (25, 50 ve 100 mg) nano katkı maddeleri ilave ederek motor performans ve emisyonlarını incelemiştir. Nanopartiküller, kimyasal reaktiviteyi artıran ve tutuşma gecikmesini art arda kısaltan geniş bir yüzey temas alanına sahiptir. Nanopartiküller, yakıt-hava karışım oranını iyileştirir ve homojen yanma, tam yanmaya yol açar. Azalan viskozite, yakıt atomizasyonunu artırır ve CO emisyonunun azaltılmasında önemli bir rol oynar (Gad ve Jayaraj 2020). Arunprasad ve Elango, dizel yakıtına %20 biyodizel ilavesi ve bu karışıma 50 ppm ve 100 ppm MgO ilave ederek motor performansı ve emisyonlarını çalışmışlardır. B20'deki düşük oksijen içeriği ve hava-yakıt karışımının eksik yanması nedeniyle B20 yakıt karışımından kaynaklanan CO emisyonlarının MgO yakıt karışımlarından daha yüksek olduğu görülmektedir. MgO yakıt karışımlarının CO emisyonundaki düşüş, karbon monoksitin karbon dioksite oksitlenmesinin bir sonucudur. Aynı zamanda azaltılmış tutuşma gecikmesi ve karışımın geliştirilmiş yanması nedeniyledir (Arunprasad ve Elango 2020a). Rastogi ve ark., yaptıkları çalışmada, dizel yakıtına farklı yüzdelerde (25, 50, 75 ve 100 ppm) CuO nanopartiküllerinin jojoba biyodizel yakıt karışımına (JB20) eklenerek bu karışımların dizel motor performansı, emisyon ve yanma özellikleri üzerindeki etkisini incelemişlerdir. Bunun nedeni JB20 içeriğinde çok daha fazla oksijen bulunması ve CuO nanopartikülünün reaksiyon yüzey alanını artırarak yakıt yanma sürecini artırması ve CO emisyonlarının azalmasına yol açmasıdır. Düşük CO emisyonunun arkasındaki sebeplerden biri CuO nanopartikülün karıştırılması ile test yakıtlarında artan oksijen olabilir, bu da daha az CO emisyonunu ve daha iyi kimyasal reaksiyonları beraberinde getirecektir (Rastogi, Sharma, ve Kumar 2021). Thirugnanam ve ark., dizel yakıtına, %20

oranında palmiye tohumu yağı biyodizel karıştırarak, bu karışıma ilave 25, 50, 75, 100 ppm Nikel oksit eklenerek motor performansını ve emisyon özelliklerini incelemişlerdir. NiO nano materyalinin eklenmesi ile tutuşma gecikmesinin kısalması ile tam yanma meydana gelmiş ve CO emisyonlarında azalma gözlenmiştir. NiO miktarı arttıkça CO emisyonu azalmış ve 100 ppm de en az olarak gerçekleşmiştir (Thirugnanam vd. 2021). Vali ve ark., dizel yakıtına %10 etanol ekleyip, bu karışıma 25 ppm AL_2O_3, TiO_2 ve 50 ppm AL_2O_3, TiO_2 karışık nano katkı maddeleri ekleyerek dizel motorun performansını ve emisyon özelliklerini iyileştirmesi üzerine çalışmışlardır. Karışık nanopartiküller harmanlanmış test yakıtları ile CO emisyonlarında daha fazla azalma gözlemlenmiştir. Bu, yanmayı iyileştiren nanopartiküllerin daha yüksek katalitik aktivitesinin bir sonucudur (Hussain Vali ve Marouf Wani 2021).
Yapılan çalışmalar incelendiğinde çeşitli nanopartikül maddelerinin farklı konsantrasyonlarda ilavelerinin CO emisyonunu düşürdüğü gözlemlenmiştir. Nanopartikül madde ilaveleri ile karışım içerisindeki oksijen miktarı artmış ve yanma özellikleri iyileşmesi ile CO azalmıştır. Nanopartikül maddelerin ilavesi ile nanopartiküllerin sahip olduğu yüksek katalitik aktiviteye bağlı olarak gelişmiş yanma özellikleri sayesinde CO seviyesi azalmıştır. Nanopartikül maddelerin yüksek setan sayısı ve iyi ısı yayılım oranı daha iyi yanmayı destekler ve CO emisyonunu azaltıcı yönde etki uygular. Nanopartikül maddeler kimyasal reaktiviteyi arttıran ve tutuşma gecikmesini kısaltan geniş yüzey alanına sahiptir. Bu da homojen ve tam yanmayı sağlar ve CO emisyonu azaltılmasında önemli rol oynar.

3.4 NO_x (Azot Oksit) Emisyonu

Azot oksitler (NO, NO_2, N_2O_2 vb.) CO gibi kandaki hemoglobin ile birleşmektedir. Ancak azot oksitlerin en önemli zehirleyici etkisi ciğerlerde nemle birleşerek nitrik asit oluşturmasıdır. İçten yanmalı motorlarda yanma odası sıcaklık değeri 1800 K'ni aştığında, havanın içerisindeki azot ve oksijen kimyasal olarak birleşerek, insan sağlığına ve¸ çevreye zararlı azot oksitlere dönüşür (Kutlar 1998).
Ağbulut ve ark., dizel yakıtı içerisine ilave edilen çeşitli metal oksit bazlı nanopartiküller ve biyodizel karışımlarının motor performans ve emisyonlarına etkisini incelemiştir. Çalışmalarda 100 ppm Al_2O_3, 100 ppm TiO_2 ve 100 ppm SiO_2 kullanılmıştır. Yakıta metal oksit bazlı nanopartiküllerin eklenmesi, yanma odasında oksijen veren bir katalizör görevi gördüklerinden tam yanmaya yol açar. Sonuçlar, nanopartiküllerin B10 yakıtına eklenmesi sonucunda NO_x'in biraz arttığı görülmektedir. Bu makalede kullanılan nanopartiküller arasında bunların özgül ısı kapasiteleri şu şekilde sıralanmıştır: SiO_2> AL_2O_3> TiO_2. Düşük özgül ısı kapasitesine sahip malzemelerde hem ortalama kinetik enerji hem de sıcaklık daha fazla artar. TiO_2 harmanlanmış yakıtta diğer nanopartiküllere kıyasla yüksek NO_x emisyonunun görülmesinin nedeni bunlar olduğu belirtilmiştir (Ağbulut vd. 2020). Maleni ve ark., saf dizel, B10 yakıtı, B10 biyodizel yakıtı içerisine farklı oranlarda (%2-4-6-8) ethanol ilave etmiş, ethanol ilave edilen B10 karışımlarına ekstra 30 ppm grafen kuantum nokta (GQD) nano parçacığının ilave ederek bu yakıtların motor performansı ve emisyonları üzerindeki etkileri araştırılmıştır. Sonuçlar, D100 yakıtının diğer yakıtlara kıyasla tüm motor hızlarında en düşük NO_x emisyonuna sahip olduğunu göstermektedir. B10 yakıtı aynı zamanda diğer yakıtlara kıyasla en yüksek NO_x emisyonuna sahiptir. Doymamış bileşikler ve aktif atom oksijen içeriği gibi biyodizelin bazı özellikleri, saf dizele kıyasla daha yüksek NO_x oluşumunu açıklamaktadır (Heidari-Maleni vd. 2020). Hoseini ve ark., 3 farklı meyve yağı biyodizel yakıtlarını farklı oranlarda (%10, %20, %30) dizel yakıtına ilave etmiş, bu karışımlara ek olarak B20 ilavesine de 60 ppm Graphane oksit ekleyerek tüm bu karışımların motor performansı ve emisyonları üzerine etkilerini araştırmışlardır. Nanopartiküllerin kullanılması, yanmayı iyileştirir ve silindir gaz basıncını artırır, bu da yanma sıcaklığını artırır ve sonuç olarak, nitrojen oksit (NO_x) emisyonları artar (Hoseini vd. 2020). Arunprasad ve Elango, dizel yakıtına %20 biyodizel ilavesi ve bu karışıma 50 ppm ve 100 ppm La_2O_3 ilave ederek motor performans ve emisyonlarını gözlemlemişlerdir. NO_x oluşumu, yüksek sıcaklık, reaksiyon sonrası için mevcut fazla oksijen ve mevcut reaksiyon süresinden kaynaklanmıştır. NOx'in bu geliştirilmiş eğilimi, önceden karıştırılmış yanma aşamasında tam karıştırmanın ardından daha yüksek silindir içi sıcaklığa neden olan La_2O_3 harmanlanmış yakıtların geliştirilmiş oksijen içeriği ile ilişkili olduğu belirtilmiştir. NO_x' de ki bu eğilim, test yakıtlarının viskozite, yoğunluk ve yüksek hava-yakıt oranları derecelendirmesinden gelen test yakıtlarının daha iyi oksijen içeriği ile ilişkilidir. La_2O_3 harmanlanmış yakıtların artan oksijen içeriği, yanma sırasında gaz sıcaklığını yükseltti ve bu da yüksek seviyelerde NO_x oluşumunu teşvik etmiştir (Arunprasad ve Elango 2020b). Rastogi ve ark., yaptıkları çalışmada, dizel yakıtına farklı yüzdelerde (25,50,75 ve 100 ppm) CuO nanopartiküllerinin jojoba biyodizel yakıt karışımına (JB20) eklenerek bu karışımların dizel motor performansı, emisyon ve yanma özellikleri üzerindeki etkisini incelemişlerdir. NO_x emisyonlarının oluşumu egzoz gazı sıcaklığına ve test yakıtının setan sayısına bağlıdır. NO_x emisyonları, nano katkı maddesinin eklenmesiyle artırılmıştır çünkü nano partiküller yakıtın yanmasını alır ve daha fazla motor silindiri sıcaklığı ile sonuçlanır. JB20 baz test yakıtına CuO nanopartikül eklemenin bir başka nedeni, daha kısa tutuşma gecikmesi ve daha iyi ısı yayılım oranıdır (Rastogi, Sharma, ve Kumar 2021). Sunil ve ark., dizel yakıtına, %20 oranında süt tozundan elde edilen biyodizel ile değişik oranlarda (125, 250, 375 ppm) TiO_2 (Titanyum oksit) karıştırarak motor performansı, emisyon ve yanma özellikleri üzerindeki etkisini incelemişlerdir. Nanopartikül harmanlanmış numunenin NO_x emisyonundaki artış, daha yüksek sıcaklık ve oksidasyon için fazla oksijen mevcudiyeti ile sonuçlanan gelişmiş yanma oranından kaynaklanıyor olabileceği belirtilmiştir (Sunil vd. 2021). Fayad ve ark., Bütanol ve Dizel karışımına (B20) farklı oranlarda Alüminyum oksit (Al_2O_3) nanopartiküller (30, 50, ve 100 mg/l) ekleyerek motor performansı ve emisyonlarını incelemişlerdir. Farklı motor yükleri için B20'ye Al_2O_3 nanopartikülleri eklendiğinde NO_X emisyonlarında önemli bir azalma gözlemlenmiştir. Al_2O_3 nanopartiküllerinin katalitik davranışı, HC bileşiklerinin minimum termal parçalanmasını

oluşturmak için yanma sürecini iyileştirmiştir. Bütanol-dizel karışımına Al_2O_3 nanopartiküllerinin eklenmesi, yakıt karışımının ısıl iletkenliğini artırmış, bu da tutuşma gecikme süresini azaltmış ve tüketimini artırmıştır. Böyle bir gelişme, CI motorlarının genel verimliliğini artırır. Nanopartiküllerin eklenmesiyle daha düşük aktif radikaller, yanma sürecinde termal NO_X oluşumu potansiyelini azaltmaya yardımcı olmuştur (Fayad ve Dhahad 2021). Thirugnanam ve ark., dizel yakıtına, %20 oranında palmiye tohumu yağı biyodizel karıştırarak, bu karışıma ilave 25, 50, 75, 100 ppm Nikel oksit eklenerek motor performansını ve emisyon özelliklerini incelemişlerdir. NiO yakıt karışımlarında NO içeriğinin yüksek değerde olduğunu göstermiştir. En iyi reaksiyon koşullarını sağlayan egzoz gazlarının sıcaklığı buna bağlanabilir. NO içeriği ile EGT modeli arasında pozitif bir korelasyon mevcuttur. Bu, EGT büyümesinin NO oluşumunda önemli bir rol oynadığını gösterir. Sonuç olarak, NiO yakıtı, en düşük CO ve en yüksek NO'ya sahip olanları en yüksek O_2 içeriğiyle birleştirmiştir (Thirugnanam vd. 2021). Vali ve ark., dizel yakıtına %10 etanol ekleyip, bu karışıma 25 ppm AL_2O_3, TiO_2 ve 50 ppm AL_2O_3, TiO_2 karışık nano katkı maddeleri ekleyerek dizel motorun performansını ve emisyon özelliklerini iyileştirmesi üzerine çalışmışlardır. Etanolün eklenmesi NO_x emisyonlarını azaltır çünkü etanol, ısıyı silindir duvarlarından emen ve daha düşük yanma sıcaklıklarını koruyan yüksek bir gizli buharlaşma ısısına sahiptir. Dizel-etanol karışımına nanopartiküller eklenerek NO_x'te daha fazla azalma gözlenmiştir. (Hussain Vali ve Marouf Wani 2021).

Yapılan çalışmalar incelendiğinde çeşitli nanopartikül maddelerinin farklı konsantrasyonlarda ilavelerinin NO_x emisyonu üzerinde farklı etkileri olduğu gözlemlenmiştir. Kimi yazarlar sonuçlarında nanopartikül madde ilavesinin NO_x emisyonlarını arttırdığını, kimi yazarlarda NO_x emisyonların azalttığını ifade etmişlerdir. Yapılan çalışmalar incelendiğinde nanopartikül maddelerin ilavesi ile NO_x emisyonunu arttığı belirtilmiştir. Bunun başlıca nedenleri, nanopartikül maddelerin iyileştirilmiş ısıl değerleri, katalitik etkisi ve yüksek setan sayıları nedeniyle silindir içi sıcaklıkları arttırması ve oksijen ile yakıtın daha çok reaksiyona girerek NO_x emisyonunu arttırması, nanopartikül maddelerin yakıt iyileştirici olarak tam yanmayı desteklemesi ile NO_x emisyonlarını arttırdığı görülse de bazı çalışmalarda bu etkenlerin azot oksit emisyonları azalttığı görülmüştür. Yapılan çalışmalar incelendiğinde nanopartikül maddelerden TiO_2, düşük özgül ısı kapasitesi nedeni ile NO_x emisyonunu arttırdığı belirtilmiştir. Bunun nedeni TiO_2'nin düşük özgül ısısı kaynaklı yüksek ortalama kinetik enerjisine sahip olması gösterilmiştir.

3.5 HC (Hidrokarbon) Emisyonu

Hidrokarbonlar karter havalandırmadan buharlaşma yolu ile egzozdan ise hatalı hava-yakıt oranı, düşük kompresyon, supap bindirmesi ve silindir içerisinde homojen olmayan sıcaklık dağılımından dolayı ya kısmen yanmış ya da yanma olayına hiç dâhil olmadan atmosfere bırakılan emisyonlardır. Atmosferde süspansiyon halinde bulunan hidrokarbon emisyonları azot oksitlerle reaksiyona girerek ‘‘fotokimyasal sismik’’ olarak bilinen bir sis tabakası oluşturup, solunum sistemi ve canlılar üzerinde olumsuz etkilere neden olmaktadırlar (Schäfer ve van Basshuysen 1995). Sanjeevarao ve ark., yapmış oldukları çalışmada dizel yakıtını, farklı oranlarda pamuk yağı (%20 ve %50) ve farklı oranlarda Al_2O_3 (50 ve 100 ppm) karıştırıp deneyler yaparak motor performans ve emisyonlarını incelemişlerdir. Eklenen nanopartiküller yeterli oksijen içeriği sağlar ve tam yanma destekler. 100 ppm ve 50 ppm örneklerle B20 ve B50 karışımı, tüm yüklerde dizele kıyasla HC emisyonlarında azalma göstermektedir (Sanjeevarao vd. 2020). Shaisundaram ve ark., dizel yakıt içerisine farklı karpuz çekirdeği yağı biyodizeli oranları ile (%10, %20, %30) 20 ppm seryum oksit ilave ederek motor performans ve emisyon özelliklerini incelemiştir. Bununla birlikte, HC emisyonlarının, yüksek ppm nano partiküllerin eklenmesiyle önemli ölçüde azaldığı bulunmuştur. Temel olarak, yakıtın oksijen içeriği, hidrokarbon emisyonlarının azaltılmasının ana nedeni olduğu belirtilmiştir (Shaisundaram ve Chandrasekaran 2020). Kumar ve ark., dizel yakıtına %20 oranında pamuk yağı biyodizeli eklemiş ve bu karışımlara ek olarak farklı oranlarda (40, 80, 120 ppm) ZnO ekleyerek motor performans ve emisyon özelliklerini incelemişlerdir. Nano katkı maddelerinin varlığı, bir bağlayıcı görevi görür ve istenmeyen yakıt birikimini ve penetrasyonunu önler, böylece HC emisyonlarını azaltır. Nanopartikül, oksijen tamponu görevi görür ve stokiyometrik karışımın oluşumuna yardımcı olan ilave oksijen sağladığı belirtilmiştir (Deepak Kumar, Hussain, ve Ramesha 2019). Arunprasad ve Elango, dizel yakıtına %20 biyodizel ilavesi ve bu karışıma 50 ppm ve 100 ppm MgO ilave ederek motor performansı ve emisyonlarını çalışmışlardır. B20 karışımının HC emisyonu, MgO nano katkı karışımlarına kıyasla artmıştır. Ayrıca, karışımda mevcut olan düşük oksijen nedeniyle B20 karışımının HC emisyonlarının arttığı, zayıf yanmaya neden olduğu ve HC emisyonlarının oluşumuna yol açtığı gözlemlenmiştir. Bağıl hava-yakıt karışımının miktarı ve daha iyi setan sayısı ateşleme gecikmesini azaltır, dolayısıyla HC emisyonu miktarı azalttığı görülmüştür (Arunprasad ve Elango 2020a). Arunprasad ve Elango, dizel yakıtına %20 biyodizel ilavesi ve bu karışıma 50 ppm ve 100 ppm La_2O_3 ilave ederek motor performans ve emisyonlarını gözlemlemişlerdir. La_2O_3 karışım oranının artmasıyla HC emisyon seviyesinin biraz azaldığı görülmüştür. La_2O_3 karışımları, tam yanmaya yardımcı olan yüzey/hacim oranını artırmıştır. La_2O_3, hidrokarbon oksidasyonunu iyileştirerek yanmayı hızlandıran oksidasyon katalizörü gibi davranır. Yüksek setan sayısı ve kendi kendine oksijenli olması nedeniyle La_2O_3 karışımlarının yanma özelliklerinin daha iyi olduğu belirtilmiştir (Arunprasad ve Elango 2020b). Jayaseelan ve ark., dizel yakıtına değişik biyodizel oranlarında (%20, %40) 25 ppm ceryum oksit ilavesi yaparak motor performans ve emisyonlarını incelemiştir. Maksimum yük koşullarında, seryum oksit eklenen biyodizel, dizele kıyasla daha az miktarda hidrokarbon emisyonu verir. B40, B20 biyodizel kıyasla daha az hidrokarbon salımı gösterir. Bir oksidasyon katalizörü olarak seryum oksit ayrıca karbon yanma aktivasyon sıcaklığını düşürür ve dolayısıyla hidrokarbon oksidasyonunu artırarak tam yanmayı teşvik eder (Antony Casmir Jayaseelan vd. 2020). Kumar

ve ark., %70 dizel yakıtı %30 limon otu yağı (LGBD) dizel-biyodizel karışımına, hacmin %5'i kadar kurkumin nanopartikül ekleyerek motor performans ve emisyonlarını gözlemlemişlerdir. Limon otu biyodizeline kurkumin nano partikül konsantrasyonu eklenerek HC emisyonu azaltılır. LGBD+C, tüm yük koşullarında LGBD ve dizele göre HC emisyonunu azaltmıştır. Çünkü LGBD+C'deki kurkumin içeriği yeterli miktarda oksijen sağlar ve bu da HC emisyonunun azalmasına neden olur. Limon otu biyodizelindeki kurkumin nanopartikül içeriği yanma oranını hızlandırır ve aynı zamanda bir tutuşmayı arttırıcı görevi görür ve tam yanmaya yol açar ve bu da HC emisyonunu azalttığı belirtilmiştir (Sunil Kumar vd. 2020). Rastogi ve ark., yaptıkları çalışmada, dizel yakıtına farklı yüzdelerde (25,50,75 ve 100 ppm) CuO nanopartiküllerinin jojoba biyodizel yakıt karışımına (JB20) eklenerek bu karışımların dizel motor performansı, emisyon ve yanma özellikleri üzerindeki etkisini incelemişlerdir. CuO nano katkı maddelerinin JB20 yakıtına eklenmesi ile HC emisyonu azalır ve bunun nedeni test yakıtlarında daha fazla oksijen molekülü bulunmasıdır. CuO Nano partikülü, daha kısa ateşleme gecikme süresine, daha iyi yakıt patlama sürecine yol açar, yanma odası içinde tam yanma sürecini destekler. CuO nanopartikül biyoyakıt kalorifik değeri artar ve viskozite azalır, bu da yakıtın uygun şekilde atomizasyonunun meydana gelmesi nedeniyle azalır, bu da HC emisyonlarını azaltma eğiliminde olduğu belirtilmiştir (Rastogi, Sharma, ve Kumar 2021). Shaisundaram ve ark., yaptıkları çalışmalarda demirhindi tohumu biyodizelinin farklı oranlarda (%10, %20, %30) (TSO) motor performans ve emisyon özellikleri incelenmiştir. Bununla birlikte, HC emisyonlarının, yüksek ppm nano partiküllerin eklenmesiyle önemli ölçüde azaldığı bulunmuştur. Temel olarak, yakıtın oksijen içeriği, hidrokarbon emisyonlarının azaltılmasının ana nedeni olduğu gösterilmiştir (Shaisundaram vd. 2020). Thirugnanam ve ark., dizel yakıtına, %20 oranında palmiye tohumu yağı biyodizel karıştırarak, bu karışıma ilave 25, 50, 75, 100 ppm Nikel Oksit eklenerek motor performansını ve emisyon özelliklerini incelemişlerdir. Nanopartiküller, hidrokarbon oksidasyon artışı ve tam yanma ile sonuçlanan bir katalizör görevi görür. HC emisyonları, maksimum yükte B20 Biyodizel karışımı için daha yüksekken, NiO katkılı yakıtlar için HC emisyonları daha düşüktür. Bu, yanma odasında yakıt-hava karışımındaki daha yüksek artış nedeniyle NiO nanopartiküllerinin tutuşmasındaki gecikmeye ve daha iyi tutuşma özelliklerine bağlanabileceği belirtilmiştir (Thirugnanam vd. 2021).

Yapılan çalışmalar incelendiğinde çeşitli nanopartikül maddelerinin farklı konsantrasyonlarda ilavelerinin HC emisyonunu düşürdüğü gözlemlenmiştir. Nanopartikül madde ilaveleri ile karışım içerisindeki oksijen miktarı artmış ve yanma özellikleri iyileşmesi tam yanmayı desteklemiş ve HC azalmıştır. Nanopartikül maddelerin ilavesi ile nanopartiküllerin sahip olduğu yüksek katalitik aktivite ve yüksek yüzey/hacim oranı ile silindir içerisinde üretilen enerji artar ve bu da eksiksiz yanma ile sonuçlanarak HC emisyonlarının azaltılmasında önemli rol oynar. Nanopartikül maddelerin küçük boyutları daha iyi bir atomizasyonu ve dolayısıyla tam yanmayı destekler ve HC emisyonlarının azaltılmasında önemli rol oynar. Nanopartikül maddeler sahip oldukları yüksek termal iletkenlik, yakıt moleküllerine daha fazla ısı aktarılmasına ve daha yüksek buharlaşma oranına neden olur. Bu da eksiksiz yanmayı destekler ve HC emisyonlarını düşürmede önemli bir rol oynar. Nanopartikül maddelerin yüksek aktivasyon enerjisi, özellikle söndürme katmanlarındaki yanmamış karbon birikimlerini yakma eğilimi göstererek HC emisyonlarının azalmasında etkili olur.

3.6 İs Emisyonu

İçten yanmalı motorlar tarafından üretilen katı taneciklerin büyük bir bölümü oluşturmaktadır. İs yanmamış karbon partikülleridir ve özellikle dizel motorlarda oluşmaktadır. İs, zararlı birleşenleri bünyesinde taşıyarak ve solunum sisteminde birikerek insan sağlığına olumsuz yönde etki etmektedir (Kutlar 1998).

Kumar ve ark., dizel yakıtına farklı oranlarda (%20, %30, %40) atık yemek yağı biyodizeli ilavesine ek olarak hacimce %2 Dietil eter ve 80 ppm CeO_2 ilavesi yapılarak çalışmalarda bulunmuştur. CeO_2 nanopartiküllerinin eklenmesi, ısı transferini teşvik ederek yanmayı artırır. Aynı zamanda oksijen tamponu görevi görürler, böylece kurum partikülünün oksitlenmesine yardımcı oldukları belirtilmiştir (Kumar vd. 2020). Kumar ve ark., dizel yakıtına %20 oranında pamuk yağı biyodizeli eklemiş ve bu karışımlara ek olarak farklı oranlarda (40, 80, 120 ppm) ZnO ekleyerek motor performans ve emisyon özelliklerini incelemişlerdir. Karışımdaki daha yüksek oksijen içeriği, yanmayı artırır ve duman emisyonlarının azalmasına neden olur. Ayrıca nanopartikül, harmanlanmış yakıtın iyileştirilmiş Kükürt ve oksijen içeriği nedeniyle, Duman opaklığında azalma oluşturduğu belirtilmiştir (Deepak Kumar, Hussain, ve Ramesha 2019). Gad ve Jayaraj, dizel yakıtına %20 Jatropha bitki yağı biyodizeline ek olarak TiO_2(25, 50 ve 100 mg), CNT (25, 50 ve 100 mg), Al_2O_3 (25, 50 ve 100 mg) nano katkı maddeleri ilave ederek motor performans ve emisyonlarını incelemiştir. Nano katkı maddeleri içeren Jatropha biyodizel karışımının (J20) duman emisyonlarındaki azalma, daha fazla oksijen molekülünün varlığından ve yakıttaki daha düşük karbon içeriğinden (saf dizele kıyasla) daha iyi yanma ile sonuçlanmasından kaynaklanmaktadır. Duman emisyonunun azaltılması, yanmanın difüzyon aşamasında daha fazla yakıt yanması ve azaltılmış ateşleme gecikmesi ve dolayısıyla daha iyi yanma nedeniyle oluştuğu belirtilmiştir (Gad ve Jayaraj 2020). Arunprasad ve Elango, dizel yakıtına %20 biyodizel ilavesi ve bu karışıma 50 ppm ve 100 ppm MgO ilave ederek motor performansı ve emisyonlarını çalışmışlardır. MgO karışımlarının duman opasitesinin B20 yakıtından daha düşük olduğu gözlenmiştir. Duman yoğunluğundaki azalma, doğal oksijen içeriğinden ve MgO karışımlarının daha yüksek setan indeksinden kaynaklanır, gelişmiş karışım oluşumunun sonucudur ve daha iyi yanma sağlar. Bunun nedeni aynı zamanda dizel yakıtla daha iyi hava-yakıt karışımının yanmayı iyileştirmesi ve duman opaklığını azaltması olduğu belirtilmiştir (Arunprasad ve Elango 2020a). Arunprasad ve Elango, dizel yakıtına %20 biyodizel ilavesi ve bu karışıma 50 ppm ve 100 ppm La_2O_3 ilave ederek motor performans ve emisyonlarını gözlemlemişlerdir. La_2O_3'ün B20

yakıt karışımları ile harmanlanmasından kaynaklanan duman emisyonları, B20'den daha azdır. Bunun nedeni, B20 ile harmanlanmış La_2O_3'ün yüksek yüzey / hacim oranının daha iyi karışım oluşumuna yol açması, daha iyi tutuşma özellikleriyle geliştirilmiş buharlaşma, kısaltılmış tutuşma gecikmesine yol açtığı gözlemlenmiştir (Arunprasad ve Elango 2020b). Gad ve ark., dizel yakıtına %20 oranında atık yemek yağı biyodizel ilave etmiş, bu karışıma ayrı ayrı 25, 50, 100 mg CNT ve CNS katarak bu karışımların motor performansını, emisyonları üzerine etkilerini incelemişlerdir. Karbon nanopartiküllerin eklenmesi, katalitik etki, reaktif yüzeyler ve iyileştirilmiş ısı transfer hızı nedeniyle yanmanın artmasına yol açmıştır. Grafen nano tabakanın iyileştirilmiş buharlaşma hızı ve ısı transfer hızı, CNT'ler hakkında duman emisyonunda daha yüksek düşüşe neden olduğu belirtilmiştir (Gad, Kamel, ve Anjum Badruddin 2021). Thirugnanam ve ark., dizel yakıtına, %20 oranında palmiye tohumu yağı biyodizel karıştırarak, bu karışıma ilave 25, 50, 75, 100 ppm Nikel Oksit eklenerek motor performansını ve emisyon özelliklerini incelemişlerdir. Duman emisyonunun, NiO nanopartikül karıştırılmış yakıtlar için B20 yakıt karışımından daha düşük olduğu bulunmuştur. Bunun nedeni, harmanlanmış yakıtlardaki NiO nanopartiküllerinin kolaylaştırdığı ateşleme gecikmesi azalması, hızlı buharlaşma hızı ve gelişmiş ateşleme özellikleri olduğu belirtilmiştir (Thirugnanam vd. 2021).
Yapılan çalışmalar incelendiğinde çeşitli nanopartikül maddelerinin farklı konsantrasyonlarda ilavelerinin is emisyonunu düşürdüğü gözlemlenmiştir. Nanopartikül madde ilaveleri ısı transferini teşvik eder ve oksijen tamponu görevi görür. U da tam yanmayı destekler ve is emisyonlarını düşürmede etkilidir. Nanopartikül maddelerin yüksek yüzey/hacim oranları silindir içinde iyi bir karışım oluşturur ve yanma veriminin artmasını sağlar. Bu da is emisyonlarının azalmasında etkilidir. Nanopartikül maddelerin yüksek katalitik etkisi, artan reaktif yüzey ve iyileştirilmiş ısı transferi yanmanın iyileşmesini sağlar ve bu da is emisyonlarının azalmasında etkilidir. Nanopartikül maddeleri ilavesi ile artan buharlaşma hızı, azalan ateşleme gecikmesi ve iyi ateşleme özellikleri yüksek yanma verimi ortaya çıkarır ve bu da is emisyonlarını azaltıcı rol oynamaktadır.

4. SONUÇLAR VE ÖNERİLER

Bu çalışma, Dizel-biyodizel karışımlarına ilave edilen nanopartikül maddelerin motor performansına ve emisyonlarına olan etkisi üzerine yapılmış çalışmaların derlenmesiyle oluşturulmuştur. Biyodizel yakıtının kullanılmasıyla yakıtların ekonomik olmasının yanı sıra dizel-biyodizel karışımlarına çeşitli nanopartikül katkı madde ilavesinin, motor performansını ve emisyonlarını olumlu şekilde etkileyeceği açıkça görülmektedir. Nanopartikül yakıt katkı maddelerinin dizel-biyodizel yakıt karışımlarının termo fiziksel özelliklerini geliştirdiği ve yanma özelliklerini iyileştirdiği görülmüştür.

Yapılan çalışmalarda elde edilen bulgular aşağıda özetlenmiştir.

- Nanopartikül katkı maddelerinin Özgül yakıt tüketimi, termik verimi, fren gücü gibi motor performanslarına olumlu etkide bulunduğu görülmüştür.
- Nanopartikül katkı madde ilavelerinin motor emisyonlarına genel olarak olumlu yönde katkıda bulunduğu söylenebilir.
- Nanopartikül maddelerin yüksek setan sayısı ve iyi ısı yayılım hızları daha iyi yanmayı desteklediği söylenebilir.
- Nanopartikül maddelerin yüksek yüzey/hacim oranları silindir içinde iyi bir karışım oluşturur ve yanma veriminin artmasını sağladığı belirtilmiştir.
- Nanopartikül maddelerin yüksek katalitik etkisi, artan reaktif yüzey ve iyileştirilmiş ısı transferi yanmanın iyileşmesini desteklediği belirtilmiştir.
- Nanopartikül madde ilaveleri ile atomizasyon arttırdığı, daha iyi buharlaşma gerçekleştirdiği ve bunun da iyi yanmayı destekleyerek verimliliği arttırdığı belirtilmiştir.
- Nanopartikül maddelerin ilavesi ile yakıt içerisinde artan oksijen yoğunluğu iyi yanmayı desteklediği görülmüştür.
- Nanopartikül maddelerin ilavesi tutuşma gecikmesini azaltarak daha yüksek silindir tepe basınçlarını oluşturduğu ve yanma verimini arttırdığı belirtilmiştir.
- Nanopartikül maddeler sahip oldukları yüksek termal iletkenlik, yakıt moleküllerine daha fazla ısı aktarılmasına ve daha yüksek buharlaşma oranına neden olur. Bu da eksiksiz yanmayı destekler ve HC emisyonlarını düşürmede önemli bir rol oynadığı belirtilmiştir.

ABSTRACT

The importance of plastic materials with advantages it provides is increasing day by day in today's automotive industry. The most important advantage it provides compared to metal and other materials is weight. For this reason, it has become a preferred position in almost every field by customers in the global market. Plastic materials are preferred for fog lamps in automotive lighting products due to both weight reduction and cost improvement requirements. Therefore, automotive manufacturers choose geometries with the smallest possible volume. In these geometries where the heat source is very high, the deformations that may occur under the temperature to which the plastic materials are exposed should be examined. As a result, fog lamps should meet the regulation optical values and different customer specific requests without any thermal deformations. The geometry of the front fog lamp in this study has been designed via Siemens NX 12.0 cad program. Numerical studies of a front fog lamp with different geometries and different radiation models were figured up using Siemens FLOEFD software. Experimental and numerical results were compared each other in details in this case.

Keywords: Plastic materials, Front Fog Lamps, Thermal deformation, Radiation Models, FLOEFD

1. INTRODUCTION

Automotive lighting systems, including both the front and rear lights, are extremely important not only during the night time but also during the daytime from a vision quality [1] and safety point of view [2]. Nowadays, important design studies are carried out in every part of the vehicles in automotive with the developing technology. These innovations in optical components constitute one of the most important steps of these studies. At the same time, the difficulty level of customer requirements brings with it complex designs. One of these expectations is to provide thermal endurance according to the power of light source requirements. This situation is of big importance in the selection of the materials preferred in the products.

Heat dissipation caused by radiation, conduction, and convection heat transfers can lead to the formation of critical deformation zones in a fog lamp. For this reason, both numerical and physical tests of the front fog lamp have been done to prevent deformation caused by high temperatures. According to the deformations seen in these studies improvements are aimed in product geometry.

In this study, an experimental and numerical examinations of a front fog lamp with bulb in Figure 1 is shown. In the first phase of this study, which was carried out in two stages, the effects of the applied design improvements on the part were examined in the numerical studies. In the second step, the prototype sample taken from the injection mold was connected to the parts with thermocouples and tested in the climatic cabin in the laboratory. The test results were compared with the numerical study.

Thermal deformations were observed in the fog lamp due to the reflector geometry designed to meet the optical requirements of style surfaces. These thermal deformations have been tried to be eliminated without interfering with the optical surfaces, depending on the reflector geometry. Yet, the changes made were not sufficient because of the fact that the H8 35W bulb used in the fog lamp emits too much heat.

2. LITERATURE REVIEW

Bayraktar et al. studied the heat transfer of the P21W bulb used in automotive lighting systems numerically and experimentally. A rectangular box made of transparent polycarbonate (PC) was used during the examination. They measured the temperature by attaching thermocouples to each surface of the box. In the numerical analysis, it was accepted that the flow was in continuous regime and laminar. 3D Navier-Stokes equations are used. It has been observed that the numerical solutions and the experimental measurement results are consistent. In their work, they also examined the effect of temperature geometric dimensioning on lighting products numerically. [3]

Moore at al. developed a code that could perform combined specular radiation and flow analysis capability using a ray tracing method. The corresponding code has been applied in automotive lamp thermal analysis to accurately estimate lamp surface temperatures caused by radiation and natural convection. The numerical results were experimentally compared with an infrared thermal imager. They saw that it works with an error rate of 10%. [4]

3. MATERIAL AND METHOD

Before performing numerical and experimental thermal studies, the parts definition and design development of the fog lamp used are given under this section.

3.1 Sample Geometry and regulation definition

Front fog lamps provide a wide, bar-shaped beam of light with a sharp cutoff at the top, and are generally aimed and mounted low. They may produce white or selective yellow light, and were designed for use at low speed to increase the illumination directed towards the road surface and verges in conditions of poor visibility due to rain, fog, dust or snow[5].

They are sometimes used in place of dipped-beam headlamps, reducing the glare-back from fog or falling snow, although the legality varies by jurisdiction of using front fog lamps without low beam headlamps.

In most countries weather conditions rarely necessitate the use of front fog lamps and there is no legal requirement for them, so their primary purpose is frequently cosmetic. They are often available as optional extras or only on higher trim levels of many cars. An SAE study has shown that in the United States more people inappropriately use their fog lamps in dry weather than use them properly in poor weather as shown Figure 1 [6].

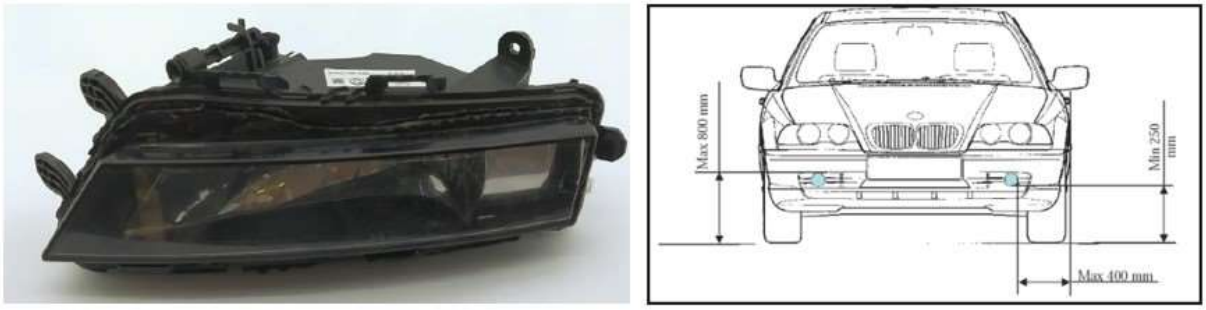

Figure 1. Sample Geometry and Regulation

The examined fog lamp consists of four main parts which are housing, lens, reflector, light bulb. The power intensity and load of the lamps increase with developments in lighting technologies such as halogen bulbs (H1, H3, H4, etc.) [7]. Single filament is used as the main heat source of the H8 bulb in the fog lamp. The aluminium metallized reflector geometry, which emits the light and provides optical regulation, is the component that is most exposed to the heat emitted by the H8 bulb. In this study, the resistance of the reflector geometry to thermal deformation was investigated. Bill of Fog Lamps' components is shown Figure-2.

Components of Fog Lamp;

1) Housing (PP GF30)

2) 2k-Lens (PC Clear and PC Black)

3) Reflector (PEI)

4) Bulb

5) Membranes

6) Adjustment Systems (PA66-GF15)

7) Gasket (Silicon)

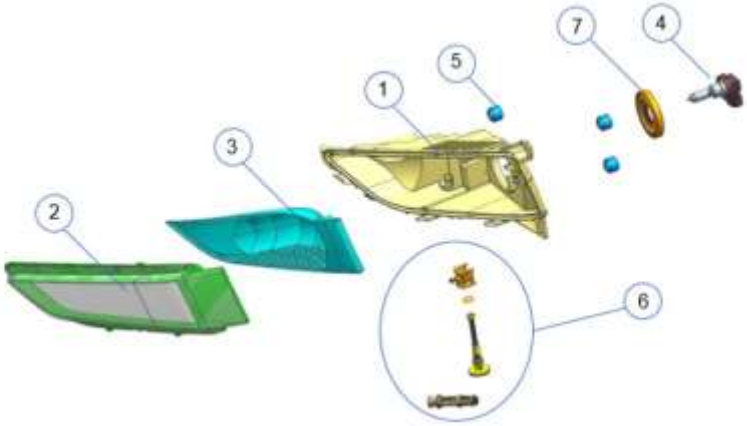

Figure 2. Component of Fog Lamp

3.2 Design Development

The design development phase took place in three stages. First of these stages, design studies have been made, ignoring the thermal requirements, and a reflector design has been made according to the style surface and optical requirements. Non-extension is made in the upper part of the reflector. In the second design stage, a reflector was designed by taking into account the style surface and optical requirements, as well as the thermal resistance requirement. There is an extension on the reflector geometry. In the latest design case, a 0.8 mm wall thickness sheet metal bulb shield has been added to the extended reflector geometry due to the high heat source is shown Figure 3.

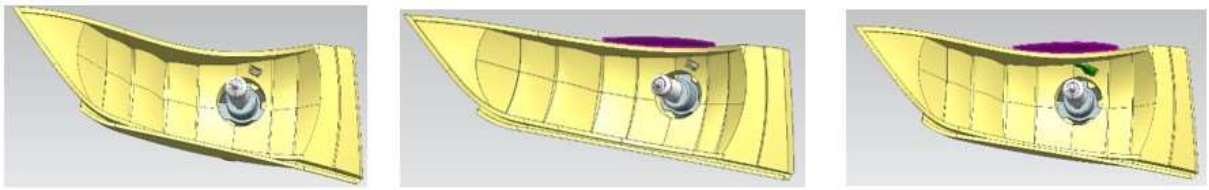

Figure 3.

Non-Extended Reflector Extended Reflector Extended with Metal Bulb Shield

3.3 Natural Convection Equation

It is a type of convection heat transfer that occurs with the natural movement of the fluid without any external influence. It occurs due to the temperature difference when a moving fluid flows over its solid surface. Rayleigh (Ra) number was defined as (1) equation Considering the diameter in the middle of the filament

$$Ra_D = \frac{g\beta\Delta T D^3}{\nu^2} Pr = GrPr \quad (1)$$

Here, ΔT is the difference between the temperature at the bulb surface temperature and the film temperature (Tf) of the ambient temperature. β = 1 / Tf is defined as volumetric thermal expansion coefficient. The Ra number can also be generated with the Grashof (Gr) number and the Prandl (Pr) number. The local Nusselt (Nu) number is defined as hD/k.

3.4 Computational Fluid Dynamics

In general, computational fluid dynamics (CFD) is a method used to analysis all kinds of fluids and flows under different conditions. Basically three main equations in this method; continuity, momentum and energy equations are taken as a basis and by solving these equations numerically, many data are obtained depending on the pressure, velocity and temperature distributions in the flow and these parameters.

In order to study a flow, continuity, momentum (Navier Stokes equations) equations must be solved with appropriate initial and boundary conditions. The most general forms of (2-5) equations are given below.

$$\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}=0 \tag{2}$$

$$\rho\left(\frac{\partial u}{\partial t}+\mathrm{u}\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}+w\frac{\partial u}{\partial z}\right)=-\frac{\partial P}{\partial x}+\rho g_x+\mu\left(\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}+\frac{\partial^2 u}{\partial z^2}\right) \tag{3}$$

$$\rho\left(\frac{\partial v}{\partial t}+\mathrm{u}\frac{\partial v}{\partial x}+v\frac{\partial v}{\partial y}+w\frac{\partial v}{\partial z}\right)=-\frac{\partial P}{\partial y}+\rho g_y+\mu\left(\frac{\partial^2 v}{\partial x^2}+\frac{\partial^2 v}{\partial y^2}+\frac{\partial^2 v}{\partial z^2}\right) \tag{4}$$

$$\rho\left(\frac{\partial w}{\partial t}+\mathrm{u}\frac{\partial w}{\partial x}+v\frac{\partial w}{\partial y}+w\frac{\partial w}{\partial z}\right)=-\frac{\partial P}{\partial z}+\rho g_z+\mu\left(\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}+\frac{\partial^2 w}{\partial z^2}\right)$$

(5)

Thermal energy conservation equation for fluid given by as Eq(6):

$$\frac{\partial(\rho \mathrm{u}T)}{\partial x}+\frac{\partial(\rho vT)}{\partial y}+\frac{\partial(\rho wT)}{\partial z}=\frac{k}{C_p}\left(\frac{\partial^2 w}{\partial x^2}+\frac{\partial^2 w}{\partial y^2}+\frac{\partial^2 w}{\partial z^2}\right)+S_e \tag{6}$$

For Solid:

$$\left(\frac{\partial^2 T}{\partial x^2}+\frac{\partial^2 T}{\partial y^2}+\frac{\partial^2 T}{\partial z^2}\right)=0 \tag{7}$$

CFD is the solution of fluid mechanics problems that require long processes by creating matrices in the computer environment. It is ensured that complex and long-term problems are solved quickly and effectively depending on the computer performance with the analysis using methods such as finite differences, finite elements, and finite volumes. [8]

3.5 Finite Volume Method

The Finite Volume Method (FVM) is a discretization method for approximation of a system of single or partial differential equations expressing the conservation or balance of one or more quantities. The finite volume method is the solution of partial differential equations by algebraic equations. These partial differential equations are often referred to as conservation laws. These can be of different nature. They are elliptical, parabolic or hyperbolic and are used as models in numerous fields, including physics, biophysics, chemistry, image processing, finance, dynamic reliability. It is quite similar to the finite difference method. Volume integrals containing the deflection term in partial differential equations in FVM are transformed into surface integrals with the divergence theorem. These terms are considered as flows across the surfaces of each finite volume. This method is especially used in computational fluid mechanics problems. Describes the relationships between partial derivatives of unknown fields such as temperature, concentration, pressure, molar fraction, density of electrons, or the probability density function, with regard to variables in the field in question. [9]

3.6 CFD Analysis Software

This study was implemented via Siemens FloEFD 2020.1 software in three steps as pre-processing, solution and post-processing. CFD method is generally used in many numerical solutions under different boundary conditions and different fluids. In the use of this method, the continuity equation, momentum and energy equations are calculated numerically depending on the pressure, temperature distribution, velocity parameters in the flow. CFD method to be used in this numerical analysis was used and Navier-Strokes equations were calculated in Siemens FloEFD software. In these calculations, Monte Carlo (MCRM) and Discrete Ordinate(DORM) Radiation Models were applied and differences between experimental studies and radiation models were compared.

The aim of the simulation is to cover the worst case that occurs during hot country tests. The virtual testing and simulation conditions are defined in the following the boundary conditions which are 70 °C ambient temperature, incompressible and buoyancy air flow without ventilation, 101.325 kPA pressure, time independent in air domain is shown figure 4.

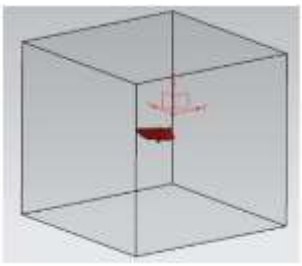

Figure 4. Air Domain

DORM is considered 2500nm Band edge, Blackbody spectrum of environment radiation. MCRM is considered 1000000 rays, blackbody spectrum of environment radiation.

The fluid volume of inside the bulb was included as Argon gas that has 202.650 Kpa. The bulb is consist of sub-parts which are filament, glass, sheet metal and bulb holder were selected as Tungsten, quartz glass, steel and PA66 GF30.Black PC material for the reflector, transparent and black PC for the Lens 2K structure, PA GF30 for the Body were identified. Filament of the bulb has comprised heat source power is 43.5Watts at 13.5 V forward voltage.

3.2 Mesh Operation

All cells 2 855 505 cells, 1 389 064 solid cells of plastic parts and bulb and 1 389 064 fluid cells of air and argon fluid domains, have been meshed via FloEFD Mesh Tool is shown figure-4. Maximum mesh refinement level has selected 9 for filament because of heat source is shown figure-5.

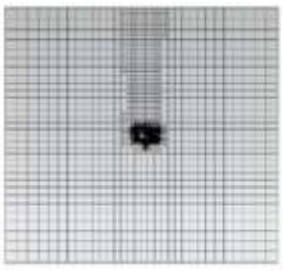

Figure 4. Mesh Operation of Domain

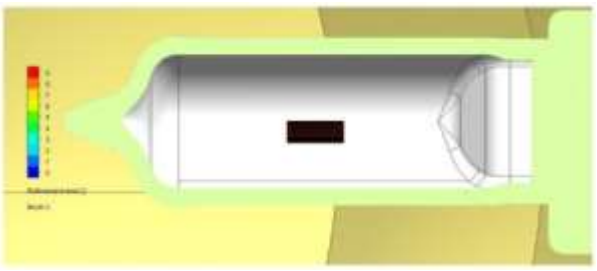

Figure 5. Refiremet Mesh Level of Filament

3.3 Experimental Study

Before testing the whole fog lamp experimentally, a thermocouple was attached to the lens surface of the fog lamp. Thermocouples were connected on this thermocouple again and errors caused by thermocouples were investigated. In

these studies, it has been observed that the differences between the values taken over the thermocouple can be neglected is shown figure 6.

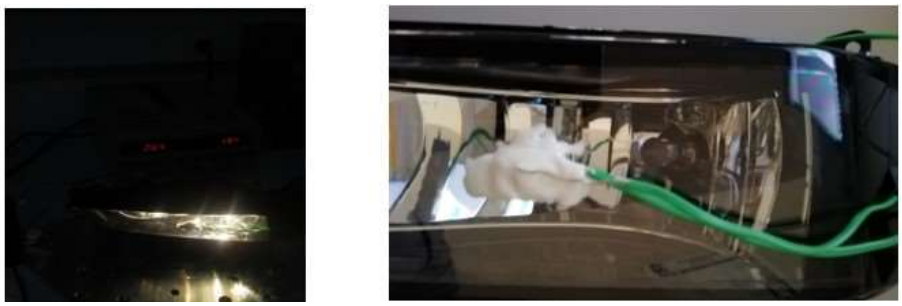

Figure 6. Thermocouple Evaluation

The fog lamp was powered by 43.5 watts at 13.5 forward voltage. The test was completed in 90 minutes. During the test, the thermocouple is connected to the subcomponents. The climatic cabin is set 70°C temperature without ventilations is shown in figure 7.

Figure 7. Climatic Cabin

4.RESULTS

The calculated numerical analysis with MCRM and DORM, and the tested fog lamp with thermocouple results have been demonstrated each all components according to reflector geometry. The error is taken into account as (8) equation.

$$\text{Error}=\frac{|(Numerical\ Result+272.15°C)-(Experimental\ Result+272.15°C)|}{(Experimental\ Result+272.15°C)} * 100 \qquad (8)$$

4.1 Experimental and numerical results with non-extended reflector geometry

The calculated numeric analyses with MCRM and DORM results of housing temperature results are 179.08°C, 183.91°C are shown figure 8, figure 9.

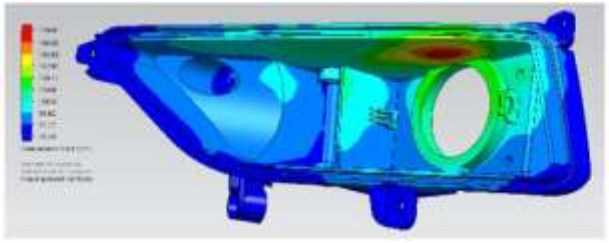

Figure 8. MCRM Result of Housing

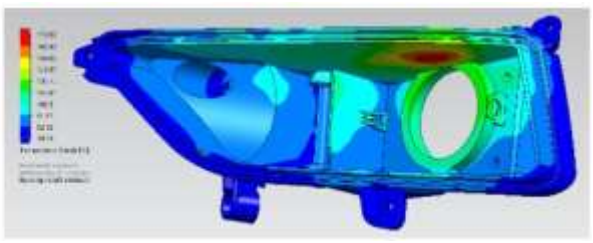

Figure 9. DORM Result of Housing

The calculated numerical results of lens temperature with MRCM and DORM are 136.09°C and 140.71°C are shown figure 10 and figure 11.

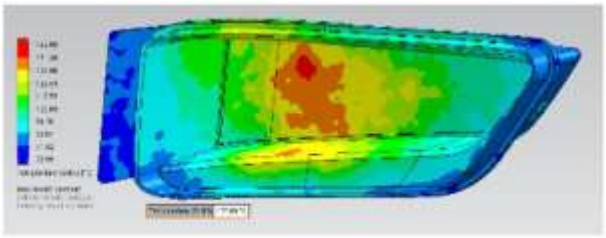

Figure 10. MCRM Result of Lens

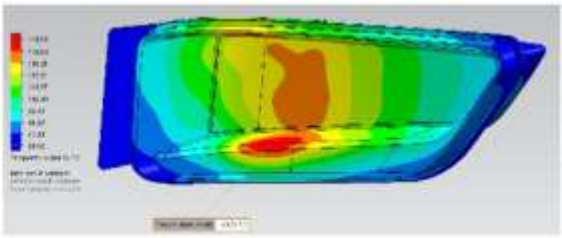

Figure 11. DORM Result of Lens

The calculated numerical result of reflector temperatures with MRCM and DORM are 214.10°C and 217.20°C are shown figure 12 and figure 13.

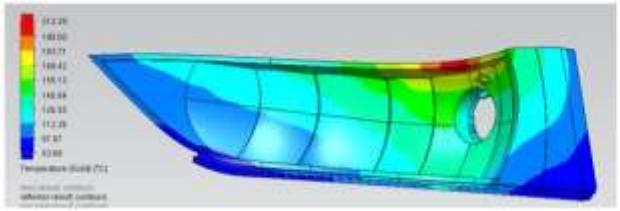

Figure12. MRCM Result of Reflector

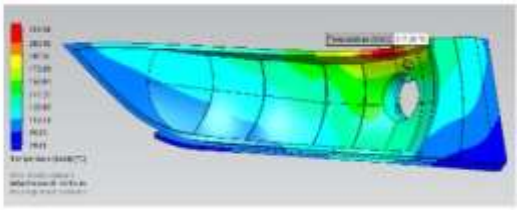

Figure 13. DORM Result of Reflector

The tested results of housing, lens, reflector temperatures are 183.1°C, 134.6°C and 217.30°C. After test, the housing is deformed is shown figure 14 and lens surface has undulation is shown figure 15.

Figure 14. Damaged Outer and Inner surfaces of Housing

Figure 15. Undulated Inner Surface of Lens

The error calculations-1 and vicat softening temperatures of all each sub-componets are demonstrated is shown table 1.

Table 1. Error calculation-1

Non Extended Reflector	Numeric Analysis Result		Test Result (°C)	Vicat Softening Temperature (°C)	Error MCRM	Error DORM
	MCRM (°C)	DORM (°C)				
Housing	179.08	183.91	183.1	155	0.883031	0.177924
Lens	136.09	140.71	134.6	141	0.366318	1.502151
Reflector	214.1	217.1	217.3	215	0.653795	0.040862

4.2 Experimental and numerical results with Extended Reflector Geometry

The calculated numeric analyses with MCRM and DORM results of housing temperature results are 168.37°C, 178.98°C are shown figure 16, figure 17.

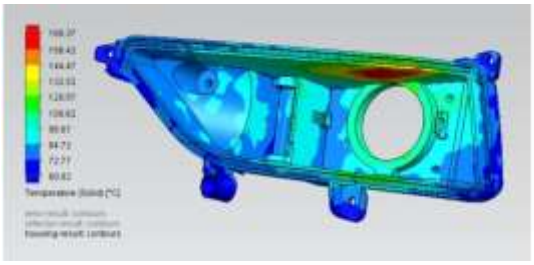

Figure 16. MCRM Result of Housing

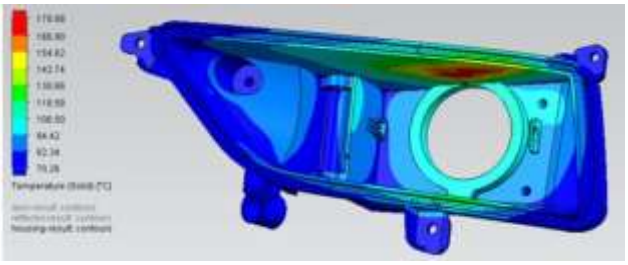

Figure 17. DORM Result of Housing

The calculated numeric analyses with MCRM and DORM results of lens temperature results are 124.67°C, 134.12°C are shown figure 18, figure 19.

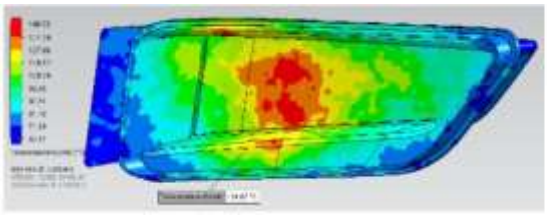

Figure 18. MCRM Result of Lens

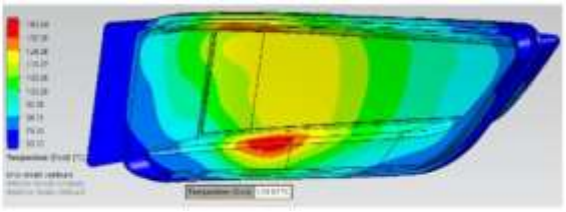

Figure 19. DORM Result of Lens

The calculated numeric analyses with MCRM and DORM results of reflector temperature results are 237.47°C, 242.01°C are shown figure 19, figure 20.

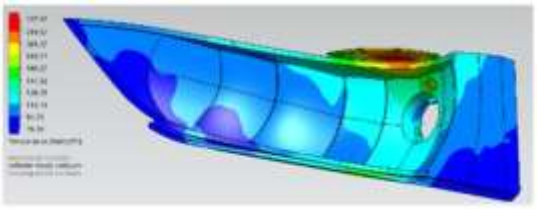

Figure 19. MCRM Result of Lens

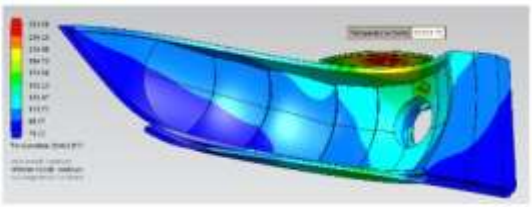

Figure 20. DORM Result of Lens

The tested results of housing, lens, reflector temperatures are 179.4°C, 121.9°C and 235.30°C. After test, the housing is deformed is shown figure 21 and extended reflector surface has undulation is shown figure 22.

Figure 21. Damaged Inner surfaces of Housing

Figure 22. Undulated surface of Reflector

The error calculations-2 and vicat softening temperatures of all each sub-componets are demonstrated is shown table 2.

5. DISCUSSION

As can be seen from the results of the first analysis, the regions where the deformation occurred in the part were determined. By making use of these results; Improvements were made in the design of the reflector product and the heat shield was used in the parts where the heating problem occurred. It has been seen as the most effective solution that provides a more thermally uniform temperature distribution. In this respect, a complete revision study was carried out by evaluating the product and environmental conditions together.

Despite, the test temperature has exceeded over 5-6 °C of vicat softening temperature the housing have not damaged. In this investigation, vicat softening temperature can be exceeded over 5-6 °C with reinforcement glass fibres. Discrete Ordinates is support more effective results than monte carlo at opaque material in spite of the fact that Monte Carlo is support more effective results that discrete ordinates reflective and clear surfaces.The first design is not robust design for housing and lens parts according to thermal aspects.The second design is extented reflector is not robust design for housing and reflector parts according to thermal aspects.The third design is extented reflector with bulb shield is robust design for all parts according to Thermal aspects

ABSTRACT

This study presents the hyperelastic deformation response of EPDM rubber grommet models subjected to prescribed kinematic motion. Studies on electrical systems in electric and internal combustion vehicles are of vital importance. Cable materials inside tailgate and door grommet that are subject to deformation due to repetitive motion of tailgate and door might experience damage and be crushed subsequently this cause fire risks on electrical systems due to the breaking effect over time. In this study, by examining the hyperelastic deformation behavior of tailgate and door grommet using finite element analysis, folding of grommets were identified. Design update on the grommet geometry was proposed and simulated using LS-DYNA in order to prevent folding failure.

1. INTRODUCTION

In Automotive cars, it requires a lot of wiring harness system to distribute power from one system to other. Any low or high voltage wiring harness should have sufficient strength to withstand any abrupt situations without affecting the performance of the total system.An opening and closing member is attached to a vehicle by a hinge enabling easy opening and closing of different moving member. Such members include side door, rear door, trunklid, tailgate etc. A guide member called rubber grommet made of elastomer has an accurate portion which can be extend and contract while twisting with. A cable grommet is a tube ring through which an electric cable passes. They are usually made of EPDM rubber. The cable grommet is used to protect, improve friction or seal cables passing through it, from a possible mechanical or chemical attack, crushing and subsequent fire risk. It becomes very important to determine the optimum length of the grommet used for particular application. Bigger length will have results into folding of grommet and lesser length will yield intostretching of rubber grommet.The objective of this paper is to suggest a methodology to model the behavior of rubber grommet under specified loading conditions. For this purpose rubber grommet has been modeled with hyperelastic material properties and simulation is conducted with a non-linear commercially available FE codes LS-DYNA. First a stable hyperelastic material model is selected using LS-DYNA Explicit then explicit hyperleastic simulation is performed.

Figure1. EPDM rubber tailgate grommet sample

2. THEORITICAL BACKGROUND OF LARGE STRAIN, LARGE ROTATION HYPER-ELASTICITY for RUBBER TYPE MATERIALS

Large deformation modes in hyper-elastic materials extend up to 200% in parts, the definition of small strain used to observe elongation levels in plastic rubber parts is not a suitable observation method for such materials. Therefore, logarithmic strain definition is used to observe deformation modes for hyper-elastic materials. Also in order to make an accurate visual comparison between all grommet models, the logarithmic strain level is fixed at the level of 0.5 (50%).

Since grommet experience large rotation and large strains during the opening-closing movement of tailgate and door, large rigid body motion should be excluded in strain definition. Accordingly two strain description is available excluding finite rotations in strain calculation: green strain and logarithmic strain. The small-strain, large-rotation approximation is often useful—especially in structural problems (shells and beams) because there the thinness or slenderness of the members often allows large rotations to occur with quite small-strains—and Green's strain is commonly used in large-rotation, small-strain formulations for such problems as shell buckling. Thus, for such cases including large rotation and large strain, logarithmic strain is a very convenient choice for computing the hyper-elastic strain which takes care of the large strain and large rotation effects accordingly.

A measure of deformation is —the stretch ratio λ. In fact, λ is itself an adequate measure of “strain” for a number of problems. To see where it is useful and where not, first notice that the unstrained value of λ is 1.0. A typical soft rubber component (such as a rubber band) can change length by a large factor when it is loaded, so the stretch ratio would often have values of 2 or more. In contrast, a typical structural steel component will be designed to respond elastically to its working loads. Such a material has an elastic modulus of about 200 × 103 MPa (30 × 106 lb/in2) at

room temperature and a yield stress of about 200 MPa (30 × 103 lb/in2), so the stretch at yield will be about 1.001 in tension, 0.999 in compression. The stretch ratio is an unsatisfactory way of measuring deformation for this case because the numbers of interest begin in the fourth significant digit. To avoid this inconvenience, the concept of strain is introduced, the basic idea being that the strain is zero at λ=1, when the material is "unstrained." In one dimension, along some "gauge length" dX, we define strain as a function of the stretch ratio, λ, of that gauge length:

$$\varepsilon=f(\lambda). \tag{1}$$

The objective of introducing the concept of strain is that the function f is chosen for convenience. To see what this implies, suppose ε is expanded in a Taylor series about the unstrained state:

$$\varepsilon = f(1) + (\lambda - 1)\frac{df}{dx} + \frac{1}{2!}(\lambda - 1)^2\frac{d^2f}{d\lambda^2} + \cdots. \tag{2}$$

We must have f(1)=0, so ε=0 at λ=1 (this was the main reason for introducing this idea of "strain" instead of just using the stretch ratio). In addition, we choose df/dλ=1 at λ=1 so that for small strains we have the usual definition of strain as the "change in length per unit length." This ensures that, in one dimension, all strain measures defined in this way will give the same numerical value to the order of the approximation when strains are small (because then the higher-order terms in the Taylor series are all negligible)—regardless of the magnitude of any rigid body rotation. Finally, we require that df/dλ>0 for all physically reasonable values of λ (that, is for all λ>0) so that strain increases monotonically with stretch; hence, to each value of stretch there corresponds a unique value of strain. (The choice of df/dλ>0 is arbitrary: we could equally well choose df/dλ<0, implying that the strain is positive in compression when λ<1.

With these reasonable restrictions (f=0 and df/dλ=1 at λ=1, and df/dλ>0 for all λ>0), many strain measures are possible, and several are commonly used. Some examples are Nominal strain (Biot's strain), Logarithmic strain, and Green's strain.

Nominal strain (Biot's strain) follows:

$$f(\lambda) = \lambda - 1 \tag{3}$$

In a uniformly strained uniaxial specimen, where l is the current and L the original gauge length, this strain is measured as (l/L)−1. This definition is the most familiar one to engineers who perform uniaxial testing of stiff specimens.

Logarithmic strain follows:

$$f(\lambda) = \ln(\lambda) \tag{4}$$

This strain measure is commonly used in metal plasticity. One motivation for this choice in this case is that, when "true" stress (force per current area) is plotted against log strain, tension, compression and torsion test results coincide closely. Later we will see that this strain measure is mathematically appropriate for such materials because, for these materials, the elastic part of the strain can be assumed to be small.

Green's strain follows:

$$f(\lambda) = \frac{1}{2}(\lambda^2 - 1) \tag{5}$$

This strain measure is convenient computationally for problems involving large motions but only small strains, because, its generalization to a strain tensor in any three-dimensional motion can be computed directly from the deformation gradient without requiring solution for the principal stretch ratios and their directions.

All of these strains satisfy the basic restrictions. Obviously many strain functions are possible: the choice is strictly a matter of convenience. Since strain is usually the link between the kinematic and the constitutive theories, the convenience of this choice in the context of finite elements is based on two considerations: the ease with which the strain can be computed from the displacements, since the latter are usually the basic variables in the finite element model, and the appropriateness of the strain measure with respect to the particular constitutive model. For example, as mentioned above, it appears that log strain is particularly appropriate to plasticity, while large-strain elasticity analysis (for rubbers and similar materials) can be done quite satisfactorily without ever using any "strain" measure except the stretch ratio λ.

3. FE SIMULATION and MODEL INFORMATION

Rubber door grommet has been modeled with very fine solid reduced integration hexa elements. One end of the grommet is connected to the plastic connector and then attached to the door and other end of the rubber grommet is connected to the door. Node of the rubber are rigidly ties to the plastic connector. To simplify the problem and reduce the computational time, door sheet metal is modeled as a rigid. Similar modeling is applied to tailgate grommet.

Hinge location of the door is fixed in all degrees of freedom. A local coordinate system is defined (whose one axis is made parallel to the hinge axis) and the door is rotated 68 degrees along the hinge axis. Explicit simulation is performed by making sure that kinetic energy is way less than internal strain energy and automatic general contact definition is used to define the contact.

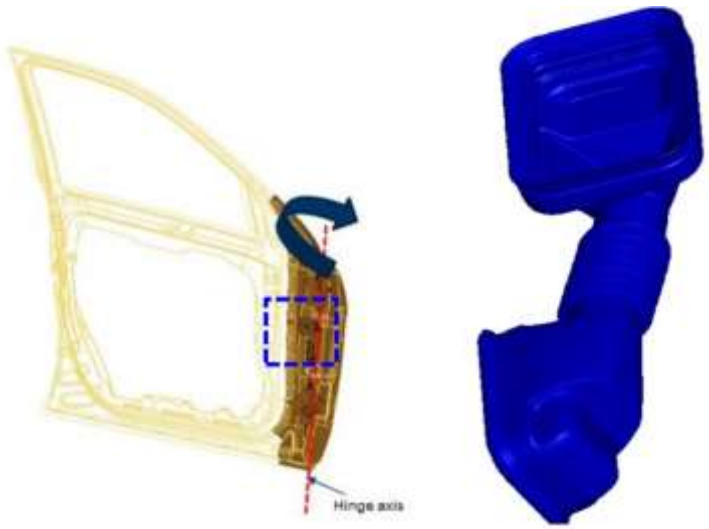

Figure 2. Typical Hinge Axis on Door and FE Model of Door Grommet

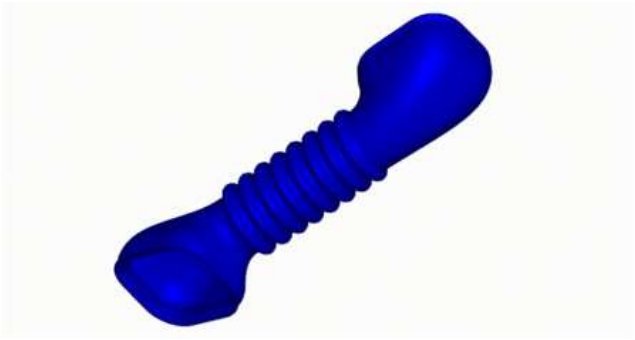

Figure 3. FE Model of Tailgate Grommet

EPDM material using SIMPLIFIED RUBBER MAT181 in LS-DYNA model was used for the grommet models used in the study and the simulation was completed in 2 load steps for each model. The angle of rotation depends on the hinge positions of the moving parts of the vehicle. Kinematic simulation of the grommet models and the position of the tailgate takes place in multiple stages as shown in the picture. All simulation model results are shown as logarithmic strain and the maximum limit is kept as 0.5.

Figure 4. Boundary conditions of Grommet and rigid parts

All grommet models have plastic parts and grooves for both mouth points.While the kinamatic movement of the grommet model occurs, the plastic parts provide the movement and fixation task. Therefore, the channel regions determine the fixed and moving points of the grommet models.

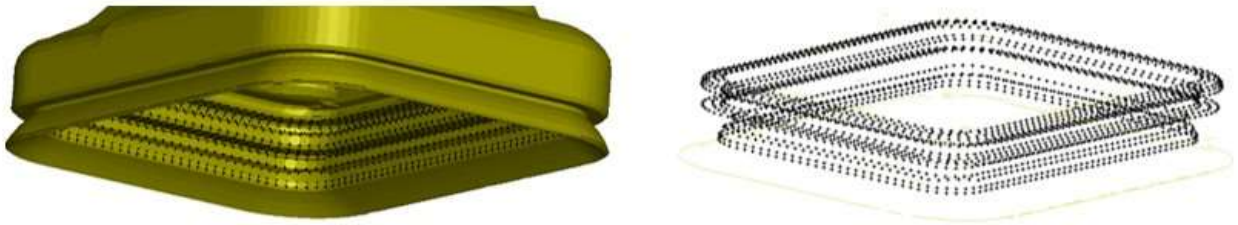

Figure 5. Fixed and Movement points at grommet parts

Number of elements for both grommet models are listed in table 1 and table 2.

Table 1. FEM model data information for Tailgate Grommet

Data Name	Initial Model	Final Model
Total # of Elements	17504	76711
Total # of Nodes	26544	21400
Total # of Rigid Elements	2537	402

Table 2. FEM model data information for Driver Door

Data Name	Initial Model	Final Model
Total # of Elements	58191	117539
Total # of Nodes	18301	34045
Total # of Rigid Elements	23645	10539

Unlike plasticity data, test data for hyper-elastic material must be given as engineering stress and strain values. For hyper-elasticity elasticity, the fitting procedure may be carried out for polynomial representations of incompressible materials. The significance of (non-equivalent) multiple tests for material modeling cannot be overemphasized.

In general, a combination of uniaxial tension/compression and simple shear is required in the very least. Data from biaxial tension or planar shear may also be needed depending on the deformation modes of the structure. Volumetric data must be included for materials undergoing large compressible deformations. The quality of the results from a simulation using hyper-elastic materials strongly depends on the material test data provided to LS-DYNA. It is always recommended to have more than one deformation state to form accurate and stable material model.

For our grommet simulation uniaxial tension and compression data is enough to capture the physics of the grommet behavior. It is common for the material model determined from the test data to be unstable at certain strain magnitude. Following Figure 6 shows the compression (negative engineering strain) and tension data (positive engineering strain) for the EPDM elastomer used for rubber grommet simulation.

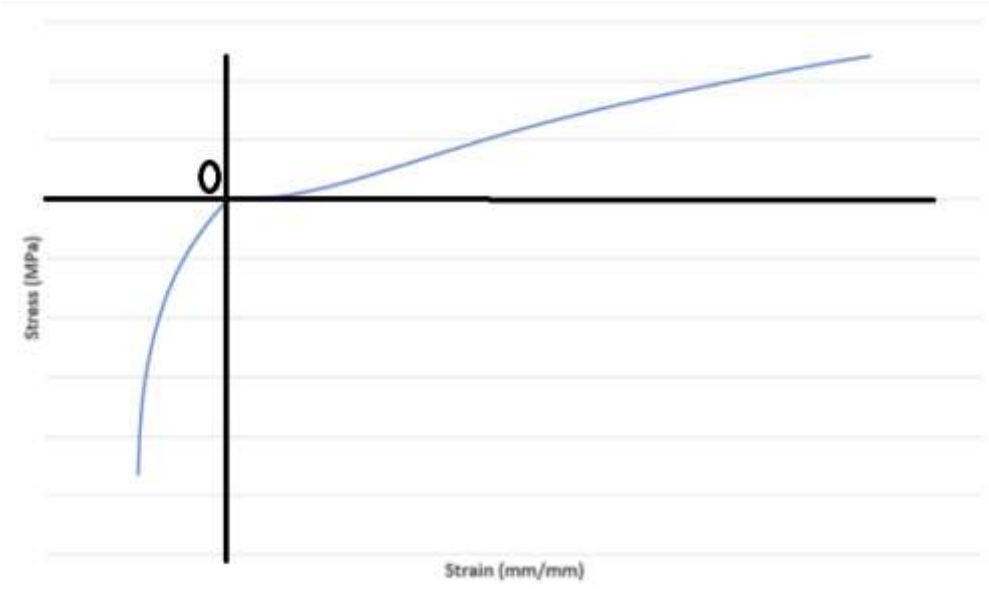

Figure 6. EPDM material tension-compression behavour

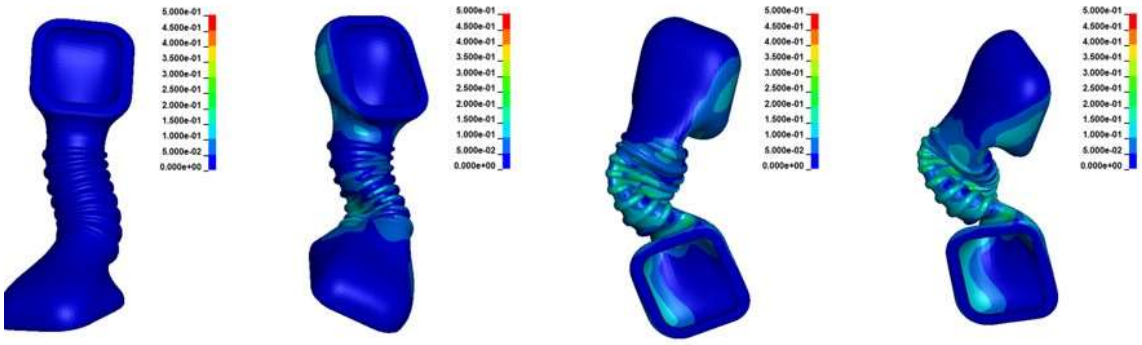

Figure 7. Logarithmic Strain of Initial Tailgate Grommet Design during Rotation

On the tailgate grommet model, breakages that will have an effect on the cable after kinematic movement were observed. All breakdown scenarios that will occur on the grommet cause deformations in the cable material that will pass through the grommet over time. For this reason, after the design updates on the existing models, the thickness on the grommet model has been increased and the distance between the rib areas and the throat area has been reduced in order to create the most optimum design model. Optimized final model is shown in figure 8. Maximum %100 logarithmic strain is observed in the initial tailgate grommet while logarithmic strain level is reduced to %70 in the final optimized tailgate grommet. Strain contours shown here is kept at maximum 50% strain deliberately for ease of visualization.

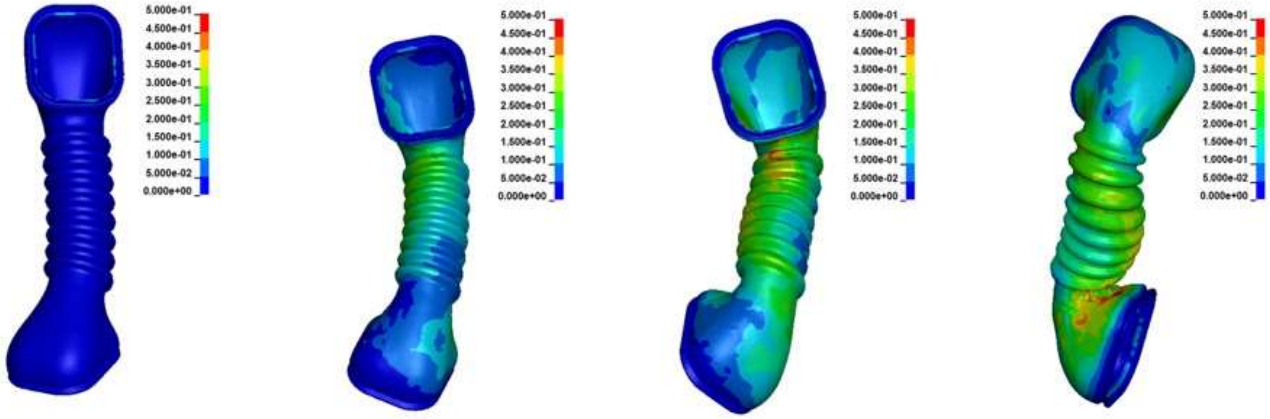

Figure 8. Logarithmic Strain of Final Tailgate Grommet Design during Rotation

Folding failure is a sign for possible low or high voltage cable crushing and damage inside the grommet pipe. Folding failure of initial tailgate grommet design is shown in figure 7. On the other hand, final optimized Tailgate grommet model shows no folding behavour as shown in figure 8 below.

Figure 9. Folding failure of Tailgate Grommet Design during Rotation

Figure 10. Final Optimized Tailgate Grommet Design during Rotation - No Folding

As a result of the simulation studies performed on the door grommet models, no folding problem was encountered that would cause deformation or crushing of the cable material on the models. Maximum logarithmic strain observed in the model is around % 58. However, as a result of the movement, interferences were observed on the peripheral components on the model. Design updates have been made on the models to prevent deformation of the plastic materials on the grommet models due to fatigue over time and the friction contact of the cable material with the grommet. The interference surface of the grommet model with peripheral components is shown in Figure 13.

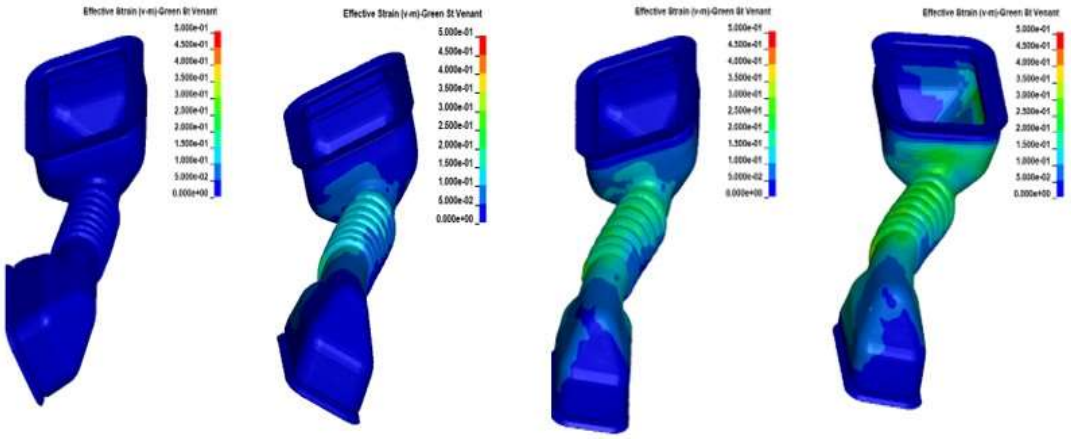

Figure 11. Logarithmic Strain of Door Grommet Initial Design during Rotation

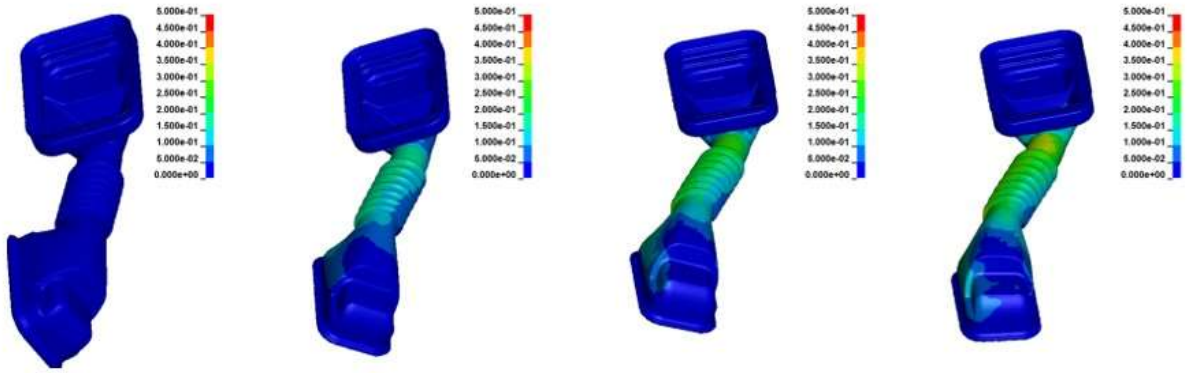

Figure 12. Logarithmic Strain of Door Grommet Final Design during Rotation

Cross sectional visualization comparison between initial and final door grommet design model is shown in Figure 13. There were no local breaks that would cause serious tension on the model and deformation on the cable material. Also, no contact areas were observed between the grommet pattern and surrounding components.

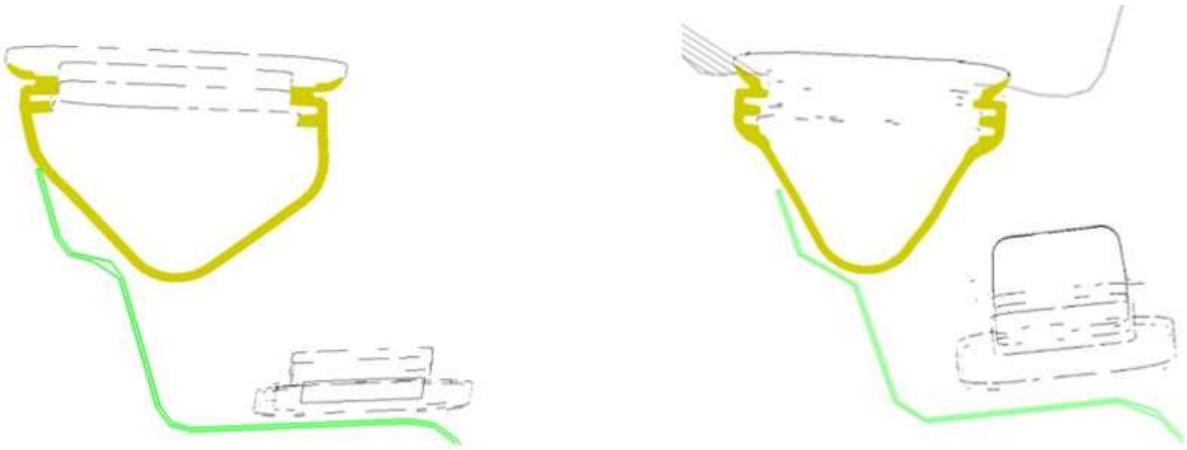

Figure 13. Door models post-collision design update

4. CONCLUSION

In conclusion, Hypermesh and Ls-Prepost was used to create the finite element model of the Grommet parts and LS-DYNA was used as a solver. In all grommet models, it is aimed that the grommet designs minimizes cable deformation at the end of the kinematic movement without folding failure and prevent contact with sheet metal plate surfaces. Various grommet profiles are created based on the simulation results. By performing the simulation with different designs with varying shape of the grommet length, thickness and rib structure, it becomes easy to find out the optimum design shape of the grommet without folding failure and fire risk.

Rubber grommet profile is not uniform. With the accurate hyper-elastic materials modeling become easy to have the precise results. With the CAE simulation it is easy for designer to design an optimized shape and size of the rubber grommet. In the development phase of the automobile vehicle this simulation will help to avoid

any last moment surprise at the end of the vehicle development cycle. This gives engineering direction to designer to do necessary changes in the beginning of the design phase freeze which leads into save of time and money.

ABSTRACT

In this study a tension and tearing of deformations modes are investigated with actual strength test and FEA simulation of laminated fabric. Tri laminar fabric is adhered by flame and composed by weaved fabrics that are plain and twill 2/2 with PU foam and PA circular knitted scrim. The fabrics are subjected to uniaxial stress with opposite forces in real test and FEA simulation carried on constructed fabric geometrically into KTEX software. The assumption of tri laminated fabric is to be linear and elastic for composites in FEA, although the composites are non-linear and viscoelastic in real. Simulation outputs has been compared with the result of the real test and its graph. Geometrical construction of tri laminar fabrics is crucial to obtain beneficial results. The tensile and tearing strength results of simulations have a good agreement with actuals coherently although the strain- stress graphs among actual and virtual may differ in several zones. The consistency of actual test results and simulation may conduce a model for surface deformation for further studies.

Keywords: Automotive seat fabric, tensile strength, modelling, simulation, finite element analysis (FEA)

1. INTRODUCTION AND MAIN SECTIONS

In the scope of this paper, tensile and tear deformations of laminated fabric as seat cover is simulated with finite element analysis.

Textile materials are used as garments which cover to inner parts of automobile. Weaving, knitting, nonwoven, braiding are the production techniques that generate cover, carpet, strap, airbag fabric as being functional and aesthetical properties. Automotive textile is a fitting garment and there is no space between covered parts and fabric.

The performance that are physical, chemical, strength and constructional properties of textile materials have been mentioned and identified in OEM's specifications with test methods. Issued specifications are determined by end user's behaviors and safety regulations. No doubt that the priority of requirement is safety, textile materials strength might be significant requirement afterwards. Fabric should have specific strength of breaking to obtain facility in the cutting, sewing, assembly process and usage period to avoid any damages because of tensions and compressions on the multi direction during the life long.

Based on all requirements of strength that fabrics are undergirded by lamination of foam and scrim for the seat cover and named as laminated fabric in textile jargon. Laminated fabric that is processed in flame lamination consist of tri layers as face fabric, foam and scrim respectively. Foam and scrim improve the stress and strain properties meanwhile aesthetical appearance. All strength tests of laminated fabric are performed in the unconstrained form and a bunch of tests as being seat. The behaviors of laminated fabric can be predicted and evaluated since to take in account test results in fabric design period and research and development phases.

In the presence of OEM's requirements of strength, designers and engineers have to chase through their targets in the short run to be in frontline among the competitors and simulations studies with software programs can be used efficiently so as to achieve their goals without many trials to reduce the cost of design, research and development, tests.

In automotive industry finite element analysis (FEA) is used in scope of simulations for the components as virtual tests. Simulation steps contain geometrical modelling to construct virtual materials as a macroscale and transferring to FEA

via interface software for the further steps that stress- strain analysis. Some of geometrical modelling as KTEX, TEXGEN, SOLIDWORK software are used for the fabrics and mechanical behavior is studied with FEA software that trademarks are called ABAQUS, LS-DYNA, ANSYS, RADIOSS. Long, Lin, Modi, Endruweit, Clifford, 2008 in their studies geometric modelling of fabric on TEXGEN and structural compaction was applied in FEA. Lin, Choi, Luximon, Yao, Hu, Li, 2008 studied compression behavior of fabric that modelled nonlinear and linear elastic as orthotropic material in ABAQUS software.

In this paper, face fabric's geometric modelling is generated KTEX software and deformation types that tensile strength behavior with the specified tests are performed experimental and simulation. The results of test and their graphs are compared. The consistency of virtual and experimental results could enable to finite element analysis mechanical behavior prediction of fabrics without experimental test. It provides to minimum production and design trials to develop expected design in a short run.

Fabric construction and its mechanics are the subject of researches and fundamental knowledges have been come out. Fabric material is classified a nonlinear and anisotropic. Constructional parameters and its variables are determined for geometrical modelling that affects mechanical properties. To prediction of mechanical behavior with empirical equations is complicated. Hearle, Potluri, Thammandra, 2001 emphasized about complexity of mechanic modelling of fabric with mathematical equations and expressions and mentioned that 3D modelling can be eliminate issued complexity. It is aimed to simulate of tensile strength of laminated fabrics under uniaxial loads by finite element analysis and to enlighten those studies for multiaxial loads and abrasion behavior of fabrics. Shen, Meir, Cao, Adanur, 2015 simulated to tensile strength of fabric that constructed monofilaments yarn in FEA. 3D geometrical modelling was created based on Pierce geometry in software. FEA analysis performed with material properties and good agreement was obtained between experimental results and simulation.

Deformation of fabric can be expressed as the displacement of yarns and shape changes of yarns in fabric constructions with external forces. Yarns assume one-dimensional and intersection of yarns construct two-dimensional fabric. Laminated fabric is named as a three-dimensional. Fabric in the maximum stress where the yarns shifting and breaking in the condition of tearing and tensile deformation is observed.

Fabric construction parameters have been identified as density of warp and weft, yarn's diameter crimp and length, space between yarns in the geometric models by Pierce 1937, Kemp 1958, Hearle 1978 for the plain fabrics. Non- plain fabrics have a floating and geometric modelling has been studied and improved in a narrow scope by take in account race- track model which belongs Kemp. Undoubtedly all studies in the past are feeding current geometric modelling software but some empirical equations of parameters may different. Complex 2D and 3D weaved models as like satin and twill can be generated with software.

2. MATERIALS AND METHOD

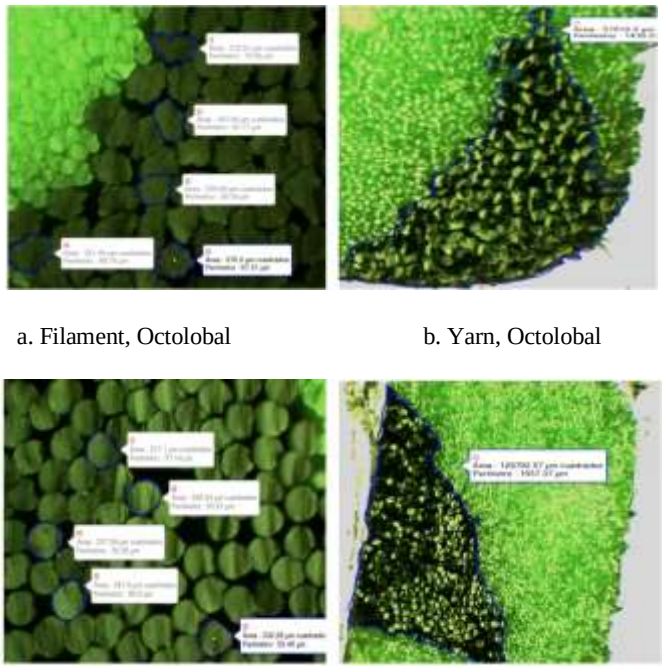
In this simulation study, the yarn parameters have been specified and a geometrical model is generated in the KTEX interface software. Force-elongation graphs and values are obtained by under uniaxial forces in FEA in accordance with mentioned standards and methods for tensile test. The result of experimental and simulation studies is compared within themselves. The fabrics that will be modelled are available in assembled vehicles concrete the moment.

2.1. Yarn and filaments parameters

In automotive industry Polyester filaments originated yarn is commonly used as raw material in presence of processibility, abrasion and strength, cleanability and soiling, flammability behaviors, color fastness and fading durability, elongation and creases behaviors.

The two types of yarn have been worked out hence are used for some automotive brands in upholstery currently, 55 tex friction textured, octolobal cross sectioned and 110 tex air-texturized, round cross sectioned yarns that contain 144 and 270 continue filaments respectively. Inputs of yarn parameters for geometrical modelling as the area and the perimeter of yarn and filaments measuring and stress-strain attitude of yarn have been tested. Yarn density, filament and yarn diameter, filament volume fraction, material properties as young moduli, shear moduli, poisson ratio have been calculated based on related empirical data.

Yarn and filament diameter measured by the method of process imaging analyses that performed in MOTIC BA-310 MET-T TRIOLCULAR Microscope have been used to identify areas and perimeters that in Figure 1 is presented with yarn and filament border line.



a. Filament, Octolobal b. Yarn, Octolobal

c. Filament, Round d. Yarn, Round

Figure 1. The areas and perimeters measurements of filaments and yarns

Geometrical formula with 1 provide to work out diameters from area and perimeter value that measured. The notations of D, A, P are diameter, area and perimeter respectively and indicated in Table 1 with shape factor (k) that determines to circularity of cross sections. In the condition k = P / (π * D) is equal to 1, the cross section of yarn or filaments is round. Shape factor gives significant information about how to be the cross section of yarn into fabric construction in the phase of geometric modelling. The shape factor of yarn that contains round filaments is higher than 1as a result of filaments number which surround to centered filaments.

$$A = \pi * D^2/4,\ P = \pi * D \quad (1)$$

Table 1. The area and the perimeters of filaments and yarns and their diameters

Yarn and Filament	Area of cross section (μm^2)	Perimeter of cross section (μm)	Diameter on area (μm)	Diameter on perimeter (μm)	Shape factor
Octolobal filament	297,77	68,98	19,44	21,97	1,13
Round filament	258,60	56,94	18,13	18,13	1
Yarn of octolobal filaments	53.755,20	1329,29	261,52	423,34	1,62
Yarn of round filaments	128.332,23	1567,54	404,08	499,21	1,24

The inputs of geometric modelling involve density and volume fraction of filaments in Table 2, calculated with equations contains diameters of filaments. The formula 2 where c, A, ρ are linear density, area, density respectively, volume fraction symbolled as TV_f, in equitation 3 where V_f, V_y are specific volume of filament and yarn respectively.

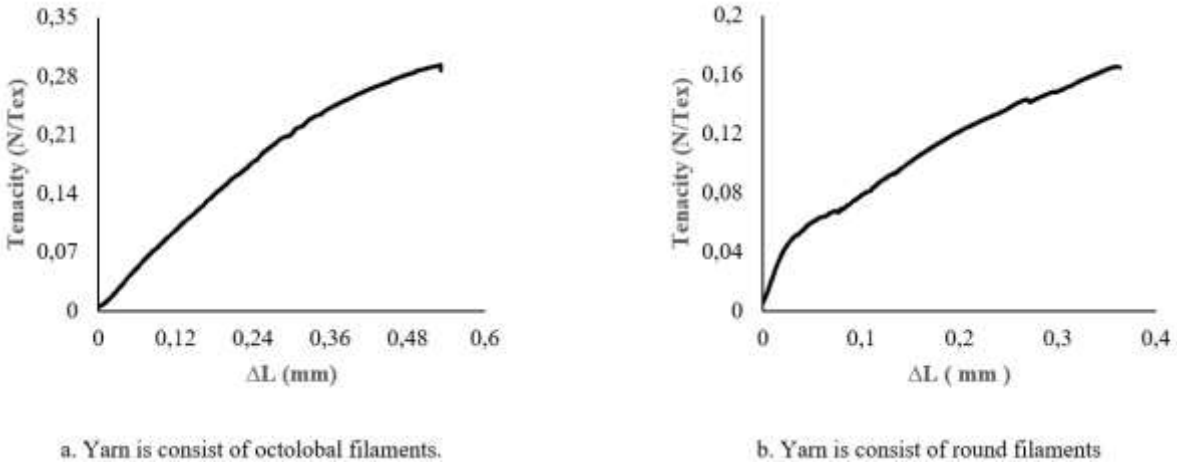
$$c = A * \rho \quad (2)$$

$$TVf = Vf / Vy \quad (3)$$

Table 2. Filaments density linear density, volume fraction results.

Filament	Density (g/cm^3)	Filament Quantites for yarn (piece)	Volume Fraction (V_f/V_y)
Octolobal filament	1,30	144	0,73
Round filament	1,47	270	0,54

The breaking force and elongation test specification is DIN EN ISO 2062 gives force-strain curve and stress-strain curve is obtained corresponding the tenacity-strain which is specified for yarn. Test equipment is ZWICK provide all data with the graph in Figure 2 and enables to determine young moduli E with equation 4 that contains stress (σ), strain (Ɛ).



a. Yarn is consist of octolobal filaments.

b. Yarn is consist of round filaments

Figure 2. Yarn tensile – elongation test graph, test specification is DIN EN ISO 2062

The other material property is shear moduli and can be obtained with equation 5 presence of the young moduli. Poisson ratio is resulted in equation 6, nevertheless yarn is assumed unidimensional material that is why values of poisson should be predicted between -1 and 1/2. Table 3 presents yarn mechanical properties that mentioned above.

$$E = \sigma / \varepsilon \quad (4)$$

$$G = E / (2\,(1 + v)) \quad (5)$$

$$v = -\varepsilon y / \varepsilon x \quad (6)$$

Table 3. Yarn mechanical properties

Yarn	Young Moduli (E), Mpa	Shear Moduli (G), Mpa	Poisson Ratio (v)
55 tex, friction texturized	424,60	147,4	0,44
110 tex, air texturized	264,01	101,5	0,30

Coefficient of friction, yarn to yarn is specified with ASTM D 3412 and results in for the 55 tex friction textured yarn is 0,82, 110 tex air texturized yarn is 0,83.

2.2 Woven property and pattern

In general definition that the fabric is constructed of yarns as warp and weft intersections at 90° and parallel each other at 180° except special conditions. Intersections of unidimensional yarn as warp and weft transform fabric two dimensional and consequently weaved in numerous pattern. Friction of filaments provide to be in form of yarns and afterwards fabric.

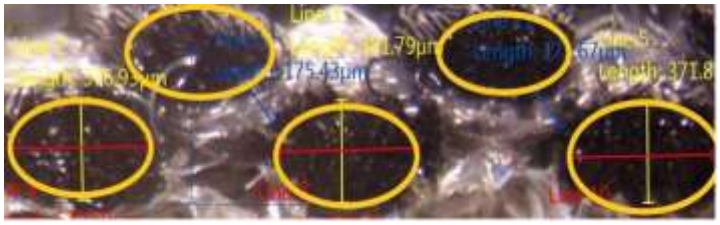
The twill and plain weave are continually used as upholstery in vehicle. Hence abrasion reaction to subject to external multi direction forces and simplicity in processability is presented in this study in scope of weaving pattern as plain with air texturized yarn and twill 2/2 with friction textured yarn are modelled geometrically to do so FEA analysis.

The warp and weft densities and its cross angles are shown in Table 4.

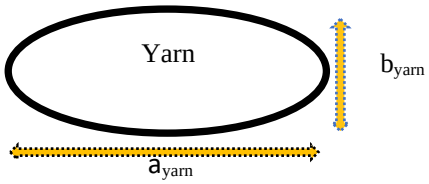
Table 4. Yarn densities and cross angles

Fabric weave parameters	Warp density (piece / cm)	Weft density (piece / cm)	Crossing angle between warp and weft (°)
Twill 2/2 (friction textured yarn)	26	16	90
Plain (air texturized yarn)	14	11	90

The yarn cross section into fabric construction is shaped elliptical than through round in Figure 3a. The diameter will be defined with two items as major (symbolled with a) and minor (symbolled with b) in case elliptical geometry in Figure 3b.



a. Elliptical yarn diameter in image of microscope



b. Minor and major diameter of yarn

Figure 3. Yarn geometry in fabric construction

Hence elliptical geometry of yarns brings out the flattening ratio that is indicated as R_{ab} and equals to a_{yarn}/b_{yarn}. The subscript of yarn for a and b are transformed as being warp and weft and calculated volume fractions are existed as well in Table 5.

Table 5. Minor and major diameter of filaments, flattening ratio, volume fraction inside fabric construction

Yarn diameters inside fabric consturction	a_{warp} mm	b_{warp} mm	R_{ab}, warp	Volume Fraction (V_f/V_y)	a_{weft} mm	b_{weft} mm	R_{ab}, weft	Volume Fraction (V_f/V_y)
Twill 2/2 (friction textured yarn)	0,28	0,24	1,15	0,795	0,48	0,14	3,43	0,79
Plain (air texturized yarn)	0,57	0,30	1,90	0,53	0,62	0,27	2,29	0,65

The yarns' volume fraction ratio that lied up weave as a result of warp and weft density which tends by jamming and settlement, is higher than free form of yarn. Equation 7 provides the value of a_{yam} with a relation among volume fraction, flattening constant, dimension of yarn and filaments by interactions in KTEX software. Elliptical area formula is enabled to obtain b_{yarn} consequently.

$$A_{yarn} = \sqrt{} (R_{ab} * \text{Filamemt Quantity} / (V_f / V_y)) * D_{filament} \quad (7)$$

The yarn quantity in direction of warp and weft in 10 mm is mentioned as the yarn density and restricts a_{yam}. The sum of major diameters of warp and weft yarns horizontally should be equal to 10 mm with total space between yarns. Spacing between the yarns depends on the yarn density as well. KTEX regulates that spacing between two weft yarns should be equal or higher than minor diameter of warp, reversely is available too. Vertically yarn minor diameter is significant parameter to determine to thickness of weave as the dimension which is affected by yarn crimps that are occurred with volume fraction and density of warp and weft. In this study the thickness of Twill 2/2 and Plain weaves have been measured and crimp height is computed in terms of KTEX software in allowed way that is identified in next title.

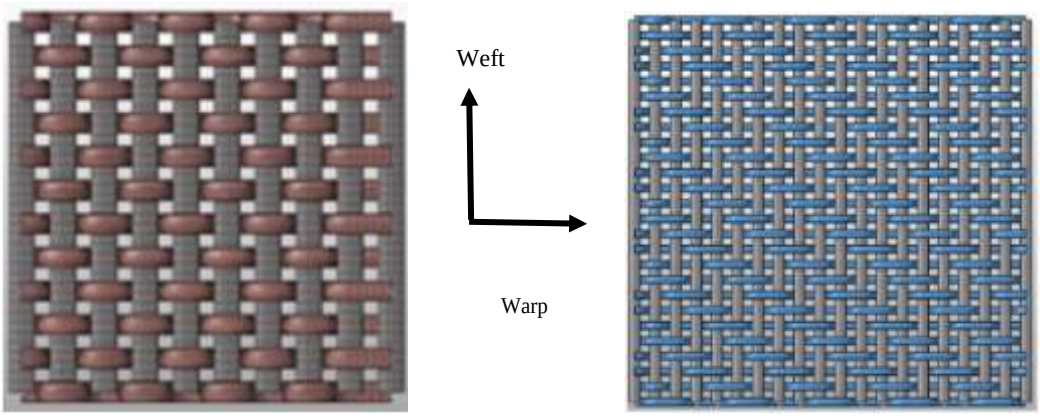
2.3 Geometric modelling of weave with yarn

KTEX is modelling the weave with macroscopic mechanical properties that are given in tables above. It has been developed by CEDREM and graphic interface is coded in Tcl/Tk, calculation of the equivalent mechanical properties is coded in C language. Studying with another complex weaves and knits is possible for example like satin, interlock…etc. The inputs except spacing between warp and yarn are given in previous chapter. Table 6 that is following contains the spacing of yarns and pattern code (array).

Table 6. The spacing of yarns and pattern codes.

Yarn spacing into fabric construction and pattern code	Unit spacing between warp yarns mm	Unit spacing between weft yarns (in xy direction) mm	Unit spacing between weft yarns (along to thickness direction) mm	Pattern code (array)
Twill 2/2 (friction textured yarn)	0,187	0,310	0,27	0-0-1-1 0-1-1-0 1-1-0-0 1-0-0-1
Plain (air texturized yarn)	0,155	0,321	0,27	0-1-0-1 1-0-1-0 0-1-0-1 1-0-1-0

With all input files material chart of two weaves have been set in interface. KTEX assumes two hypothesis and one of them is to consider the yarn cross sections as elliptical, the second one is to consider to ratio of minor and major as depending only its material. Running software generates twelve output files with graphic interface so to process in FEA software. Figure 4 demonstrate the weaved structure of plain and twill 2/2.



a. Plain weave pattern

c. Twill 2/2 weave pattern

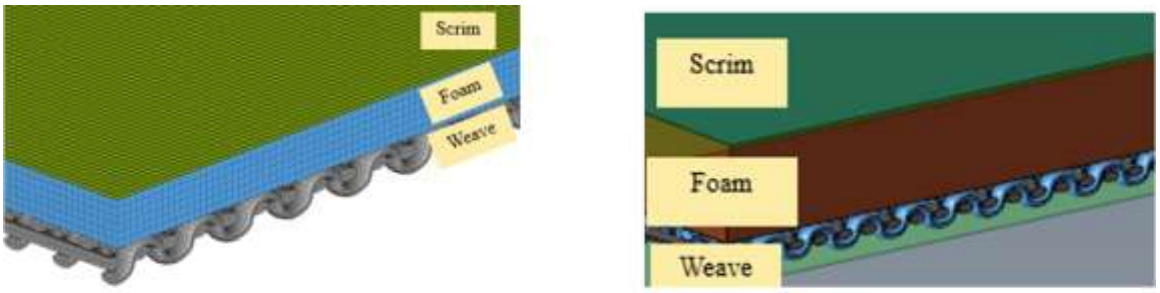
b. Cross sections of Plain weave

d. Cross section of Twill 2/2 weave

Figure 6. KTEX Geometrical models of Plain and Twill 2/2

2.4 Laminated fabric modeling with subcomponents in FEA

Weaved material that is called face fabric is laminated with flame so to adhere PU foam and PA circular knitted scrim in actual process. The scrim and the foam are tested with the standard of TSL 2104G tensile strength, stress-strain datums leads to identify mechanical properties for inputs of laminated conditions. The subcomponents have been virtual modelled as 3 layered and assumption that cannot be peeled from each other in FEA. Figure 7 is modelling of laminated construction besides the foam is a solid element and scrim is a shell. 3D composite and 6 – element cross section meshing is chosen for the frame of model and material chart is gathered in MAT/LAW12 to perform tensile analysis. FEA meshing is presented in Figure 7 as well.



a. Laminated fabric,Plain weave – foam - scrim

c. Laminated fabric, Twill 2/2 weave – foam -scrim

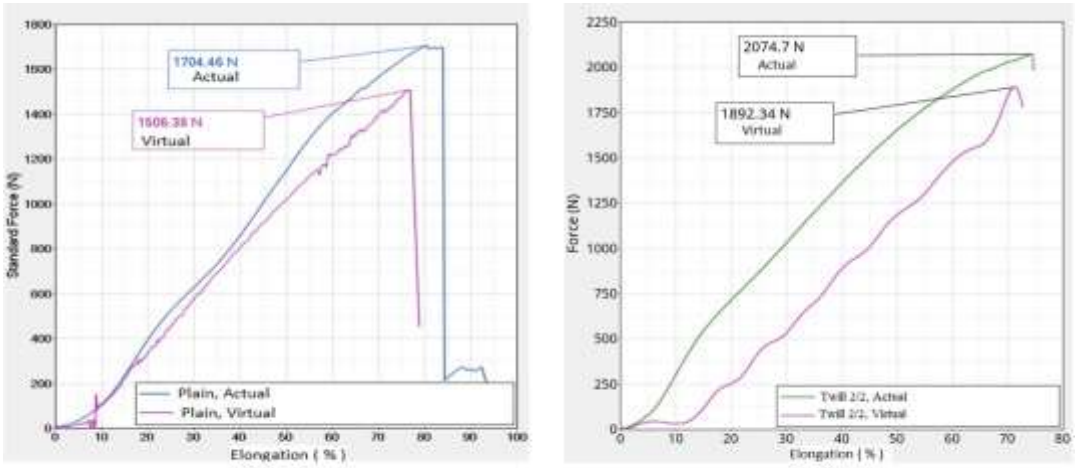
Figure 7. FEA Model of **l**aminated weave with foam and scrim

In laminated fabric, the foam and the scrim are modelled in joint nodes and it is assumed that not to be any shearing between layers. On the other hands the fabric and the foam contacts have been identified as tied nodes and ideal adherence exist between layers is the assumption.

2.5 Tensile strength analysis in FEA

The fabric properties as being textile material are anisotropic and nonlinear that means deformable in low stress simply. Non homogenous material brings to complexity in modelling and simulation. In FEA analysis laminated fabric is modelled to be elastic and linear, orthotropic.

Tensile strength test is TSL 2104G includes 1,96N pre-stress, 200 mm/min. stress speed applying to dimension of 50*200 mm sample in uniaxial direction. The actual test has been performed in ZWICK test equipment and quantified the numerical data of breaking force and obtained graphic of curves that belongs to force - elongation. The test method has been defined in FEA and processed the test condition in a manner of test condition, in a consequence the results of actual and virtual tests have been compared in Figure 8.



a. Laminated plain fabric

b. Laminated Twill 2/2 fabric

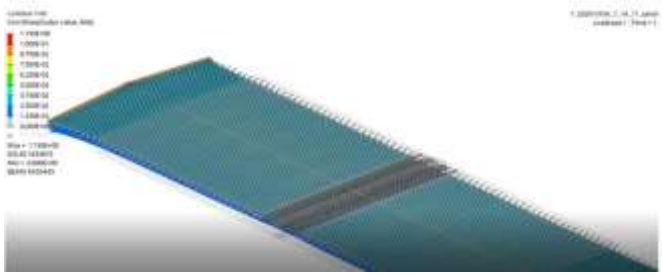
Figure 8. Tensile test results and graphs of force – elongation for laminated plain fabric and laminated twill 2/2

Real weave construction subjected to tensions in all stages of production in order to processibility. The tensions lead to the yarns to be arranged evenly into weave structure and are compacted to gain attitude of fabric. No doubt to virtual studies demands a compaction step to be more realistic in warp and weft direction and along the thickness, too. In this study compaction is initiated with set off the test starting.

The breaking forces of virtual test is lower than actual test for plain and twill 2/2 fabric as laminated. The plain fabric breaking test for actual results in 1704,46N, virtual test results in 1506,38N and the twill fabric breaking test for actual results in 2074,47N, virtual test results in 1892,34N. Force – strain curve for actual and virtual are resembled. The initial of curves are not exactly compatible. The virtual curves have some fluctuation.

Breaking line in virtual sample is occurred in middle of samples as similar as actual test, nevertheless linearity through the breaking line can be discussed as the virtual test demonstrated in Figure 9. The breaking line placement can vary in specimen in period of testing.

a. Breaking line of actual plain fabric in the middle of specimen



b. Breaking line of virtual plain fabric in the middle of specimen

c. Breaking line of virtual twill 2/2 fabric in the middle of specimen

Figure 9. Breaking line placement in actual test specimen and virtual specimen for plain and twill 2/2 fabric

3. CONCLUSION

In this study the yarns that contains octolobal and round filaments have been studied for simulation of deformation with tensile strength. The software KTEX accomplishes to generate of weave with inputs of yarn parameters, subsequently it can be improved with theories which are studied by Pierce and the others. Yarn parameters is determined by tensile strength test datums and computing material properties as young moduli, shear moduli and poisson ratio. Besides to be nonlinear and anisotropic material for textile, determined value of properties can be deviate in different bulk samples that belongs to one production batch in real. Virtual model of fabric is created with constant material properties homogeneously although actual fabric is not. Therefore, simulation's findings may differ with actual results and deviation tolerances can be clarified with more studies for the specific weave.

The virtual test results in lower than actual for the plain and twill 2/2 laminated fabric and deviation are 10% and 8,8%. Force – elongation curve for the plain fabric is more similar according to twill 2/2. The initial curve of virtual test differs due to compaction step. Although deviation from actual condition, virtual tests conform with actual results in high rate.

Tensile strength simulation and available results can encourage to simulate of deformation modes as tearing and abrasion test.

ACKNOWLEDGEMENTS

This work has been carried out with collaboration of MARTURFOMPAK INTERNATIONAL through doctorate thesis "Investigation of Woven Fabric Deformation in Car Seat Cover Form" is in progress.

ÖZET

Manifold malzemesi olarak tercih edilen demir esaslı alaşım grupları çalışma sıcaklıklarına göre sınıflandırılır. Yüksek sıcaklık uygulamalarında östenitik matriksli dökme paslanmaz çelik ve dökme demirler tercih edilirken nispeten düşük sıcaklıklarda ferritik matriksli olanlar kullanılır. Artan sıcaklık talepleri nedeniyle östenitik alaşımların dizaynı önem kazanmasına rağmen, yeterli oksidasyon direnci ve yüksek sıcaklık mukavemeti sağlayan ferritik matriksli yüksek silisyum ve molibden içerikli küresel grafitli dökme demirler (SiMo) düşük maliyeti ve dökülebilirliğiyle hala tercih edilmektedir. Bu çalışmada, egzoz manifold malzemesi olarak geliştirilmiş, silisyum içeriği yüksek, Nb ve W katkılı, 6Si1Nb (3.0 C, 6 Si, 1 Nb ağ.%) ve 6Si1W (3.0 C, 6 Si, 1 W ağ.%) alaşımlarının mikroyapısal ve ısıl özellikleri ticari olarak kullanılan SiMo ferritik sünek dökme demir ile karşılaştırılmıştır. Mikroyapısal karakterizasyon çalışmaları, tüm dökme demirlerin esas olarak ferrit, küresel grafit ve kompozisyona bağlı olarak değişen bileşimde karbürlerden oluştuğunu göstermiştir. Termal analiz çalışmaları sonucunda ise SiMo alaşımının en düşük A_1 sıcaklığına (825 °C) sahip olduğu tespit edilmiş, artan silisyum miktarı sonucunda A_1 sıcaklıklarının yaklaşık 120 °C artarak 6Si1Nb ve 6Si1W döküm alaşımları için sırasıyla 951 °C ve 946 °C sıcaklık değerlerine ulaştığı belirlenmiştir. Deneysel çalışmalar kapsamında elde edilen sonuçlar, geliştirilen alaşımların özellikle yüksek sıcaklıklarda egzoz manifoldları için aday malzemeler olabileceğini göstermiştir.

Anahtar kelimeler: Egzoz manifoldu, SiMo dökme demir, alaşım dizaynı.

1. GİRİŞ

Otomotiv üreticileri gün geçtikçe tolere aralığı daralan emisyon standartlarına uyum sağlayacak, artan yüksek motor gücü ihtiyacını karşılayacak ve yakıt tasarrufuna katkı sağlayacak tasarımlar ile bu tasarımları mümkün hale getirecek yeni nesil malzemelere ihtiyaç duymaktadır. Bu ihtiyaçlar doğrultusunda motor sistemi, taşıyıcı unsurlar ve egzoz sistemi gibi bileşenler için yeni teknolojiler ve yeni malzemeler geliştirilmektedir [1-5]. Örneğin egzoz emisyon standartları sonucu egzoz sisteminde gaz emisyonunu azaltan tasarımlar geliştirilirken [6], artan motor gücü ihtiyacı sonucu turboşarjör sistemleri ile yüksek sıcaklık koşullarına uygun egzoz manifoldu tasarımları ve malzemeleri geliştirilmiştir [7]. Yapılan çalışmalar artan motor gücü ile yanma sonucu oluşan egzoz gazının 1000 °C sıcaklığa ulaşabildiğini göstermektedir. Gaz sıcaklığındaki bu artış sonucu özellikle motor bloğu ile temasta çalışan egzoz manifoldu yüksek termal ve termomekanik gerilmelere maruz kalmaktadır [8]. Egzoz manifoldunun bu koşullar altında uzun süre çalışabilmesi için yüksek sıcaklık mukavemeti, yüksek sıcaklık korozyon direnci, mikroyapısal ve fiziksel özelliklerin kararlılığı, ısıl şok direnci ve termomekanik yorulma direnci sağlayan uygun alaşım dizaynına sahip alaşımlardan üretilmesi gerekmektedir [9, 10].

Egzoz manifoldu olarak tercih edilen demir esaslı alaşım grupları servis sıcaklıklarına göre sınıflandırılır. Yüksek sıcaklık uygulamalarında östenitik matriksli dökme paslanmaz çelikler ve dökme demirler tercih edilirken nispeten düşük sıcaklıklarda ferritik matriksli olanlar kullanılır [11-13]. Artan sıcaklık talepleri nedeniyle östenitik alaşımların dizaynı önem kazanmasına rağmen, yeterli oksidasyon direnci ve yüksek sıcaklık mukavemeti sağlayan ferritik matriksli yüksek silisyum ve molibden içerikli küresel grafitli dökme demirler (SiMo) düşük maliyeti ve dökülebilirliğiyle hala tercih edilmektedir [14-16]. Yapılan çalışmalar ferritik matriksli dökme demir ve paslanmaz çeliklerin östenitik matriksli olanlara göre daha yüksek ısıl iletkenliğe, daha düşük ısıl genleşme katsayısına ve daha yüksek elastik modüle sahip olduğunu göstermiştir [17]. Yüksek ısıl iletkenlik manifoldun daha hızlı soğumasını dolayısıyla çıkılan sıcaklığa daha kısa süre maruz kalmasını sağlar [18]. Çıkılan sıcaklığın egzoz sistemi üzerindeki etkisini azaltmak amacıyla Volkswagen, 1800 cc hacimli motorlarında egzoz manifoldlarını su soğutmalı olarak tasarlamıştır [19]. Düşük ısıl genleşme katsayısı ise ısınma-soğuma çevrimi sırasında oluşan hacimsel değişim (genleşme/büzülme) nedenli çatlakların oluşumunu engeller. Egzoz manifoldunda oluşan çatlaklar yolcu kabinine CO salınımına neden olabilir. Reuters ve CNBC'nin 13 Ekim 2017 tarihli haberine göre Ford F150 araçlarında egzoz

sisteminde oluşan sorunlar nedeniyle yolcu kabinine CO salınımı gerçekleşmiş ve bu nedenle Ford F150 araçlarını geri toplatmıştır [20, 21]. Ferritik matriksin sağladığı bu yüksek ısıl ve mekanik özellikleri ile daha yüksek sıcaklıklarda kullanılabilmesi ancak ferrit-östenit dönüşüm sıcaklığı olan A_1 sıcaklığının arttırılarak ferrit fazının daha yüksek sıcaklıklarda kararlı hale getirilmesi ile mümkündür. Bu sıcaklık artışı ise ferritik sünek dökme demir kompozisyonlarının Al, Si, Cr, Nb, W gibi alaşım elementleri ile modifiye edilmesi ile sağlanabilmektedir [1, 13, 17, 22-23].

Bu çalışmada yüksek silisyum miktarına sahip, niyobyum ve tungsten alaşım elementlerinin ilavesi ile geliştirilmiş 6Si1Nb ve 6Si1W ferritik sünek dökme demirlerin mikroyapısal ve ısıl özellikleri incelenmiş ve elde edilen sonuçlar ticari egzoz manifoldu malzemesi olarak kullanılan SiMo sünek dökme demirin özellikleri ile karşılaştırılmıştır.

2. DENEYSEL ÇALIŞMA

Deneysel çalışma kapsamında kum kalıba döküm yöntemi ile üretilmiş ticari SiMo ve geliştirilen 6Si1Nb ve 6Si1W alaşımlarının mikroyapısal ve ısıl özellikleri karakterize edilmiştir. Tüm alaşımlar ASTM A 536 - 84 standardına göre kum kalıba döküm yöntemi ile Y blok olarak üretilmiştir. Ticari SiMo alaşımı yerli bir firmadan temin edilmiş olup, geliştirilen alaşımların dökümü için 25 kg kapasiteli 35 KW Inductotherm indüksiyon ocağı kullanılmıştır. Alaşımların kimyasal kompozisyonu optik emisyon spektrometresi (OES, Foundary Master) kullanılarak belirlenmiştir. Deneysel çalışma kapsamında kullanılan alaşımların kimyasal kompozisyonları Tablo 1'de verilmiştir. Tabloda ticari SiMo alaşımı için SiMo kodu kullanılırken, geliştirilen 6Si1Nb ve 6Si1W alaşımları sırasıyla SiNb ve SiW olarak kodlanmıştır.

Tablo 1. Döküm alaşımlarının kimyasal kompozisyonları (ağ.%)

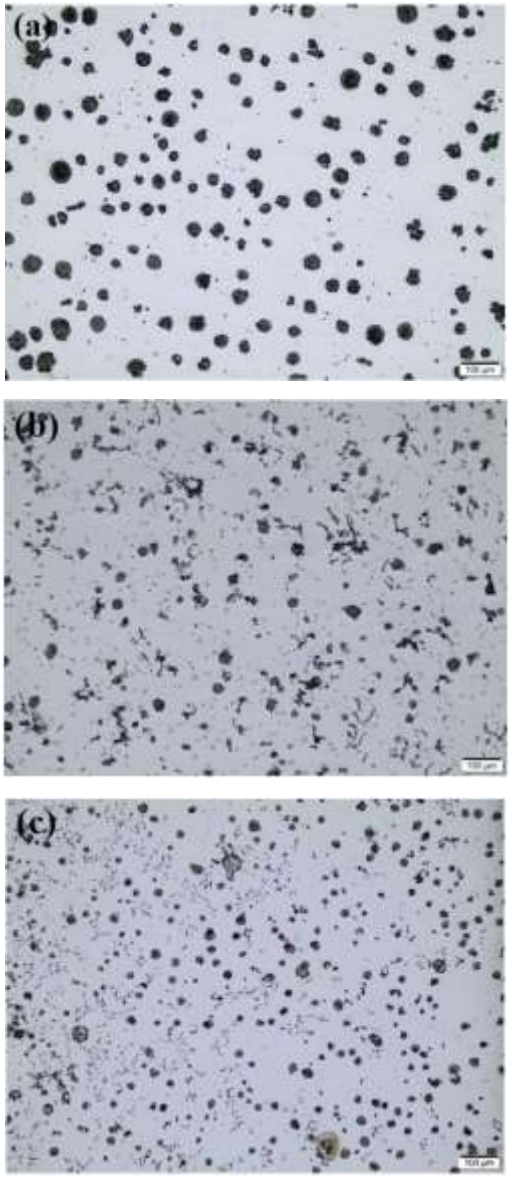
Alaşım	C	Si	Nb	W	Mo	Mg
SiMo	3,42	3,62	-	-	0,81	0,04
SiNb	3,08	6,04	1,06	-	-	0,08
SiW	3,04	6,09	-	0,99	-	0,08

Döküm alaşımları mikroyapısal incelemeler ve termal analiz yöntemleri ile karakterize edilmiştir. Mikroskobik incelemeler için alaşımlar metalografik yöntemlerle hazırlanmış ve Nital (% 3 NHO_3) ile dağlanmıştır. Alaşımların mikroyapıları ışık mikroskobu (IM, Olympus BX41M-LED) kullanılarak karakterize edilmiştir. Alaşımlarda bulunan mevcut fazlar, Cu-Kα radyasyonu ve 1.0 °/dak tarama hızı kullanılarak X-ışını kırınım yöntemi (XRD, Rigaku Ultima +) ile tanımlanmıştır. Belirlenen fazların miktarı, ISO 945-2'ye göre görüntü analiz yöntemi (Leica Las V4.12) ile ölçülmüştür. Termal analiz çalışmaları, Diferansiyel Termal Analiz cihazı (DTA, Netzsch STA 409 PG Luxx) kullanılarak gerçekleştirilmiştir. Bu işlem sırasında numuneler 5 °C/dak ısıtma hızı ile 1460 °C' ye ısıtılmış, bu sıcaklıkta 5 dakika tutulmuş ve sonra 5 °C/dak hız ile oda sıcaklığına soğutulmuştur.

3. BULGULAR VE TARTIŞMA

3.1. Mikroyapısal Karakterizasyon

Dökme demirlerin içerdiği grafit miktarının ve grafit morfolojisinin dökme demirlerin mekanik ve ısıl özellikleri üzerine etkisi bulunmaktadır [24]. Alaşımların grafit miktarının ve morfolojisinin belirlenebilmesi için alaşımlar parlatılmış konumda ışık mikroskobu ile incelenmiş ve elde edilen mikroyapılar Şekil 1'de verilmiştir. Görüntü analizlerine göre SiMo, SiNb ve SiW alaşımları sırasıyla 6,4 ± 0,1 (% alan), 6,4 ± 0,4 (% alan) ve 7,4 ± 0,4 (% alan) grafit içeriğine sahiptir. Yapılan çalışmalar, silisyumun grafit kristalinde yer alarak çekirdeklenmesini desteklediğini ve silisyum miktarındaki artışın grafit nodül sayısını arttırdığını göstermiştir [25, 26]. Ayrıca niyobyumun grafit miktarını azaltıcı etkisi Bedolla-Jacuindde ve arkadaşlarının yaptığı çalışmada belirtilmiştir [27]. Elde edilen verilere göre SiNb alaşımında silisyum miktarının yüksek olmasına rağmen, SiW ile SiMo alaşımlarına benzer aralıkta grafit miktarına sahip olmasının Nb ilavesinin grafit miktarına azaltıcı yönde etki etmesinden kaynaklandığını söylemek mümkündür.



Şekil 1. Alaşımların grafit morfolojilerini gösteren IM görüntüleri (a) SiMo, (b) SiNb ve (c) SiW

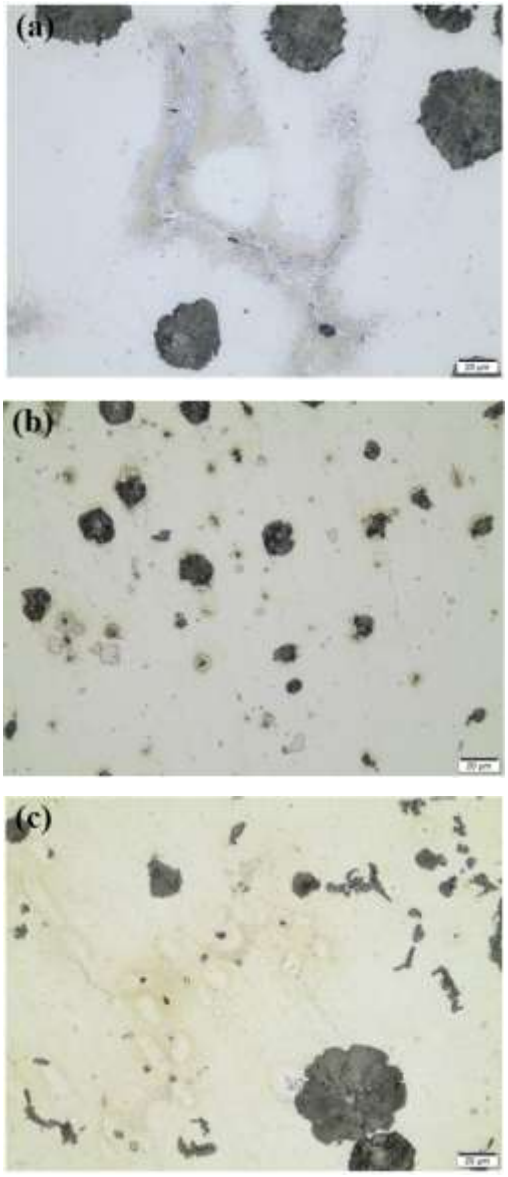
Grafit morfolojisine ilişkin görüntü analizi ile elde edilen veriler Tablo 2'de gösterilmiştir. Tüm alaşımlarda kısmi küresel grafit morfolojisi baskın olsa da, silisyum miktarının artması ile vermiküler morfolojinin (III) arttığı ve küreselliğin (V ve VI) azaldığı görülmektedir. Özellikle Nb ilavesi sonucu SiNb alaşımında vermiküler grafit morfolojisi oldukça yüksek bir değere ulaşmıştır. Yapılan çalışmalar, silisyum miktarındaki artışın soğuma hızını azaltarak grafitin küreselliğinin azalmasına ve niyobyum ilavesinin de vermiküler grafit miktarının artmasına yol açtığını göstermiştir [25-27].

Tablo 2. Grafit morfolojisi için DIN EN ISO 945-2 tarafından belirlenen görüntü analizi sonuçları (alan%).

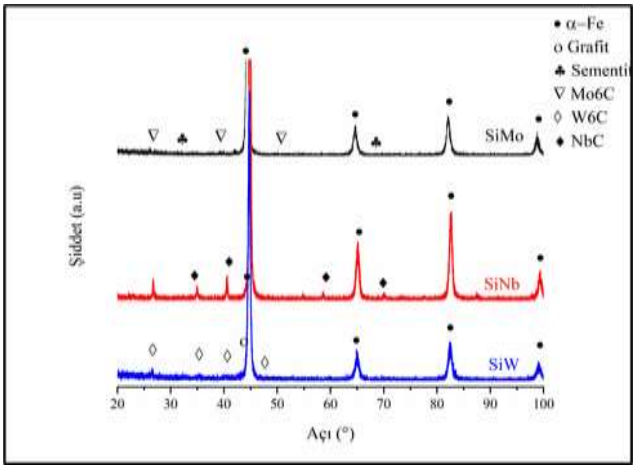
Alaşım	III	V	VI	Diğer
SiMo	7,2	55,2	35,5	2,1
SiNb	21,1	49,9	21,9	7,1
SiW	9,5	37,6	45,5	7,4

Alaşımların mikroyapısal bileşenlerinin belirlenebilmesi için alaşımlar dağlanmış konumda IM ile incelenmiş ve mikroyapı görüntüleri Şekil 2'de verilmiştir. SiMo alaşımına ait mikroyapı görüntüsünde ferritik matriks içerisinde küresel grafit (G) ve hücre sınırlarında çökelmiş ötektikvari karbür ile bu karbürün etrafında granular sementit içeren perlitik (P) yapınun varlığı görülmektedir (Şekil 2a). Niyobyum içeren alaşımın mikroyapısında ise temel olarak matriks

fazına gömülü küresel grafitler ve fasetli karbür çökeltileri yer almaktadır (Şekil 2b). SiW alaşım mikroyapısı ise küresel grafitlerin yanı sıra hücre sınırlarında çökelmiş ötektik benzeri karbürlerden oluşmaktadır (Şekil 2c). Tüm alaşımların faz bileşenlerinin belirlenebilmesi için XRD analizleri yapılmış ve elde edilen sonuçlar Şekil 3'te verilmiştir. XRD sonuçlarına göre tüm alaşımlarda ferritik matriks ve grafit fazları bulunmakta olup, karbür yapıları SiMo, SiNb ve SiW için sırası ile Mo_6C, NbC ve W_6C olarak belirlenmiştir. Ayrıca SiMo alaşımı perlitik yapının varlığını gösteren sementit pikine sahiptir. Bilindiği üzere silisyum, sementit çökelmesini geciktirmektedir [28] ve yapılan çalışmalar, küresel grafitli dökme demirlerin katılaşması sırasında silisyumun hücresel büyüme boyunca ters segrege olarak hücre sınırlarında azaldığını bu nedenle hücre sınırlarında sementit çökelmesinin oluşabileceğini göstermiştir [29]. Ancak silisyum miktarının ağ.% 6 olduğu SiW ve SiNb alaşımlarında tüm hücre boyunca çözünen silisyum miktarının artması, hücre sınırlarında sementit çökelmesini engellemiştir.



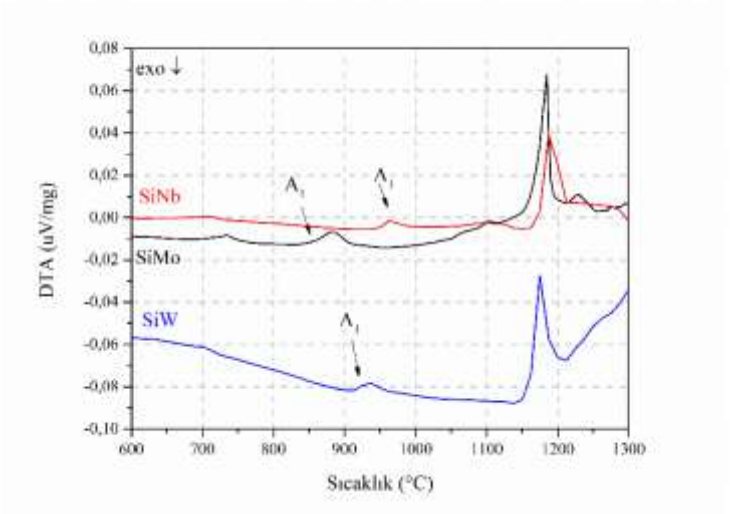
Şekil 2. Alaşımlara ait IM mikroyapı görüntüleri (a) SiMo, (b) SiNb ve (c) SiW



Şekil 3. Alaşımlara ait XRD paternleri

3.2. Termal Analiz Verilerinin Değerlendirilmesi

Alaşımların maksimum çalışma sıcaklıkları olarak nitelendirilen ferrit-östenit faz dönüşümümün gerçekleştiği A_1 sıcaklıkları DTA analizleri belirlenmiş olup Şekil 4'te verilen termogramlar üzerinde işaretlenmiştir. SiMo alaşımına ait A_1 sıcaklığı 825 °C iken, geliştirilen SiNb ve SiW alaşımlarının A_1 sıcaklıkları ise sırası ile 951 ve 946 °C olarak belirlenmiştir. Gonzales-Martinez ve arkadaşları yaptıkları çalışmada artan silisyum miktarı ile ferrit fazının daha yüksek sıcaklıklarda stabil olabileceğini ve hatta katılaşma sırasında sıvıdan ferrit çekirdeklenmesinin gerçekleşebileceğini göstermişlerdir [30]. Geliştirilen alaşımların silisyum miktarının SiMo alaşımına göre yüksek olması ile bu alaşımlarda A_1 sıcaklığı yaklaşık 120 °C artarak oldukça yüksek değerlere ulaşmıştır. Karbür yapıcı elementlerin (Nb ve W) ilavesi sonucu A_1 sıcaklığı üzerinde önemli değişim gözlenmemiştir.



Şekil 4. Alaşımların ısıtma koşulunda A_1 sıcaklıklarını gösteren DTA eğrileri

SONUÇLAR

Bu çalışmada, egzoz manifold malzemesi olarak geliştirilmiş yüksek silisyum bileşimine (6 ağ.%) sahip, Nb ve W içeren 6Si1Nb (3.0 C, 6 Si, 1 Nb ağ.%) ve 6Si1W (3.0 C, 6 Si, 1 W ağ.%) alaşımlarının mikroyapısal ve ısıl özellikleri ticari olarak kullanılan SiMo ferritik sünek dökme demir ile karşılaştırılmıştır. Mikroyapısal karakterizasyon çalışmalarına göre tüm dökme demirler esas olarak ferrit, küresel grafit ve kompozisyona bağlı olarak değişen bileşimde karbürlerden oluşmaktadır. Bu karbürlerin SiMo alaşımında molibdence zengin M_6C, 6Si1Nb alaşımında niyobyumca zengin NbC ve 6Si1W alaşımında tungstence zengin M_6C olduğu belirlenmiştir. Termal analiz çalışmaları sonucunda ise SiMo alaşımının en düşük A_1 sıcaklığına (825 °C) sahip olduğu tespit edilmiş, artan silisyum miktarı sonucunda 6Si1Nb ve 6Si1W döküm alaşımlarının A_1 sıcaklıkları ise sırasıyla 951 °C ve 946 °C olarak belirlenmiştir. Deneysel çalışmalar kapsamında elde edilen sonuçlar geliştirilen alaşımların özellikle yüksek sıcaklıklarda egzoz manifoldları için aday malzemeler olabileceğini göstermiştir.

TEŞEKKÜR

Bu çalışma Kocaeli Üniversitesi Bilimsel Araştırma Projeleri Birimi tarafından 2017/118 no'lu proje ile desteklenmiştir. Çalışmaya olan katkılarından dolayı Kocaeli Üniversitesi Bilimsel Araştırma Projeleri Birimi'ne teşekkür ederiz.

ÖZET

Günümüzde artan motor gücü talepleri, motor bloklarında gerçekleşen yanma sonucu oluşan egzoz gaz sıcaklıklarının artmasına neden olmaktadır. Oluşan yüksek sıcaklık ve oksitleyici gaz atmosferi koşullarında ticari egzoz manifoldu olarak kullanılan SiMo ferritik sünek dökme demirin maksimum kullanım sıcaklığı ve oksidasyon direnci yetersiz kalmaktadır. Bu nedenle maksimum çalışma sıcaklığı yükseltilmiş, oksidasyon direnci geliştirilmiş düşük maliyetli alaşımların dizaynı gerekli hale gelmiştir. Bu kapsamda, Si, Al, Cr gibi alaşım elementlerinin kullanılması ile daha yüksek kullanım sıcaklıklarında mekanik stabilite sağlayan ve koruyucu oksit tabakaları oluşturabilen alaşımların elde edilmesi mümkün olabilmektedir. Bu çalışmada, alaşım dizaynı ile geliştirilmiş 6Si1Nb (3.0 C, 6 Si, 1 Nb ağ.%) ve 6Si1W (3.0 C, 6 Si, 1 W ağ.%) yeni sünek dökme demir bileşimlerinin oksidasyon davranışları incelenmiş ve ticari SiMo sünek dökme demirin oksidasyon özellikleri ile karşılaştırılmıştır. Deneysel çalışma kapsamında bir yüksek sıcaklık fırınında, 800 °C sıcaklıkta 24 saat boyunca atmosferik şartlarda oksidasyon testleri gerçekleştirilmiştir. Testler sonrası oksit tabakaları metalurjik analizlerle karakterize edilmiştir. Elde edilen veriler, geliştirilen alaşımların SiMo dökme demire göre daha ince oksit tabakasına, dolayısı ile daha yüksek oksidasyon direncine sahip olduğunu göstermiştir.

Anahtar Kelimeler: Egzoz manifoldu, SiMo dökme demir, alaşım dizaynı, oksidasyon.

1. GİRİŞ

Sünek dökme demirler nispeten düşük maliyetleri ve yeterli mekanik, yüksek sıcaklık oksidasyon direnci özellikleri nedeniyle otomotiv endüstrisinde egzoz manifoldu gibi yüksek sıcaklığa ve oksidasyona maruz kalan parçalarda yaygın bir şekilde kullanılmaktadır [1-3]. Üreticilerin araçları hafifletme çalışmaları sonucunda hafifletilmiş döküm parçalara olan yönelim artmış olsa da, artan motor gücü ihtiyacı nedeniyle özellikle yüksek sıcaklığın oluştuğu egzoz manifoldu gibi parçalarda demir esaslı alaşımların kullanılması devam etmektedir [4-6]. Bu süreçte demir esaslı parçaların ince kesitli üretilmesi ile hafifleştirme çalışmalarına destek verilebilmektedir [7]. Sünek dökme demirler çeliklere göre nispeten düşük yoğunlukları nedeniyle ince kesitli parça üretimi mümkün olduğunda ağırlık kazancı sağlayabilmektedir. Sünek dökme demirlerin yüksek sıcaklık oksidasyon direnci arttırıldığında daha ince kesitli parçaların kullanılması mümkün olabilmektedir [8].

Oksidasyon direnci özellikle artan motor gücü nedeni ile motor bloklarında oluşan sıcaklığın artması sonucu daha da önemli bir özellik haline gelmektedir. Yapılan çalışmalar motor bloklarında gerçekleşen yanma sonucu oluşan egzoz gazının sıcaklığının 1000 °C'ye ulaşabildiğini göstermiştir [9-13]. Yanma sonucu oluşan egzoz gazı NO_x, SO_x, CO, CO_2 ve H_2O içermesi nedeniyle yüksek oranda korozif/oksidatif özelliğe sahiptir ve sıcaklığın artması sonucu gazın oksitleyici özelliği daha da artmaktadır [13]. Yapılan çalışmalar motor bloğu ile temas halinde çalışan egzoz manifoldlarının uzun süre yüksek sıcaklığa ve oksidatif ortama maruz kaldığını, oksidasyon nedenli malzeme kaybının arttığını ve ayrıca ısıl yorulma ile oluşan çatlakların oksidasyon nedenli olarak hızlıca ilerlediğini göstermiştir [14, 15]. Manifoldun bu koşullar altında çalışabilmesi için, yüksek oksidasyon direnci ve yüksek sıcaklıkta mekanik stabilite göstermesi gerekmektedir [16, 17]. Yapılan çalışmalar bu koşullar altında, ticari egzoz manifoldu olarak kullanılan SiMo ferritik sünek dökme demirin maksimum kullanım sıcaklığı ve oksidasyon direncinin yetersiz kaldığını ortaya koymaktadır [17, 18]. Bu nedenle termal ve mekanik gerilmelerin oluştuğu bir oksidatif ortamda düşük maliyetli ve hafifleştirmeye katkı sağlayabilecek yeni alaşımların geliştirilmesi gereklidir. Yeni alaşımların geliştirilmesinde, daha yüksek kullanım sıcaklıklarında mekanik stabilite sağlayan ve koruyucu oksit tabakaları oluşturabilen Si, Al, Cr gibi alaşım elementleri dikkate alınır [16-19]. Dökme demir kompozisyonlarında bu alaşım elementlerinin varlığı ile metal-

oksit tabakası arayüzeyinde koruyucu oksit tabakası oluşumu desteklenmekte, oluşan bu tabaka oksijen ve demir iyonlarının difüzyonuna karşı bariyer görevi yaparak oksidasyon direncini arttırmaktadır [15, 20]. Özellikle yükseltilmiş silisyum miktarına sahip alaşım kompozisyonlarında oluşan silisyumca zengin oksit tabakaları (Fe_2SiO_4 ve SiO_2) yüzeye daha iyi tutunan kompakt yapıda oluşmakta böylece malzeme kaybına neden olan demir oksit tabakalarının büyüme hızını yavaşlatmaktadır [20-23].

Bu çalışmada, arttırılmış silisyum bileşimine sahip, Nb ve W içeren 6Si1Nb (3.0 C, 6 Si, 1 Nb ağ.%) ve 6Si1W (3.0 C, 6 Si, 1 W ağ.%) alaşımlarının oksidasyon davranışları SiMo ferritik sünek dökme demir ile karşılaştırılmıştır.

2. DENEYSEL ÇALIŞMA

Deneysel çalışma kapsamında kum kalıba döküm yöntemi ile üretilmiş ticari SiMo ve geliştirilen 65Si1Nb ve 6Si1W alaşımlarının mikroyapısal ve ısıl özellikleri karakterize edilmiştir. Tüm alaşımlar ASTM A 536 - 84 standardına göre kum kalıba döküm yöntemi ile Y blok olarak üretilmiştir. Ticari SiMo alaşımı yerli bir firmadan temin edilmiş olup, geliştirilen alaşımların dökümü için 25 kg kapasiteli 35 KW Inductotherm indüksiyon ocağı kullanılmıştır. Alaşımların kimyasal kompozisyonu optik emisyon spektrometresi (OES, Foundary Master) kullanılarak belirlenmiştir. Deneysel çalışma kapsamında kullanılan alaşımların kimyasal kompozisyonları Tablo 1'de verilmiştir. Tabloda ticari SiMo alaşımı için SiMo kodu kullanılırken, geliştirilen 6Si1Nb ve 6Si1W alaşımları sırasıyla SiNb ve SiW olarak kodlanmıştır.

Tablo 1. Döküm alaşımlarının kimyasal kompozisyonları (ağ. %)

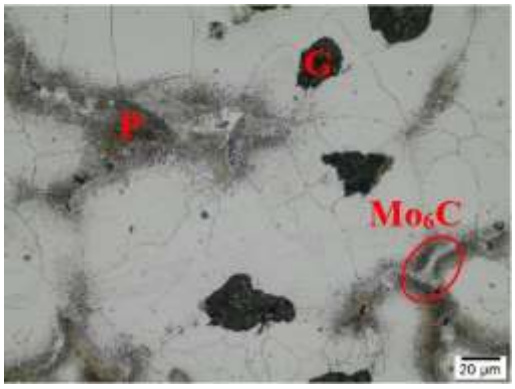
Alaşım	C	Si	Nb	W	Mo	Mg
SiMo	3,42	3,62	-	-	0,81	0,04
SiNb	3,08	6,04	1,06	-	-	0,08
SiW	3,04	6,09	-	0,99	-	0,08

Döküm alaşımları mikroyapısal incelemeler ve termal analiz yöntemleri ile karakterize edilmiştir. Mikroskopik incelemeler için alaşımlar metalografik yöntemlerle hazırlanmış ve Nital (% 3 NHO_3) ile dağlanmıştır. Alaşımların mikroyapıları ışık mikroskobu (IM, Olympus BX41M-LED) kullanılarak incelenmiştir. Oksidasyon testleri bir ısıl işlem fırınında (MSA) 800 °C'de 24 saat atmosferik koşullar altında gerçekleştirilmiştir. Oksidasyon testlerinden sonra alaşımların kesitleri metalografik olarak hazırlanmış ve ışık mikroskobu kullanılarak incelenmiştir. Oksit fazlarını tanımlamak için, alaşımların oksitlenmiş yüzeyleri, Cu-Kα radyasyonu ve 1.0 °/dak tarama hızı kullanılarak X-ışını kırınım (XRD, Rigaku Ultima +) yöntemi ile karakterize edilmiştir.

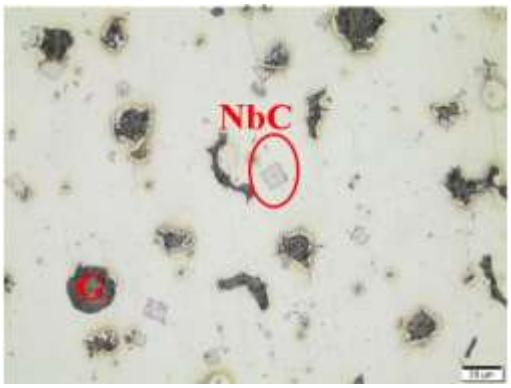
3. BULGULAR VE TARTIŞMA

3.1. Mikroyapısal Karakterizasyon

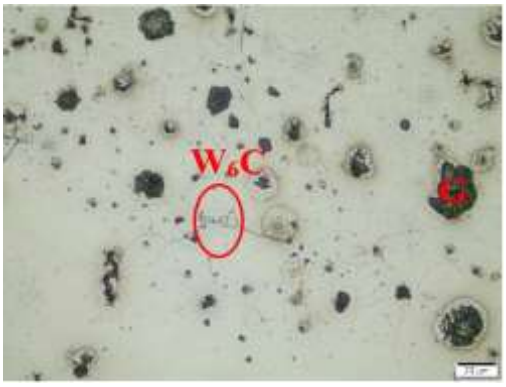
Alaşımların mikroyapısal bileşenlerini gösteren IM mikroyapı görüntüleri Şekil 1'de verilmiştir. Tüm alaşımlar ferritik matrikse gömülü grafit (G) ve karbür çökeltilerine sahiptir. Matrikste yer alan karbür yapıları SiMo, SiNb ve SiW için sırası ile Mo_6C, NbC ve W_6C olarak belirlenmiştir. SiMo alaşımı mikroyapısında ayrıca hücre sınırlarında Mo_6C karbürlerin etrafında perlitik (P) yapı bulunmaktadır. Çökelen bu perlitik yapı döküm sırasında silisyumun ters segregasyon eğiliminden dolayı hücre sınırlarında silisyum miktarının azalmasından kaynaklanmaktadır [24]. Ancak silisyum miktarının ağ.% 6 olduğu SiW ve SiNb alaşımlarında tüm hücre boyunca çözünen silisyum miktarının artması, hücre sınırlarında sementit çökelmesini engellemiştir. Alaşımların grafit morfolojileri incelendiğinde, silisyum miktarındaki artış sonucu SiNb ve SiW alaşımlarında vermiküler grafit miktarının arttığı ve özellikle niyobyum içeren SiNb alaşımında bu miktarın 21,1 alan% değerine ulaştığı belirlenmiştir.



(a)



(b)



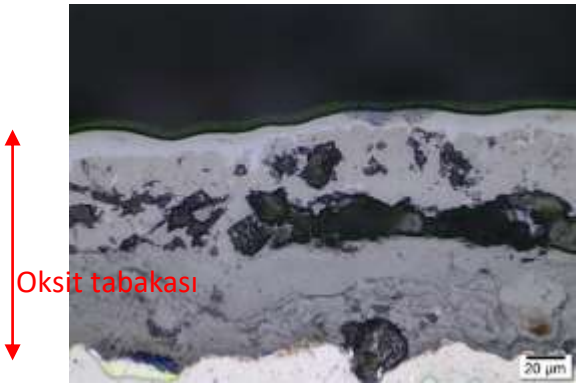
(c)

Şekil 1. Alaşımlara ait IM mikroyapı görüntüleri (a) SiMo, (b) SiNb ve (c) SiW

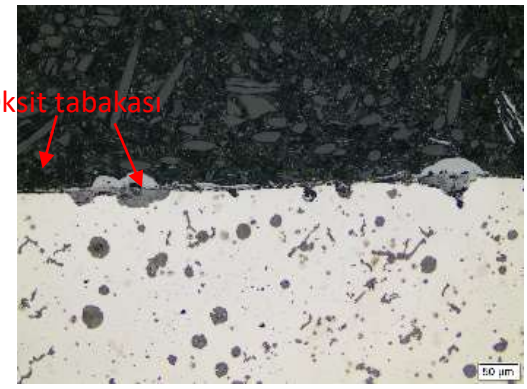
3.2. Oksidasyon Test Sonuçlarının Değerlendirilmesi

Alaşımlara fırın atmosferinde 800 °C sıcaklıkta 24 saat boyunca oksidasyon testleri uygulanmış olup testler sonrasında alaşımların kesitleri ışık mikroskobu ile incelenmiştir. Elde edilen kesit görüntüleri ise Şekil 2'de verilmiştir. SiMo alaşımının kesitinde oluşan oksit tabakası tipik dökme demir oksit tabakası görünümündedir. Bilindiği üzere dökme demirlerin yüzeyinde oluşan oksit tabakası iç ve dış oksit katmanlarından meydana gelmektedir. Yapılan çalışmalar iç oksit tabakasının FeO ve Fe_2SiO_4 / SiO_2 oksit bileşenlerinden, dış tabakanın ise Fe_3O_4 ve Fe_2O_3 oksit yapılarından oluştuğunu göstermiştir [18]. Özellikle iç tabakada elde edilen silisyumca zengin oksit yapıları (Fe_2SiO_4 / SiO_2) oksit – metal arayüzeyinde ince bir hat şeklinde büyümekte olup oksijen ve demir iyonlarının difüzyonuna karşı bariyer oluşturmaktadır [18, 20]. Silisyum miktarının artması ile silisyumca zengin oksit tabakası daha kompakt yapıda oluşmakta ve böylece oksidasyon direncini arttırmaktadır [20-22]. Yapılan çalışmalar silisyum miktarının artması sonucu dökme demirlerin yüzeylerinde oluşan oksit tabakalarının daha ince olduğunu göstermiştir [20]. SiNb ve SiW

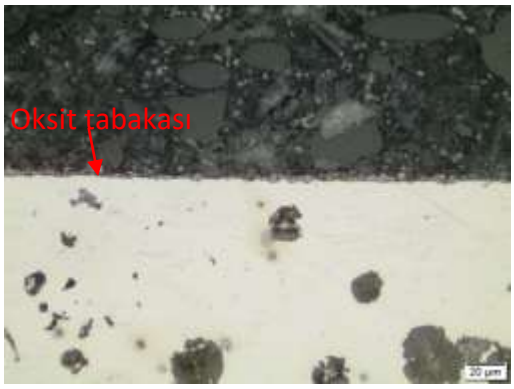
alaşımları yüzeyinde daha ince oksit tabakalarının oluşumu alaşımların sahip olduğu yüksek silisyum miktarı ile açıklanabilmektedir.



(a)



(b)

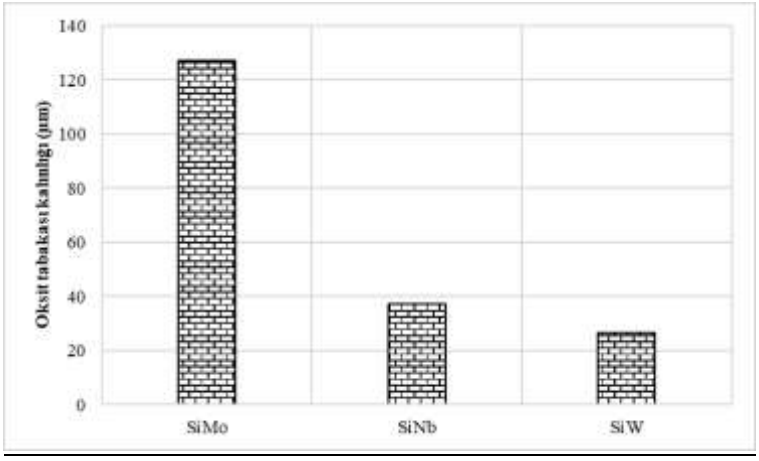


(c)

Şekil 2. 800 °C sıcaklıkta 24 saat boyunca oksidasyon testleri sonrası alaşımların kesitlerine ait IM görüntüleri (a) SiMo, (b) SiNb ve (c) SiW

Bilindiği üzere oksit tabakalarının kalınlığı alaşımların oksidasyon direnci hakkında bilgi vermektedir. Bu amaçla alaşımların yüzeylerinde oluşan oksit tabakalarının kalınlıkları ölçülmüş ve değerler Şekil 3'te verilmiştir. En kalın oksit tabakasının SiMo alaşımında (127 ± 12 µm) olduğu görülmektedir. Silisyum miktarının artması sonucu SiNb ve SiW alaşımlarında oluşan oksit tabakalarının kalınlıklaı sırasıyla 37,4 ± 5,6 µm ve 26,6 ± 2,5 µm değerlerine sahiptir. Bu alaşımların oksit tabakalarının kalınlıkları SiMo oksit tabakasının yaklaşık dörtte bir değerindedir. Bu sonuç yüksek

silisyum miktarının oksidasyon direncini önemli ölçüde arttırdığını göstermektedir. SiNb ve SiW arasında oluşan farklı oksit tabakası kalınlınlıkları ise grafit morfolojisi üzerinden açıklanabilmektedir. Bilindiği üzere dökme demirlerde oksidasyon, metalin oksidasyonunun yanı sıra grafit oksidasyonu üzerinden de ilerlemektedir [25-26]. Vermiküler grafit morfolojisinin baskın olduğu SiNb alaşımında, oksijen iyonu yüzeyden merkeze doğru daha fazla ilerleyebilmekte ve grafitler üzerinde oksit nodülleri oluşturarak oksidasyonu arttırmaktadır [20, 26].



Şekil 3. 800 °C sıcaklıkta 24 saat boyunca oksidasyon testleri sonrası alaşımların yüzeylerinde oluşan oksit tabakalarının ortalama kalınlık değerleri

SONUÇLAR

Bu çalışmada, egzoz manifold malzemesi olarak arttırılmış silisyum bileşimine sahip, Nb ve W içeren 6Si1Nb (3.0 C, 6 Si, 1 Nb ağ.%) ve 6Si1W (3.0 C, 6 Si, 1 W ağ.%) alaşımları geliştirilmiş olup, oksidasyon özellikleri ticari olarak kullanılan SiMo ferritik sünek dökme demir ile karşılaştırılmıştır. Mikroyapısal karakterizasyon çalışmaları tüm dökme demirlerin esas olarak ferrit, küresel grafit ve kompozisyona bağlı olarak değişen karbürlerden oluştuğunu göstermiştir. Oksidasyon çalışmaları ise daha yüksek silisyum miktarına sahip SiNb ve SiW alaşımlarının SiMo ticari sünek dökme demire göre çok daha ince oksit tabakasına, dolayısı ile daha yüksek oksidasyon direncine sahip olduğunu ortaya koymuştur. Deneysel çalışmalar kapsamında elde edilen sonuçlar geliştirilen alaşımların egzoz manifoldları için aday malzemeler olabileceğini göstermiştir.

TEŞEKKÜR

Bu çalışma Kocaeli Üniversitesi Bilimsel Araştırma Projeleri Birimi tarafından 2017/118 no'lu proje ile desteklenmiştir. Çalışmaya olan katkılarından dolayı Kocaeli Üniversitesi Bilimsel Araştırma Projeleri Birimi'ne teşekkür ederiz.

Correponding Author: Gonca Esmer Unal, Gonca.unal@tofas.com.tr

ABSTRACT

In the automotive sector, the prototype part production time plays a major role in order to manage the time well, which is one of the important parameters during the launching of the new project. In this study, information is given about SLA (Stereolithography) technology, which is one of the oldest rapid prototyping methods. 5 different automobile parts discussed in the previously written article 'Automobile parts produced by rapid prototyping methods production speed comparison' were also used in this study. The time required for the production of 5 different parts from Tough 2000 material using the SLA method was calculated. When the results are compared with the outputs of the other article, the fastest method is MJF (Multi Jet Fusion), the slowest method is SLA, but the method where the parts have the best surface quality is the SLA method.

Keywords: Rapid Prototyping, Additive Manufacturing, Stereolithography, Tough 2000

1. INTRODUCTION

Additive manufacturing is a manufacturing technology that enables physical models to be obtained from 3D CAD data prepared in computer environment without the need for mold production (Jaiganesh continued, 2014). Additive manufacturing devices enable the production of all kinds of product data designed in three dimensions in virtual environment within hours or a few days.

There is a wide variety of additive manufacturing methods in the industry. While a wide variety of classifications can be made in rapid prototyping systems, the most common of these is the classification performed by taking into account the initial state of the material used in prototype production. Accordingly, rapid prototyping systems can be divided into 3 groups as (1) liquid-based, (2) solid-based and (3) powder-based (Çelik continued, 2013).

The material used in liquid-based rapid prototyping systems is initially in liquid form. The liquid material becomes solid thanks to the hardening process performed by laser or heat application. Solid-based rapid prototyping technologies include all forms in solid form except powder material. Sheet, granule, filament or roll forms can be given as examples for this method. In powder-based rapid prototyping systems, bonding of the powder material to each other is achieved by adding binders and adhesives to the contact areas or by melting these surfaces.

Generally, solid and powder-based rapid prototyping methods are used in the R&D Prototype unit of TOFAŞ (Turkish Automobile Factory). Solid-based FDM (Fused Deposition Modeling) technologies are available within the Tofaş R&D prototype. Powder-based SLS (Selective laser sintering) and MJF technologies and liquid-based SLA technology are frequently used in the project development phase by taking service from sub-industry companies.

In this study, the time spent on the production of 5 different volumes of automobile parts using Tough 2000 material in the SLA method was calculated and compared with the outputs obtained in the article 'Automobile parts produced by rapid prototyping methods production speed comparison'.

2. MAIN SECTIONS

In this study, firstly information about SLA production method is given. Then, the time spent when 5 automobile parts of different volumes are produced with the SLA method is presented.

2.1. SLA (Stereolitografi) Method

Stereolithography (SLA) is an additive manufacturing process belonging to the Vat Photopolymerization family. In SLA, the part is created by solidifying the polymer resin layer by layer using ultraviolet (UV) laser beam. The materials used in SLA are photosensitive thermoset polymers in liquid form (URL 1).

SLA is the first 3D Printing technology. If very smooth surface quality is required, SLA is a very suitable rapid prototyping technology for this.

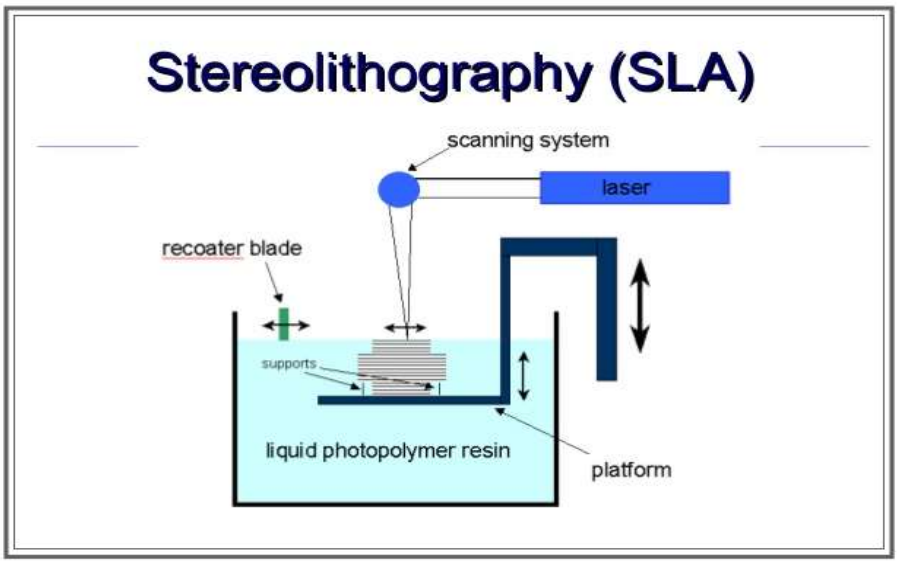

Figure 1. Schematic representation of SLA method (URL 2)

2.1.1. How does the SLA work?

SLA production process summary:

The platform is first positioned in the liquid photopolymer tank at a distance of one layer height from the surface of the liquid.

Then the UV laser hardens and solidifies the photopolymer resin to form the next layer. The entire cross-sectional area of the model is scanned.

When a layer is finished, the platform moves and the sweeping blade re-covers the surface. The process is then repeated until the part is complete (URL 2).

The liquid resin is solidified by a process called photopolymerization: during solidification, the liquid resin is activated by the light of the UV laser and solidifies. The photopolymerization process is irreversible and there is no way to convert SLA parts back into their liquid form. When heated, they burn rather than melt. This is because materials produced with SLA are made of thermoset polymers (URL 2).

2.2. Geometries and Volumes of Parts to be Produced

To be produced; Front door panel with a model volume of approximately 2400 cm^3, a door panel pocket with a model volume of approximately 500 cm^3, a door pull handle with a model volume of approximately 850 cm^3, a support piece with a model volume of approximately 40 cm^3 and a tank cover plastic parts with a model volume of approximately 70 cm^3 are given in Table 1 below. (Unal continued, 2019)

Table 1. Geometries and volumes of parts

	Parts Name	Parts Volume(cm3)
	Door Panel	≅2400
	Door Panel Pocket	≅500
	Door Pull Handle	≅850
	Support Part	≅40
	Tank Cover	≅70

2.3. SLA Parts Production Time

All parts are produced Tough 2000 material using the SLA method. The durations of the produced parts; the door panel was produced in 240 hours, the door panel pocket in 105 hours, the door pull handle in 20 hours, the support piece in 5 hours, and the tank cover in 10 hours. A curing time of 1 hour was required for each piece produced. Production times are given in Table 2 below.

Table 2. SLA Production Time

	Parts Name	Production Times(h)	Cooling Times(h)	Curing Times(h)	Total Production Times (h)
	Door Panel	240	-	1	241
	Door Panel Pocket	105	-	1	106
	Door Pull Handle	20	-	1	21
	Support Part	5	-	1	6
	Tank Cover	10	-	1	11

3. Conclusions and Recommendations

5 different automobile parts were produced from Tough 2000 material using the SLA method and the times needed to obtain the parts were found. When the results are compared with the results of the previously published article 'Automobile parts produced by rapid prototyping methods production speed comparison', it was determined that the fastest method was MJF and the slowest method was SLA. For situations where time is important, it will be appropriate to produce using MJF method. If surface quality is more important than production time, SLA method can be used. The speed comparison of the parts produced using FDM, SLS, MJF and SLA technologies is given in table 3.

Table 3. FDM,SLS,MJF, SLA Production Speed Comparison

Production Method	Total production hours	Ratio
MJF	100	t
FDM	160	1,6t
SLS	244	2,4t
SLA	380	3,8t

ÖZET

Araç endüstrisinin elektrifikasyonunun önündeki ana engel, EV'nin sınırlı menzilidir. Elektrikli araç kullanıcılarının çoğu, boş bir bataryayla yol kenarında mahsur kalma korkusu yaşamaktadır. Gerçek menzil tanımı (gerçek ve beyan değeri arasındaki boşluk daha az), gerçek müşteri sürüş verilerini kullanarak müşteri beklentilerini karşılamak için önemlidir. Uzun yıllardan beri süregelen bu problemin çözümü için otomotiv üreticileri birçok farklı konuda çalışma yapmaktadırlar. Bu çalışma kapsamında, enerji tüketimine etki eden değişken setinin tespit edilmesi için makine öğrenmesi modellemesine dayalı bir çıkarım analizinin yapılması amaçlanmıştır. Bu sayede müşteriye seyahati sırasında kalan menzil mesafesinin doğru bir şekilde sunulmasını hedeflenmektedir. Yapılan bu çalışmada müşteri profiline uygun test senaryoları oluşturulmuştur. Aracın CAN-BUS ve kapsamlı dış koşul bilgileri kullanılarak, tanımlı yol profillerinden toplanan veriler ile yüksek oranda bir tahmin performansı elde edileceği gözlemlenmiştir.

ANALYSIS OF THE PARAMETERS AFFECTING AN ELECTRIC COMMERCIAL VEHICLE RANGE DEPENDS ON CUSTOMER USAGE VIA MACHINE LEARNING APPROACH

ABTRACT

The main barrier to electrification of the vehicle industry is the EV's limited range. Electric vehicle customers are afraid of getting stranded on the side of the road with an empty battery. Actual range definition (less gap between real and declaration value) is important to satisfy customer expectation by using real customer driving datas. Automotive manufacturers are working on many different subjects to solve this problem that has been going on for many years. Within the scope of this study, it is aimed to make an inference analysis based on machine learning modeling in order to determine the variable set that affects energy consumption. In this way, it is aimed to provide the customer with the correct distance remaining during customer's travel.The customer's driving profile compatible test sceneraios are created. It has been observed that a high rate of prediction performance will be obtained with the data collected from defined road profiles by using the vehicle's CAN-BUS and comprehensive external condition information.

1.GİRİŞ

Elektrikli araç (EV) sahibi olmak isteyen müşterilerin akıllarındaki en büyük soru, aracın sağlayabileceği menzil yeterli olacak mıdır? Ayrıca araç endüstrisinin elektrifikasyonunun önündeki ana engel, EV'nin sınırlı menzili olmak ile birlikte, müşteri tarafından bakıldığında; seyahat sırasında boş bir pille yolda kalma korkusudur.
Uzun yıllardan beri süregelen bu problemin çözümü için otomotiv üreticileri birçok farklı konuda çalışma yapmaktadırlar. Bu çalışma müşterinin kullanım parametrelerine odaklanmış olup, teorik ve pratik kullanım farklarına göre menzili optimize etmeye ve müşterilere en doğru sonucu vermeye odaklanmıştır.

Bu bağlamda, taşıt egzoz emisyonları açısından en temiz ulaşım alternatifi olması beklenen EV'lerin en önemli dezavantajı tek bir şarjla görece kısa bir menzile sahip olmalarıdır (Sarıkurt et al. 2017). Bununla beraber araçların broşürlerindeki verilen tam şarj ile gidilebilecek mesafelerin gerçek kullanım koşulları ile farklı olması ve elektrikli araçların mesafe hesaplamaları hakkındaki yazılan makalelerde bu konuya ilişkin hesaplamalar çelişkiler mevcuttur (URL 1).
Bataryalı elektrikli araç (BEV) sürücüleri, geleneksel yakıtlı araçlara kıyasla tipik olarak daha fazla menzil kaygısına sahip olma eğilimindedir.

Yüksek menzil kaygısı seviyeleri, BEV sürücülerinin duyguları üzerinde potansiyel olarak olumsuz etkilere ve hatta tehlikeli sürüş davranışlarına yol açabilir. (Yuan et al. 2018)

Gerçek müşteri verilerini kullanarak müşteri beklentilerini karşılamak için gerçek aralık tanımı (gerçek ve beyan değeri arasındaki fark daha az) yapılarak müşterinin menzil kaygısı hissini ortadan kaldırabilmek için testler yapılmıştır.

Bu konuda yapılan birçok çalışmada gerçek kullanıcı olan müşteri tarafından bulunan gerçek menzil aralığı, araç üreticisi tarafından görüntülenen aralığın (beyan edilen) ±% 40'ıdır (Haaren et al. 2011).

Benzer bir ticari araç Yeni Avrupa Sürüş Çevrimi (NEDC-New European Drive Cycle) ve Dünya Genelinde Uyumlu Test Çevrimi (WLTC-Worldwide Harmonized Light Vehicle Test Cycle) çevrimlerine göre incelendiğinde ve MATLAB Simulink ortamında simülasyon yapılmıştır. Bu durumda, şehir içi ve şehir dışı test çevrimlerinde kilometre başına harcanan enerji olarak incelendiğinde WLTC sonuçlarının NEDC' ye göre %10 ila %12 oranında fazla olduğu, simülasyon sonuçlarında ise %7 ila %9 oranında bir fark oluştuğu görülmüştür. Şehir dışı koşullarda kilometre başına harcanan enerji olarak incelendiğinde WLTC sonuçlarının NEDC'ye göre %8 ila %10 oranında fazla olduğu görülmüştür. Şehir içi kilometre başına harcanan enerji olarak incelendiğinde WLTC sonuçlarının NEDC' ye göre %7 ila %9 oranında fazla olduğu görülmüştür (Akıllı et al. 2020).

EV'nin farklı yol türleri için enerji tüketimini yüksek doğrulukla tahmin eden bu makale farklı yol türleri için enerji tüketim faktörü modellerini yapay zekâ ile oluşturmaya ve farklı yol türleri arasında bir karşılaştırma yapmaya çalışmaktadır (Yao et al. 2013).

Yapılan bu çalışma ile makine öğrenmesi yöntemi kullanılarak araç menziline etki eden parametreler, hassas bir şekilde hesaplanmak için kendi içlerinde ağırlıklandırılacaktır.

2. LİTERATÜR TARAMA

EV'lerin tüketici kitle pazarında benimsenmesini desteklemek için, politika yapıcıların bir otomobil kullanıcılarının davranışlarını etkileyen faktörleri ve engelleri anlamaları çok önemlidir. Çalışmalar, sınırlı BEV aralığı, uzun şarj süreleri ve kamuya ait açık altyapı mevcudiyetinin, menzil kaygısı olarak bilinen duruma neden olabilecek önemli engeller oluşturduğunu göstermiştir. (Mellinger et al. 2018). Mellinger ve arkadaşlarının yaptığı bir çalışmada ABD ulusal seyahat anketi üzerinden kapsamlı fiziksel modelleme ve simülasyon ile araç gezileri uygulandı. Yapılan çalışma, 2016 yılındaki seyahatlerin %87'sinin araçların yeniden şarj edilmeye gerek kalmadan düşük menzilli ve uygun fiyatlı BEV'lerle karşılanabileceğini ortaya koyuyor. Yüksek menzilli araçlarda ise bu oran %98'e çıkmaktadır (Mellinger et al. 2018).

GPS tabanlı başka bir çalışma, gün içinde BEV şarj etmenin ve BEV ile seyahatin bazı kısımlarını geciktirmenin etkisini incelemiştir (Pearre et al. 2011).

EV'nin enerji tüketimi tahminiyle ilgili birçok araştırma, sonuçları gerçek araç çalışma durumunun etkisini yansıtamayan ideal çalışma durumuna dayanmaktadır. Araç sürüş parametrelerini (yani ortalama seyahat hızı) hesaba katan fiziksel temelli yöntemler, genellikle benzinli ve dizel motorlu araçların yakıt tüketiminin modellenmesinde kullanılır. Bu modellerde, araca özel güç (AÖG), enerji arasındaki ilişkiyi kurma yeteneği için tüketim ve araç mikroskobik sürüş parametreleri (yani anlık hız ve hızlanma) bir ara değişken olarak tanıtılmıştır. Şehir içi yolların gerçek sürüş durumunu yansıtmak için verilerin toplanmasındaki zorluk nedeniyle, mevcut araştırmalar farklı yol türleri için AÖG dağılımlarının farkını pek dikkate almamaktadır. Birçok uygulama, hızlanma ve yavaşlamanın frekansı ve aralığı her zaman farklı olduğundan, araçlar sabit bir ortalama hızda giderken bile enerji tüketiminin farklı yol türlerinde büyük ölçüde değiştiğini kanıtlamıştır. EV'nin enerji tüketimi modellerinin araştırma alanında, enerji tüketimi genellikle

pilin gücünün zamanla çarpımına eşittir, ancak bu yöntem çalışma durumunun enerji tüketimi üzerindeki etkisini yansıtmada başarısız olur. Çalışma durumunun enerji tüketimi üzerindeki etkisinin nasıl sunulduğuna dair bazı çalışmalar halihazırda yapılmıştır. Aracın ortalama seyahat hızı her zaman bağımsız değişken olarak kullanılır ve hız düzeltme faktörleri, belirli tesis türleri için enerji tüketimi faktörlerini ayarlamak için kullanılır. (Yao et al. 2013)

Menzil ve ilgili sorularla ilgili önceki bir çalışma, her biri birkaç gün örneklenmiş küçük bir araç setini inceledi ve günlük sürüşün 95%'inden fazlasının 160,93km (100mil) elektrikli menzil ile gerçekleştirilebileceğini öne sürdü. (Pearre et al. 2011)

Müşterilerin elektrikli araçlar ile ilgili batarya ömür ve kalan menzil mesafesi kaygısının giderilmesine yönelik diğer çalışmalara ek olarak yapay zekâ alanında birçok çalışma mevcuttur. Bazı çalışmalar, bataryanın kullanımına bağlı olarak ömrünün tahminlenmesine yönelik iken bazıları da anlık olarak müşteriye kalan menzil mesafesinin ya da kalan batarya seviyesinin sunulmasına yönelik tahminleme çalışmalarıdır.

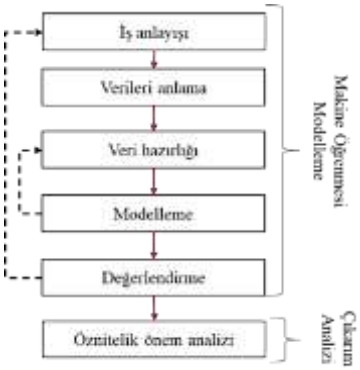
Batarya ve pil-süper kapasitör hibritleri şarj durumu tahminlemesi için yapay sinir ağlarını kullanılmıştır. Çalışmada deşarj eğrisinin kısa bir başlangıç segmentine dayalı olarak enerji depolama cihazlarının batarya tüketimini tahmin etmeyi amaçlamışlardır. (Weigert et al. 2011). Lityum-ion bataryalar için uzun-kısa hafıza ağı (LSTM)'na dayalı şarj durum tahmin çerçevesi önerilmiştir. Akım, voltaj, sıcaklık ile şarj durum arasındaki ilişki ortaya çıkarmaya çalışılmıştır. (Liu et.al, 2021). Elektrikli araç lityum-ion batarya şarj durumu elektrokimyasal empedans spektroskopisinden yola çıkarak tahmin edilmek için araştırma yapılmıştır ve doğrusal regresyon, Gaussian süreç regresyonu gibi makine öğrenmesi algoritmaları kullanılmıştır (Babaeiyazdi et al. 2021). Farklı bir çalışmada da batarya faydalı ömrünü tahminlemeye çalışılmıştır. Yaşam döngüsü açısından bataryanın ömrünün optimize edilmesini sağlayacak tasarım çalışmaları sırasında simülasyon sürecinin kısaltılması hedeflenmiştir (Ma et al. 2021).

Sürücüler için kaygı problemi olan kalan menzil mesafesinin tahminlenmesi problemi üzerine Radial basis function neural network (RBF NN) isimli bir makine öğrenmesi modelleme tekniği kullanılarak çalışılmıştır (Bi et al. 2018). Elektrikli golf arabasının menzil mesafesinin tahminlenmesi için enerji tüketimini etkileyen parametreleri dikkate alarak fuzzy logic classifier isimli bir teknik uygulanmıştır. Farklı yük ve parkur şartlarında testler gerçekleştirilmiştir (Bi et al 2018). Elektrikli bir aracın hız, çekiş gücü ve yol eğimi gibi değişkenleri dikkate alan ve enerji tüketimini tahminlemeyi amaçlayan Deep Convolutional Neural Network isimli bir yapay sinir ağı modellemesi önerisinde bulunulmuştur (Modi et al. 2020).

Yayın taramasında elektrikli araç menzil mesafesini tahminleyen çalışmalar olsa da müşterilerin farklı hava koşullarında ve farklı sürüş davranış stillerinde enerji tüketimini tahminlemeyi amaçlayan bir çalışma rastlanmamıştır. Bu sebeple enerji tüketim tahminleme çalışması; dört mevsim koşulları, farklı sürüş modları, farklı parkurları ve ısıtma/soğutma tercihlerini kapsayacak şekilde genişletilmiştir.

3.METODOLOJİ

Karmaşık bir problem olan elektrikli araçların menzil mesafesinin gerçek zamanlı olarak tahminlenmesi için enerji tüketimini etkileyen değişkenlerin anlaşılması gerekmektedir. Batarya tüketimine etki eden özniteliklerin keşfi için makine öğrenmesi yaklaşımlarına dayanan iki aşamalı bir metodoloji önerisinde bulunulmuştur. Önerilen metodolojinin makine öğrenmesi modelleme aşaması olarak isimlendirilen ilk aşamasında, endüstride veri madenciliği uygulamalarında yaygın bir şekilde kullanılan CRISP-DM (Cross Industry Standard Process for Data Mining) isimli sürecin adımları takip edilmiş ve belirlenen performans kriterine göre en iyi sonuç veren makine öğrenmesi modeli seçilmiştir. İkinci aşamada ise batarya tüketimine en etki eden özniteliklerin belirlenmesini sağlayacak çıkarım analizi için belirlenen makine öğrenmesi modeli üzerinden permütasyon öznitelik önem derecesi hesaplama yönteminden yararlanılmıştır.



Şekil 1. Makine Öğrenmesi Modelleme ve Çıkarım Analizi Metodolojisi

Makine öğrenmesi modelleme aşamasının ilk adımında, problem tanımı "elektrikli araçların enerji tüketimini etkileyen en önemli özniteliklerin belirlenmesi" olarak yapılmıştır. Enerji tüketimi ölçüm kriteri olarak da "km başına enerji tüketim değeri" seçilmiştir. Bu problem için de farklı müşteri sürüş stilleri ve çevresel koşullara göre bazı senaryolar oluşturularak saha testleri/deneyleri tasarlanmıştır. Farklı müşteri deneyimlerinin yansıtılması için ilgili senaryolar; genel olarak dört mevsim koşullarını içeren farklı hava durumlarını, farklı sürücü davranış karakterini, araç içi ısıtma veya soğutma tercihlerini ve farklı seyahat parkurları dikkate alınarak tasarlanmıştır.

İş ihtiyacı anlaşılmasından sonra ikinci adımda, ilgili senaryolar doğrultusunda veri toplama sürecine geçilmiştir. Farklı mevsimlerde tanımlanan durumlar ve test parkurları altında aracın CAN-BUS modülü yardımıyla saniyenin onda bir frekans/çözünürlük ile veri toplanmıştır. İlgili veri seti; aracın batarya güç sistemi, ısıtma/soğutma sistemi, kabin sıcaklık sistemi, aktarma organı ve sürüş sistemi, coğrafi bilgi sistemi gibi alt sistemlerine ait verileri barındırmaktadır. Veri hazırlama ve modelleme adımları öncesinde, bu girdiler, Ar-ge uzmanları tarafından en ilişkili özniteliklerin belirlenmesi için değerlendirilmiştir.

Veri hazırlığı adımında yüksek çözünürlük ile toplanan veriler, parkur bazlı olarak özetlenmiş ve özellikle değişken değerlerinin parkur boyunca salınım hareketlerini yansıtılması için de çeşitli istatistik metriklere göre yeni değişkenler türetilmiştir.

Veri hazırlığının ardından, modelleme adımına geçilmiştir. Veri modelleme adımında kilometre başına tüketimi ifade eden "enerji/km" değeri çıktı olarak seçilip, geçmiş verilerden çıktı ve girdilerden yararlanarak öğrenme yaklaşımı olan denetimli makine öğrenme (supervised machine learning) yaklaşımı uygulanmasına karar verilmiştir. Bu doğrultuda veri seti, eğitim ve test kümesi olarak iki ana kümeye ayrılmıştır. Eğitim veri kümesi; çeşitli denetimli makine öğrenmesi algoritmalarının geliştirilmesi için kullanılmış ve daha sonra geliştirilen makine öğrenmesi algoritmaları test kümesi ile doğrulanmıştır. Modelleme adımında Bayesian Lineer Regression, Boosted Decison Tree Regression, Decision Tree Regression and Lineer Regression algoritmaları eğitilmiş ve test edilmiştir.

Model sonuçlarının değerlendirmesi adımında ise, modelleme adımında her bir öğretilmiş model kullanılarak test kümesi verileri ile enerji/km tahminlemesi yapılmış ve tahmin çıktıları gerçekleşen enerji tüketimi ile kıyaslanmıştır. Model sonuçları; ortalama mutlak hata (MAE: mean absolute error), Kök Ortalama Kare Hata (RMSE), Determinasyon katsayısı (R2: coefficient of determinations) gibi performans ölçütlerine göre kıyaslanmıştır.

$$MAE = \frac{1}{n}\sum_{t=1}^{n}|e_t| \tag{3.1}$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{t=1}^{n}e_t{}^2} \tag{3.2}$$

$$R2 = \frac{\sum_i(\hat{y}_i - \bar{y})^2}{\sum_i(y_i - \bar{y})^2} \tag{3.3}$$

Denklem 3.1 ve 3.2'de yer alan "e", tahmin edilen değer ile gerçek değer arasındaki farkı, yani hatayı ifade etmektedir. "n" değeri ise gözlem sayısını ifade eder. Denklem 3.3'te yer alan y_i değeri her bir gözlemin enerji tüketim değerini, $\bar{y}$ ortalama enerji tüketimini, $\hat{y}_i$ her bir gözlem için tahmin edilen enerji tüketimi değerini temsil etmektedir. MAE ve RMSE değerlerinin sıfıra yakın olması ya da düşük olması, tahminleme de hata payının düşük olduğunu gösterir. R2 değerinin de 1'e yakın olması ise gerçek değer ile tahmin edilen değer arasındaki ilişkinin güçlü olduğunu göstermektedir. Bu performans ölçütleri doğrultusunda en iyi model seçilmiştir.

Çıkarım analizi aşamasında ise seçilen model kullanılarak en etkili özniteliklerin tespit edilmesi amaçlanmıştır. Permütasyon öznitelik önem algoritmaları kullanılarak özniteliklerin önem derecesi belirlenmiştir. Bu algoritmalar, özniteliklerin değerlerini sırası ile rasgele karıştırarak, seçilen performans ölçütü doğrultusunda model performansının ne kadar değiştirdiğini ölçmeye yarar. Dolayısıyla model performansında en fazla bozulmaya sebep olan öznitelik değer değişikliği, en yüksek önem derecesine sahip değişkenin tespit edilmesine imkân sağlar. İlgili çalışma ile belirlenen öznitelikler, batarya menzil tahminleme sistemi tasarımı için girdi oluşturacak değişkenlerdir.

3.1 MÜŞTERİ GERİBİLDİRİMLERİNİN TEST KOŞULLARINA DÖNÜŞÜMÜ

Test koşulları, bir ticari araç kullanıcısının karşılaşabileceği tüm senaryoların deneyimlenmesi için aşağıda bahsedilen metotlar analiz edilerek oluşturulmuştur.

- Firma bünyesindeki birimlerin geçtiğimiz süreçlerde yaptığı anketler göz önüne alınarak %50 şehir içi, %25 şehir dışı, %25 dağ yolu oranına yaklaşılması planlanmıştır.

Tablo 1. Firma bünyesinde yapılan anketler sonucu ortalama kullanıcı yol tipi kullanım yüzdesi

Firma bünyesinde yapılan anketler sonucu ortalama kullanıcı yol tipi kullanım yüzdesi	
Şehir içi	%50
Otoban	%25
Dağ yolu	%25

- Şirketin partnerleri ile çalışmalarının analiz edilerek yol tipi, trafik durumu, rakım değişimi parametreleri belirlenmiştir.

Tablo 2. Partner firmanın çalışmalarının analizi sonucu yol tipi kullanım yüzdesi

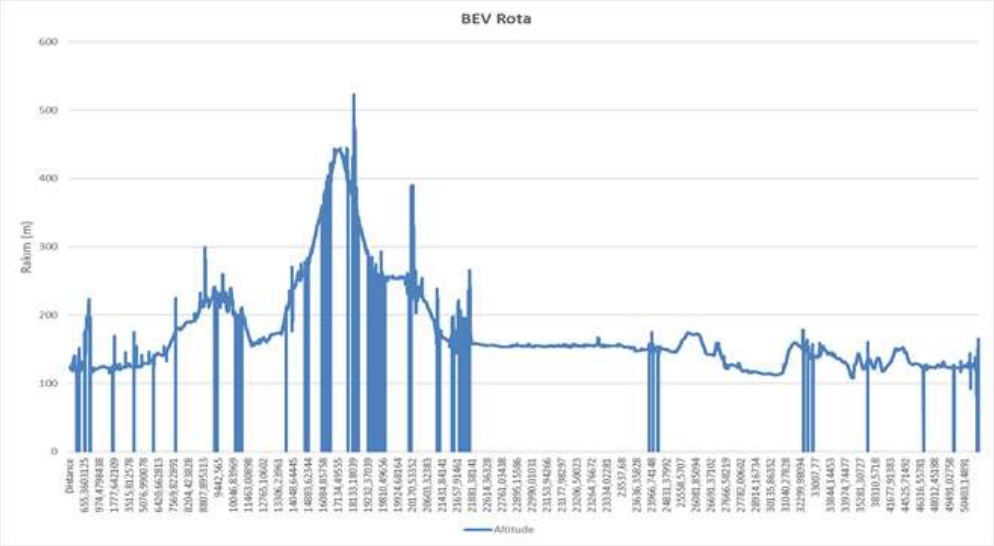
Partner firmanın çalışmalarının analizi sonucu yol tipi kullanım yüzdesi	
Şehir içi	%57
Otoban	%28
Dağ yolu	%15

- NEDC çevrimi yerine geçen WLTP çevrimleri analiz edilmiştir.

Yukarıda belirttiğimiz girdilerin analiz edilmesi sonucunda firma konumundan çıkışlı ve dönüşlü, içerisinde şehir içi sıkışık trafik, şehir içi akıcı trafik, şehir dışı, otoban, dağ yolu çıkışı ve inişi rota oluşturulmuştur.

Tablo 3. Proje için oluşturulan rota yol tipi kullanımı yüzdesi

Proje için oluşturulan rota yol tipi kullanımı yüzdesi	
Şehir içi	%60
Otoban	%25
Dağ yolu	%15



Şekil 2. Elektrikli Araç Test Rotası Rakım Bilgisi

4. KULLANIM DURUMU

Önerilen iki aşamalı makine öğrenimi metodolojisi, ticari bir aracın batarya menzil mesafesi için en ilişkili değişkenleri bulmak için uygulanmıştır. Metodoloji bölümünde de bahsedildiği üzere geçmiş verilerden yararlanılarak makine öğrenmesi algoritmaları kullanılarak batarya menzil mesafesinin en önemli bileşenlerinden biri olan "enerji/km" değerinin tahmini yapılmıştır.

Veri anlama (Data Understanding) adımında; elektrikli aracın CAN-BUS modülü üzerinden toplanan çeşitli değişkenlerin yanında; parkur bilgisi, yolcu ağırlık bilgileri vb. değişkenler de veri setini genişletmek amacıyla eklenmiştir. Farklı iklim koşullarının yansıtılması amacıyla araç testleri 4 mevsim koşulları altında planlanmıştır. Bu mevsimlerde; farklı sürüş modu, klima veya ısıtma sistemi kullanım durumu, araç ağırlığı gibi farklı sürüş durumlarını yansıtan 8 ayrı senaryo çalışması yapılmıştır. Böylece, müşterilerin maruz kaldığı farklı çevresel koşullar ve sürüş deneyimleri simüle edilmiştir. Ayrıca, farklı trafik yoğunluğu ve coğrafik koşulları yansıtacak şekilde ilgili senaryolar parkurlarda test edilmiştir. Otoyol, şehir içi, kırsal, dağ tırmanışı, dağdan iniş gibi yol tipleri bu parkurları oluşturmaktadır.

SÜRÜŞ KOŞULLARI	DURUM
SÜRÜŞ MODU	EKONOMİK/SPORTİF SÜRÜŞ
KLİMA	AÇIK/KAPALI
ISITICI	AÇIK/KAPALI
AĞIRLIK	VAR/YOK

Şekil 3. Testlerdeki Araç Testi Sürüş Koşulları.

Bu çalışma kapsamında, veri toplama sürecinde yukarıda bahsedildiği üzere 2 mevsim ve 5 farklı parkur ve 8 ayrı sürüş senaryosunu dengeli bir biçimde barındıracak şekilde 940 ayrı ölçüm verisi tutulmuştur. Saniyenin onda biri sıklıkta 26 farklı değişken için toplanan veriler, farklı istatistiksel değerler elde etmek için parkur bazında özetlenmiştir. Değişken türetme çalışmaları ile değişkenlerden yeni değişkenler elde edilerek 51 adet değişken modele girdi olarak verilmiştir. Benzer şekilde her bir parkur için enerji/km değeri de elde edilerek modele çıktı değişken olarak verilmiştir.

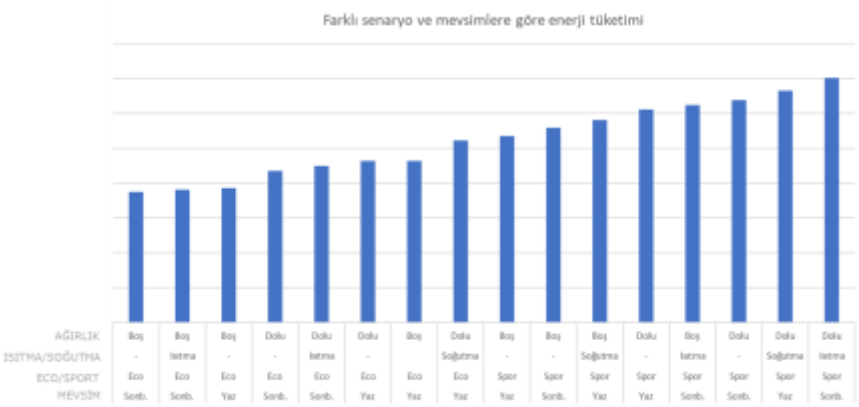
Modelleme adımında, toplanan ve özetlenen veri kümesi, %70-%30 oranında eğitim ve test seti rassal bir şekilde ikiye ayrılmıştır. Eğitim veri kümesi, makine öğrenmesi algoritmalar eğitilmek için kullanılmıştır. Model eğitme işleminin ardından, eğitim dışında tutulan küme olan test veri kümesi kullanılarak ilgili algoritmalar ortalama mutlak hata (MAE: mean absolute error), Kök Ortalama Kare Hata (RMSE), Determinasyon katsayısı (R2: coefficient of determinations) gibi performans ölçütlerine göre kıyaslanmıştır.

5. BULGULAR VE TARTIŞMA

Enerji tüketimine etki eden değişkenlerin belirlenmesi için mevsimsel olarak veri toplama süreci yürütülerek, makine öğrenmesi modellemesi yapılmıştır. Yaz ve sonbahar mevsimlerinde, belirlenen parkurlardaki enerji tüketimleri Şekil 5'de sunulmuştur. Veri hazırlığı adımında yapılan tanımlayıcı istatistik analiz çalışmalarına göre; enerji tüketiminin özellikle soğutma sisteminin etkisi ile yaz mevsiminde sonbahar mevsimine göre daha fazla olduğu gözlenmiştir. Ayrıca parkurlar arasındaki enerji tüketim farkları incelendiğinde, coğrafi koşul ve trafik yoğunluğu etkisinin beklendiği gibi etkisi görülmüştür. Tüketim oranı sırasıyla, yokuş tırmanış, şehir içi, kırsal, otoyol ve yokuş iniş olarak saptanmıştır. Özellikle yokuş iniş parkurunda rejeneratif enerji etkisi ile tasarruf sağlandığı gözlemlenmiştir.

Şekil 4. Mevsim ve Parkura Göre Enerji Tüketimi

Tanımlı senaryolara göre enerji tüketimi incelendiğinde mevsimden bağımsız olarak spor sürüşün enerji tüketimini artırdığı gözlenmiştir. Ayrıca beklendiği gibi ısıtma ya da soğutma sisteminin devrede olması enerji tüketimini artırmaktadır. Ayrıca aracın yüklü olması da tüketimi artıran bir etkendir.



Şekil 5. Farklı senaryo ve mevsimlere göre enerji tüketim

Tanımlayıcı istatistiksel analiz çalışmaları, enerji tüketimine sebep alan bazı unsurların keşfini sağladığı gibi, yapılan deneylerin farklı müşteri sürüş ve çevresel koşullarını yansıttığını göstermiştir.

Uzman görüşüne dayalı olarak seçilen öznitelikler ve bu özniteliklerden türetilen yeni değişkenler ile 12 farklı makine öğrenmesi algoritması eğitilmiş ve test edilmiştir. Tablo 4'te bu algoritmaların performans sonuçları paylaşılmıştır. Algoritma sonuçları kıyaslandığında en iyi tahmin başarısını elde eden algoritmanın yapay sinir ağları (ANN) olduğu gözlemlenmiştir.

Seçilen algoritmaların tamamı tahminlenen ile gerçek tüketim değeri arasındaki ilişkinin gücünü gösteren R2 (Belirleme katsayısı) 0.9'un üzerinde olup, güçlü bir tahmin çıktısı olduğunu göstermektedir. ANN algoritması 0.99 değeri ile başı çekmektedir. Ortalama mutlak hata değeri ise 11.6 değeri ile tatmin edici bir seviyededir.

Tablo 4. Model performans kıyaslaması

Makine Öğrenmesi Algoritması	MAE	MSE	RMSE	r2
LinearRegression	12.000	233.440	15.279	0.988
Random Forest Regression	14.603	356.944	18.893	0.982
PolynomialRegression3	22.911	1530.932	39.127	0.921
Decision Tree	17.175	553.348	23.523	0.972
SVR (Supported Vector Regressor)	13.930	654.660	25.586	0.966
Extra_Tree_Regressor	11.336	251.811	15.869	0.987
Ada_Boost_Regressor	22.361	746.928	27.330	0.962
Gradient Boosting Regressor	12.620	279.486	16.718	0.986
StackingRegressor	11.913	238.166	15.433	0.988
Hist_gradient_boosting	11.804	223.593	14.953	0.988
VotingRegressor	12.351	260.691	16.146	0.987
ANN (Artificial Neural Network)	11.609	230.467	15.181	0.992

6. SONUÇLAR

Gerçek enerji tüketim değeri ile tahmin edilen enerji tüketim değeri arasındaki korelasyonun yaklaşık %99 gibi bir değerde olması, uzmanlar tarafından seçilen değişkenlerin enerji tüketiminin açıklanması için yeterli olduğunu işaret etmektedir. (Tablo 4). Yapılan çalışma; iki mevsim koşulları ve araç üzerindeki connectivity donanımında gelmesi beklenen yol durum bilgileri, algoritmaya yansıtılmış ve %98-%99 oranlarına tahmin başarısı elde edildiğini gözlemlenmiştir. Ancak farklı koşulların etkisi ile ve anlık yol durum bilgisinin erişilebilir olmadığı durum için tahmin

performansının %95 seviyelerine gerilemesi beklenmektedir. Bu sebeple, ileriki dönemde farklı mevsim koşullarının algoritma geliştirme sürecine eklenmesi ve anlık yol durum bilgisinin batarya tüketim tahminleme algoritmasına entegre edilmesi ile ilgili çalışmalar yapılması gerekmektedir.

Geliştirilen bu tahminleme modelinden yola çıkılarak; değişken havuzunda hangi girdi setlerinin enerji tüketimini daha iyi açıkladığının tespiti için çıkarım analizi yapılmıştır. Bu analiz kapsamında seçilen ANN algoritmasındaki girdiler, teker teker dışarı alınmış; model eğitimi yapılarak testler tekrarlanmış ve performansın nasıl değiştiği incelenmiştir.

Her bir girdi değişkeni çıkarıldıktan sonra; model performansında en fazla düşüşe sebep olan değişkenlerin model açıklayıcılığı açısından önemli olduğu, model performansında yükselmeye sebep olan değişkenlerin ise tahmin performansını negatif etkilediği ya da diğer değişkenler tarafından temsil edildiği sonucunun çıkarılmasını sağlamıştır. Böylece enerji tüketimi için ön plana çıkan değişken kümesi tespit edilmiştir.

Bu bilgiler doğrultusunda oluşan parametreler & değişkenler aracın kontrol ünitesinde koşan algoritmaların optimize edilmesinde kullanılacak olup, müşterinin kullanım parametrelerine göre hesaplama yapılarak müşteriye en uygun menzil değeri sunulması planlanmaktadır. Bu sayede müşterinin kullanım sırasında batarya menzili ile ilgili kaygılarının azaltılması hedeflenmektedir.

Bu çalışmaya sağlanan girdiler sonbahar ve yaz mevsim verilerine göre yapılmış olup, ilerleyen çalışmalarda kış ve ilkbahar verileri ile zenginleştirilecektir.

ÖZET

Son yıllarda bataryalı elektrikli araçların (BEV) kullanıcılar tarafından bilinirliğinin artması ve kullanımının günden güne yaygınlaşması ile gelişen teknolojilerin otomotiv üreticileri tarafından benimsendiği ve üreticilerin elektrifikasyon alanındaki çalışmalarını arttırdıkları gözlemlenmektedir. Araç elektrifikasyonu, araç güç aktarma organlarının verimliliğini artırmak, azalan fosil yakıt kaynaklarına bağımlılığı azaltmak ve politika yapıcılar tarafından belirlenen katı emisyon hedeflerini karşılamak için daha yüksek potansiyele sahip stratejilerden biridir. Mevcut araçların tüm teorik değerlendirmelerine ve üreticinin iddia ettiği verimlilik ve emisyon kayıtlarına rağmen, elektrikli araçların (BEV), içten yanmalı motorlu (ICE) araçlarla gerçek hayattaki karşılaştırmalarına ilişkin veri eksikliği bulunmaktadır. Şehir lojistiği, kentsel mobilite emisyonlarının yaklaşık %25'ini oluşturduğundan, bataryalı elektrikli araçlar (BEV) ve dizel dağıtım araçlarına odaklanılmıştır. Yapılan karşılaştırmalarda farklı OEM'lerin aynı tip araçlarının elektrikli ve dizel değerleri karşılaştırılmış olup, çıkan sonuçlara göre elektrikli araçların WLTC karışık ölçümlerde dizel versiyonlara göre %62,2 ila %70,6 arasında daha az enerji harcadığı görülmüştür.

COMPARISON OF LIGHT COMMERCIAL VEHICLES USING FULL ELECTRIC AND DIESEL FUEL IN TERMS OF ENERGY CONSUMPTION

ABSTRACT

In recent years, with the increasing awareness and usage of battery electric vehicles (BEV) by users, it is observed that developing technologies have been adopted by automotive manufacturers and OEM have increased their work in the field of electrification. Vehicle electrification is one of the higher potential strategies to increase the efficiency of vehicle powertrains, reduce dependence on dwindling fossil fuel sources and meet strict emission targets set by policymakers. Despite all the theoretical evaluations of existing vehicles and the manufacturer's claimed efficiency and emission records, there is a lack of data on real-life comparisons of electric vehicles (BEVs) with internal combustion engine (ICE) vehicles. The focus is on battery electric vehicles (BEVs) and diesel delivery vehicles, as city logistics accounts for about 25% of urban mobility emissions. In the comparisons, the electric and diesel energy consumption values of the same type vehicles of different OEMs were compared, and according to the results, it was seen that electric vehicles consumed %62,2 to %70,6 less energy than diesel versions in WLTC mixed measurements.

Keywords: Electric Vehicles, WLTC, Fuel, Energy Consumption, Diesel, Internal Combustion Engine, ICE, Electrification, Light Commercial Vehicle, LCV

1.GİRİŞ

Araç elektrifikasyonu, araç güç aktarma organlarının verimliliğini artırmak, azalan fosil yakıt kaynaklarına bağımlılığı azaltmak ve politika yapıcılar tarafından belirlenen katı emisyon hedeflerini karşılamak için daha yüksek potansiyele sahip stratejilerden biridir. Mevcut araçların tüm teorik değerlendirmelerine ve üreticinin iddia ettiği verimlilik ve emisyon kayıtlarına rağmen, elektrikli araçların (BEV), içten yanmalı motorlu (ICE) araçlarla gerçek hayattaki karşılaştırmalarına ilişkin veri eksikliği bulunmaktadır (Martin et al. 2013).

1990-2010 zaman çerçevesi için karayolunda yük taşımacılığında %40 daha fazla yolcu-kilometre ve %80 daha fazla ton-kilometre artış ile görülebileceği gibi, otomobille daha fazla kilometre gitme eğilimi rapor edilmiştir (Hooftman et al. 2016).

Şehir lojistiği, kentsel mobilite emisyonlarının yaklaşık %25'ini oluşturduğundan, bataryalı elektrikli araçlar (BEV) ve dizel dağıtım araçlarına odaklanılmıştır. Yeni BEV araçların, eski dizel araçların yerini aldığı ve elektrik karışımının nispeten temiz olduğu şehirlerde CO_2 emisyonları ve hava kirleticileri sırasıyla %93–98 ve %85–99 oranında azalır (Giordano et. Al. 2018).

Elektrikli ticari araçlar, kilometre başına düşük operasyon ve bakım masrafları ile sera gazı emisyonlarını ve kirliliği önemli ölçüde azaltma potansiyeline sahiptir. CO_2 emisyonlarıyla ilişkili etkileri sınırlamak için sosyal ve politik baskılar ve fosil yakıtlara olan bağımlılığımız hızla artmaya devam ediyor. Şehir içi kullanımında navlun ve ticari araçlar kükürt oksit, azot oksitler ve partikül madde gibi sağlıksız hava kirleticilerinin büyük bir kısmından sorumludur (Feng et al. 2012).

Avrupa'yı uzun vadeli iklim nötrlüğüne doğru bir yola sokmak için ulaşım emisyonlarının büyük ölçüde azaltılması gerekiyor. E-ticaretin yükselmesi nedeniyle ticari taşımacılığın ve özellikle son kilometre teslimatının artması bekleniyor. Bu çerçevede, elektrikli hafif ticari araçlar (eLCV'ler) gelecek vaat eden düşük emisyonlu bir çözüm olabilir (Tsakalidis et al. 2020).

Tek başına eLCV'lerin yüksek penetrasyonu, 2030'a kadar toplam nakliye CO_2 emisyonlarında %3'ün üzerinde bir azalmaya yol açabilir. Azot oksit (NOx) ve partikül madde (PM) gibi kirletici emisyonlar için azalma eşit veya hatta daha yüksek olacaktır. 2030'a kadar PM durumunda, çeşitli kentsel alanlarda konsantrasyonlarda yaklaşık %2 oranında azalma anlamına gelebilir (Tsakalidis et al. 2020).

Elektrikli araçlar rölanti kayıpları ve başlangıçta verimsiz kavrama olmadığından, rejeneratif frenleme yoluyla fren enerjisinin bir kısmını geri kazanabildiklerinden şehir içi trafiğinde ICE'den daha verimlidirler (Martin et al. 2013).

2.LİTERATÜR TARAMA

2.1.Kuyudan Tekerleğe Yaklaşımı (WTW)

Kuyudan tekerleğe çalışmaları farklı yolcu araçlarının enerji tüketimini, ekonomik maliyetini, çevresel etkilerini değerlendirmek ve karşılaştırmak için bir araç olarak kullanılabilir (Orsi et al. 2016).

Emisyon ve tüketim rakamları, yalnızca yakıtın tüketimini ve araç kullanımı sırasındaki emisyonları yansıttığı için daha fazla analiz gerektirir. Elektrik şebekesinden aracın bataryalarına yüklenen elektrik enerjisi ayrıca üretim, nakliye ve dağıtım aşamasında ilişkili emisyonlara sahip olacaktır. Araç yaşam döngüsünün birincil enerji tüketimi ve CO_2 emisyonlarının tam kaydının ölçülmesi gerekiyorsa, yalnızca araç kullanımı sırasındaki emisyonlar otomotiv endüstrisi zorunlu hedef uyumluluğunun temeli olsa bile, bir kuyudan tekerleğe (Well-to-Wheel: WTW) enerji verimliliği ve emisyon hesaplaması kullanılmalıdır. WTW analizi, Kuyudan Tanka (Well-to-Tank: WTT) ve Tanktan Tekerleğe (Tank-to-Wheel: TTW) aşamalarına ayrılabilir (Martin et al. 2013).

2.2.Kuyudan Tanka Yaklaşımı (WTT)

Avrupa'da benzin ve dizel yakıtları çıkarmak, rafine etmek ve tedarik etmek için harcanan enerji sırasıyla yaklaşık 0,08 ve 0,10 MJ / MJ olup, sırasıyla %93 ve %91 WTT enerji verimliliği sağlar. (Martin et al., 2013)

BEV'lerde WTT kısaltması elbette analog olarak kullanılır, yani birincil enerji kaynağından aracın enerji depolama sistemine giden yol anlamına gelir. Hidroelektrik barajların enerji dönüşüm verimliliği %90'ı aşabilirken, dünyadaki en gelişmiş kombine çevrim santralinin (gaz + buhar türbini) verimliliği %60'ı neredeyse geçmez (yeni tesisler için tipik verimlilik %55'tir). Buhar türbini tesisleri ortalama %44 verimlilik içinde yer alır (Martin et al. 2013). Elektrik enerjisi taşımacılığının verimliliği de %92 civarındadır (Eaves al., 2004).

2.3.Tanktan Tekerleğe Yaklaşımı (TTW)

İçten yanmalı motora (ICE) sahip bir araç ile elektrikli aracı karşılaştırmak pek kolay değildir. Her araç tipinde, araca sağlanan enerji, aracı hareket ettirmek için etkin bir şekilde kullanılıncaya kadar bir enerji tedarik ve dönüşüm süreçleri zinciri gerçekleşir. Bu süreçlerin her biri, çeşitli faktörlere bağlı olduğu için ölçülmesi her zaman kolay olmayan belirli bir enerji verimliliğine sahiptir ve bunların bazılarının ölçülmesi çok zordur (Martin et al., 2013).

2.4.Tedarik ve Şarj Verimliliği

ICE arabaları, yakıt ikmali sırasında neredeyse hiç yakıt kaybı olmadığından (özellikle uçucu olmayan dizel durumunda) ve işlem sırasında herhangi bir enerji içeriğini kaybetmediğinden neredeyse %100 enerji tedarik verimliliğine sahiptir. Aynısı BEV için doğru değildir, çünkü pilleri yeniden şarj etme sürecinde, esas olarak şarj cihazı ve pil hücrelerinin iç direnci nedeniyle sırasıyla yaklaşık %89 ve %94 enerji kayıpları vardır. Ancak bu değerler, şarj moduna (yavaş / hızlı) ve pilin kimyasına göre kesinlikle önemli ölçüde değişecektir. (Eaves et al, 2004, Martin et al., 2013)

2.5.Bataryadaki Enerji Dönüşümü

Bir BEV'de deşarj olan pillerin enerji dönüştürme verimliliği, pilin şarj durumu (State of Charge: SoC), deşarj oranı, pilin şağlık durumu (State of Health: SoH) veya pil sıcaklığı gibi faktörlere bağlıdır. Lityum pillerdeki yüksek sıcaklıklar kullanım ömrü boyunca bozulmaya neden olur. Soğuk sıcaklıklar ise güç ve enerji çıkışını düşürerek performansı ve BEV sürüş menzili özerkliğini sınırlar. Pillerin çok çeşitli deşarj oranlarında ve harici sıcaklıklarda çalışabilmesini sağlamak, pillerin verimini, güvenliğini ve ömrünü artırmak için pillerin termal yönetim sistemlerini kullanması esastır (Martin et al., 2013).

En önemli özellik, amper-saat (Ah) cinsinden ölçülen pil kapasitesidir. Bunun yanında watt-saat (Wh) olarak ölçülen bataryada depolanan enerji (kapasite- boşalma sırasındaki ortalama gerilim) dikkatlice hesaplanmalıdır. Yüzde olarak gösterilen bataryanın kullanılabilir şarj durumu (SOC) mevcut şarj durumunu gösterdiği için önemlidir. Lityum pil, hafifliği, yüksek özgül enerjisi, yüksek özgül gücü ve yüksek enerji yoğunluğu nedeniyle gelecek vaat eden enerji depolama cihazlarından biridir (Tie et al, 2013).

2.6.Elektrik Makinası ve Güç Elektroniği

BEV güç aktarma organları komponentleri olan; güç elektroniği ve elektrik makinasındaki teknolojik gelişmeler nedeniyle güç aktarım sistemi verimlilik rakamları %89'a ulaşabilmektedir. Bu oran motor sürücü ve motorun birleşik verimliliklerini içerir (Eaves et al, 2004). ICE aracında olduğu gibi, elektrik motorlarının verimliliği esas olarak tork ve hız haritasındaki konumdan etkilenecektir. Yüksek hızlar, yüksek mekanik kayıplara neden olurken; yüksek torklar yüksek akımlar gerektirecek ve joule etkisinden kaynaklanan kayıpları artıracaktır (Martin et al., 2013).

Tablo 1. EV Komponent Verimlilikleri (Albatayneh et al. 2020)

EV Komponentleri	Verimlilik (%)
AC-DC Dönüştürücü	90-96
Batarya Girişi	90-99
Batarya Çıkışı	93-98
DC-AC Dönüştürücü	96-98
Elektrik Makinası	81-95
Mekanik Aktarma	89-98

2.7.İçten Yanmalı Motor (ICE)

ICE'li araçlar, gelen enerjiyi (yakıtta / bataryada bulunan kimyasal enerji) motor aracılığıyla çekiş mekanik enerjisine dönüştürürken genellikle elektrik motorlarından daha düşük enerji verimliliği sergiler. Termal motorların verimliliği, tipik elektrik motoru verimliliğinden (teorik sınırı olmayan) çok daha düşük olan teorik bir maksimum (Carnot verimliliği, yaklaşık %60) ile sınırlıdır. Motor verimliliği, sürüş sırasında kullanılan motor haritasının bölgesine bağlıdır. Tipik olarak verimlilik, tam yük koşullarına yakın (gaz pedalına tam basıldığında) ve hafif ila orta motor hızlarında zirveye ulaşır. Bu koşullar için bir benzinli motor yaklaşık %33 verimlilik gösterirken, dizel motorlar genellikle %40'ı aşar. Bununla birlikte, özellikle şehir içi sürüş veya yüksek performanslı sürüş koşullarında ortalama verimlilik önemli ölçüde düşecektir. Bazı kaynaklar, %12 ila %20 arasında değişen bir ortalama verimlilikten bahsederler (Martin et al., 2013).

ICE'nin TTW verimliliği, hız, yük koşulları, araç ağırlığı, sürücü davranışı ve yol koşulları gibi çeşitli faktörlere bağlıdır. ICE'nin TTW verimliliği benzinli ICE'ler için %14–33, dizel ICE'ler için % 28–42 aralığında bulunmuştur (Albatayneh et al. 2020).

2.8.Aktarma

Elektrikli otomobillerin çoğu sıfır hızlarda bile yüksek torka sahip olduğundan sabit bir aktarım ilişkisine sahiptir. BEV'lerin aksine, ICE arabalarının çok vitesli bir şanzımana ihtiyacı vardır. Bununla birlikte, elektrikli araçlarda çok vitesli bir dişli kutusunun kullanılması, yüksek motor hızından kaynaklanan enerji kaybını azaltmak ve daha esnek bir tork aralığı elde etmek için yararlı olabilir. Örneğin, bir küçük motor, kabul edilebilir bir başlangıç torku sağlamak için yüksek redüksiyon oranları kullanmalıdır. Ancak bu durum, aracın en yüksek hızını düşürecektir. Genel iletim verimliliği yaklaşık %98 civarında olup, oldukça yüksek olarak ifade edilebilir (Martin et al., 2013).

3.ARAÇLARIN KARŞILAŞTIRILMASI

BEV'ler ile ICE'ler arasında enerji tüketimini etkileyen iki temel fark vardır. Birincisi, BEV'lerdeki elektrik motorları neredeyse tüm çalışma durumlarında %85-90 civarında verimlilik değerlerine sahipken, içten yanmalı motorların enerji verimliliği maksimum %40 mertebesindedir ve bu sadece sınırlı bir tork ve hız aralığı dahilindedir. İkincisi, BEV'lerin frenlemeden rejeneratif enerji üretme yeteneği bulunmaktadır (Braun et al. 2017).

Tahrik türlerinin teknik yerleşiminden başlayarak, farklı sürüş durumları için BEV'lerin ve ICE'lerin göreceli tüketim farklılıklarında varyasyonlar beklenmektedir. Sürüş durumu, sürüş ortamının özelliklerine (örneğin yol tipi, ortam sıcaklığı, yol eğimi) ve ayrıca çeşitli araç içi özelliklerine (örneğin sürüş stili, yük durumu vs.) göre belirlenir (Braun et al. 2017).

Elektrikli bir araçtaki enerji tüketimi, aracın genel verimliliğini ve performansını etkilediği için bir diğer önemli husustur. Geleneksel ICE araç, toplam enerjinin yalnızca yaklaşık %15'ini faydalı harekete dönüştürür (Tie et al, 2013).

Genel olarak, geleneksel ICE araçlardaki çoğu elektrikli aksesuar yükü, BEV yükleriyle karşılaştırılabilir. Bunun nedeni, çoğu otomobil üreticisinin elektrikli araçlarda kullanılan enerji depolama sistemi ile aracın menzilini en üst düzeye çıkarılmasına odaklanmış olmasıdır. Araçtaki elektrikli aksesuar yükleri arasında elektrikli direksiyon, elektrikli frenler, klima sistemleri, farlar, radyo sistemi, navigasyon sistemi, yardımcı akü vb. yer almaktadır. Bununla birlikte, yeni teknoloji, geleneksel yüklerden daha yüksek güç tüketen ve daha gelişmiş elektrik yükünün (yüksek verimli ayarlanabilir hızlı klima ünitesi, güç elektroniği kontrollü direksiyon, elektronik fren kuvveti dağıtımı vb.) kullanılmasına yol açmıştır (Tie et al., 2013).

Yol özellikleri hem BEV'ler hem de ICE'ler için önemli tüketim faktörleridir. Yol özellikleri; yol genişliği, hız sınırları ve çevre yapısı gibi bir yolun sabit koşullarının yanı sıra trafik hacmi gibi değişken koşulları içerir. Bu özellikler birbiriyle ilişkilendirildiği için, genellikle tipik yol türlerini içeren tek bir değişkene yoğunlaşmaktadır (Örneğin, "kentsel", "şehir dışı" ve "otoyol"). Daha büyük hız salınımları ile karakterize edilen yol koşullarında (örneğin şehir içinde, yoğun saatlerde) BEV'lerin verimlilik avantajlarının, daha istikrarlı sürüşle karakterize edilen yol koşullarından (örneğin şehir dışı yollarda, yoğun olmayan yollarda) daha önemli olması beklenmektedir. Bu durumun ilk faktörlerinden biri, BEV'lerin geri kazanımlı frenleme (frenlemeden enerjiyi yeniden üretme) kabiliyetidir. Diğeri ise, içten yanmalı motorların maksimum verimliliği yalnızca belirli bir yükte elde edildiğinden, ICE'lerin güçlü değişen yük aralıklarının olduğu kentsel alanlarda daha az avantajlı olmasıdır (Braun et al. 2017).

Avrupa Komisyonu, mevcut politikaların bir tip onay sürecinde yeni ve daha gerçekçi test prosedürünü devreye almıştır. Dünya Genelinde Uyumlu Test Çevrimi- Worldwide Harmonized Light Vehicle Test Cycle (WLTC) kirletici ve CO_2 emisyonlarını belirlemek için küresel bir standart olarak geliştirilmiştir. WLTC ile daha sağlam bir test temeli ve gerçek karayolu taşıtlarının operasyonunu daha iyi temsil eden bir prosedür sağlamak amaçlanmaktadır (Tsiakmakis et al. 2017).

Karşılaştırılan her iki ticari araç da aynı şartlar altında karşılaştırma yapılabilmesi için WLTC çevrimlerinde araçlar test edilmiştir. Çıkan sonuçlar da bu çevrimden elde edilen veriler ile karşılaştırılmıştır.

Tablo 2'de test edilen EV ve ICE araçların özellikleri gösterilmiştir.

Tablo 2. Test Edilen EV ve ICE Özellikleri

Motor Tipi	AC Endüksiyon	1.6 lt Dizel
Maksimum Güç	85 kW	90 kW
Maksimum Moment	240 Nm	300Nm
Maksimum Hız	135 km/s	177km/s
0-100 km/s Hızlanma Süresi	12,7 sn	13,4sn
Saklanan Enerji (kWh)	29,3	636**
Araç Test Ağırlığı	2125 kg	1980 kg
Vites	Direct drive (1 vites)	6 vites
Yakıt Tüketimi (Şehirlerarası / Şehiriçi / Karışık) lt/100km) *	-	6 / 7,8 / 6,6

* Firma tarafından sağlanan gösterilen yakıt tüketimi değerleri kati değerler olmayıp, üretim döngüsündeki değişiklikler sonucunda fark gösterebilir. GCA bayi ağındaki belirli resmi bayilerde daha güncel değerler bulunacaktır. Her durumda, müşteri tarafından satın alınan aracın resmi yakıt tüketimi değerleri araçla birlikte verilen belgelerle sunulacaktır. CO_2 ve yakıt tüketimi değerlerinin araçla ilgili vergi ve harçların hesaplamasında kullanıldığı durumlarda her bir ülkedeki ilgili kanunlar anılmalıdır.
** 1 lt dizel'den elde edilen enerji 10,6 kWh'dır (URL 1, 2016). 60lt'lik yakıt deposunun enerji değeri 636kWh'dur.

Her iki aracı da karşılaştırdığımızda; daha az güce sahip bir motora sahip olmasına rağmen ivmelenmesi ICE'li araca göre (%5) daha iyi durumdadır. Bunun temel nedeni elektrik makinesinin çok düşük hızlardan itibaren maksimum torku üretebilmesidir. Ayrıca BEV'de yalnızca bir vites varken, ICE araçta 6 vitesli bir vites kutusu bulunmaktadır. Bu sebeple ICE'in maksimum hızı BEV'e göre daha yüksektir. Ancak araçlar arasındaki en büyük fark depolanan enerji miktarıdır. ICE araçta BEV'den yaklaşık 21,7 kat daha yüksek olan saklanan bir enerji vardır.

4.SONUÇLAR

Yapılan karşılaştırmalarda OEM 1'in elektrikli ve dizel aracı WLTC çevriminde test edilmiştir.
Karşılaştırılan veriler Tablo 3'te verilmiştir.

Tablo 3. Test edilen Hafif Ticari Aracın WLTP Testleri Ortalama Enerji Harcama Değerleri

Araç (WLTP Karışık (kWh/100km)	Delta
OEM 1	%65,8

Diğer OEM WLTP testleri ortalama enerji harcama değerleri firmaların paylaştığı verilerden alınmış olup, karşılaştırılan veriler Tablo 4'te verilmiştir.

Tablo 4. Diğer OEM WLTP Testleri Ortalama Enerji Harcama Değerleri

Araç (WLTP Karışık (kWh/100km)	Delta
OEM 2	%70,6
OEM 3	%63,4
OEM 4	%62,2

Yapılan karşılaştırmalarda farklı OEM'lerin aynı tip araçlarının elektrikli ve dizel değerleri karşılaştırılmış olup, çıkan sonuçlara göre elektrikli araçların WLTC karışık ölçümlerde dizel versiyonların göre %62,2 ila %70,6 arasında daha az enerji harcadığı görülmüştür.

WLTC çevriminin 4 farklı kategorisinde belirtilen şekilde testler gerçekleştirilmiş edilmiş olup, analiz sonuçları aşağıda bulunan Tablo 5'te verilmiştir.

Tablo 5. WLTC Testleri Alt Kırılıma Göre Dizel- BEV Enerji Harcama Değerleri

WLTP Alt Kırılım (kWh/100km)	Delta
Düşük	%75
Orta	%68,4
Yüksek	%63,7
Ekstra Yüksek	%63,1

WLTC testleri alt kırılımlarına göre test edilen araç incelendiğinde; düşük bölümde (56,5 km/h'a kadar olan hızlarda) fark %75, orta bölümde (76,6km/h kadar olan hızlarda) fark %68,4, yüksek bölümde (97,4km/h'a kadar olan hızlarda) %63,7, ekstra yüksek olan bölümde (131,3km/h'a kadar olan hızlarda) fark %63,1 bulunmuştur. BEV araçların ICE dizel araçlara göre daha az enerji tükettiği gözlemlenmiştir.

Yapılan bu çalışma ile BEV ve ICE araçların enerji tüketimi farkları incelenmiş olup, çıkan sonuçların sonraki çalışmalara katkı sağlanması beklenmektedir.

ABSTRACT

Automotive manufacturers tried to meet challenges created by clean transport revolution. As more emphasis is put on the request for clean transport, as well as passenger cars, demand for electrified medium/heavy duty vehicles that can fully function on the road will increase. However, even though, electric/hybrid electric vehicles (EVs/HEVs) have demonstrated significant fuel consumption and emissions reductions, range and cost effectiveness has still been a barrier faced by many vehicle manufacturers. And this shifts the balance of technologies used in the vehicles even further in the direction of electrically powered auxiliary systems. The focus of this study is on energy consumption of the auxiliary systems. In this study, detailed vehicle simulation MATLAB/SIMULINK is used to investigate how to reduce the auxiliary sub system systems energy consumption. The methods used for reducing energy and fuel consumption are better control of the auxiliary system loading vehicle driveline and selection of more energy efficient components for the auxiliary systems.

Keywords: Auxiliary system, Energy consumption, Hybrid Electric Refuse Truck

1. INTRODUCTION AND MAIN SECTIONS

Day by day, increasing awareness of global warming, environmental concerns and fossil fuel reduction triggered demand for clean transport. Therefore EVs are the most preferred technology for substituting the fossil fuel-driven vehicle. Within this frame, world's major cities set ambitious emissions targets to reduce carbon dioxide emission levels. Therefore, municipalities push the use of EVs mainly for waste collection and public transport.
The Series Hybrid Refuse Trucks (Se-RTs) have several distinct advantages over conventional ones, which are:

- Quieter Operation, which reduces the environmental noise pollution.
- Reduced Tailpipe Emissions
- Low Maintenance Cost due to the better time investment policy [1]

The hybrid electric truck is suitable for reducing emissions and making fuel economy more efficient. Therefore, a detailed analysis of the energy consumption of the battery electric truck, innovative features such as recharging the battery with regenerative braking should be taken into account.

It is not only the traction system on board a vehicle that consumes power. The number of, and diversity of, loads that are used either to just facilitate the operation of the vehicle, or to increase the comfort and usability of the vehicle is steadily increasing. Some of these loads are mechanically driven via a belt from the crankshaft of the ICE, and yet some are electrically driven. In hybrid vehicles, and especially those without an ICE like the Fuel Cell vehicle, it is beneficial or necessary to drive the auxiliary loads with electric power. There are several advantages of doing so:
1 The load can be more freely placed within the vehicle since they do not have to be connected to the belt in the front of the ICE. This give both a weight and volume benefit.
2 The efficiency can be significantly increased, since the possibilities to control the power consumption is bigger when an electric machine is driving the load. The AC compressor, as an example, can be driven at the optimal speed all the time. In a conventional vehicle the AC compressor is tied hard to the ICE speed which is related to the vehicle speed, not to what is best for the AC compressor [2].

West Virginia University (WVU), National Renewable Energy Lab (NREL), and the Department of Energy (DOE) have compared hybrid buses to conventional buses run under different drive cycles. Hybrid buses showed 11% to 65%

fuel economy compared to conventional buses. Contributing factors to the fairly wide range included the drive cycle and the hybrid engine manufacturer. [3]

In 2002 NREL study has a project that BAE Orion VI system with a series configuration, the Orion system found that the average in-service fuel economy for the fleet was 10% higher than that of a similar diesel bus fleet. But it showed that it could be up to 22% higher than diesel buses operating in a similar service. While greater differences in fuel economy were observed between hybrid and diesel buses in the colder months, this difference was observed to decrease further in the warmer months. For hybrid buses, this reduction in fuel economy was thought to be due to air conditioning loads and / or thermal problems in the battery, which had less energy storage capacity at hot temperatures. However, they did not do any quantitative studies to determine the effect of air conditioning. [3]
Transit organizations consider investing in a new fuel saving technology. But their main concern will be the time it takes to get a return on their investment in the form of fuel savings. Due to the limited amount of third-party test data, many organizations have to make a number of predictions and assumptions when performing these calculations. More real-world, third-party, fleet-specific data are required to enable fleets to make the most accurate predictions possible. Rachel L.'s work seeks to contribute to filling some of the many gaps in the data pool that fleet owners use in their decision-making processes. Anderson's study included electrification and modeling of commercial vehicle auxiliary load based on buses. As a result of his studies, the total fuel consumption improvements achieved by combining the Control and the new technology selection “New + Control” for the conventional bus were calculated as 8 - 12% and for the hybrid bus 3.5 - 5%. [4].

The enhancing electrification of the truck powertrain in the 2020s means that most trucks need to be completely redesigned. Therefore, the detailed analysis of the energy consumption of the electric garbage truck should be reviewed. In addition to the basic forces, auxiliary systems should also be considered in the modeling. Also whole road transport greenhouse gas emissions (GHG), about 25% of the emissions are due to heavy duty vehicles including buses especially trucks [5]. Improving truck energy efficiency through the development and introduction of new engines and cleaner fuels is cited as a key objective in the EU White Paper.[6] In addition, the decommissioning of internal combustion engine vehicles is another goal set for the road transport industry.

Many studies [7-12] update their models to enhance energy efficiency in commercial vehicles and keep up with the upcoming electrification of 2020. These studies are mainly for buses and auxiliary loads are rarely taken into account. However, the auxiliary loads of garbage trucks, as well as buses, are quite important. The novelty of this work is that the auxiliary loads of refuse trucks are modeled and run in two real-world driving cycles.
The following discussion on potential savings with sub systems are based on extensive measurements and simulations on a fuel cell series hybrid vehicle. There are two main pathways for reducing auxiliary energy consumption, technology selection and control. The following auxiliary sub system improvements have been analysed by use of the new model:

- Technology selection
- Pneumatic to electric
- Mechanical to electric
- Hydraulic open loop to closed loop
- Hydraulic to electric
- Control Selection
- Load shaving (peak power reduction)
- Intelligent use of braking energy

Some technology selections are more long-term solutions than other as e.g. electrical steering assist for heavy trucks will not be available in the near future. The relevant control strategy, according to our study, would be to prioritise activation of all sub systems during braking and to increase peak propulsion system power demand by deactivating auxiliary sub system loads during acceleration.

Vehicle architecture of the rear loading hybrid refuse truck is first presented in Section II. In Section III where auxiliary system that involves functional and powertrain auxiliaries are presented. In Section IV forward facing vehicle simulation model developed in MATLAB®/Simulink environment to examine the effect of auxiliary system on the overall energy consumption of the vehicle is given. In section V hybrid truck model, auxiliaries and demand control unit are integrated together and simulation results for real world drive cycles (Figure 5) is given to demonstrate the correlation of demand control and the with energy consumption of the vehicle. Finally, the paper ends up with the conclusions section that proposes some valuable comments on the management of electrified auxiliary systems.

2. REAR LOADING HYBRID REFUSE TRUCK

Rear Lift vehicles (also referred to as 'Rear Loaders') come in many different sizes, from small two-axle units with a 6m3 body for use in narrow alleys or parks and reserves, etc. to heavy three-and four-axle units with a 30m3 body and 25 tonne or more GVM for the collection of municipal and commercial and industrial wastes.

The rear lift collection system is appropriate for sites with limited vehicle access and storage space, customers who generate small quantities of waste and recyclables and customers who generate large volumes of recyclables that are separated into individual streams and stored at the source (source-separated) e.g., white paper, cardboard, plastics, glass, metals etc., for recycling. Rearlift containers require the least amount of capital investment.

The container is wheeled to the rear of the vehicle by the driver and mechanically lifted and emptied into the hopper of the compactor. A sweep and slide panel collects and forces the material inside the main compaction chamber where the material is compacted against the ejector blade. As more material is loaded into the compactor body, the ejector blade moves forwards towards the vehicle cabin until the body is full. The waste is then unloaded at the disposal facility using the ejector blade to push the material through the open tailgate.

3. AUXILIARY SYSTEMS FORMULATIONS

In this chapter the different auxiliary system, mechanical and electric, of the bus and the corresponding auxiliary systems simulation models are described. In the simulation model description there are references to constants and component information that are set in a special data set up file. MATLAB™ runs the set up file before the simulations.

3.1. Air Condition

Due to design and aerodynamic modern vehicles are equipped with large windows. The windows size will increase the cooling demand. The AC-system is the largest energy consumer of the auxiliary subsystem. In small cars the power demand is lower, approximately 4 kW [4]. Whereas the AC-system of a medium duty consumes up to 25-30 kW [4]. This energy consumption of the AC system is also a large part of the total vehicle's energy. When the AC starts working in a small car the idling speed of the engine usually to go down.
The AC system performance is strongly influenced by the efficiency of the compressor. In an AC system the compressor is the most energy consuming part.

$$P_{comp\,A/C}=\mathrm{b}_{comp\,A/C}\{0,1\}K_{comp\,A/C} \tag{1}$$

$$\mathrm{b}_{comp\,A/C}\{0,1\}=u_{preq-L}\{0,1\}\wedge u_{preq-H}\{0,1\} \tag{2}$$

where $P_{comp\,A/C}$ is compressor power, $\mathrm{b}_{comp\,A/C}\{0,1\}$ is A/C compressor on/off contol signal, and $K_{comp\,A/C}$ is the power constant of A/C compressor.

$$P_{fan\,A/C}=\begin{cases}P_{fan\,A/C}, & u_{preq-H}\{0,1\}<u_{preq-L}\{0,1\}\\ 0, & u_{preq-H}\{0,1\}>u_{preq-L}\{0,1\}\end{cases} \tag{3}$$

where $u_{preq-H}\{0,1\}$ is high propusion power request signal, $u_{preq-L}\{0,1\}$, is low propusion power request signal and $\mathrm{P}_{\mathrm{fan\,A/C}}$: 24V Fan Power Consumption [W]

3.2. 24 V System

The development has gone from DC generator to alternators. There are always losses when converting mechanical energy to electric. A normal operated alternator has the average efficiency of 50 %. At higher speeds the efficiency falls-away. The losses are: iron losses (hysteresis and eddy current), copper losses (resistance in the windings), friction (bearings) and aerodynamic losses (cooling fan). In a hybrid vehicle a DC/DC converter will be used instead of an alternator. A DC/DC converter has no moving parts accept for a small cooling fan. All transformations from high voltage to low voltage are done by power electronic components. The efficiency will rise dramatically if it is possible to use a DC/DC converter instead of an alternator. A DC/DC converting power from 500 V to 12 V will have an efficiency of about 90 %.

$$P_{g,dc/dc}=\overline{u_{preq-H}\{0,1\}}\,[\min(P_r,P_{N,dc/dc})\mathrm{b}_{dc/dc}\{0,1\}] \tag{4}$$

$$P_{c\,dc/dc}=\frac{\overline{u_{preq-H}\{0,1\}}[min(P_r,P_{N\,dc/dc})\mathrm{b}_{dc/dc}\{0,1\}]}{\eta_{dc/dc}} \tag{5}$$

where $P_{c\,dc/dc}$ is DC/DC converter power consumption, $P_{g\,dc/dc}$ is DC/DC converter generated power, $u_{preq-H}\{0,1\}$ is high propulsion power request, $\eta_{dc/dc}$ is DC/DC efficiency, $P_{N\,dc/dc}$ is DC/DC converter nominal power, P_r is residual power from regenative brake power and $\mathrm{b}_{dc/dc}\{0,1\}$is DC/DC on/off control signal.

$$SOC_{24}=\begin{cases}\dfrac{1}{Q_{24}V_{N/24}}\displaystyle\int\left[\frac{P_{g\,dc/dc}-P_{c\,dc/dc}}{\eta_{chr/24}}\right]dt, & P_{g\,dc/dc}-P_{c\,dc/dc}\geq 0\\ \dfrac{1}{Q_{24}V_{N/24}}\displaystyle\int\left[\frac{P_{g\,dc/dc}-P_{c\,dc/dc}}{\eta_{dchr/24}}\right]dt, & P_{gdc/dc}-P_{c\,dc/dc}<0\end{cases} \tag{6}$$

Q_{24} is 24 V Battery capacity, $V_{N/24}$ is 24 V battery nominal voltage, $\eta_{chr/24}$ is 24 V battery charge efficiency, $\eta_{dchr/24}$ is 24 V battery discharge efficiency

3.3. Hydraulic System

Hydraulic electric power steering is a combination of electric motor driven hydraulic pump instead of engine shaft driven. The steering will not be dependent on the power supply of vehicle engine. Driving characteristics will be as a standard hydraulic power steering system. Power-savings of about 70% compared to standard hydraulic systems. This steering system will also be suitable for hybrid vehicle. Figure 1 shows that hydraulic steering power according to vehicle speed.

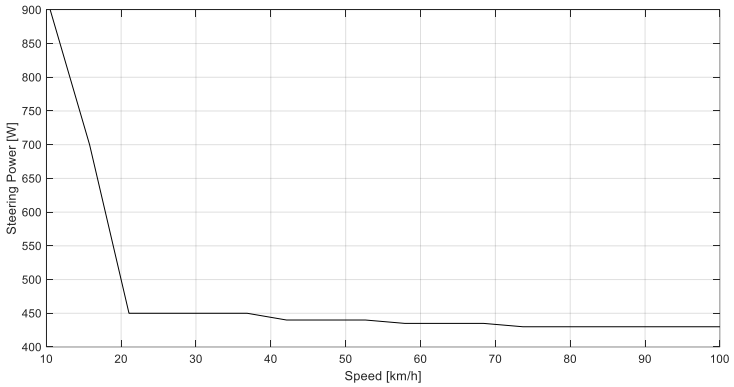

Figure 1. Hydraulic Steering Power with respect to vehicle speed

3.4. Pneumatic System

Pneumatic systems are used in most commercial vehicles. The purpose is to facilitate power braking or remote refuse pneumatic. Other application of pneumatic technology is used in are EGR (Exhaust-Gas Recirculation) valve control and operation of other engine valves. The use of pneumatically controlled engine valves is increasing to meet stronger emission regulations.

Most commercial vehicles use pneumatic brake systems. Laws and regulation are controlling the number of full brakes that the air tanks should supply. They also control the time the compressor needs to refill the tanks.

$$\mathrm{b}_{pn}\{0,1\}=\overline{\left(\int(\ell_{cm}-\ell_c)\,dt+V_0\right)} \tag{7}$$

$$P_{cm}=\mathrm{b}_{pn}\{0,1\}\,K_{pn} \tag{8}$$

$$\mathrm{l}_{cm}=\left|\mathrm{b}_{pn}\{0,1\}K_i\right| \tag{9}$$

where $b_{pn}\{0,1\}$ is pneumatic compressor on/off, l_c is air flow consumption, l_{cm} is compressor generated air flow and V_0 is initial volume of air tank, P_{cm} is compressor power, l_{cm} is compressor air flow, $b_{pn}\{0,1\}$is pneumatic compressor On/Off, $K_{pn}$is power constant of pneumatic compressor, K_l is air production constant.

3.5. Cooling Fan

The cooling fan supplies the engine with substantial cooling capacity at low speeds, when the force-air ventilation is smaller. Most of time (95%) the air stream is enough to provide a sufficient radiator cooling. In small cars a single-piece injection-molded plastic fan. An electric motor (up to 600 W) is used to drive the fan in small cars. The electric fan is easy to deactivate and than be activated when the temperature reaches a certain level. Due to costs the fan is connected to the engine via a belt in lager cars.

In a hybrid vehicle there are more than one coolant circuit. The engine or fuel cell has a higher temperature and the electric motor, battery and electronics have separate liquid cooling with lower temperature. All cooling fans in hybrid vehicle can easily be electric powered when high voltage is available.

$$P_{cfan} = C_{cfN} \tag{10}$$

where P_{cfan} is cooling fan power consumption and C_{cfN} is nominal cooling fan power.

3.6. Cooling Fan of ICE

In a hybrid vehicle there are more than one coolant circuit. The engine or fuel cell has a higher temperature and the electric motor, battery and electronics have separate liquid cooling with lower temperature. All cooling fans in hybrid vehicle can be electric powered since electric energy is available.

The engine is mechanically connected to the hydraulic pump. The latter drives the hydraulic motor that is mechanically connected to the fan. The relation between the hydraulic pump displacement [cc/rev] and the hydraulic motor displacement [cc/rev] represent the maximum gear ratio of the pump/motor. A bypassing (slip) valve controls the oil flow in the circuit. Slow speed of the hydraulic motor is achieved by opening the bypassing valve. From an efficiency and energy point of view it would be preferable to control the oil flow with a variable displacement pump instead of using the bypassing valve, which is subject to greater losses.

$$P_{ice_f} = \frac{\left[\frac{n_{ice,max}}{\delta_{cf}}\right]}{\min\left(\frac{n_{ice,max}}{\delta_{cf}}, n_{ice}\right)} \cdot \left[f\left(n_{ice,max}\right).1000\right]\delta_{cf}/\eta_{cf} \tag{11}$$

where P_{ice_f} is ICE fan power, n_{ice} is ICE speed δ_{cf} is cooling fan slip, $n_{ice,\,max}$ is ICE maximum speed and η_{cf} is ICE cooling fan efficiency. Figure 2 shows thar ICE cooling power function.

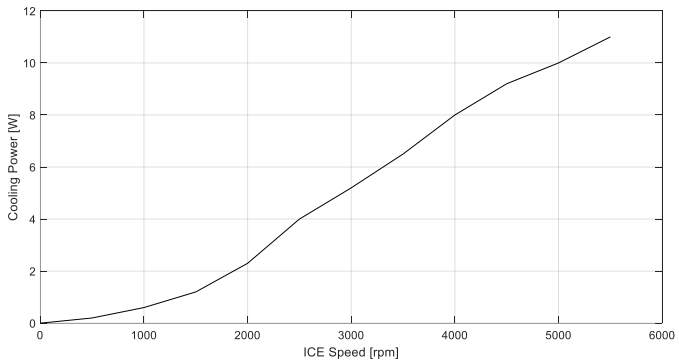

Figure 2. ICE Cooling Power with respect to shaft speed

3.7. Refusing

A model for calculating energy consumption during the refuse collection with compacting trucks is presented. Refuse collection process energy consumption as shown in Figure 3 takes about 68 sec. During the simulation, the model determines the intervals where the speed is zero during 68 seconds of the driving cycle. Along the planned road, the vehicle collected refuse 19 times.

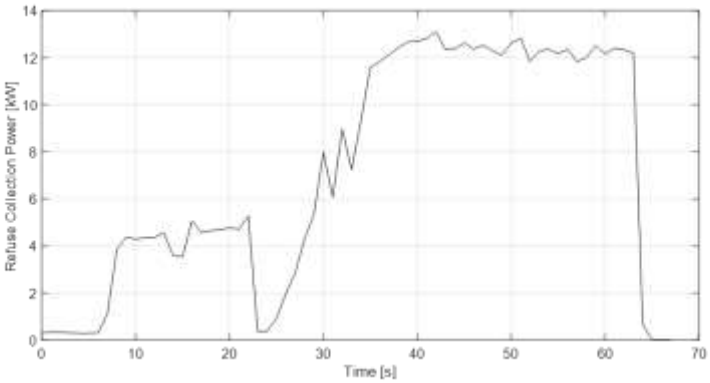

Figure 3. Refuse Collection Power

3.8. Auxiliary System Control

Control of auxiliary system loads can improve total consumption. When the propulsion system needs full power at acceleration, the auxiliary system power is reduced. Such shutdowns are only necessary. Also in braking regenerative power can be charge 24 V battery [4].

$$u_{preq-H}\{0,1\} = \begin{cases} 1 & P_{pr} \geq 0 \\ 0 & P_{pr} < 0 \end{cases} \quad (12)$$

$$P_r = \begin{cases} 0, & -P_{pr} - P_{aux} < 0 \\ -P_{pr} - P_{aux}, & -P_{pr} - P_{aux} > 0 \end{cases} \quad (13)$$

$$u_{preq-L}\{0,1\} = \begin{cases} 0 & P_{pr} \geq 0 \\ 1 & P_{pr} < 0 \end{cases} \quad (14)$$

$u_{preq-H}\{0,1\}$ is high propusion power request [1/0], $u_{preq-L}\{0,1\}$ is low propusion power request [1/0], P_r is residual power, P_{pr} is propulsion power, P_{aux} is auxiliary power.

4. SIMULATION MODEL

Figure 4 shows the model of auxiliary loads. The system has 3 inputs; engine speed for ICE cooling, vehicle speed for detection of refusing, and propulsion power of the vehicle to save energy from auxiliary loads. In Figure 5, a diagram of the operation of the S-HEV vehicle with auxiliary loads is given. The forward model method was used in the model of the vehicle. The dynamic model of the vehicle has been created with MATLAB SimDriveline library.

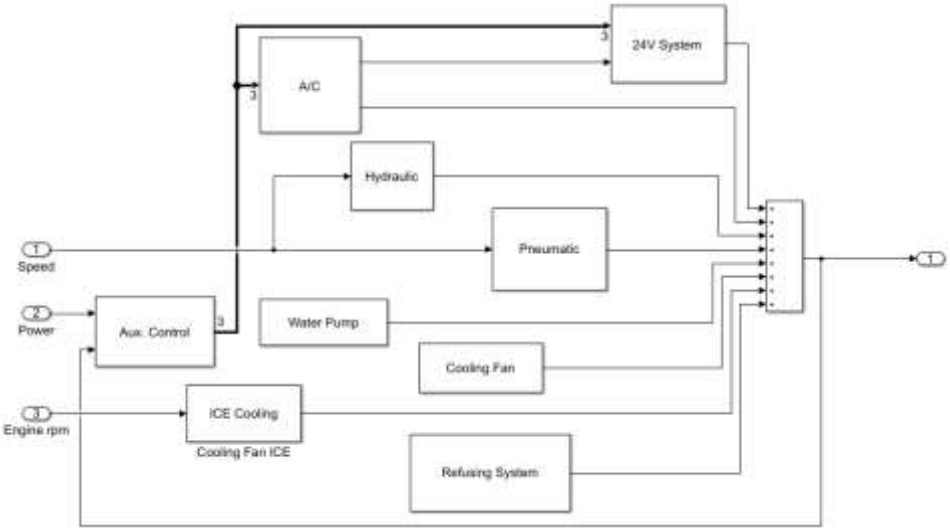

Figure 4. Auxiliary Load Simulation

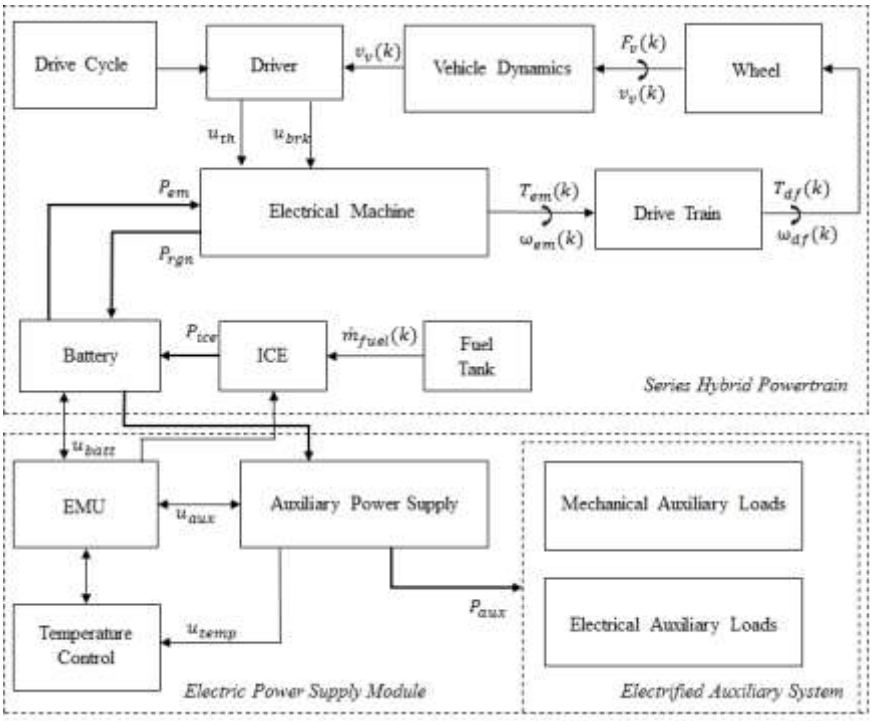

Figure 5. S-HEV Powertrain and Auxiliary System

5. RESULTS

In this part simulation results for hybrid refuse trucks speed, propulsion power and auxiliary systems power has given. Figures 6 and 7 Refuse Cycle speed and power consumption are given. This cycle is the route of a conventional refuse truck in Gebze. In the cycle, the vehicle collects 19 times and unloads it once. Figure 10-15 is the auxiliary power consumptions of the refuse cycle. Each refuse collection times are shown in Figure 14. Another driving cycle used is the Avcılar-Zincirlikuyu cycle. The Avcılar-ZK cycle and power consumption are given in Figure 8-9. Also, the minimum, maximum and average powers of various loads in both driving cycles are given in Table 1.

Refusing System	2.66	0.9	13.11	0.88	1.19	13.11
Auxiliary System	9.7	3.32	18.15	3.13	4.23	21.67

5. CONCLUSION

In refuse trucks, the auxiliary systems consume large amounts of energy. Some of these systems should be changed to electric and/or controlled with respect to the propulsion system. This paper aimed that such improvements can reduce the energy consumption by electrification. The electrification of auxiliaries has a great potential for improving the total fuel consumption. By means of advanced design tools, like simulation software, it is possible to design well optimized auxiliaries with a suitable and efficient management. This optimized design can make the switch from a mechanical or thermal system to an electrical system affordable. In the near future, electrified auxiliaries will be progressively introduced in superior class vehicles, likely starting with electric air conditioning units and electric power steering.

ABSTRACT

The main goal of this study is to investigate the change of the consumer preferences in the new vehicle market of Turkey. Regardless of social and macro-economic variables, the study shows the change in consumer preference in other words, the study investigates changes in the new vehicle market in Turkey. The sub analyses include evaluate of type of vehicle, brand groups, segment type, body type. The data between 2004 and 2018 will be used for these analyses. The data set of the study provided by Automotive Distributors' Association. The data set includes the variables such as brand, model, segment, body type and monthly sales of the all these details. The result includes the percentage changes and trend analysis for each detail. The study emphasizes the changes of consumer preferences and explains the change in numerical results. The results would be used for the prediction for the following years to inspect to Turkish new car markets.

ÖZET

Bu çalışmanın amacı Türkiye'deki tüketicilerin yeni araç alımı tercihlerindeki değişimi ortaya koymaktır. Sosyal ve makro ekonomik verilere bakılmaksızın tüketicinin yeni otomobil tercihi değişimi diğer ifade ile Türkiye'deki yeni araç piyasasındaki değişimler incelenecektir. Tercih değişimleri; araç tipi, sınıf, kasa tipi (karoser) alt başlıklarında incelenecektir. 2004-2018 yılları arasındaki veriler incelenerek tercih değişimleri ortaya konacaktır. Kullanılacak olan veri seti otomobil distribütörleri derneğinden elde edilmiş olup; marka, model, sınıf, kasa, tipi vs bazında detaylı aylık satış rakamlarını içermektedir. Pazardaki hareketler rakamsal ve yüzdesel olarak hesaplanacak ve analiz edilecektir. Bu çalışma Türkiye yerli otomobil tercihleri değişimlerini rakamsal olarak ortaya koyması acısından önem arz etmekte, otomobil üreticilerine gelecek ile alakalı tahminlerde yardımcı olabilecek çıktılar ortaya koyacaktır.

Anahtar Kelimeler: Yeni araç pazarı, Otomobil tüketici tercihi, market analizi, otomobil tercihi

1. GİRİŞ

Bu çalışmanın amacı yani araç piyasasındaki ve binek otomobil piyasasındaki tüketici tercih değişimlerini ortaya koymaktır. İki kısımdan oluşan analiz kısmında ilk kısımda binek otomobil ve hafif ticari araçların öncelikle yıl bazında sonrasında ise ay bazında satış rakamları değerlendirilecek, pazardaki her iki araç tipi için önemli noktalar belirlenecek ve bu önemli noktanın sebepleri açıklanacaktır. Yıl bazında yapılacak olan analiz daha çok yeni araç pazarındaki değişimi uzun vadede görmeyi amaçlamaktadır. Uzun vadede gerçekleşen özellikle makro ekonomik değişimleri her bir araç grubunun tepkisini bu tepkilerin benzerliğini ve farklılıklarını ortaya koyma amacındadır. Öte yandan aylık olarak yapılacak analiz yıl içindeki ay ve çeyrek bazlı talep miktarı değişimlerini içermektedir. İkinci kısımda ise daha detaya inilerek sadece binek otomobil piyasası incelenecek ve binek otomobil tüketicisinin tercih değişimleri ortaya konacaktır. Bu tercih değişimleri öncelikle binek otomobil sınıfına göre, sonra kasa (karoser) tipine göre ve son olarak sınıf-kasa kombinasyonuna göre değerlendirilecektir. Bu analizler yapılırken herhangi bir bağımlı değişken ile ilişki kurarak bir sonuç ortaya koyma amacında değildir. Bu sebeple herhangi bir regresyon metodu kullanılmamış olup, tüketici tercih değişimleri gösterecek temel ve basit istatistik kullanılmıştır. Regresyon yaparak yani araç piyasası analizi yapan birçok çalışma literatürde mevcuttur. Bunlardan seçilenlere literatür kısmında değinilmiştir.

Bu çalışma belirtilen sırada ilerlemektedir: seçilmiş makalelerin değinildiği; literatür taraması, kullanılan veri setinin açıklandığı; data, yeni araç pazarındaki kısa ve uzun vadeli değişimin incelendiği; genel market analizi, binek otomobil pazarındaki tercih değiminin incelendiği; binek otomobil tüketici tercih analizi ve kısaca analizlerin özetlendiği; sonuç.

2. LİTERATÜR TARAMASI

Otomotiv sektörü üzerinde yapılan çalışmalardan bir kısmında ise otomobil talebini etkileyen faktörler üzerinde durulmuştur. Tüketicinin otomobil tercihini açıklayacak olan mikro verilerin araştırıldığı çalışmalar şöyledir. Arslan (2003), çalışmasında tüketici tatminini ön planda tutarak tüketicinin hangi pazarlama bileşenleri veya hangi markalardan tatmin olduğunu incelemiş ve otomobil pazarlamasında müşteri odaklı yaklaşım anlayışının faydaları üzerinde durmuştur. Otomobil sektöründe satın alınan otomobilin niteliği ve özelliği gereği satın alma işleminin temelinde marka seçiminin ön planda olduğu sonucuna ulaşmıştır. Satın alma davranışını etkileyen dış değişkenlerin yani aile sosyal sınıf danışma gruplarının tüketicilerin satın alma kararında hata payının azaltılmasına yardımcı olduğu sonucuna varmıştır.

Otomobil tüketicisinin satın alma karar sürecini değerlendiren Aksoy (2006), bilgi arama aşamasının oldukça önemli olduğunu belirtmiştir. Bilgi arama aşamasında tüketicilerin hangi bilgi tiplerine ve bilgi kaynaklarını daha çok önemsediklerini araştırmıştır. 486 kişi üzerinde yaptığı araştırmada tüketicilerin otomobil tüketiminde estetik ve konfor özelliği içeren bilgileri ve geleneksel pazarlama iletişim araçlarını daha fazla önemsediklerini saptamıştır.
Bir diğer çalışmada ise mikro verilere ek olarak, dönemin reel faizleri de göz önünde bulundurulmuştur. Alper ve Serdar (2000), çalışmasında 1996 ve 1999 yılları arasında satışa çıkarılan otomobil modellerine ait fiyat, satış, kalite verileri ile bu döneme ait reel faizleri kullanarak otomobil talebini tahmin etmişlerdir. Otomobil piyasası talebinin hesaplanmasında otomobilin üretildiği ülkenin yani menşeinin önemli bir etken olduğunu ve yerli, AB'den ve diğer ülkelerden ithal edilen otomobillerinin talep eğri değerinin ayrı ayrı hesaplanmasının gerekliliği sonucuna ulaşmıştır.

Ayrıca, otomobil talebinde tüketici tercihlerinin yanı sıra sektörün genel durumunu ve ülkedeki ekonomik durumun otomotiv sektörü üzerindeki etkisini inceleyen çalışmalar da mevcuttur. Görener ve Görener (2008), çalışmasında dünya otomotiv sektörünün mevcut durumunu inceleyerek ülke ekonomilerine katkılarından bahsetmiş, Türkiye'de otomotiv Sektörünün gelişimini incelemiştir. Türkiye'de otomotiv sektörünün çözülmesi gereken sorunlarına ve geleceğe yönelik sektörel beklentilerine değinmiştir.

3. DATA

Çalışmamızda kullanılacak olan veri seti çeşitli ulusal ve uluslararası güvenilir kuruluş olan Otomobil Distribütörleri Derneği'nden (ODD) alınmıştır. ODD, 1987 yılında beş Avrupalı otomobil üreticisi tarafından kurulmuş olup, otomotiv sektörünün önemli bir kısmını oluşturan otomobil-hafif ticari araçlar kapsamında satış, pazarlama, ithalat, satış sonrası servis, promosyon, finansman gibi alanlarda etkinlik kazanmıştır. ODD'den elde edilen veri seti, 2004 Ocak ayından 2017 Aralık ayına kadar yeni araç piyasasındaki yeni araç satışlarını aylık olarak göstermektedir. Bu çalışma, binek otomobil ve hafif ticari araçlar dışındaki tüm araçlar (otobüs, kamyon, hafif ticari araçlar ve benzerleri) veri setinden elimine edilmiştir.

4. GENEL MARKET ANALİZİ

Genel market analizi veri setindeki binek otomobil ve hafif ticari araçların birlikte değerlendirilip, detay analizlere girilmeden her bir ürün grubu (hafif ticari araçlar – binek otomobiller) için pazardaki dalgalanmayalı ortaya koymayı hedeflemiştir. Bu analiz öncelikli olarak 14 yıldaki dalgalanmayı göstermek amacı ile yıl bazlı, sonrasında ise yıl içi dalgalanmayı göstermek amacı ile aylık bazda yapılmıştır.

4.1. Yıllara Göre Binek Otomobil ve Hafif Ticari Araç Pazarı

Yıllık bazda yeni araç satış grafiklerini incelediğimizde genel olarak yukarı yönlü olan trend global krizlerin etkisiyle dalgalı olarak seyretmektedir. Tablo 1'de yeni araç pazarı yıllık toplam satışta en yüksek adete 2016 yılında 983.720 adet ile ulaşılmış, en düşük satış rakamı ise 2008 yılında 494.023 olarak gerçekleşmiştir.

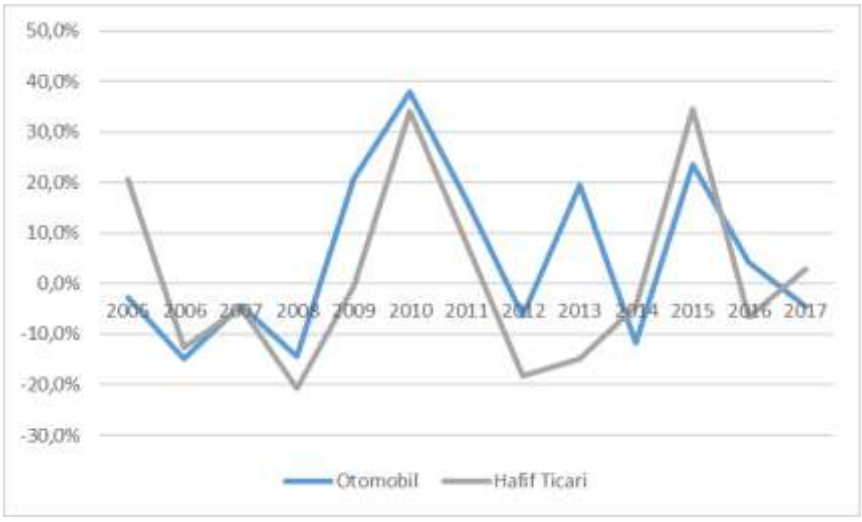
Tablo 1:Yıllara Göre Binek Otomobil Hafif Ticari Araç Pazar Satışları

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Otomobil	451.209	438.597	373.219	357.465	305.998	369.819	509.784	593.519	556.280	664.655	587.331	725.596	756.938	722.759
Pazar Payı	65,6%	60,6%	60,0%	60,1%	61,9%	66,4%	67,0%	68,7%	71,5%	77,9%	76,5%	75,0%	76,9%	75,6%
Yıllık Değişim		-2,8%	-14,9%	-4,2%	-14,4%	20,9%	37,8%	16,4%	-6,3%	19,5%	-11,6%	23,5%	4,3%	-4,5%
Hafif Ticari	236.561	285.257	249.122	237.297	188.025	187.307	251.129	270.920	221.481	188.723	180.350	242.421	226.782	233.435
Pazar Payı	34,4%	39,4%	40,0%	39,9%	38,1%	33,6%	33,0%	31,3%	28,5%	22,1%	23,5%	25,0%	23,1%	24,4%
Yıllık Değişim		20,6%	-12,7%	-4,7%	-20,8%	-0,4%	34,1%	7,9%	-18,2%	-14,8%	-4,4%	34,4%	-6,5%	2,9%
Toplam	**687.770**	**723.854**	**622.341**	**594.762**	**494.023**	**557.126**	**760.913**	**864.439**	**777.761**	**853.378**	**767.681**	**968.017**	**983.720**	**956.194**

2004 yılında yıllık 687.770 satış hacmi olan yeni araç pazarı, 2017 yılında ise 956.194 adete ulaşmış, 14 yıllık zaman diliminde %39,03 oranında büyümüştür. Diğer ifade ile yıllık ortalama büyüme %2,79 olarak gerçekleşmiştir. Bu zaman diliminde bir önceki yıla göre pazar genişleme ve daralması incelendiğinde, pazar 2010 yılında %39,58 büyüdüğü, diğer yandan yeni araç pazarının 2008 yılında %16,94 küçüldüğü gözlemlenmektedir. Bu durum açık bir şekilde 2009 yılında yaşanan global krizin etkisi olarak yorumlanabilir. Kriz dönemi öncesi pazar en büyük küçülmeyi yaşarken krizin aşılması ile birlikte ötelenen araç alımları gerçekleşmiş ve en büyük pazar genişlemesi ortaya çıkmıştır.

Bu veriler araç tipi bazında incelendiğinde; 2004 yılında 451.209 olan yeni otomobil satış rakamı 2017 yılında 722.729'a ulaşmıştır, bu da yeni otomobil pazarının 14 yıllık sürede %60,18 büyüdüğünü göstermektedir. Bu oran yıllık ortalama %4,30 Pazar büyümesine denk gelmektedir. Yeni otomobil satışlarında yüksek rakama 2016 yılında yaşanmış, en düşük ise krizin etkisinin görüldüğü 2008 yılında gerçekleşmiştir. İncelenen dilimin yedi yılında otomobil satışlarının bir önceki yıla göre arttığı yani yeni otomobil pazarının büyüdüğü görülmektedir, kalan 7 yılda ise pazarda daralma meydana gelmiştir. Yüzdesel olarak en büyük artış %37,8 ile 2010 yılında gerçekleşir iken pazardaki en büyük daralma ise %14,9 ile 2006 yılında gerçekleşmiştir. Yeni otomobil pazarı 2004-2009 yılları arası üst üste dört yıl bir önceki yıla göre küçülmüştür. Bu küçülme sonucu 2004 yılına göre, 2008 yılında pazar %32,18 küçülmüş duruma ulaşmıştır.

Diğer yandan, hafif ticari araçlarda en yüksek yıllık satış adedi 2005 yılında 285.257 ile ulaşılmıştır, en düşük satış rakamı ise 2014 yılında 180.350 adet ile gerçekleşmiştir. Hafif ticari araç pazarı 14 yıllık zaman diliminde %1,32 oranında küçülmüştür, bu da yıllık ortalama %0,09'luk bir küçülmeyi göstermektedir. Bir önceki yıla göre oranlar incelendiğinde 2010 yılında hafif ticari araç pazarı 2009 yılına göre %34,1 oranında genişlemiş, en büyük daralma ise 2008 yılında %20,8 oranında gerçekleşmiştir. İncelenen dilimin beş yılında hafif ticari araç pazarı genişlemesi gerçekleşmiş iken kalan dokuz yıl pazarda daralma meydana gelmiştir.



Şekil 1: Bir Önceki Yıla Göre Satışlardaki Değişim

Binek otomobil ve hafif ticari araç bir önceki yıla göre değişimler tek bir Şekil 1'de incelendiğinde birbiri ile büyük oranda uyum içinde hareket ettiği gözlemlenmektedir. Sadece 2013 yılında pazar daralma genişleme durumunda en büyük fark gerçeklemiş, hafif ticari pazarı %14,8 daralırken, otomobil pazarında %19,5 genişleme gerçekleşmiştir. Bu durumun yürürlüğe giren ticari araçlar ile alakalı düzenlemenin etkisi olduğu düşünülebilir.

Yeni araç pazarındaki tüketici tercihini daha iyi analiz edebilmek adına yapılan hafif ticari aracın orantısal değerlendirmesinde, 2006 yılında hafif ticari araç oranı %40'a ulaştığı görülmektedir. Yani satılan her 100 yeni aracın 40 tanesi hafif ticari araç grubundandır. Öte yandan, 2013 yılında ise binek otomobil satış oranı yaklaşık yüzde 80'ne ulaşmış otomobil ve hafif ticari araç arasındaki en büyük oransal fark ortaya çıkmıştır. 14 yılın ortalamasında ise yeni araç marketindeki satışların, yaklaşık olarak %70'i otomobil %30'u hafif ticari araç grubunda gerçekleşmiştir. Pazarda

bulunan bazı firmaların sadece otomobil pazarında satışı olduğu, hafif ticari araç piyasasında satışının olmadığı gözlemlenmektedir. Ortaya çıkan sonuç, bu durumdaki firmaların sattıkları otomobil sayısının yaklaşık olarak yarısı kadar ticari araç satabileceklerini fakat bunu değerlendirmedikleri şeklinde yorumlanabilir.

4.2. Aylara Göre Binek Otomobil ve Hafif Ticari Araç Trendi

Bu bölümde yeni araç pazarının yıl içinde nasıl hareket ettiğini göstermek amaçlanmıştır. Pazar içi aylık dalgalanmalar firmalara finansal ve pazarlama açısından verdikleri kararlarda önem arz etmektedir. Burada firmalardan kasıt sadece üreticiler değil sektörde satış yapan bayileri de içermektedir. Firmalar fon akışı, finansal anlaşmalar vs. de yapılacak olan reklam çalışmasının doğru zamanda olmasına kadar birçok kararda yıl içi trendi öngörmeleri yararına olacaktır.

İlk olarak yılı 3 aylık dilimlere bölerek yapılan 4 çeyreğin değerlendirilmesi yapılmıştır. Bu değerlendirmede 1. Çeyrekte yıllık satışların ortalama %17,8 i gerçekleşmektedir. Bu oran diğer çeyreklerde sırası ile %26,8, %23,6 ve %31,8 olarak gerçekleşmektedir. Satışların en yüksek olduğu çeyrek 4. Çeyrek olarak ortaya çıkmıştır. Bu durumun özellikle aralık ayıda gerçekleşen araç kampanyalarının etkisi şeklinde açıklanabilir. Diğer yandan, satışların en düşük olduğu çeyreğin birinci çeyrek olmasının sebebi yeni araçların teslimatında yaşanan gecikmeler olabilir. Ayrıca bir önceki yılın son çeyreğinde özellikle aralık ayındaki yüksek satışların sonuçu da yeni araç alımı için pazardaki tüketici sayısında azalma olması da önemli bir etkendir.

Tablo 2:Aylara Göre Binek Otomobil ve Hafif Ticari Araç Satışları

	Ocak	Şubat	Mart	Nisan	Mayıs	Haziran	Temmuz	Ağustos	Eylül	Ekim	Kasım	Aralık
Otomobil	285.966	391.438	626.135	645.999	705.285	671.235	570.313	563.538	589.578	575.478	678.754	1.109.450
Yıl İçi Oran	3,86%	5,28%	8,45%	8,71%	9,51%	9,05%	7,69%	7,60%	7,95%	7,76%	9,16%	14,97%
Hafif Ticari	138.899	177.712	264.794	265.537	292.193	268.862	246.607	256.870	276.451	243.732	278.830	488.323
Yıl İçi Oran	4,34%	5,56%	8,28%	8,30%	9,13%	8,41%	7,71%	8,03%	8,64%	7,62%	8,72%	15,27%
Genel Toplam	424.865	569.150	890.929	911.536	997.478	940.097	816.920	820.408	866.029	819.210	957.584	1.597.773

Tablo 2'de ay bazında yeni araç satışlarına bakıldığında; Aralık ayında hem otomobil satışlarında hem de hafif ticari araç satışlarında ciddi manada yükseliş dikkat çekmektedir. Firmaların yapmış olduğu yıl sonu kampanyalarının etkinliği, yeni yılın başlaması ile başlayacak olan vergi harç vs. gibi masraflar bu dönemdeki artışın sebebi olarak gösterilebilir. Bu ortaya çıkan rakamlar tüketicinin fiyata ve ek maliyete olan tepkisinin ne denli yüksek olduğunu da gösterir. Herhangi bir hesaplama yapılmaksızın, bu veriler ve grafik yeni otomobil ve hafif ticari araç talebinin esnek olduğuna işaret etmektedir. Ayrıca yine bunu destekler doğrultuda, tüketicilerin bir ay bekleyip yeni model (yıl) ve yeni dizaynı ile araç almaktansa yıl sonu indirimini tercih etmesinde fiyatın ne kadar önemli bir noktada olduğunu göstermektedir.

Aylık değerlendirmede 3. ile 10. Aylar arası Pazar satışları belirli bir seviyede gerçekleştiği aylık bazda bakıldığında da çok fazla dalgalanmadığı söylenebilir. Bu durumu ilk iki aydaki yukarıda açılanan sebepler kaynaklı düşük satışlar ve son iki aydaki fiyat kaynaklı yüksek satışlar bozmaktadır. Kısaca 12 aylık zaman diliminin yaklaşık 8 ayında daha az dalgalanan bir pazardan bahsedilebilir.

Ortalama aylık satış rakamlarında otomobil ticari araç dengesinde ise aylara göre çok ciddi bir farklılık gözükmemektedir. Ortalama olarak yeni satılan araçların %70'i otomobil %30 civarı ise hafif ticari araç sınıfındadır ve bu ay bazında incelendiğinde de aynı şekilde olduğu görülmektedir.

5. BİNEK OTOMOBİL TÜKETİCİ TERCİHLERİ ANALİZİ

Bu bölümde yeni otomobil pazarındaki tüketici analizi yapılacaktır. Bu analizin amacı yıllar içinde binek otomobil tüketimindeki müşteri tercihinin nasıl değiştiğini ortaya koymaktır. Binek otomobil tüketici tercihi analizi, otomobilin büyüklüğüne göre olan; sınıf, otomobilin dizayn ve karoser tipini gösteren; kasa, ve bu iki özelliğin birlikte değerlendirildiği; kasa- sınıf yönelimlerinden oluşmaktadır.

5.1. Otomobil Sınıfına (Segment) Bağlı Tüketici Tercihi

Tablo ve grafikte her bir otomobil sınıfındaki satış adetleri gösterilmektedir. Ayrıca pazardaki tüketicilerin tercihlerindeki değişimi daha net ortaya koyması adına, her yıl kendi içinde sınıflara göre yüzdesel olarak analiz edilmiştir. Araç sınıfları A dan F ye doğru ilerledikçe aracın büyüklüğü artmakta bu da doğru orantılı bir şekilde fiyata yansımaktadır.

Sınıf tipine göre yıllık satışlar incelendiğinde, en küçük sınıf olan A sınıfının de satış adetleri aynı seviyelerde kalmış olup büyüyen pazar nedeniyle yüzdesel payı düşmüştür. 14 yıl sonunda satışlar %9,3 oranında düşmüş bu da ortalama olarak %0,67'lik bir daralmayı göstermiştir.

Benzer bir sonuç B sınıfının geçen 14 yılda satışların %3,7 oranında arttığını, bunun sonucu olarak bu sınıfın pazar payında yüzdesel olarak azalma gerçekleştiği ortaya çıkmaktadır. Yaklaşık olarak her yıl ortalama 195 bin aracın satıldığı B sınıfının 2004 yılında %46,5 olan pazar payı 2017 yılında %30,1 e düşmüştür. Bu azalmaya rağmen B sınıfı halen en çok tercih edilen 2. Sınıf durumundadır. Yanı araç firmaları için önemli satış potansiyeline sahip durumdadır.

Tablo 3: Otomobil Sınıflarına Göre Yıllık Satış Rakamları

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
A Sınıfı	2.536	4.379	3.680	2.972	1.768	3.709	2.659	2.941	1.458	2.959	4.424	4.214	2.588	2.299
	0,6%	1,0%	1,0%	0,8%	0,6%	1,0%	0,5%	0,5%	0,3%	0,4%	0,8%	0,6%	0,3%	0,3%

	10,7%	11,3%	11,2%	11,2%	12,7%	12,4%	12,1%	12,6%	12,0%	10,7%	11,9%	13,1%	14,5%	13,6%
E Sınıfı	6.413	5.888	6.702	8.334	6.603	7.021	12.515	17.557	14.385	18.960	20.194	23.464	22.558	22.699
	1,4%	1,3%	1,8%	2,3%	2,2%	1,9%	2,5%	3,0%	2,6%	2,9%	3,4%	3,2%	3,0%	3,1%
F Sınıfı	2.357	2.580	3.678	3.693	2.674	2.502	3.533	3.883	2.458	2.906	3.620	5.237	5.041	4.270
	0,5%	0,6%	1,0%	1,0%	0,9%	0,7%	0,7%	0,7%	0,4%	0,4%	0,6%	0,7%	0,7%	0,6%
Yıl Toplam	**451.209**	**438.597**	**373.219**	**357.465**	**305.998**	**369.819**	**509.784**	**593.519**	**556.280**	**664.655**	**587.331**	**725.596**	**756.938**	**722.759**

Tablo 3 'te A ve B sınıfı yani en küçük hacme sahip araçlar tüm araç sınıfları içinde pazar payı azalan sınıflar olmuştur. Açık bir şekilde 14 yıllık yönelim göstermektedir ki yeni otomobil pazarında tercihler giderek daha büyük hacimli araçlara kaymıştır. Bu tercih değişimi B sınıfındaki araç modelleri için bir ipucu vermektedir. B sınıfındaki araçlardan müşterisine daha fazla iç hacim sunabilen modeller diğer rakip modellere göre rekabette avantajlı konumda olabileceğini gösterir.

Öte yandan 2004 yılında %40 civarında olan C sınıfının payı 2017 yılında %52 seviyelerine ulaşarak en çok tercih edilen araç sınıfı durumuna gelmiştir. Kısaca yeni satılan 2 otomobilden 1 tanesi bu sınıftan satılmıştır. B sınıfındaki yaklaşık %16'lık azalma, C sınıfına kaydığını söyleyebiliriz. Ayrıca fiyat ortalaması B sınıfına göre daha yüksek olan C sınıfına olan talep kayması, tüketicilerin alım gücündeki artışın da bir sonucu olabilir.

Daha üst sınıflar olan D ve E sınıflarında yüzdesel artış sınırlı olmasına rağmen yıllık satış adetlerindeki artış dikkat çekicidir. D sınıfındaki araç satışı yaklaşık olarak 14 yılda iki katına çıkmıştır. Ayrıca E sınıfındaki araçların satışı ise 2004 yılına göre yaklaşık iki buçuk kat artış göstermiştir. D ve E sınıfına benzer durum F sınıfı için de geçerlidir. Satış yüzdesi değişmemiş olmasına rağmen, satış adedi yaklaşık olarak iki katına çıkmıştır.

Kısaca özetlemek gerekirse, tüketicilerin tercihlerinin daha geniş araçlara kaydığı gözlemlenebilmektedir. Küçük sınıflara olan talep azalırken C sınıfı ve üstü araçlara olan talepler artış göstermiştir. 14 yıllık veri incelendiğinde B ve C sınıfı halen satışların yaklaşık %80 inin oluşturmaktadır. Bu durumun çok değişmemesi yeni araç pazarında başarılı olmak isteyen firmalar için bu sınıfta satışa sunacakları modellerin markanın pazardaki başarını doğrudan etkilediğini gösterir.

5.2. Otomobil Kasa (Karoser) Tipine Bağlı Müşteri Tercihi

Tüketici tercihlerini gösteren bir diğer değişken ise kasa (karoser) tipidir. Sedan kasa tipi her yıl en çok tercih edilen kasa tipi olmuş olup, 2004- 2017 yılları arası bu sınıftaki araç satışları %66,62 oranında artmıştır. Ortalama olarak satılan her iki araçtan bir tanesi sedandır. Yıllar içinde pazar daralma ve genişleme olmasında dahi bu durumun

değişmemesi yeni otomobil piyasasındaki tüketici için bu karoser tipinin diğer değişle bagajı olan otomobil modellerin önemini göstermektedir.

İkinci tercih edilen karoser tipi olan hatchback kasa tipindeki araçlar ise 14 yıllık zaman diliminde satışları sadece %8,64 oranında artmıştır. Bu durum ise diğer karoser tipine göre olan değerlendirmede hatchback araçlarının payının yüzdesel olarak azalmasına sebep olmuştur. 2004 yılında yüzde 40 Civarında olan payı 2014 Sonrası yaklaşık %30 seviyelerine düşmüştür.

Tablo 4:Otomobil Kasa Tipine Göre Yıllık Satış Rakamları

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Sedan	214.175	214.514	183.426	190.907	165.181	201.609	253.780	289.145	239.516	296.336	278.534	351.598	362.292	356.852

Kasa tipine göre olan değerlendirmede dikkat çeken değişim ise SUV kasa tipinde gerçekleşmiştir. %4 civarında olan pazar payı 2017'de yaklaşık %18'e ulaşıp zirve yapmıştır. Yıllık satış adedinin bu sınıfta 2004 yılında 16.000 seviyesinde olan satış adedi 2017'de 130.000 seviyesine kadar çıkıp %707,05'lik artış gerçekleşmiştir. Diğer kasa tiplerinde ise, 14 yıllık sürede pazarın büyümesinden dolayı adetsel olarak artışlar yaşanmasına rağmen yüzdesel olarak çok ciddi bir farklılık ortaya çıkarmamıştır.

Kısaca sedan kasa tipinin otomobil satışlarının yarını oluşturduğu, hatcback kasa tipinin satışlardaki payının azaldığı görülmektedir. Kasa tipindeki en önemli değişiklik ise SUV kasa tipinin yaklaşık %20 ye ulaştığı, bu kasa tipindeki modellerin üretici firmalar için günden güne daha önemli hale gelmesi olarak belirtilebilir.

5.3. Kasa-Sınıf (Karoser -Segment) Tipine Göre Müşteri Tercihi

Kasa – Sınıf tipinin analizinin yapılmasının amacı tüketici tercihlerindeki değişimini daha detaylı bir şekilde ortaya koymaktır. Otomobil firmaları genellikle her bir kasa – sınıf kombinasyonu için bir araba modeli pazara sunar ve belirli bir süre bu model ismi kullanılarak o araba modelini pazarda tutundurmaya çalışırlar. Bu açıdan Türkiye'deki yeni araç pazarındaki tercihler önemlidir. Otomobil firmaları pazardaki değişen tercihleri dikkate alarak üretim pazarlama stratejilerini belirleyebilirler.

Her bir sınıfın her bir kasa tipi ile kombinasyonu çok fazla sayıda kasa sınıf kombinasyonu ortaya çıkarmaktadır. Bu nedenler Tablo5'te sadece dikkat çekici olan kombinasyonları gösterilmiştir.

Rakamlar incelendiğinde C sınıfı Sedan (C1) araçların Pazar payı %22,04'ten %31,06'ya çıkmıştır. Bu tüketici tercih değişimi etkisi ile 99.426 olan C1 satışlarının pazar büyümesinin de etkisi ile yaklaşık 224.500'e ulaşmış C1 araçlar için pazarda 14 yılda %125,80'lik artış ortaya çıkmıştır.

Tablo 5: Kasa-Sınıf Kombinasyonları İçin Yıllık Satış Rakamları

	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
C-Sedan	99.426	92.634	79.143	96.159	85.253	90.874	122.878	151.199	145.456	175.209	174.763	215.557	214.638	224.500

	16,64%	19,35%	19,17%	18,11%	17,63%	20,31%	15,65%	12,11%	6,28%	8,54%	6,65%	6,66%	7,02%	6,91%
D-Sedan	35.063	33.207	27.697	24.280	21.595	31.009	41.376	52.875	48.732	50.044	49.223	69.713	77.186	64.851
	7,77%	7,57%	7,42%	6,79%	7,06%	8,38%	8,12%	8,91%	8,76%	7,53%	8,38%	9,61%	10,20%	8,97%
C-SUV	3.150	4.261	3.070	4.814	5.172	8.218	17.809	28.374	38.896	45.232	41.578	57.215	64.844	76.308
	0,70%	0,97%	0,82%	1,35%	1,69%	2,22%	3,49%	4,78%	6,99%	6,81%	7,08%	7,89%	8,57%	10,56%
D-SUV	8.373	11.863	11.202	12.582	13.304	11.390	16.785	18.522	12.314	15.149	14.356	18.331	26.110	23.971

Öte yandan 2004 yılın en çok tercih edilen sınıf kasa tipi olan B sınıfı hatcback araçlar 14 yıllık dilimde sadece %9,93 oranında satışı artmıştır. Bunun sonucu olarak tercih edilirliği %25,46'dan %17,47 ye düşmüştür.

C sınıfı sedan (C1) ve B sınıfı hatcback (B2) sınıf kasa tipi araçlar ortalama tüm satışların %47,41 ini oluşturmaktadır. Bir markanın tüm araç modelleri içindeki en önemli iki modelini bu C1 ve B2 modelleri oluşturduğu, firmanın özellikle pazarlama stratejilerini bu modeller üzerinden yapması gerektiğini göstermektedir.

Pozitif yönde dikkat çekici artış C sınıf SUV (C7) satışlarında hem adetsel olarak hem de yüzdesel olarak çok ciddi artış görülmüştür. Adetsel olarak 2004 yılında 3150 olan satış rakamları 2017 yılında 76.308'e ulaşmıştır. Bu da 2004 yılında satılan her 100 aracın sadece 1 tanesi bu sınıf kasa grubunda iken, 2017 de satılan her 100 aracın 10 tanesine bu gruptan satıldığını göstermektedir. Bu sonuçların benzeri daha küçük sınıf olan B7 grubu satış rakamları 1223 olan satış rakamları adet seviyelerinde 20.937 adet seviyelerine gelmiştir. Bu sınıflardaki artış özellikle piyasaya yeni girecek olan markalar için şans oluşturmaktadır. Yeni otomobil piyasasına giriş yapacak markalar gitgide daha çok tercih edilen sınıfta kendilerine yer bulabilir ve oluşturacakları olumlu marka yönetimi ile diğer gruplardaki payını arttırabilirler.

6. SONUÇ

Bu çalışma 2004 – 2017 yılları arası yeni araç marketindeki satış verileri kullanılarak marketteki genel durumu ve otomobil marketindeki tüketici yönelimini ortaya koymayı amaçlamıştır. Herhangi bir ekonometrik model kullanılmadan yapılan analizler aşağıdaki sonuçlara ulaşılmıştır.

14 yıllık süre içinde pazarın en çok etkilendiği olay 2009'da global olarak gerçekleşen daralma olmuştur. Binek otomobil ve ticari araç satışları büyük oranda birlikte hareket etmektedir. Ortalama olarak yeni araç satışının %30'u civarında olan ticari araç satışları, oransal olarak azalmaktadır. Diğer ifade ile binek otomobilin satışındaki artış ticari araçların satış artışından fazladır. Yeni araç satış adetleri yıl sonu kampanyaları etkisi ile yılın son aylarında artmaktadır. Bu durum yeni araç piyasasında tüketicilerin ne kadar fiyat odaklı yani esnek bir talebi olduğunu gösterir.

Binek otomobil pazarında ise tüketicilerin açık bir şekilde daha geniş hacimli otomobil sınıflarına yöneldiğini söylemek mümkündür. Bu durum alım gücünün arttığının bir göstergesidir. B ve C sınıfları binek otomobil satışlarının yaklaşık %80'inin gerçekleştiği sınıflar olarak dikkat çekmektedir. Sedan kasa tipi pazardaki satışların her yıl yaklaşık %50'sini oluşturmaktadır. İlgi çekici değişim ise SUV kasa tipine olan pazar payı 5 kat artmış durumdadır. Tüketicilerin geniş araç tercih etmesi doğrultusunda C sınıfı sedan araçlar en popüler kasa sınıf kombinasyonu olmuştur. Pazarda yeni giriş yapacak olan veya geçmişte ciddi Pazar payı elde edememiş firmalar için tüketicilerin talebinin artmış olduğu Segment kasa kombinasyonu hamle yapmak için uygun bir strateji olarak görülebilir.

ÖZET

Farlar otomobiller için yol aydınlatmanın yanında güvenlik elemanıdır. Bu yüzden farlarda yoğuşma problemi otomobil üreticisi firmalar için ürün problemi iken yolcular içinde yol aydınlatma şiddetini etkilediği için güvenlik problemi durumundadır. Çalışmamızda araç ön farlarında yoğuşma problemi ele alınmıştır. Analizler ANSYS 12.1 CFX yazılımında yapılmış Analizlerde far bileşenlerindeki iletim etkileri (conjugate effects) dikkate alınmıştır. Doğal taşınım için Boussinesq yaklaşımı, radyasyon etkilerinin dikkate alınmasında da Monte Carlo yaklaşımı kullanılmıştır. Öncelikle eleman sayısından bağımsız çözüm elde edilmiş ve sonuçlar 11620786 eleman sayısı üzerinden alınmıştır. Isıl analizler zamandan bağımsız çevre sıcaklığı T_∞=25 ^oC alınarak yapılmıştır. Analiz sonucunda iç hava sıcaklık dağılımı, hava akış profilleri incelenmiş yoğuşmanın nerede olacağı tahmini yapılmıştır. Daha sonra ısıl analiz sonuçları başlangıç şart olarak okutularak %95 hava nem koşullarında 7^oC çevre sıcaklığında yoğuşma analizi yapılmıştır. Yoğuşma literatüre uygun şekilde hava akış hızının az olduğu yerlerde tespit edilmiştir. Far geometrisinde yapılan değişiklik ile yoğuşma bölgesinde hava akış hızı artırılmış ve sıcak havanın yoğuşma olan yüzeye erişimi sağlanarak gerekli zaman içinde yoğuşmanın kalktığı tespit edilmiştir.

Anahtar Kelimeler: Yoğuşma, ısı tranferi, hesaplamalı akışkanlar mekaniği.

ANALYSIS OF THE CONDENSATION PROBLEM IN VEHICLE HEADLIGHT WITH COMPUTATIONAL FLUID MECHANICS ANALYSIS AND ITS EFFECT ON DESIGN

ABSTRACT

Headlights are a safety element for automobiles as well as road lighting. Therefore, while the problem of condensation in the headlights is a product problem for automobile manufacturers, it is a safety problem as it affects the intensity of road lighting among the passengers. In our study, the problem of condensation in vehicle headlights is discussed. Analyzes made in ANSYS 12.1 CFX software. In the analyzes, the conjugate effects of the headlight components are taken into account. Boussinesq approach is used for natural convection and Monte Carlo approach is used for taking into account the effects of radiation. First of all, a solution independent of the number of elements is obtained and the results are taken over the number of 11620786 elements. The thermal analysis is made with the time independent and ambient temperature is taken 25^oC. As a result of the analysis, indoor air temperature distribution and air flow profiles have been examined and an estimate of where the condensation will occur has been made. Then, the thermal analysis results are read as the initial condition and the condensation analysis is performed at 95% air humidity conditions at 7^oC ambient temperature. Condensation has been detected in places where the air flow rate is low in accordance with the literature. With the change made in the headlight geometry, the air flow rate in the condensation zone was increased and it was found that the ondensation disappeared within the required time by providing the access of the hot air to the condensation surface.

Keywords: Condensation, heat transfer, computational fluid mechanics.

1.GİRİŞ

Yoğuşma alanındaki öncü çalışmaların başında Nusselt (1914) gelmektedir. Nusselt basit teorik analizlerle dik levha ile durgun yoğuşmuş su buharı arasındaki ısı transferini hesaplama üzerine çalışmıştır. Nusselt'in teorik çözümünün geliştirilmesi üzerinde bir çok araştırmacı çalışmıştır. Örneğin Bromley (1952) yoğuşmuş su tabakasında lineer sıcaklık dağılımı kabul etmiştir. Dehbi ve Guentay (1997) buhar ve yoğuşmayan gaz karışımından oluşan dikey yoğuşturucu tüpünde ısı ve kütle transferinin oranının teorik tahminini türetmiştir. Çalışmada film tabaka kalınlığı için cebri denklem türetilmiş ve ısı ve kütle transferi analojisi yoğuşma oranını anlayabilmek için incelenmiştir. Che ve ark. (2005) Colburn ve Hougen (1934)'in metodolojisini kullanarak tüpteki nemli havanın su buharının yoğuşma sürecince ısı ve kütle transferinin analiz etmiştir.

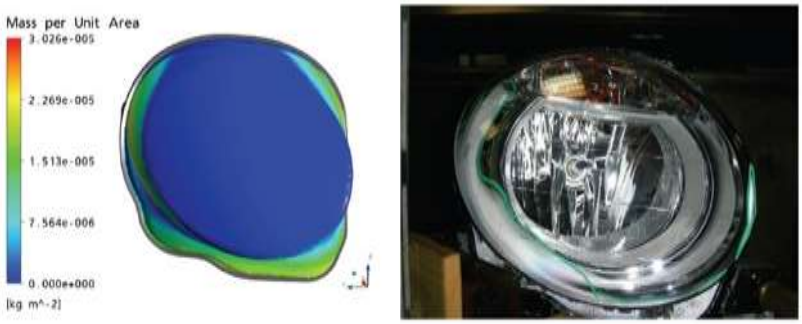
Simülasyonla yoğuşma konusu çalışılırken not edilmesi gereken iki önemli nokta üzerinde durulmuştur. Bunlardan birincisi TenWolds (1993) yaptığı çalışmada nem problemini çözmek için çok bölgeli modeli kullanmıştır. İkincisi Liu ve ark. (2003) tarafından yoğuşmanın ne zaman ve nerde olacağının tahminine dayanan uygulamada zamana bağlı yoğuşma hesabı yapılmıştır. Doğrudan otomobil ön lambalarıyla ilgili olarak ise teorik ve deneysel bir çalışma Preihs (2006) tarafından yapılmıştır. Preihs (2006)'in çalışması çiğ noktası sıcaklık alanının tahmini ve hava sıcaklığıyla karşılaştırılmasına dayanan Preihs (2006)'in çalışmasında, tahminlerin ölçümlerle iki boyutlu bir geometri için yeterince uyumlu olduğu sonucuna varılmıştır. Ayrıca otomobil farlarının yoğuşma açısından daha güçlü (robust) tasarımı için üç boyutlu ve radyasyon etkilerinin dikkate alındığı bilgisayar analizlerinin önemini de vurgulamıştır. Liu ve ark. (2003) yaptığı çalışmada ticari Japon CFD yazılımı olan STREAM 4.0 kullanarak küp yüzeyi üzerindeki yoğuşmayı sayısal ve deneysel olarak incelemiştir. İlk önce yoğuşma modeli geliştirilmiş ve deneysel olarak doğrulanmış ve arkasından da havalandırmanın yoğuşma üzerindeki etkisi araştırmışlardır. Kontrol hacmine hava girişi ekleyerek ve havalandırma deliklerinin uygun konumlandırarak yoğuşmanın önemli ölçüde azaldığını gözlemlemişlerdir.

Deponti ve ark. (2009) yaptıkları çalışmada ile araç aydınlatma sistemlerinde yoğuşma problemi ele alınmıştır. Çalışmada yapılan analiz, deneysel veriler ile karşılaştırılmış ve sonuçlar doğrulanmıştır. Yoğuşma ısı transferi ile birlikte gerçekleşen kütle transferine dayandırılmıştır. Yoğuşmanın trafikte önemli rol sahibi olan ön farlar üzerindeki olumsuz etkisine değinilmiştir. Özellikle ön far üzerinde oluşan yoğuşmanın farın fotometrik değerlerini olumsuz etkilediği belirlenmiştir. Çalışmada Şekil.1.a'da örnek bir farda yoğuşma gösterilmiştir (Deponti ve ark. 2009). Yine çalışmada kullanılan özel test kabini Şekil.1.b'de görülmektedir.

a) b)

Şekil.1. a) Ön farda yoğuşma b) Yoğuşma test kabini (Deponti ve ark. 2009)

Yoğuşma problemi multifaz bir problemdir. Hava içinde bulunan su buharının sıvı hale geçmesi ile lensin iç yüzeyinde birikmesi sonucu oluşmaktadır. Çalışmada dikkat edilmesi gerekenlerin iç havanın değişen yoğunluk değerleri, sıcaklık değerleri ve dış havanın sıcaklığı olduğu ifade edilmiştir. Çalışmada far içinde akış şeklinin karaktersitiği laminar olarak kabul edilmiştir. Çözümde ampullere güç verilmiş ve analizde ışınım dikkate alınmıştır. Hava için tanımlamada içinde su buharı bulunan hava tanımı olarak ayrıca yapılmıştır. Yapılan yeni tanmımlama ile ısıl analizde değişen sıcaklıklarla değişen yoğunluk dikkate alınmıştır. Yoğuşmayı engellemek ve ön far içinde havanın sirkülasyonu için yardımcı olan havalandırma deliklerinin yoğuşma analizinde modellenmesi gerekliği belirtilmiştir. Deponti ve ark. (2009) çalışmasında yapılan yoğuşma testinin aşamaları şöyledir. İlk adımda far prototipi araba modeli üzerinde yerleştirilmiş şekilde %95 izafi nemde ve 3-7 ºC aralığında değişen hava şartlarında 12 saat boyunca tutulur. İkinci adımda far içindeki ısı kaynakları, ampuller 20 dakika boyunca çalıştırılır ve son olarak 8ºC su far üzerine püskürtülür, kabin içinde 30 km/s hızda rüzgar oluşturulur. Bu sırada motor düşük rejimde 30ºC'de çalıştırılır. Bu adım sonunda yoğuşma olup olmadığı kontrol edilir. Son basamakta %95 izafi nemde ve 3-7 ºC aralığında değişen hava şartlarında yoğuşmanın giderilmesi için su püskürtme olmadan, motordan 50ºC hava üretilmiş, 80 km/s hızda rüzgar oluşturulmuş ve yoğuşmanın yok olması beklenmiştir. Çalışma sonunda test ve analiz sonuçları karşılaştırılmalı olarak verilmiştir (Şekil.2.a ve b).



Şekil.2 .Yoğuşma a) Analiz sonucu b) Test sonucu (Deponti ve ark. 2009)

Çalışma sonunda analiz sonuçları ile test sonuçlarının uyumlu olduğu tespit edilmiştir. Çalışma sonrası hava sirkülasyonunun az olduğu ve havanın sıkıştığı bölgelerde yoğuşma olduğu tespit edilmiştir.

Kitada ve ark. (2002) hesaplamalı akışkanlar dinamiği kullanarak geçici rejimde yoğuşma giderilme olayını tahmin etmeye çalışmışlardır. Çalışmada yeni bir damlacık yoğuşma-buharlaşma modeli geliştirmişlerdir. Geliştirilen modelle CFD kod kullanılarak zamana bağlı buharlaşma simülasyonu yapılmıştır. Çalışmaları sonucunda damlacık yoğuşma ve buharlaşmaya dayanan modelin yoğuşma esnasında oluşan buğunun atılması fazının hesaplanabilmesi için uygun olduğunu ayrıca bu modelle damlacık yarıçapının zamana bağlı olarak değişimini sıcaklık, akışın hız ve bağıl nem dağılımları yardımı ile tahmin edilebileceğini belirtmişlerdir. Yoğuşma konusu üzerine hesaplamalı yöntemler kullanılarak yapılan bir başka çalışma Kitada ve ark.(2002) tarafından yapılmıştır. Ancak bu araştırmalardan çoğu oluşan buğunun karakteristiğinin ön camdaki hız profillerinden yola çıkarak tahmini temeline dayanmaktadır. Hassan ve ark.(1999) ön camın buğudan atılması sürecini zamana bağlı olarak film tabaka kabulü ile tahmin etmiştir. Araç dış aydınlatma sistemlerinde olduğu gibi otomotiv elektronik kontrol ünitelerinde de yoğuşma problemi görülebilmektedir.

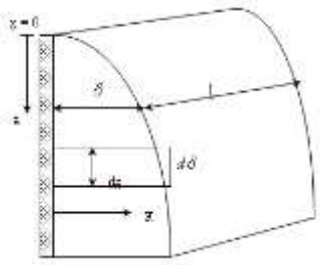
Gulawani ve ark. (2006,2009) çalışmalarında ANSYS CFX 5.7 kullanmışlardır ve bu çalışmalar sayısal akışkanlar dinamiğinin yoğuşma analizlerinde kullanılması açısından dikkat çekicidirler. Otomotiv uygulaması açısından ise Croce ve ark. (2007) çalışmaları iç kabin camlarındaki yoğuşmanın sayısal analiziyle ilgilidir. Shozawa ve ark. (2005) çalışması ise araç aydınlatma sistemlerindeki yoğuşmayla doğrudan ilgili olması açısından önemlidir ve bu konuda sayısal bir hesaplama yöntemi geliştirerek daha sonra bunu ön fardaki yoğuşma analizine uygulamışlardır. Ayrıca bu tür analizlerde dikkat edilmesi gereken noktalar hakkında da ilgilileri uyarmışlardır.

2. MATERYAL METOT

Doymuş haldeki buhar, aynı basınçtaki doyma sıcaklığından daha küçük sıcaklıkta bir yüzeyle temas ettiğinde yoğuşmaya başlar. Yoğuşan damlalar yüzeyde birleşmeden yoğuşma devam ederse damla yoğuşması adını alır. Yoğuşan damlalar yüzeyde birleşip bir film teşkil ederse buna da film yoğuşması adı verilir. Yüzeyde oluşan film kalınlaştıkça ısı transferi direnci artar. Damla yoğuşması durumunda ısıl direnç çok küçüktür. Damla yoğuşması durumunda ısı transferi, film yoğuşmaya göre yaklaşık 10 kat daha fazla olmaktadır. Fakat damla yoğuşmasını yüzeylerde sağlamak pek mümkün değildir. Çünkü yoğuşan damlaların birleşmemesi için özel madde veya yüzey kullanılmalıdır. Bu da pek pratik değildir. Dolayısıyla, aksi belirtilmedikçe, yoğuşma film yoğuşma anlamında kullanılacaktır. Yoğuşma kütle geçişi konusu altında, izafi neme, akış şekline, akışkan ve yüzey sıcaklıklarına bağlı olan ısı ve kütle geçişisidir.

2.1. Dikey levha üzerinde yoğuşma

Yoğuşma ısı transferi açısından düşey bir levhada incelendiğinde ilk olarak Nusselt tarafından analitik olarak incelendiği için Nusselt teorisi adı altında incelenir. Film teorisi veya Nusselt teorisi olarak bilinen bu analitik analizde bazı kabullerle olay incelenmiştir. Bu kabuller; buhar düşük hızlı veya durgun, akışkan özellikleri sabit ve sıvı buhar yüzeyinde viskoz sürtünme ihmal edilmiştir. Bu kabullerle levha sıcaklığı Ty ve doymuş buhar sıcaklığı Td olarak alınmaktadır. Yoğuşan sıvı filmi, levha üst noktasından itibaren gittikçe kalınlaşarak levha altına doğru ağırlık etkisiyle akacaktır.



Şekil.3..Dik levhada yoğuşma

Şekil.3'te görüldüğü gibi, sıvı filmine; aşağı doğru etkiyen ağırlık kuvvetleri ve yoğunluk değişimi sebebiyle oluşan kuvvetler vardır. Yukarı doğru ise, etkiyen viskoz sürtünme kuvvetleri olmaktadır. Akış alanında alınan bir hacim elemanına etkiyen kuvvetlerin dengesi yazılır ve gerekli sınır şartı kabulleri yapılırsa $\delta = \delta(x)$ sıvı film kalınlığına bağlı kütlesel sıvı debisi için Eşitlik.1, Film kalınlığı için şu Eşitlik.2 kullanılır.

$$m(x) = \frac{g\rho_s(\rho_s-\rho_b)\delta^3}{3\mu_s} \tag{1}$$

$$\delta(x) = \left[\frac{4\mu_s k_s(T_d-T_y)x}{g(\rho_s-\rho_b)p_s h_{sb}}\right]^{\frac{1}{4}} \tag{2}$$

Film yoğuşma durumunda ısı taşınım katsayısını tarif etmek için, levha uzunluğu boyunca iletim ihmal edilecek olursa, yoğuşma esnasında ortaya çıkan yoğuşma ısısı levha yüzeyinden iletimle transfer edilecektir. L boyundaki levhada ortalama ısı taşınım katsayısı için ise, daha önce yapılan tarif ve integrasyondan, Eşitlik.3'teki şekliyle ifade edilir.

$$h_m = 0.943\left[\frac{g\rho_s(\rho_s-\rho_b)h_{sb}k_s^3}{\mu_s(T_\infty-T_y)L}\right]^{1/4} \tag{3}$$

Bu eşitliklerdeki termo-fiziksel özellikler $T_f = (T_d + T_y)/2$ sıcaklığında, h_{sb} ise T_d sıcaklığında alınmalıdır. Dik boru veya levhada yoğuşma durumunda, bir boru veya birim genişlikteki levha üzerinde yoğuşan sıvı miktarı m_{1L} Eşitlik.4'teki ifadeden bulunur:

$$m_{1L} = \frac{h_m(T_\infty-T_y)}{h_{sb}} \tag{4}$$

Re sayısı, Eşitlik.5'te olduğu gibi tarif edilir. Reynolds sayısına bağlı olarak dik bir levhada yüzeyi dalgasız laminer film akış halinde ısı taşınım katsayısı Eşitlik.6'dan bulunabilir.

$$Re_\delta = 4\frac{m_L}{\mu_s} \tag{5}$$

$$\frac{h_m(V_s^2/g)}{k_s} = 1.47\,Re_\delta^{-1/3} \qquad Re_L \le 30 \tag{6}$$

Yüzeyi dalgalı lamimer film akış için ısı taşınım katsayısı bağıntısı, Kutatelzade tarafından Eşitlik.7'deki gibi ifade edilmiştir.

$$\frac{h_m(V_s^2/g)}{k_s} = \frac{Re_\delta}{1.08\,Re_\delta^{1.22}-5.2} \qquad 30 \le Re_L \le 1800 \tag{7}$$

Türbülanslı film akış için ise aşağıda Eşitlik.8'de verilen Labuntsov bağıntısı kullanılır:

$$\frac{h_m(V_s^2/g)}{k_s} = \frac{Re_\delta}{8750 + 58\,Pr^{-0.5}(Re_\delta^{0.75} - 253)} \qquad Re_L \leq 1800 \qquad (8)$$

Levha belli bir eğimle duruyorsa, ϕ levhanın yatayla yaptığı açı olmak üzere, ortalama ısı taşınım katsayısı için Nusselt teorisinden faydalanarak şu Eşitlik.9 verilmiştir:

$$h_m = 0.943\left[\frac{g\rho_s(\rho_s - \rho_b)h_{sb}k_s^3}{\mu_s(T_\infty - T_y)L}Sin\phi\right]^{1/4} \qquad (9)$$

Bu bağıntıların yanı sıra ısı ve kütle transferinin bir arada olması durumundan yola çıkarak akışın laminar ya da türbülanslı olması Re sayısı aracılığı ile tespit edildikten sonra dikey levha üzerinde doğal akış kabulü yapılarak,

Laminer akış için $Nu = 0{,}59(Gr.Pr)^{1/4}$ (10)

Türbülanslı akış için $Nu = 0{,}13(Gr.Pr)^{1/3}$ (11)

eşitlikleri kullanılır. Dik levha kabulünün yapılma nedeni lens elemanının dik levha kabul edilmesidir.

$$Nu = Sh = \frac{hL}{k} \qquad (12)$$

$$Sc = Pr \qquad (13)$$

Gr.Sc>109 Türbülanslı, Gr.Sc<109 Laminar kontrolü ile laminar veya türbülanslı olduğu tespit edilen sistem eşitlik 10 ve 11'e göre çözümlenir. Nusselt–Sherwood ve Prandtl-Schmidt benzeşmesi üzerinden yoğuşan kütle ifadesi Eşitlik.14'te verilmiştir. (Yamankaradeniz ve ark. 2010)

$$m_b = h_m(C_w - C_\infty) \qquad (14)$$

1.Adım: İncelenecek farın ısıl analizi çevre sıcaklığında yapılır. Isıl analizden çıkan sonuçlar aşağıda verilen kriterlere göre değerlendirilir. Far içinde havanın sıkıştığı yerler, hızının ve dolaşımının yavaşladığı hacimler ve kapalı hacimler yoğuşmaya sebep olacak bölgelerdir. (Farlarda estetik çerçeve-lens arası bölge, far içinde iç lens ile bölünmüş kapalı hacimler, özellikle ampul eksenlerinin altında kalan far geometrisinin sıkıştığı alt ve kenar bölgeler, arka farlarda geometrinin sıkıştığı dar bölgeler ile kenar ve dip bölgeler dikkate alınmalıdır.)

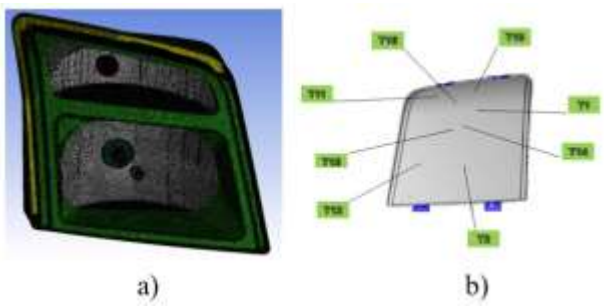
2.Adım: Sıcaklık farkının yüksek olduğu bölgelerde, lens iç yüzey ve yoğuşma beklenen bölgedeki iç hava değerleri esas alınır. Girdi olarak elde edilen sıcaklıklar, aracın kullanılacağı bölgenin izafi nem oranı ve yoğuşmanın beklendiği L mesafesi dikkate alınarak dik levha üzerinden doğal akış, eğik levha üzerinden doğal akış prensibine dayanan yoğuşma excel makrosu ile yoğuşma olup olmayacağı belirlenir.

2.2.Sayısal Analiz

Bu çalışmada sayısal analiz, ANSYS 12.1 CFX yazılımı yardımıyla gerçekleştirilmiştir. Hacim içi, laminar doğal taşınımlı, üç boyutlu ve sürekli rejimde hava akışı kabul edilmiştir. Far bileşenlerindeki iletim etkileri (conjugate effects) dikkate alınmıştır. Doğal taşınım için Boussinesq yaklaşımı, radyasyon etkilerinin dikkate alınmasında da Monte Carlo yaklaşımı kullanılmıştır. Monte Carlo metodunda rastgele erişim ile bir foton, ışınıma tabi tutulmaktadır. Deneme analiz başında belirlenen maksimum foton sayısına göre N kere tekrarlanmaktadır. Her tekrar bir öncekinden bağımsız olduğu için benzerlikten çok farklı kombinasyonlar üretilmektedir. N adet erişim bittiğinde bütün fotonların ortalama değeri sonuç olarak alınmaktadır (Rubinstein ve Kroese, 2007). Özellikle ışınım problemlerinin çözümünde Monte Carlo metodu çok yaygın olarak kullanılmaktadır (Carter ve Cashwell, 1975). Çözülen denklemler ve kullanılan yaklaşımlar hakkında detaylı bilgiler ANSYS CFX 12.1 Solver Theory Guide de bulunabilir. Analizlerde öncelikli olarak gerçek testlere uygun şekilde zamandan bağımsız şekilde çevre sıcaklığı 25°C olarak yapılır. İkinci aşamada ısıl analiz sonuçları başlangıç şart olarak belirlenerek testlerde su ile soğutulan dış yüzey 7°C hava ile temas edecek şekilde sınır şartları belirlenerek yoğuşma analizi yapılmıştır.

2.3. Geometri ve Ağ Yapısı

Çalışmamızda öncelikli olarak delaunay ağ yapısı kullanılmış ve Şekil.4.a'da verilmiştir. Eleman sayısından bağımsız çözüme ulaşabilmek için eleman sayısı çeşitlendirilmiştir ve eleman sayısı 7486846, 9363553,11620786 ve 14286595 olarak oluşturulmuştur. Şekil.4.b'de eleman sayısından bağımsız çözümü bulmak adına far üzerine yerleştirilen termokupulların yerleri verilmiştir.



Şekil 4. a) Delaunay ağ yapısı b)Termokupul yerleşim konumları

Deney ölçüm sonuçları ve farklı eleman sayılarından oluşan sonuçlar termokupul lokasyonlarına göre karşılaştırılmıştır. 11620786 Eleman sayısının en hataya sahip olduğu tespit edilmiş ve çalışmada bu eleman sayısı üzerinden sonuçlar alınmıştır.

Tablo.1. Eleman sayısından bağımsızlık çalışması

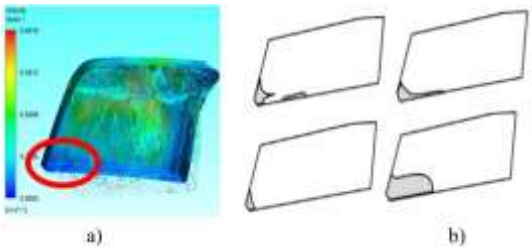
3. SONUÇLAR VE TARTIŞMA

Çalışmamızda zamandan bağımsız değişen çevre, iç hava sıcaklıklarına ve izafi nem oranına göre çözümler ele alınmıştır. Çalışmada çiğ noktası sıcaklığı, T_y=48ºC, T_∞=60ºC %60 izafi nemde 49ºC elde edilmiştir. Bu veriler ışığında L=0,025 m için yoğuşma miktarı 0,0000171 kg/m^{2}s olarak hesaplanmıştır. Isıl analizler sonucu yoğuşma tahmin edilen bölge olarak Şekil 5.a'da işaretlemiş bölgede yoğuşma beklenmektedir. Bölge hava hızının sıfıra çok yakın olduğu ve literatürde Okada ve ark. (2002) yaptığı çalışma ile paralel olarak hava hareketinin olmadığı bölgeleri işaret etmektedir (Şekil.5.b).



Şekil 5.. a) Yoğuşma beklenen bölgenin kesiti b) Okada ve ark. (2002) yoğuşma tahmini bölgesi

Bölgede yoğuşmanın olma sebebi, bölgede hava sirkülasyonunun oldukça az olması ve yüzey sıcaklığının çiğ noktası sıcaklığının altında kalmasıdır. Bölge tam kapalı olmasa da hava hareketi için dar bir bölgedir. Çalışmada L değeri yoğuşma beklenen lensin alt bölgesinden tahmini 25 mm'lik bir düzlem olarak kabul edilmiştir. İzafi nem değeri teorikte kabul edildiği üzere ilk analizde %60 daha sonra %50 alınmıştır. Değişken iç hava, izafi nem ve yüzey sıcaklıklarında yapılan incelemelerde yoğuşma miktarı sırasıyla Tablo.2, 3 ve 4'te verilmiştir. Sıcaklık farkının yoğuşmayı etkileyen en önemli etkenlerin başında geldiği tespit edilmiştir.

Tablo.2..Değişken iç hava sıcaklığına bağlı parametrelerin değişimi

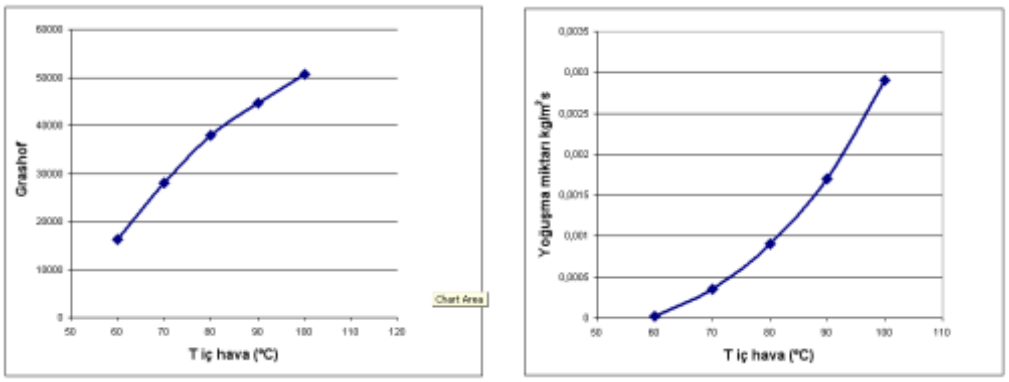
25	0,0000278	50136	0,629	8	31536	49,00	0,00051

Tablo.4..%50 izafi neme göre parametrelerin değişimi

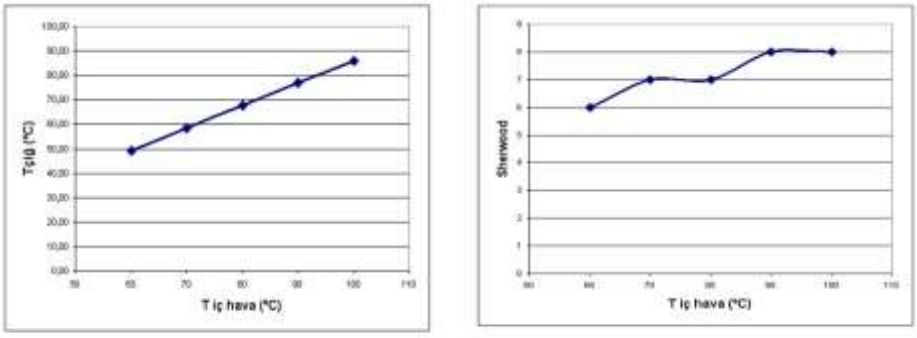
		İzafi Nem= 50%		**L=0,025 m**		**T_y = 48°C**	
T_∞	**D(m^2 / s)**	**Gr**	**Sc**	**Sh**	**Gr.Sc**	**$T_{çiğ}$ (°C)**	**m (kg/m^2s)**
60	0,00002981	16180	0,630	6	10107	49,00	0
70	0,0000307	28125	0,622	7	17519	54,67	0,000192
80	0,0000316	37862	0,621	7	23523	63,66	0,000646
90	0,0000325	44585	0,619	8	27631	72,51	0,00132
100	0,0000334	50615	0,618	8	31294	81,59	0,0023

Sıcaklık farkından sonra farın çalıştığı bölgenin izafi nemin önemi de çalışmada tespit edilmiştir. Aynı çevre sıcaklığı ve aynı yüzey sıcaklığında %50 izafi nemde yoğuşma olmadığı tespit edilmiştir.



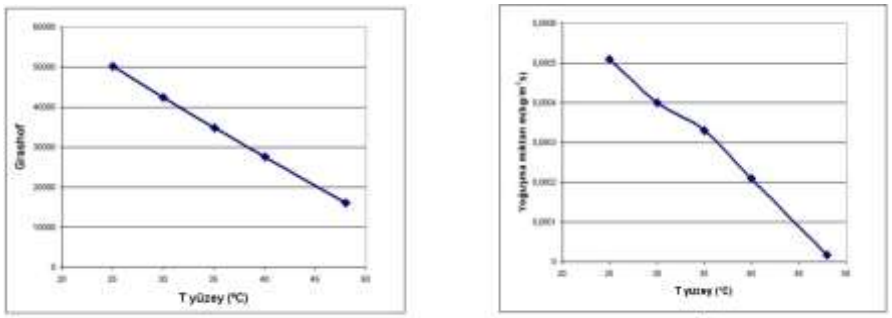
a) ***b)***

Şekil 6. a) Yoğuşma bölgesi iç hava sıcaklığına göre Gr sayısı değişimi b) Yoğuşan su miktarı değişimi



a) b)

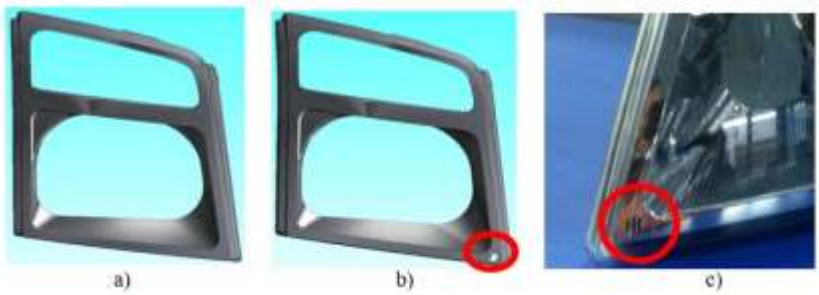
Şekil 7. a) Yoğuşma bölgesi iç hava sıcaklığına göre Tçiğ sıcaklığı değişimi b) Sherwood sayısı dağılımı



a) b)

Şekil 8. a) Değişen yüzey sıcaklığına göre Gr sayısı değişimi b) Yoğuşan su miktarı değişimi

Yoğuşma hesap sonuçlarına göre yoğuşma bölgesinin iç sıcaklık artışı, sabit yüzey sıcaklığında Gr sayısı, çiğ noktası sıcaklığı, yoğuşan su miktarı ve Sherwood sayısı ile doğru orantılıdır (Şekil.6.a, b ve 7.a, b). Diğer taraftan sabit iç hava sıcaklığında yoğuşma tahmin edilen yüzeyin sıcaklığının arttırılması, yoğuşma miktarını ve Grashof sayısını azaltmaktadır (Şekil.8.a, b). Elde edilen bu önemli veri sonucu yoğuşma tahmin edilen yüzeyin sıcaklığının arttırılması gerektiği bölgede hava sirkülasyonunu rahatlatacak, sıcak havanın yüzeye ulaşmasına yardımcı olacak geometrik tasarım değişikliğine gidilmiştir. Elde edilen veriler ışığında yoğuşma beklenen bölgede hava dolaşımının sağlanması, yüzey sıcaklığının arttırılarak yüzey sıcaklığının 49ºC olan çiğ noktası sıcaklığının üzerine çıkarılması gerektiği tespit edilmiştir. Bu maksatla, estetik çerçeve üzerinde yoğuşma beklenen bölüme doğru hava akışı sağlayacak, hava akımına izin verecek Şekil 9 (b) ve (c)'de görüldüğü gibi Şekil.9.a'da görülen geometriye delik açılmıştır.

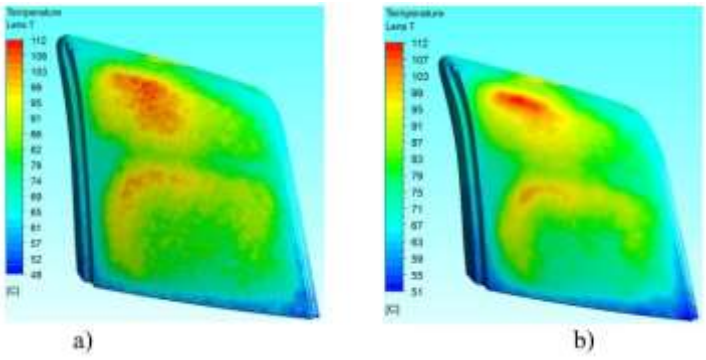


a) b) c)

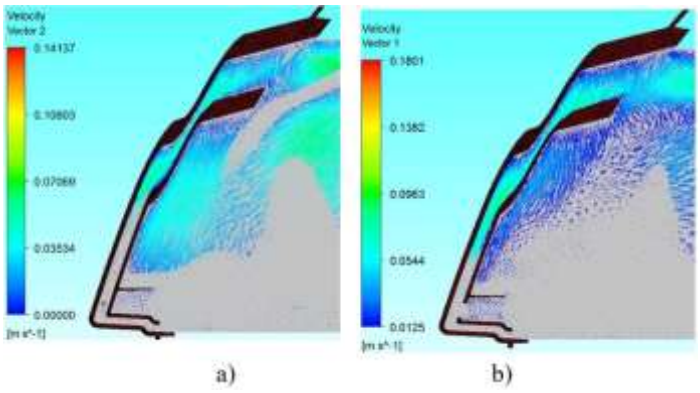
Şekil 9.Yoğuşmayı engellemek için açılan delik geometrisi a) Önce b) Sonra c) Ürün üzerinde

Tasarımdaki geometri değişikliğinden sonra yoğuşma beklenen yüzeyde sıcaklık artışı tespit edilmiştir. Geometri değişikliği sonucu ısıl analiz tekrarlanmış ve Şekil 10. a'da 48ºC olan bölge Şekil.10.b'de göre görüldüğü gibi 51ºC ile

çiğ noktası sıcaklığının üzerine çıkmıştır. Yine Şekil.11.a ve b'de önce ve sonra yaklaşımı ile yoğuşma olan bölgede hava hızının sıfırın üzerine çıktığı tespit edilmiştir.



Şekil 10. Lens iç yüzey sıcaklığı a)Geometri değişikliği öncesi b) Geometri değişikliği sonrası



Şekil 11.İç hava vektörel hız dağılımı a) Geometri değişikliğinden önce b) Geometri değişikliğinden sonra

Gerekli görülen geometri değişikliğinden sonra yoğuşma olan yüzeyde sıcaklık artışı ve hava akış hızında artma olduğu gözlemlenmiştir. Yoğuşma problemine basit temel bir yaklaşım olan çözüm yöntemi, temel anlamda bazı öngörüler ve sonuçlar vermektedir. Elde edilen sonuçlara göre Okada ve ark. (2002) Şekil.5.b'de ve Deponti ve ark. (2009) çalışmalarında Şekil.2'de olduğu gibi farın hava hareketinin kısıtlı olduğu bölgede yoğuşma olduğunu göstermiştir. Ayrıca çalışmamızda yaptığımız yoğuşma olacak bölgenin tahmini Kitada ve ark. (2002) çalışmasında olduğu gibi sıcaklık analizi ve hava hareketi üzerinden yapılmıştır. Literatürde bu iki çalışma baz alındığında yoğuşma tahmin yaklaşımının doğru olduğu görülmüştür. Yoğuşmanın ortadan kaldırılması için ise hava akış hızının arttırılması ile yüzey sıcaklığının arttırılmasının yeterli olduğu tespit edilip analizlerle doğrulanmıştır.

ÖZET

Günümüzde sektörde farklı disiplinlerin işbirliği ile bir araya gelen çok sayıda fonksiyonel ürün bulunmaktadır. Bu sistemlerin istenilen çıktıyı sağlamak için birden fazla parametresi vardır ve bazen bu sistemi matematiksel olarak ifade etmek oldukça zordur. Dolayısıyla matematiksel olarak ifade edilmesi zor bir sistemi modellemek zorlaşmakta ve fiziksel bir prototip olmadan böyle bir ürünün tasarımından üretimine kadar olan süreçte sistemin nasıl çalışacağını simüle etmek mümkün olmamaktadır. Ancak bazı istatistiksel yaklaşımlarla tahminler yapılabilmektedir. Otomobil bagaj kapağı, bahsedilen karmaşık sistemlerden biridir. İstenilen sonuç, kolayca açılan ve kapanan bir arka kapak olmasına rağmen, bu sonucu etkileyen çok fazla girdi parametresi vardır. Bu çalışma ile bir otomobil bagaj kapısının açılma ve kapanma kuvvetlerini etkileyen parametreler (aslında sistemin mevcut bir matematiksel modelinden alınmıştır) belirlenmiş ve önceki testlerden elde edilen verilerle bir makine öğrenme (ML) modeli oluşturulmuştur. Bu modelin daha önce bilmediği girdi parametrelerine karşı sonucu tahmin etmesi sağlanmış ve bu sonuçlar fiziksel olarak gerçek değerlerle karşılaştırılmıştır.

Anahtar Kelimeler: Bagaj kapağı, bagaj kapağının öznel değerlendirmesi, mekanizma analizi, makine öğrenimi, doğrulama.

MACHINE LEARNING USE IN TAILGATE USE AND VERIFICATION

ABSTRACT

Today, there are many functional products in the industry that come together with the cooperation of different disciplines. These systems have more than one parameter to provide the desired output, and sometimes it is quite difficult to express this system mathematically. Therefore, it becomes difficult to model a system that is difficult to express mathematically, and it is not possible to simulate how the system will work in the process from design to production of such a product without a physical prototype. However, estimates can be made with some statistical approaches. The automobile tailgate is one of the complex systems mentioned. Although the desired result is a tailgate that opens and closes easily, there are too many input parameters that affect this result. With this study, the parameters that affect the opening and closing forces of an automobile tailgate (which are actually taken from an existing mathematical model of the system) were determined and a machine learning model was created with the data obtained from previous tests. This model was enabled to predict the result against input parameters that it did not know before and these results were compared physically with the real values.

Keywords: Tailgate, trunk lid, subjective evaluation of a tailgate, mechanism analyze, machine learning, verification.

1. GİRİŞ

Bu makale, otomobil gövde hareketli parçalarından bagaj kapağının çalışma karakteristiklerinin makine öğrenmesi algoritmaları ile hesaplanmasını ve sonucun geleneksel metotlar ile kıyaslanmasını kapsamaktadır. Geçmişte yapılan pistonlu bagaj kapağı geliştirme çalışmaları sırasında elde edilen büyük veri kullanılarak makine öğrenmesi algoritmaları beslenmiş ve verilen 8 farklı giriş parametresine istinaden etkilenen 2 çıkış parametresinin tahminlemesi yaptırılmıştır. Proje, henüz tasarım aşamasında olan HB, SW veya hafif ticari araç bagaj kapağının müşteri tarafından kullanılması sırasında gereken açma kapama kuvvetlerinin henüz fiziken araç ortada yok iken en kısa yoldan hesaplanması, deneyimlenmesi ve yorumlanması amacı ile yapılmıştır.

2. AMAÇ

Bu çalışma kapsamında makine öğrenmesi algoritmalarının otomobil hareketli parça sistemlerinin tasarım ve analizinde kullanılması, geliştirme süreçlerinin kısaltılması amaçlanmıştır.

3. LİTERATÜR ARAŞTIRMASI

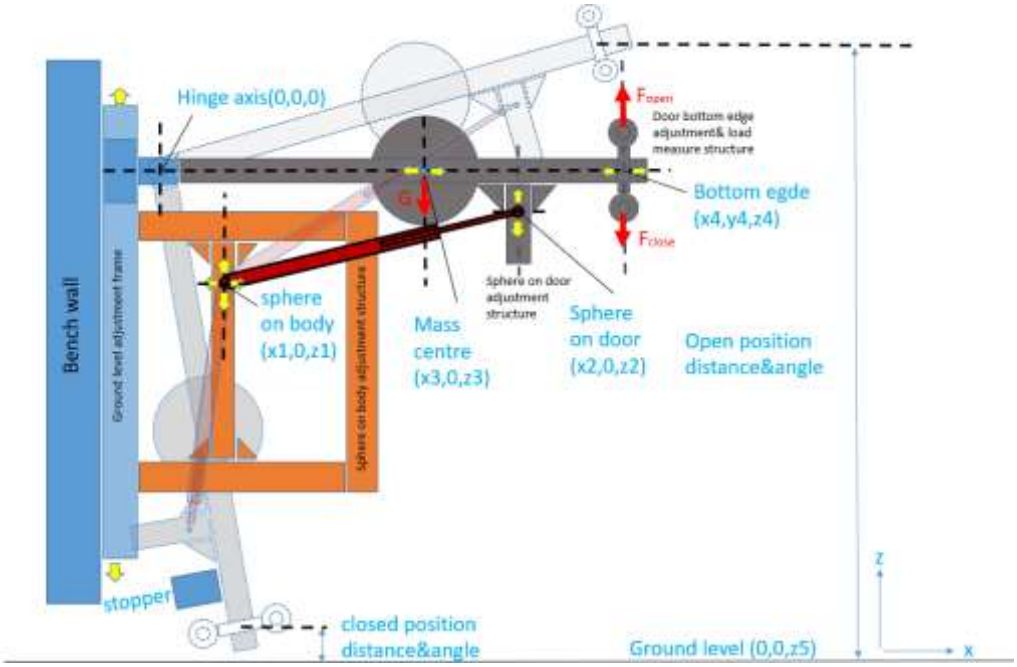
Yapay zeka, en basit tanımı ile, insan zekasının belli bir parçasını taklit etmeye çalışan sistemlerin genel adıdır. Bu açıdan bakıldığında, yapay zeka dendiğinde aklımıza insanın zekasını tamamen taklit edebilen veya amacı bu olan sistemler gelmemelidir[1]. Makine öğrenmesi ise yapay zekanı bir alt kümesidir[2]. Diğer yapay zeka uygulamalarından farklı olarak, makine öğrenimi bilgisayarların algılayıcı verisi ya da veritabanları gibi veri kaynağı türlerine dayalı öğrenimini olanaklı kılan algoritmaların tasarım ve geliştirme süreçlerini konu edinen bir bilim dalıdır. Makine öğrenimi araştırmalarının odaklandığı konu bilgisayarlara karmaşık örüntüleri algılama ve veriye dayalı akılcı kararlar verebilme becerisi kazandırmaktır. Bu, makine öğreniminin istatistik, olasılık kuramı, veri madenciliği, örüntü tanıma, yapay zekâ, uyarlamalı denetim ve kuramsal bilgisayar bilimi gibi alanlarla yakından ilintili olduğunu göstermektedir[3]. Bu açıdan bekıldığında ML algoritmalarında yapılmak istenen belirli bir girdi parametresi setine göre çıkış parametresinin veya parametrelerinin nasıl etkilendiğini hesaplamaktır. Bunun için de çok büyük veri setlerine ihtiyaç duyulur. Elde ne kadar fazla test verisi var ise ML algoritmaları ile yapılan işlem başarısı da o kadar yüksek olacaktır.

Makine öğrenmesi yöntemlerine baktığımızda, denetimli öğrenme, denetimsiz öğrenme, yarı denetimli öğrenme ve pekiştirmeli öğrenme olmak üzere dört farklı kategoriye ayrılmaktadır. Bu makine öğrenmesi algoritmaları, müşteri ilişkileri yönetimi, iş zekası, insan kaynakları bilgi sistemleri, otonom araçlar, sanal asistanlar gibi bir çok farklı alanda karşımıza çıkmaktadır.

Bu çalışma sırasında "Lineer regresyon" metodu ile "Boosted Decision Tree" metodları ayrı ayrı uygulanmış olup her iki yöntemin de çıktıları kıyaslanmıştır.

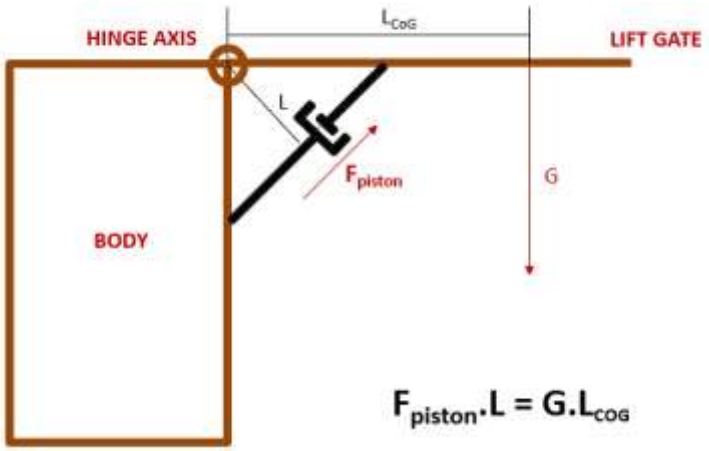
4. GELİŞTİRME SÜRECİ ÖNGÖRÜSÜ

Öngörülen tasarım ve geliştirme süreci için otomobil bagaj kapağının fiziksel özelliklerini simüle eden bir banko (Bkz şekil 1) ve bagaj kapağının statik analizini yapabilen bir excel makrosu kullanılmıştır.



Şekil 1. Bankonun şematik gösterimi[4]

Araç tasarımının müsaade ettiği sınır şartlar içersinde değiştirilen giriş parametrelerine göre makroda elde edilen sonuçların aynı parametreler ile test bankosunda yapılan ölçümlerde de değişiklik göstermediği daha önce yapılan çalışmalarımızda ispatlanmıştır[4]. Mekanizmanın statik analizinde aracın menteşe ekseni referans alınıp, aşağıdaki belirtilen parametreler kullanılarak sistemin matematik modeli oluşturulur (şekil 2).



Şekil 2. Kapağın herhangi bir açıdaki fiziksel denge denklemi[4]

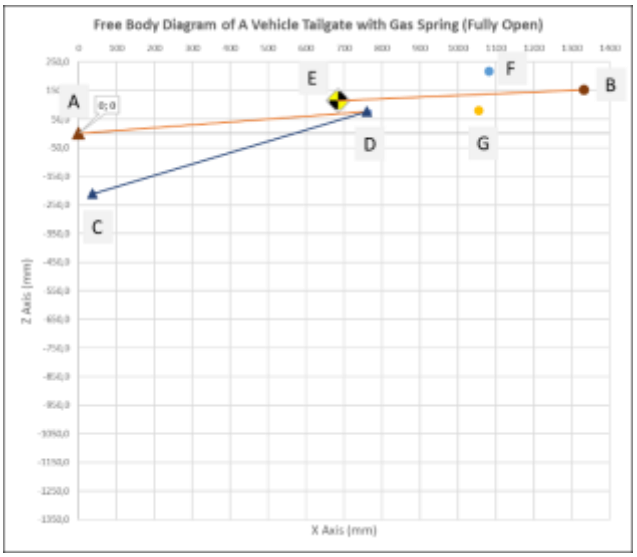
- Menteşe dönme Merkezi koordinatları
- Gazlı piston gövde bağlantı koordinatları,
- Gazlı piston kapı bağlantı koordinatları
- Araç kapısının ağırlık merkezinin koordinatları
- Kapı açma kolu koordinatları
- Kapı kapatma kolu koordinatları
- Kapı ağırlığı,
- Piston kuvveti,
- Piston Stroğu

Bu parametreler kullanılarak elde edilen denklem kapı açısına göre çözdürüldüğünde teorik olarak bir araç bagaj kapağının kuvvet-açı grafiği elde edilerek static kuvvet analizi yapılmaktadır.

Statik kuvvet analizinden sonraki adımda, bankonun kurulumu kapı parametrelerini simüle edecek şekilde yapılmakta ve banko kuvvet ve açı sensörleri ile enstrümante edilmektedir. Iç ve dış tutamaklardan uygulanan quasi static yükleme ile veri toplanarak kapının fiziksel kuvvet-açı grafiği de elde edildikten sonra teorik grafik ile ölçülen grafik karşılaştırılmaktadır.

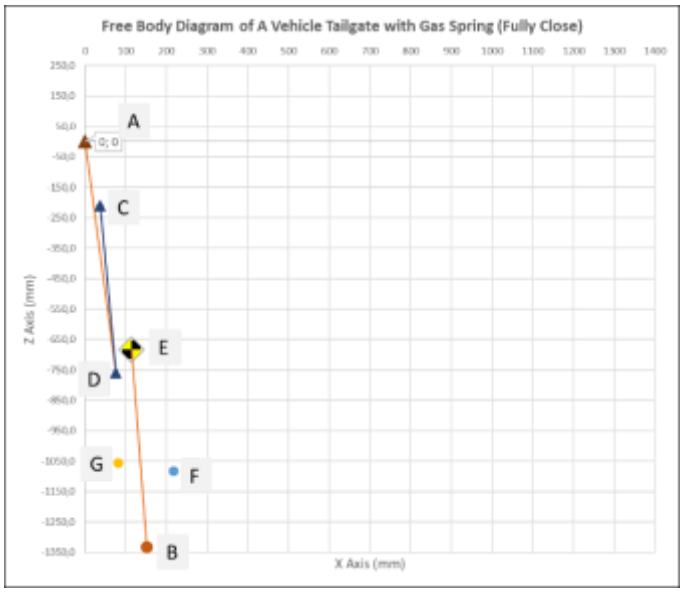
4.1. Sistemin Serbest Cisim Diyagramı

Gazlı yay tahrikli bir bagaj kapağı mekanizmasının serbest cisim diyagramı şekil 3 ve 4 ‘de gösterilmektedir.



Şekil 3. Kapı açık durumda serbest cisim diyagramı[4]

AB: Bagaj Kapağı
CD: Gazlı yay
E : Ağırlık Merkezi pozisyonu
F: Dış açma kolunun pozisyonu
G: İç açma kolunun pozisyonu



Şekil 4. Kapı kapalı durumda serbest cisim diyagramı[4]

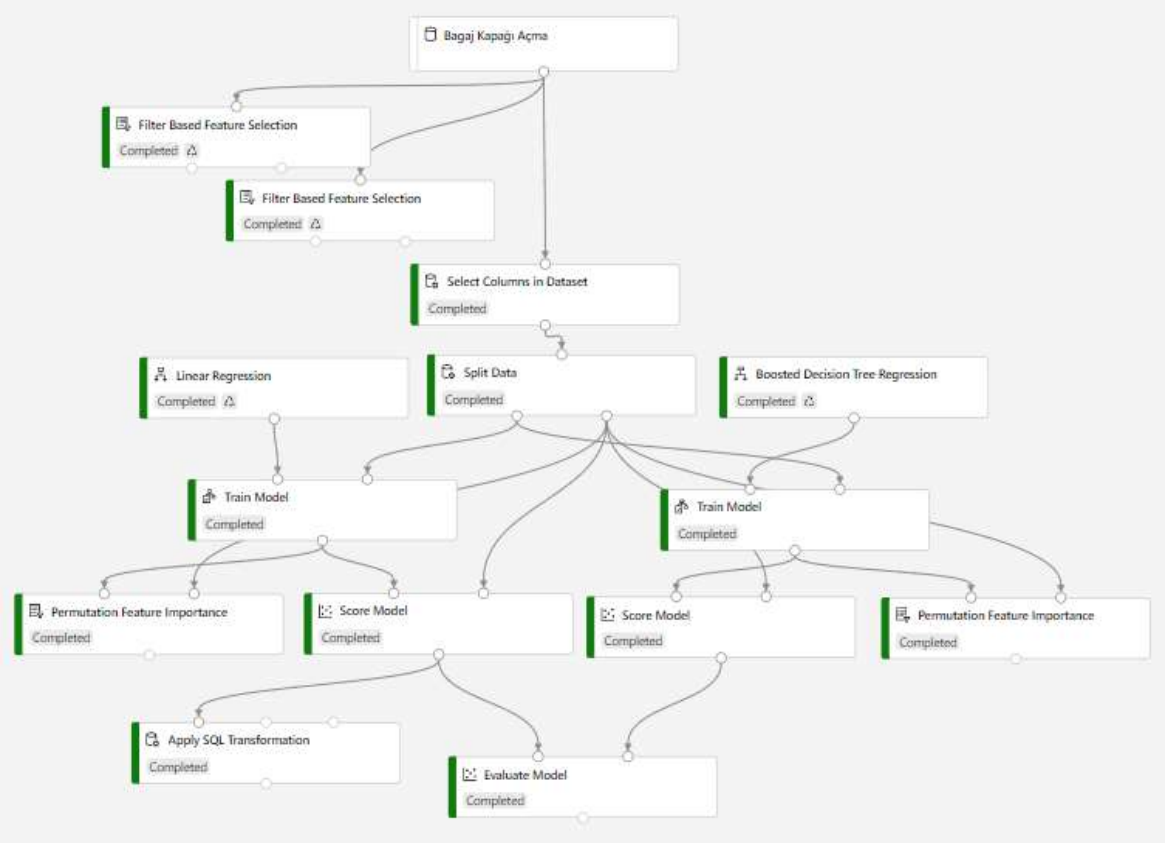
4.2. Makine Öğrenmesi Modelinin Oluşturulması

Bu çalışmada denetimli makine öğrenmesi alt türlerinden regresyon modellemesi kullanılmış olup geliştirme ortamı olarak Microsoft Azzure Machine Learning Studio[5] kullanılmıştır. Bütün giriş parametreleri için aracın izin verdiği ölçüde sınır şartlar belirlenip, bu sınır şartlar içerisinde her bir parametrenin diğerleri ile farklı kombinsayonlarından oluşan 1000 satırlık bir girdi veri seti oluşturuldu. Daha sonra bu veri seti sistemin fiziksel denklemine dayanarak hesaplama yapan makrodan faydalanarak çözdürülüp çıkış parametreleri hesaplatıldı.

Parametre İsmi	Parametre Tipi
Kapının ağırlığı	Input
Kapı COG X koordinatı	Input
Kapı COG Z koordinatı	Input
Kapı X koordinatında pistonun dönme noktası	Input
Kapı Z koordinatında pistonun dönme noktası	Input
Gövde X koordinatında pistonun dönme noktası	Input
Gövde Z koordinatında pistonun dönme noktası	Input
Piston Kuvveti	Input
Açılma Kuvveti	Output
Kapanma Kuvveti	Output

Şekil 5. Veri seti parametreleri

Elde edilen bu 1000 satırlık veri seti Microsoft Azzure ML studio[5] ortamına yüklenerek model, verinin %60'lık bir kısmı ile eğitildi. Öncelikle "Linear Regression" ile çözüm yaptırıldı. Aynı modelde aynı veriler ile "Boosted Decision Tree Regression" yöntemi ile de öğrenme yaptırılıp sonuçlar karşılaştırıldı.



Şekil 6. Makine Öğrenmesi Modeli

Yüzde 60 gibi bir veri ile eğitilen modellerin kalan %40lık giriş parametreleri için yaptığı sonuç tahminlerindeki başarı oranı "Linear Regression" metodunda %96,8 olurken, "Boosted Decision Tree Regression" metodundaki tahmin doğruluğu %98,6 olmuştur.

Tablo 1. Sonuç Tablosu

ML Çözüm Metodu	Linear Regression	Boosted Decision Tree Regression
Determinasyon Katsayısı	%96,8	%98,4

5. SONUÇLAR VE DEĞERLENDİRME

Elde edilen sonuçların makroda çözdürülen veriler ile kıyaslaması yapıldığında ML modelinin başarımının %96 nın üzerinde olduğu görülmektedir. Dolayısı ile matematiksel olarak ifade etmesi zor olan herhangi bir sistem için bu yaklaşımın uygulanması ve sonuçların doğru tahmin edilmesi imkanı oldukça yüksektir. Bu açıdan bakıldığında otomobil disiplininde bir çok alanda ML uygulamaları ürün geliştirme süreçlerinde karmaşık işlerin kolaylaşmasını ve hızlıca sonuç elde edilmesini sağlayacaktır. Örneğin daha önce defalarca yapılmış benzer CAE analizlerini tekrardan yapmaktansa, eldeki veriler kullanılarak sonuç hakkında ML ile bir öngörü yapılabilir. Böylece uzun zaman gerektiren mesh oluşturma ve modelleme işlemlerinin atlanarak doğrudan sonuca gidilmesi sağlanabilir. Dolayısı ile ML ile oluşturulan modellerde mühendislik geliştirme saatlerinin azaltılması ve farklı alan ve disiplinlere yaygınlaştırma potansiyeli vardır.

Öte yandan, tüm bu avantajlarının yanı sıra düzgün bir tahminleme yapılabilmesi için modelin iyi eğitilmesi gereklidir ki bu da çok fazla sayıda veri girdisi anlamına gelmektedir. Makine öğrenmesi metodunu tanımlarken de söylediğimiz gibi algoritmaların başarımını arttıran en önemli unsur veri setleri içerisindeki örüntü ve ilişkileri yakalayabilmesi için fazlaca test verisinin modele öğretilmesidir. Kısacası bu fazla test verisi gerekliliği yüksek test maliyetleri nedeni ile çoğu zaman ML nin uygun bir çözüm olmayacağı anlamına da gelmektedir.

Kaldı ki tüm bu avantaj ve dezavantajlarının yanı sıra ML ile parametre optimizasyonu yapılması işlemleri çok mümkün olmadığından benzer işlemler DOE metodu ile de çözülebilmekte ve görece daha kısa zaman almaktadır.

TEŞEKKÜR

Bu çalışmanın gerçekleştirilmesinde emeği geçen ve desteklerini sunan arkadaşlarım İbrahim Utanır, Şadan Dönmez, Gökhan Ruşen Safran ve Salih Zeki Tarım' a teşekkürlerimi sunarım.

ÖZET

LED kullanımının yaygınlaşmasıyla otomotiv aydınlatması üreticiler için araçların kimliğinin önemli bir parçasını oluşturan göz alıcı bir tasarım öğesi haline gelmiştir. Bu çalışmada ticari araç ön aydınlatmasında farklı bölgelerde kullanılan gündüz farı, sinyal lambası ve pozisyon lambası tek bir üründe birleştirilmiş ve ünite içinde bulunan mikroişlemci ile gömülü bir sistem tasarımı yapılmıştır. Aydınlatma çıkışında kullanılan sayıca az, güçlü LED grubu ile ışık tüpüne aydınlatma sağlanmıştır.

Anahtar kelimeler: Otomotiv aydınlatma, LED, gündüz farı, sinyal lambası, pozisyon lambası, park lambası, ticari araç

MULTIFUNCTIONAL FRONT LIGHTING UNIT DESIGN IN COMMERCIAL VEHICLES

ABSTRACT

Automotive lighting with the widespread use of LED has become eye-catching design element that composing an important part of the car identity for car manufacturers. In this study, daytime running light, signal light and position light used in different regions for commercial vehicle front lighting are combined in a single product and an embedded system has been designed with the microprocessor in the unit. Lighting is provided to the lightguide with the small number of power LEDs.

Keywords: Automotive lighting, LED, daytime running light, signal light, position light, parking light, commercial vehicle

1. GİRİŞ

Gündüz farı (DRL, Day Running Light) son yıllarda regülasyon şartlarına dahil edilmiş yeni üretilen her araçta uygulanma zorunluluğu konulmuş bir ön aydınlatma fonksiyonudur. Otomobil üreticileri bu fonksiyonu içeren lambayı araç ön farlarına yakın bölgelere yerleştirmektedir.

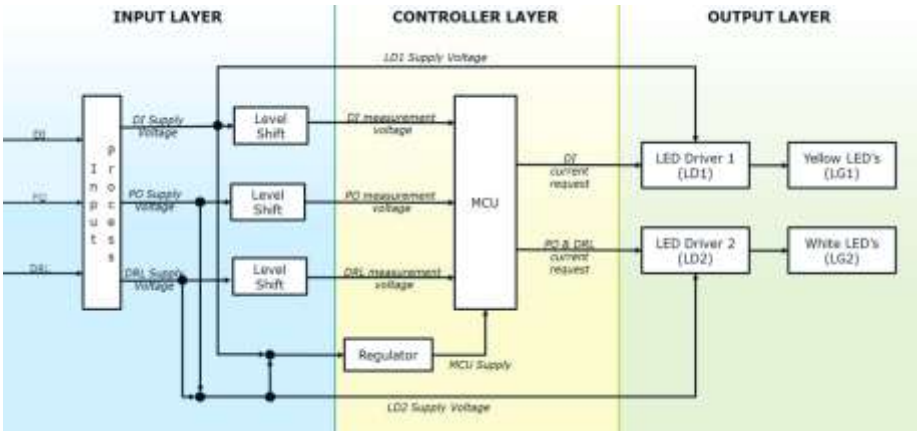
Ön aydınlatma grubunda bulunan sinyal lambası ve özellikle otobüs, kamyon gibi ticari araçlarda bulunan pozisyon lambaları üreticiler için araç ön aydınlatmasında yönetilmesi gereken farklı lamba tipleridir. Gündüz farı, sinyal lambası ve pozisyon lambasını tek bir ünitede toplayarak kompakt bir ürün haline dönüştürülmesi, maliyet ve araç ağırlığı açısından fayda sağlamaktadır. Ağırlığın azalması da doğrudan aracın karbon salınımına olumlu etki yapmaktadır.

Son yıllarda çok fazla duymaya başladığımız otonom araç teknolojisi ve elektrikli araçlara olan ilginin artması ile birlikte otomotiv sektöründe de elektronik devrelerin kullanımı ivmelenerek artmaya devam etmektedir. Elektrikli araçların üretim bandında olduğu bu yıllarda otomobilin çevreye yaydığı ve çevreden aldığı elektromanyetik dalgalar araç sistemini etkilemektedir. Dolayısıyla elektronik devre tasarımında genel olarak koruma komponentleri olarak

geçen, ESD koruma komponentleri ile EMI/EMC etkisine karşın kullanılan komponentler, bunların değerleri ve bu komponentlerin elektronik kart üzerindeki dizilişleri büyük önem arz etmektedir [1].

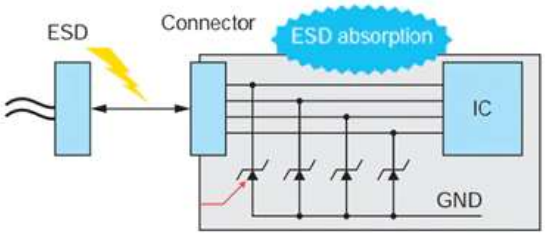
2. SİSTEM TASARIMI

Sistem ticari araçlar için geliştirilmiştir. Ünite, araç içi voltajı minimum 16V ile maksimum 32V arasında; nominal 28V'de çalışmaktadır. Tasarlanan ön aydınlatma grubunu elektronik olarak iki ana başlık altında toplayabiliriz. Ünite için donanım tasarımı ve gömülü yazılım tasarımı yapılmıştır. Donanım tasarımı da kendi için de yine üç alt başlığa ayrılmıştır. Birinci kısım; araç üzerinden gelen akü voltajını düzenlemek ve devre üzerinde kullanılan hassas elektronik komponentleri korumak için filtre ve koruma devreleri kullanılmıştır.



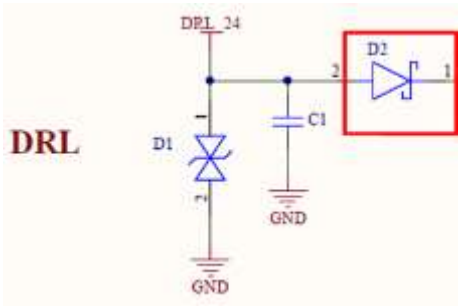
Şekil 1. Sistemin yapısı

Akü voltajını ilk karşılayan TVS diyot (Süreksiz Gerilim Sönümleyici, Transient Voltage Suppression) ile elektrostatik deşarj durumu ve anlık yüksek gerilim kontrolü sağlanmıştır. Giriş devresinde kullanılan filtre yapıları ile elektromanyetik alan testlerine karşı dayanıklı bir devre yapısı oluşturulmuştur.



Şekil 2. ESD koruma devresi diyagramı

Yine aynı kısım koruma devresinde montaj esnasında oluşabilecek olası ters bağlantı durumları için devreyi ve diğer çevre ekipmanları korumak için birer adet şotki diyot kullanılmıştır.

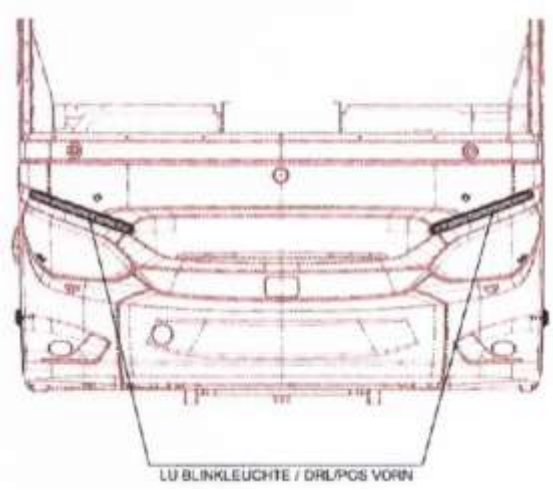


Şekil 3. Giriş devresi ters gerilim koruması

Tasarlanan elektronik devrede bulunan mikroişlemcinin besleme voltajı olan +5V seviyesi için akü üzerinden gelen voltajı bir voltaj regülatörü üzerinden geçirerek temiz bir DC sinyal elde edilmiştir. İkinci kısım; araç ECU'su üzerinden gelen bildirim ile ilgili aydınlatma fonksiyonunun algılanması ve karar vermesi için kullanılan mikroişlemcisi devresidir.

Mikroişlemci katı gelen bilginin kontrol edildiği, yorumlandığı ve ilgili sürücü katına tetik yapıldığı devre yapılarını içerir. Bu katta PWM sinyali ve LED sürücüleri aktifleştiren sinyal üretilir, LED sürücülerin hasar aldığındaki geri bildirimleri kontrol edilir.

Mikroişlemciye bağlı LED sürücü devreleri yine mikroişlemcinin karar verme yapıları doğrultusunda aktifleştirilir. Gündüz farı açılma talebi ECU tarafından üniteye bildirilince beyaz renk LED'lerin bağlı olduğu kanal PWM sinyali üretir. Beyaz LED'ler yaklaşık 4 saniye içerisinde sıfır parlaklıktan tam parlaklığa doğru bir artış ile yanar. ECU tarafından pozisyon lambası açılma sinyali geldiğinde bu kez beyaz LED'ler sıfırdan %10 parlaklık seviyesine 100ms. içerisinde çıkar ve sabit kalır. ECU tarafından sinyal lambası açılma sinyali geldiğinde devre üzerindeki beyaz LED'ler söner ve devre üzerindeki turuncu LED'ler sıfırdan %100 parlaklık seviyesine 100ms. içerisinde çıkar.



Şekil 4. Aydınlatma ünitesinin ticari araçtaki konumu

Üçüncü kısım; elektronik devrede bulunan mikroişlemcinin araç ECU'su üzerinden aldığı bildirimler doğrultusunda ilgili fonksiyonları gerçekleyebilmesi yani ilgili LED'lerin ışık verebilmesi için kullanılan LED sürücü devreleridir. Ön aydınlatma ünitesinde kullanılan LED'lerin istenilen ışık değerine göre ortalama nominal akımı 666mA olarak ayarlanmıştır. Bu ayarlanan akım değeri ile açılan LED'lerin yaydığı ışık, ışık tüpü üzerinden tüm ünite boyunca iletilir. Gündüz farı ve pozisyon lambası için kullanılan LED'ler beyaz, sinyal lambası için kullanılan LED'ler turuncu renkli olarak seçilmiştir. Bu LED'ler kendi gruplarında seri olarak bağlıdır.

LED sürücüleri ve LED katı aydınlatma değerlerinin güçlü LED'lerde uygulandığı kattır. Anahtarlama frekansları bu katta ayarlanır.

3. SİSTEM GEREKLİLİKLERİ

Elektronik devre tasarımı ve gömülü yazılım çalışmalarında ISO 16750-2 Road vehicles — Environmental conditions and testing for electrical and electronic equipment standardına [2], A 960 001 93 99 Design Specification for Electric/Electronic Components in the common CVD Powernet şartnamesine [3], ECE R10 Uniform provisions concerning the approval of vehicles with regard to electromagnetic compatibility regülasyonuna [4], MBN 10284-4 EMC Performance Requirements – Component Tests şartnamesine [5], ECE R48 Uniform provisions concerning the approval of vehicles with regard to the installation of lighting and light-signalling devices [6] regülasyonuna uyulmuştur.

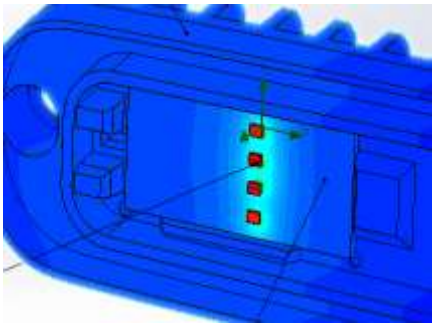
4. ANALİZ ÇALIŞMALARI

LED ile aydınlatma sağlayan elektronik devrelerde yönetilmesi gereken en önemli kısım sistemin termal davranışıdır. Tasarlanan bu ön aydınlatma ünitesinde bir LED üzerinden geçen ortalama akım 666mA olmasından dolayı LED'ler üzerinde yüksek miktarda ısı birikmeleri olmaktadır. Bu durum sistemde güç kayıplarını da meydana getirmektedir. Ortalama bir LED'in üzerinde olan gücün yaklaşık %85'i ısıya %15'i de ışığa dönüştüğü bilinmektedir. Bu sebeple sistemin termal performansı genel ürün performansına doğrudan etki etmektedir.

Kullanılan LED'in nominal çalışma voltajı 3V'dir. Bir LED üzerinden geçen 666mA ile beraber LED üzerinde oluşan gücü hesaplayacak olursak;

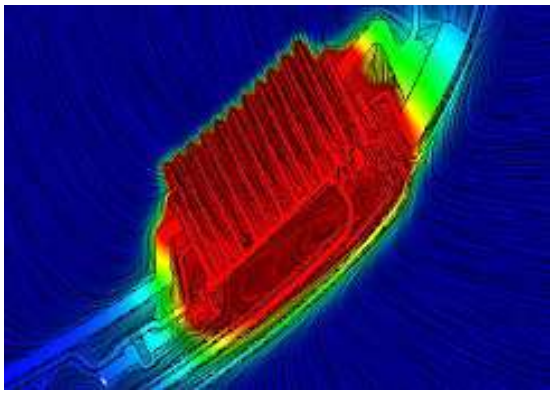
$$Pled = \frac{3x666}{1000} = 1.99W \quad (1)$$

1.99W tek bir LED üzerinde oluşacak ortalama güç değeridir. Aynı anda 4 LED'in de yanacağı hesaba katarsak ortalama 7.99W'lik bir güç değeri oluşacaktır. Oluşan gücün %85'lik bir kısmının ısı olarak açığa çıktığı bilinmektedir. Bu doğrultuda ortalama 6.79W'lik bir ısı meydana gelecektir. Ön aydınlatma ünitesinin kapalı ve dar bir alanda olduğunu düşündüğümüzde bu durumu termal olarak yönetmek zor bir hal almaktadır.



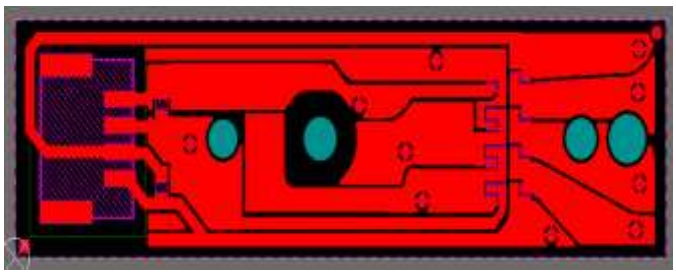
Şekil 5. LED kartı termal analiz görüntüsü

Yapılan termal analizler sonucunda LED'lerin açılmasından belli bir süre sonra soğutucunun oluşan ısıyı dağıtmakta yetersiz kalıp, fazla ısının ünitede yer alan plastik kısımlara zarar verdiği görülmüştür.



Şekil 6. Soğutucu termal analiz görüntüsü

Termal yönetimi iyileştirebilmek için LED kartının boyutlarında, kartın materyalinde ve LED çevresi bakır alanlarında revizyonlar yapılmış ve analizler tekrarlanmıştır. Böylece LED'lerden açığa çıkan ısının PCB üzerinde daha homojen dağılması ve soğutucuya daha iyi iletilmesi sağlanmıştır.



Şekil 7. Termal Yönetim uygulanmış LED kartı tasarım görüntüsü

5. ELEKTRONİK KART TASARIMI

Ön aydınlatma grubu iki ayrı elektronik kart ile tasarlanmıştır. Kartlardan biri aracın ECU'su ile haberleşerek ilgili fonksiyonların yönetimini gerçekleştiren anakart, diğeri ise fonksiyonların ışık vermesini sağlayan LED'lerden oluşan LED karttır.

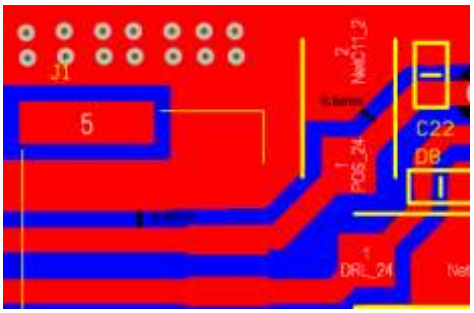
5.1 ANAKART TASARIMI

Ana kart üzerine 1 adet mikroişlemci, 2 adet buck modeli dönüştürücü olmak üzere toplamda 90 adet elektronik komponentten oluşmaktadır. Kart FR-4 tip malzemeden seçilmiştir. 1.6mm PCB kalınlığı ve 2 oz bakır kalınlığına sahiptir. Kart çift yüzlü şekilde tasarlanmıştır. Kart üzerinde kullanılan tüm komponentler otomotiv sektöründe elektronik komponentlerin standartlarına AEC-Q100, AEC-Q101 ve AEC-Q200'e sahiptir. [7][8][9].

Şekil 8. Anakart tasarımının 3D ortamındaki görüntüsü

Ana kart üzerinde kullanılan 2 adet LED sürücü entegresinin altlarına termal delikler konularak kartın hem üst hem alt yüzeyde bulunan toprak hattına geçişleri sağlanmıştır. Böylece termal yönetim bakımından kartın performansının korunması amaçlanmıştır.

Müşteri şartnamelerine uygun olarak giriş sinyal hattı ve toprak hattı (GND) arasındaki mesafenin IPC-2221A Generic Standard on Printed Board Design standardına göre en az 0.6mm olması sağlanmıştır [10].



Şekil 9. IPC-2221A standardına uygun bakır yolları tasarım görüntüsü

Termal delikler üzerinden dizgi işlemi sırasında alt tarafa lehim akmaması için delik çaplarının 0.3mm'den büyük olmamasına özen gösterilmiştir.

5.2 LED KART TASARIMI

LED kart, üzerinde 4 adet beyaz ve 4 adet turuncu renk LED'ler olmak üzere toplamda 10 komponentten oluşmaktadır. Kart özel bir alüminyum malzemeden yapılmakta olup 1.5mm kalınlığına ve 1 oz bakır kalınlığına sahiptir.

Şekil 10. LED kartı tasarımı 3D ortamındaki görüntüsü

6. SONUÇLAR

Bu çalışmada otomotiv elektroniği için bir ön aydınlatma sistem olan, komponentleri otomotiv standartlarına uygun olarak seçilmiş, yapılan termal analizlerle devre yapısı test edilmiş, ticari araçlar için bir ön aydınlatma ünitesi geliştirilmiştir. Tasarımı bitirilmiş elektronik kartın üretimi yapılmıştır. Ünite otomotiv sektörü zorlu testlerinden başarı ile geçmiştir ve ECE R10 regülasyon belgesini almıştır.

Çok fonksiyonlu ön aydınlatma ünitesi araç önü bölgesinde tasarım ekibine yer kazandırmış, fonksiyonel özelliği sayesinde 3 ayrı fonksiyonun toplam maliyetine oranla bir maliyet düşümü sağlamıştır. İçindeki elektronik devrenin bir getirisi olarak toplam ağırlıkta hafifleme sağlanmıştır. Bu durum da doğrudan olarak aracın emisyon salınımına olumlu yönde etki yapmıştır. 3 fonksiyonun tek ünitede toplanması aracın önünde markaya özel tasarımların daha özgürce uygulanmasına olanak sağlamıştır.

Bu aşamadan sonraki çalışmalar ticari araç marka bilinirliliğini artıracak ön kısım aydınlatmaları, diğer fonksiyonlarla birleştirilebilen modüler aydınlatma uygulamaları olacaktır. Otomotiv sektöründe bu konudaki çalışmaların çeşitlenerek artması hedeflenmektedir.

ABSTRACT

The main objective of this study was to evaluate the potential benefits that can be achieved with application of various electrified components to a 40 tons heavy-duty long-haul truck. A realistic base long-haul truck with its conventional powertrain components is modelled in a simulation environment and on top of that, by adding degree of freedom to the system with electrified components and their controllers, the opportunities of hybridization in terms of fuel economy improvement are examined over Heavy Heavy-Duty Diesel Truck (HHDDT) and Urban Dynamometer Driving Schedule Heavy-Duty (UDDSHD) cycles. Every hybrid vehicle configuration as well as the base vehicle used in this study were modeled using representative internal combustion engine (ICE), battery pack and electric drive components in AVL CruiseM™. Hybridization of the long-haul truck offers up to 4.9% fuel economy compared to conventional vehicle. In addition, the same powertrain configuration provides an 24.4% reduction in tailpipe NO_x emissions and an 22% reduction in urea consumption.

Keywords: Hybrid Powertrains, Heavy-Duty Vehicles, HEV, Commercial Vehicles, Diesel Electrification

INTRODUCTION

Road transport is an activity that is fundamental to society and the economy of any nation. Besides giving freedom to people to carry out their activities, it also links people, companies, and countries economically. Just in the EU region alone, approximately 44% of products are transported this way [1]. Our modern society acquires most of its energy for this transportation from petroleum-based fuels to power our vehicles to transport goods or people from point A to B. Using these fuels for these purposes produces a lot of poisonous emissions and contributing to the global warming. Also, the efficiency of internal combustion engines (ICE) is usually around %35 which is not enough for future goals of humanity for limiting global warming and creating efficient transportation solutions [2]. Because of these issues, maintaining such way of transportation is impossible for our future and electrification might be a good solution for increasing efficiency while decreasing greenhouse gas emissions and NOx emissions [3]. On the other hand, there are no subsidies for electrified Heavy-Duty Vehicles (HDV) like there are for passenger ones [4].

Hybrid electric vehicles (HEV) appear to be the fastest short-term measure we can take to reduce the environmental impacts of conventional ICE powered powertrains. Hybridization allows the rightsizing of an engine, by doing so we can lower the heat loss and increase efficiency [5]. The reduced ICE power can be derived from the electric motor (EM). Especially at low speeds, EMs provide torque quicker than their ICE counterparts. By doing so launching performance might be improved even with a less powerful ICE [6]. Notions about HEV were described in detail in W. Enang and C. Bannister's study HEV control methods were touched on. The methods were compared to fuel economy and emissions with velocity cycles. A detailed cost-saving analysis was not made in this study [7].

METHODOLOGY

Model Development

Dynamic models of long-haul tractor and semi-trailer have been developed in AVL CruiseM. Simulation is essentially based on the longitudinal equation of motion of the vehicle generated using the forces shown in **Figure** . The details of the vehicle parameters can be seen in **Table 1**, and the equations of motion using these parameters are given below [8]:

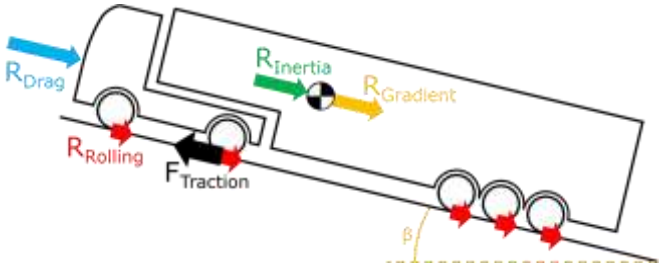

Figure 1. Forces acting on the vehicle

$$F_{Traction} = R_{Drag} + R_{Rolling} + R_{Gradient} + R_{Inertia} \quad (1)$$

$$R_{Drag} = \frac{1}{2} * \rho * C_d * A_f * v^2 \quad (2)$$

The drag resistance force acting on the vehicle [8]:
Where C_d refers to drag coefficient of the vehicle, ρ refers to density of the air, A_f refers to front area of the vehicle and v refers to velocity of the vehicle.

$$R_{Rolling} = C_r * m * g * \cos(\beta) \quad (3)$$

The rolling resistance force acting on the vehicle [8]:
Where C_r refers to rolling coefficient of the vehicle, m refers to mass of the vehicle and g refers to gravitational acceleration and β refers to slope of the road.

$$R_{Gradient} = m * g * \sin(\beta) \quad (4)$$

The gradient resistance force acting on the vehicle [8]:
Where m refers to mass of the vehicle, g refers to gravitational acceleration and β refers to slope of the road.

$$R_{Inertia} = m * a \quad (5)$$

The inertial resistance force acting on the vehicle [8]:
Where m refers to mass of the vehicle and a refers to the acceleration of the vehicle. Please note that, rotational inertias of rotating parts and gross vehicle mass decrease due to consumed fuel are not taken into account in simulations.

Table 1. Model Parameters

Parameter	Unit	Value
Gross vehicle mass	kg	40000
Drag coefficient	-	0.6
Rolling resistance coefficient	%	0.65
Frontal area	m^2	8.5
Density of air	kg/m^3	1.225
Gravitational acceleration	m/s^2	9.81
Wheel rolling radius	m	0.5

In **Figure** , conventional vehicle powertrain layout and hybrid powertrain layout are visualized. In this study, electric machine is placed in between gearbox and the main clutch, where this configuration is also known as P2 hybrid configuration. A 13 L diesel engine model, whose maximum power is 465 PS and maximum torque is 2500 Nm, combined with an exhaust system model including diesel oxidation catalyst (DOC), diesel particulate filter (DPF) and selective catalytic reduction (SCR) has been implemented to the model. A 12-speed automated manual transmission (AMT) model is used in the simulation.

A look-up table-based engine control unit (ECU) converting ICE torque demand to engine actuator commands, a dosing control unit (DCU) determining the necessary amount of urea mass flow depending on the temperature of SCR and

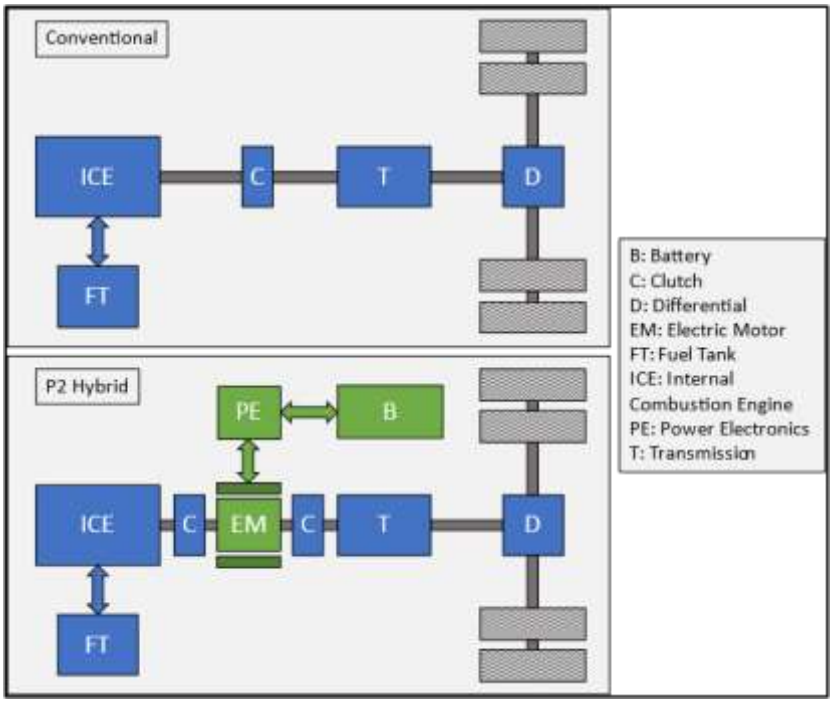

Figure 2. Arrangement of powertrain elements of the tractor. Conventional powertrain (top). Hybrid powertrain (bottom).

engine out nitro-oxides (NO_x) mass flow, and a transmission control unit (TCU) determining the clutch position and gear shifts are also embedded to the model. The simulations are done with two different P2 hybrid configurations as well as conventional powertrain over Heavy Heavy-Duty Diesel Truck (HHDDT) and Urban Dynamometer Driving Schedule Heavy-Duty (UDDSHD) cycles. The velocity and slope profile of these cycles are given in **Figure 11**.

Using two different electric motors and two different batteries; two different hybrid powertrain combinations have been studied, in which the EM and single-ratio transmission are located as a package between the two clutches between the internal combustion engine and the transmission. Details of electric components can be seen in **Table** .

For result comparability, the overall vehicle speed based maximum traction force of the hybrid powertrains are limited to the conventional vehicle maximum traction force curve. Additionally, since there is no direct correlation between battery state of charge (SOC) and consumed diesel fuel, the cycles are simulated with an SOC deviation ±0.1% difference between simulation start and simulation end, so that an SOC independent fuel consumption comparison between different layouts could be done.

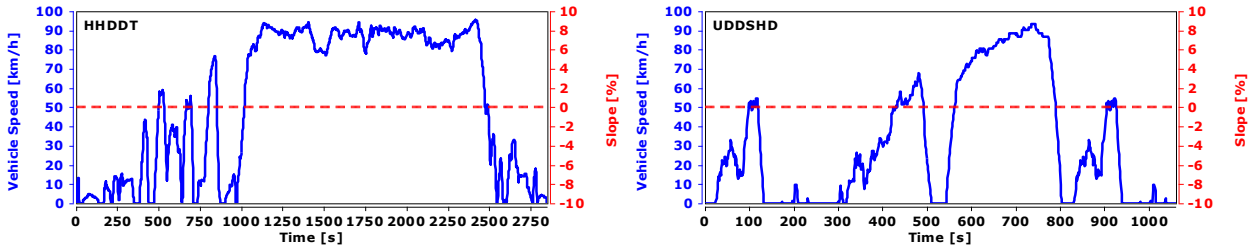

Figure 11. HHDDT ve UDDSHD test cycles

Table 2. Elements and details of hybrid architectures

		Configuration #1	Configuration #2
Electric machine	-	EM1	EM2
Voltage	V	660	538
Max. speed	rpm	2200	6000
Max. torque	Nm	625	405
Max. power	kW	75	75
Max. efficiency	%	93.7	92.9

Battery	-	BAT1	BAT2
Nominal voltage	V	660	538
Cell resistance	mOhm	1.6	1.8
Total capacity	kWh	31.7	32.5

Hybrid Controller Development

The hybrid control unit is placed between the driver pedal commands and the actuators of the system, in terms of signal flow, in order to intervene and manipulate the inputs from the driver according to the decision and calculation methodology. Different energy management strategies used in hybrid vehicles are shown in **Figure**. In this study, a

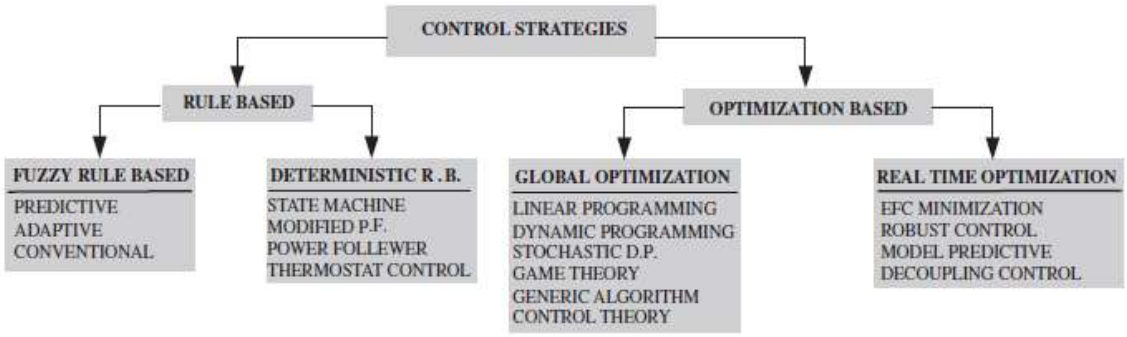

Figure 4. Energy management strategies on hybrid vehicles [9]

"Deterministic Rule Based" hybrid energy control algorithm has been developed. Such hybrid controllers, by definition [9], use the predefined information of the power transmission elements and perform their functions in three basic stages:

- Identifying hybrid modes
- Designing a single-output decision mechanism for all mode transitions
- Calculation of driver commands to be sent to the actuators to realize the selected hybrid mode.

According to the conditions occurring in the previous discrete time step, that is, when the accelerator pedal or the brake is pressed, the state of the vehicle at the next moment is chosen first, such as traction or braking. Assuming that it is in traction mode, after this selection is made, a single mode is activated by looking at which traction modes are available at that time and which of the appropriate modes has the highest priority. At the last stage, calculations are made in order to send the correct and appropriate commands to the actuators in the system in accordance with this selected mode, and the system is ensured to work both in the most optimum way and not exceeding the hardware limits. Four main modes used in the hybrid controller are explained below:

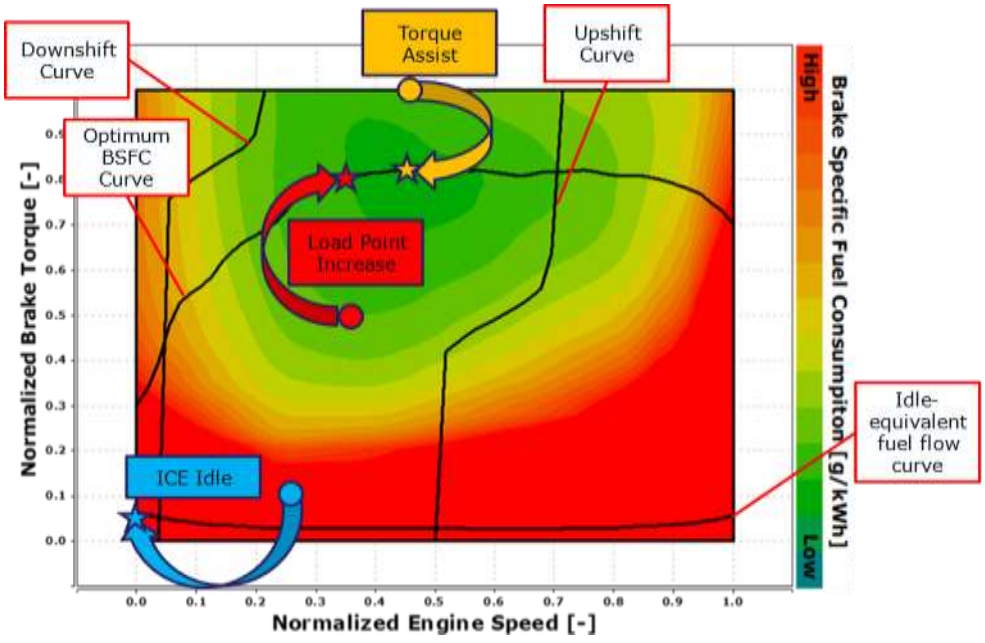

Figure 5. Demonstration of actions of various hybrid modes on an internal combustion engine map

- "Torque Assist" mode: The load of the internal combustion engine operating with a torque higher than "Optimum BSFC torque curve" is reduced to the load at which it obtains the lowest specific fuel consumption at its current speed, by providing the electric motor in the system to assist traction. This event is shown in orange in **Figure** .
- "Load Point Increase" mode: The load of internal combustion engine operating at a partial load is increased in order to have the best possible brake specific fuel consumption at the corresponding ICE speed. In this mode, electric motor works as a generator and charges the battery even when the overall powertrain generates traction forces on the wheels. This event is shown in red in **Figure** .

- "Electric Drive" mode: In cases where EM power is enough to meet driver demand, ICE torque demand is cut-off and vehicle is driven by the use of electric power. In this mode, ICE can be disengaged from the driveline using the main clutch and it can even be stopped while driving in order to avoid unnecessary fuel consumption which is shown as "ICE Idle/Stop" in blue in **Figure** . "Idle-equivalent fuel flow curve" represents a torque, which can be generated using the same amount of fuel flow as in idling, and it is used to quantify whether an "ICE Idle" action is more efficient or not in terms of fuel consumption.
- "ICE Drive" mode: In this mode only ICE produces traction force on wheels where EM generates zero torque. This mode is enabled when the other modes are not available which is determined by the hybrid controller.

RESULTS AND CONCLUSION

The main factor affecting the distribution of these points is knowing the ICE specific fuel consumption information by the hybrid controller and determining the operating points of the actuators based on this information. The obtained results show that the additional degree of freedom given to the vehicle by the hybridization of the system, makes a serious contribution to fuel economy when used for the following purposes.

- Torque assist to ICE
- ICE load point increase in order to obtain a better brake specific fuel consumption (BSFC)
- Idling or stopping ICE completely while driving

Table 3. HHDDT cycle results (Improvements based on conventional vehicle)

HHDDT		Configuration #1	Configuration #2
Fuel consumption decrease	%	3.4	3.6
CO_2 (Tailpipe) decrease	%	5.3	4.7
NO_x (Tailpipe) decrease	%	35.2	31.5
Urea consumption decrease	%	0	9
Energy recuperated while braking	kWh	3.1	2.2
Energy recuperated while torque-assist	kWh	5.1	2.7
Average BSFC decrease	%	4.1	3.3

Urea consumption decrease	%	22	22
Energy recuperated while braking	kWh	1.0	0.6
Energy recuperated while torque-assist	kWh	0.9	0.3
Average BSFC decrease	%	2	1.5

Results, in **Table 3** and **Table 4**, show that configuration 2 gives the best results in both cycles. While a 3.6% fuel consumption reduction was observed in the HHDDT cycle, this figure was 4.9% in the UDDHD cycle. In addition to fuel economy, there was a remarkable decrease in exhaust emissions and NOx emissions were observed to decrease by approximately 25-30% in both cycles.

ABSTRACT

Today, by inhibiting the growth of bacteria during the use of plastics, making it more hygienic for users has become a significant requirement. Microbes cause negative effects on plastics such as surface degradation, staining, and dust accumulation. In addition, they become dangerous for human health in contact with the surface. Objective of this study is to develop polypropylene composite materials with antibacterial properties. Two different antibacterial additives, silver and organic, are used., Composite granules were obtained by melt mixing of antibacterial additives and polymer with a twin-screw extruder. Physical properties (density, melt flow rate), mechanical properties (tensile and impact properties) were determined to understand how the inclusion of antibacterial additives in the formulation effects the properties of polypropylene composite materials. It is seen that the physical and mechanical properties of polypropylene are preserved without any serious deterioration. In addition, antibacterial activity tests are performed according to ISO 22196 Standards for Antibacterial Activity Measurement on Plastic Surfaces. polypropylene composite materials with antibacterial additives showed 99% antibacterial activity against gram-negative and gram-positive bacteria.

Keywords: Polypropylene, Antibacterial Composite, Automotive Industry

1. INTRODUCTION

Plastics, which have a wide range of uses, constitute an important part of our lives. Synthetic polymer surfaces are defenseless to microbial growth. Bacteria on plastic surfaces can easily multiply in a short time in the case of a humid environment. The adhesion and proliferation of bacteria on plastic surfaces adversely affects human health since plastics are used repeatedly in our daily life. Therefore, the need for antibacterial polymeric composites has increased over the last decade (Wadi, 2017). The need for antibacterial composites is increasing in various industries especially automotive industry because there are many parts where hand contact is very high. Polypropylene -based compounds are commonly used in automotive interior trim parts. Antibacterial polymer composites consist of polymer-based raw materials and antibacterial additives. Antibacterial additives should not be toxic for human health and environmental safety. Also, it should not deteriorate the properties of the polymer and should be compatible with the polymer used. In addition, it should be effective in the long term (Vieira, 2012). Antibacterial additives are added to polymer composites to get rid of the negative effects of microorganisms. The effectiveness of antibacterial additives is affected by factors such as temperature and the polymer type. Various antibacterial additives such as zinc oxide, silver, zeolite, and organic are used to obtain antibacterial properties in polymer composites. Zinc oxide is a metal oxide structured inorganic material with an antibacterial property, electrical conductivity, and UV absorption (Cengiz et al., 2018). The antibacterial properties are obtained using the zeolite ion exchange method, where the ions used in the ion exchange method are silver and zinc. When the studies in the literature are examined, it has been observed that silver embedded zeolite is antibacterial against gram-negative and gram-positive bacteria. (Yilmaz Atay et. al., 2015). Silver shows an antibacterial effect against *E. coli*, *S. aureus*, and *Klebsiella sp*. bacteria, and shows the antifungal and antiviral effect too (Rai et. al., 2009). Organic additives are metal-free, non-toxic, and suitable for food contact applications. It is environmentally friendly and not harmful to human health, which positively affects its use in antibacterial polymeric composites. Polymer composites with antibacterial properties are commonly produced by two methods that are dry mixing and extrusion. The biggest disadvantage of dry mixing is the difficulty of obtaining a homogeneous mixture for polymer and the antibacterial additives. If a homogeneous mixture is not obtained, antibacterial properties cannot be achieved. Another commonly used method is the extrusion. Production is carried out by feeding homogeneously from

suitable feeders using a twin-screw extruder. In one of the conducted studies about antibacterial polymeric composite materials, polypropylene composites containing silver and zinc nanoparticles were produced with an extruder and their antibacterial properties were investigated. Extruded composite fibers containing 0.72% silver and 0.60% zinc nanoparticles showed antibacterial activity against *Escherichia coli* and *Staphylococcus aureus* bacteria (Gawish et al., 2012). Shi et al. investigated the antibacterial properties of green cinnamaldehyde, and thymol modified zinc oxide polymeric composites with double synergistic antibacterial effect in polypropylene. They found that it has the antibacterial activity of 90% and 95% against *E. coli* and *S. aureus* (Shi et al., 2021). The aim of this study is to develop and characterize polypropylene based antibacterial composite materials containing silver and organic as antibacterial additives. In addition, talc was added to polypropylene-based composite with antibacterial properties and its effect on antibacterial properties was examined. The physical and mechanical properties of polypropylene based antibacterial composites were also investigated.

2. MAIN BODY

2.1. Materials and Method

Polypropylene (PP) supplied by Sabic company was used as the polymer matrix. Silver and organic additives (1wt.%) were used as antibacterial additives. Talc was used (0, 3 wt.%) as a filler in PP based composites. Polypropylene composite materials containing antibacterial additives were produced using a twin-screw extruder (Leistritz Extruder Corporation Model ZSE 27 MAXX). Composites were produced at 200-220°C barrel temperatures with a screw speed of 400-450 rpm. Test plates were obtained using an injection molding machine (Bole model BL90EK).

2.2. Characterization

Density measurements of composite materials were tested in accordance with ISO 1183-1 standard by using Density Meter MD-200S Average of three measurements were recorded for density values. Tensile tests of PP composite specimens were conducted using Shimadzu Autograph AG-IS Series universal testing machine equipped with a video extensometer system (SHIMADZU Noncontact Video Extensometer DVE-101/201) in accordance with ISO 527-2 standard. Izod notched impact tests were performed according to ISO 180 standard using an impact testing machine (INSTRON). The antibacterial properties of the composites have been tested in accordance with the ISO 22196 standard.

2.3. Results and Discussions

Physical, mechanical, and antibacterial properties of polypropylene based composite materials are given in Table 1 in comparison with the properties of the control group raw polypropylene. It is seen from Table 1 that here is no visible change in the density value of the composites. While the tensile strength of the control group polypropylene was obtained as 23 MPa, it was obtained to be 22MPa when antibacterial additives were added. It has been observed that when antibacterial additives were added into PP notched impact strength value decreased from 12 kj/m^2 to 10 kj/m^2. Elastic modulus values were obtained to be 1170 and 1100 MPa for raw PP and PP with antibacterial additives, respectively. From results, one could say that antibacterial additives did not have a significant effect on the mechanical properties of the polypropylene based composites. The method of testing antibacterial properties is designed to quantitatively test the ability to inhibit the growth of or kill microorganisms on plastics. According to the ISO 22196 standard, *S. aureus* was selected as gram positive bacteria and *E. coli* as gram negative bacteria (URL 1). Antibacterial activity given as R-value is calculated by testing against *E. coli* and *S. aureus* bacteria. In order for polymeric composites to have antibacterial properties, the R-value must be greater than 2. R values of PP composites including organic and silver-containing antibacterial additives tested against gram-negative and gram-positive bacteria are shown in Table 1.

Table 1. Physical, Mechanical and antibacterial properties of PP and its composites.

Properties	Unit	Standard	PP Composite (Control Group)	Antibacterial (Organic) PP Composite	Antibacterial (Silver) PP Composite
Density	g/cm^3	ISO 1183	0,89	0,9	0,9
Melt Flow Rate	g/10min	ISO 1133	19	17	12
Tensile Strength	MPa	ISO 527	23	22	22
Elastic Modulus	MPa	ISO 527	1170	1100	1100
Izod Notched Impact Value (23°C)	kJ/m^2	ISO 180	12	10	10
Antibacterial Activity (R value)	-	ISO 22196	-	>2	>2

In the automotive industry, polypropylene composite materials containing talc are generally used in interior trim parts. In our study, talc was included in polypropylene composite and its antibacterial properties were investigated. Table 2 shows the density, melt flow rate, tensile and impact strength of PP based composites containing 3 wt.% talc and antibacterial additives. Physical and mechanical properties of PP based composites containing antibacterial additives were obtained similarly when compared with the PP composites without antibacterial additives. control group. Antibacterial activities (R-value) of PP-3Talc composite containing organic and silver antibacterial additives were obtained higher than 2. It was seen that talc did not have a negative effect on antibacterial properties of the PP based composites.

Table 2. Comparison of the properties of PP based composites including talc and antibacterial additives.

Properties	Unit	Standard	PP-3Talc Composite (Control Group)	Antibacterial (Organic) PP-3Talc Composite	Antibacterial (Silver) PP-3Talc Composite
Density	g/cm^3	ISO 1183	0,91	0,91	0,91
Melt Flow Rate	g/10min	ISO 1133	15	20	18
Tensile Strength	MPa	ISO 527	22	21	22
Elastic Modulus	MPa	ISO 527	1200	1070	1100
Izod Notched Impact (23°C)	kJ/m^2	ISO 180	10	10	10
Antibacterial Activity (R- value)	-	ISO 22196	-	>2	>2

3. CONCLUSION AND RECOMMENDATIONS

In this study, organic and silver antibacterial additives containing polypropylene composite were produced using a twin-screw extruder. Additionally, the effect of talc on antibacterial activity was investigated. Polypropylene composites containing silver and organic additives showed 99% antibacterial activity against *E. coli* and *S. aureus* bacteria. Antibacterial additives did not affect the physical and mechanical properties of the PP based composites. Similarly, the addition of talc to the formulation did not adversely affect the antibacterial properties. In addition, it has been observed that antibacterial additives do not change their physical and mechanical properties.

ÖZET

Elektrikli araçların hızla hayatımızda yer almaya başlamasıyla birlikte ağırlık azaltımı konusu araç üretici firmalarının gündeminde günden güne daha fazla yer etmeye başlamıştır. Ağırlık; pil ömrü, tek şarjda alınan mesafe, güvenlik, karbondioksit salınımı gibi birden fazla parametreyi doğrudan etkilemektedir. Bu çalışmada şehir içi ulaşımda önemli bir yeri olan belediye otobüslerindeki koltuklar üzerinde çalışılmıştır. Sonlu elemanlar analizi metodu yardımıyla koltuk şasesinde farklı malzemelerin davranışlarını inceleyerek kalınlıklarını değiştirmek suretiyle bir takım hafifletme çalışmaları yapılmıştır. Sonlu elemanlar analizleri için HyperWorks programı kullanılmıştır. Şase üzerindeki plastik koltuklar rijit kabul edilerek analiz esnasında plastik malzemenin davranışı göz ardı edilmiştir. Belirlenen malzeme özellikleri analiz programına girilerek şaselerin uygulanan kuvvetler karşısındaki davranışları incelenmiştir.

WEIGHT REDUCTION WITH FINITE ANALYSIS METHOD USING ALTERNATIVE MATERIALS ON THE PASSENGER SEAT CHASSIS

ABSTRACT

The weight directly affects battery life, distance covered on a single charge, safety and carbon dioxide emissions more than other parameters. Therefore, the issue of weight reduction is gaining importance day by day with the increasing usage of electric vehicles. In this study, passenger seats in the municipal buses, which have an important place in urban transportation, were studied.Weight reduction studies were made with the finite element analysis method which examining the behaviours of different materials and different thicknesses in the seat chassis. HyperWorks package program was used for the finite element analyses. During the analyses the plastic seats were assumed as rigid and behavior of plastic materials were ignored. The behavior of the chassis under the applied forces was examined by the inputs of determined material properties in the analysis program.

1.GİRİŞ

Emisyon oranlarına getirilen kısıtlamalar ile artan sera gazı emisyonları sonucunda taşıtlarda yakıt tasarrufu zorunlu hale gelmiştir. Araçlarda yakıt tasarrufunu sağlamanın birçok yolu vardır. Bunlardan biri ise ağırlık azaltma yani hafifletmedir. Bunların dışında gelişen teknoloji sonrası elektrikli ve hibrit araçların giderek popüler hale gelmesi yine araçların hafifletilmesini önemli hale getirmiştir.

Yapılan çalışmalarda sera gazı salınımları açısından ulaştırma sektörünün önemli bir paya sahip olduğu ortaya çıkmıştır. Bu sektörde faaliyet gösteren toplu taşıma araçlarında bulunan yolcu koltukları sayıları nedeniyle kayda değer bir yer almaktadır. Bu sebeple bu koltuklarda yapılacak bir hafifletme, sayıları nedeniyle aracın tamamının hafiflemesi açısından önemli bir faktör olacaktır [1].

Yapılan bir başka çalışmada ise yakıt tüketimi ne kadar motor özellikleri ile bağlantılı olsa da aracın ağırlığı ile de doğrudan bağlantılı olduğunu bildirilmiştir. 1 kg'lık hafifletme yakıtın sarfiyatında 100 kilometrede 0.004 litre kazanç ile birlikte CO_2 tüketimi için ise km'ye 0.1 gr kadar pozitif yönde katkısı olacağını hesaplamıştır. Ortalama 190 bin km yol üzerinde deneme yapılan bir araç üzerinde belirlenen rakamlarda; CO_2 tüketiminde yaklaşık olarak 1900 kg azalma ve yakıt 4 tüketiminde ise 760 litre daha az kullanılmıştır [2].

Sonlu elemanlar analiz metodu gerek otomotiv sektöründe gerekse savunma sanayi sektöründe oldukça yoğun bir şekilde kullanılmaktadır. Her ne kadar gerçek testlerle doğru veriler elde edilse de, zaman ve maliyet açısından düşünüldüğünde, sektörlerde önemli bir yeri bulunmaktadır. Bu nedenle analiz ortamında yapılan çalışmaların gerçeğe en yakın olması büyük önem arz etmektedir.

2. MATERYAL VE YÖNTEM

2.1.Kullanılacak Malzemelerin Belirlenmesi

Yapılan analizlerde kullanılan ve Şekil 1'de gösterilen Cantilever tipi yolcu koltuğu şaselerinin genellikle hammaddeleri saç parçalarda DD11 malzeme iken, profil ve borularda ise E235 malzemeden oluşmaktadır. Bu çalışmanın ilk aşamasında, bu malzemelerden oluşan şaseye uygulanan kuvvetler karşısındaki davranışları, analiz programı ile incelenmiştir.

Şekil 1.Cantilever Tipi Yolcu Koltuğu

Yolcu koltuğunda malzeme kalınlığını azaltarak hafifletme yapabilmek için mevcut kullanılan DD11 ve E235 malzemelerinden daha yüksek mukavemet değerlerine sahip çelik malzeme kullanılmalıdır Yapılan piyasa araştırmalarında otomotiv sektöründe en yaygın şekilde kullanılan, yüksek mukavemetli çeliklerden S420MC, S550MC ve DP600 malzemeler seçilerek bu koltuk parçalarında hafifletme amaçlı çalışmalar yapılmıştır.

2.1.1. DD11 ve E235 Malzemeleri

DD11 malzemesi soğuk şekillendirme için sıcak haddelenmiş düşük karbonlu çelik grubundadır. Akma dayanımı 170 MPa ile 360 MPa arasında olup malzeme kalınlığına göre değişmektedir. St 37 kalite olarak adlandırılan çelikler Amerika çelik standardına sahip yani kalite karşılığı E235'tir. Bu sınıf çelikler karbon oranı maksimum 0.20 civarındadır. Sıcak haddelenmiş çeliklerin en yumuşak olanıdır. St 37 kalite çelikler kolay işlenebilmesi, kaynak yapımının ve kesiminin sorunsuz olması gibi özellikleri ile bilinir [3].

Tablo 1.DD11, S235 Malzeme Özellikleri

Çelik Kalitesi	Akma Gerilmesi (N/mm²)	Kopma Gerilmesi (N/mm²)	Uzama Miktarı (Elongation) (%)
DD11	170-360	440	22
E235	235	360-510	19

2.1.2. S420MC, S550MC VE DP600 Malzemeleri

S420MC ve S550MC malzemeler soğuk şekillendirme için yüksek mukavemetli çelikler olarak da bilinmektedir. Yüksek mukavemet gereken yerlerde tercih edilirler. DP600 çelikleri ise çift fazlı çelik olarak da bilinmektedirler. "Çift fazlı çelikler için kullanılan çift faz durumu içerdikleri ferrit ve martenzit fazlarından dolayıdır. Ferritik matrisin içinde sert martenzitik ikincil fazı içeren çeliklere denir. Sert martenzitik fazın yüksek mukavemetle birlikte hacim oranı artar. Ferrit yumuşaktır, genel olarak yapıya süneklik katar ve çeliğin şekillendirilebilme kabiliyetini artırır. Martenzit ise sert ve kırılgan fazdır. Bu özelliği ile çeliğe mukavemet kazandırır. Yüksek mukavemetli düşük alaşımlı çeliklere göre çift fazlı çelikler iyi derecede mukavemet ve süneklik gösterir. Bu sebepten dolayı otomotiv sanayinde tercih edilir. Ağırlık azaltma da ve yakıt tasarrufunda önemli rol oynar. Bu sebeple otomobillerde kullanılan parçalarda genel olarak çift fazlı çelikler kullanılır." [4]

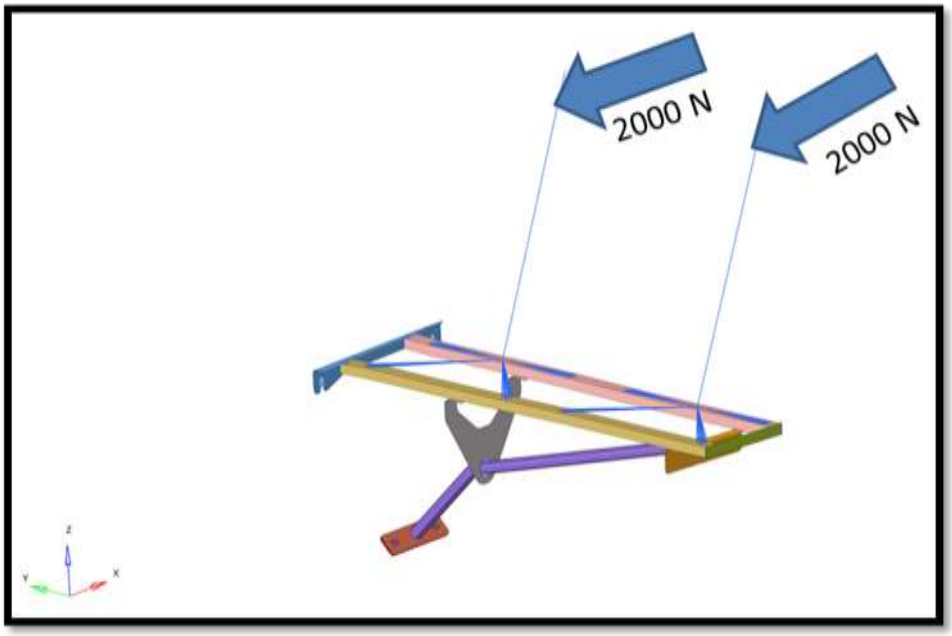
Tablo 2.S420MC, S550MC ve DP600 Malzeme Özellikleri

Çelik Kalitesi	Akma Gerilmesi (N/mm²)	Kopma Gerilmesi (N/mm²)	Uzama Miktarı (Elongation) (%)
S420MC	170-360	440	22
S550MC	235	360-510	19
DP600	430	680	20

2.2. Sonlu Elemanlar Analizleri

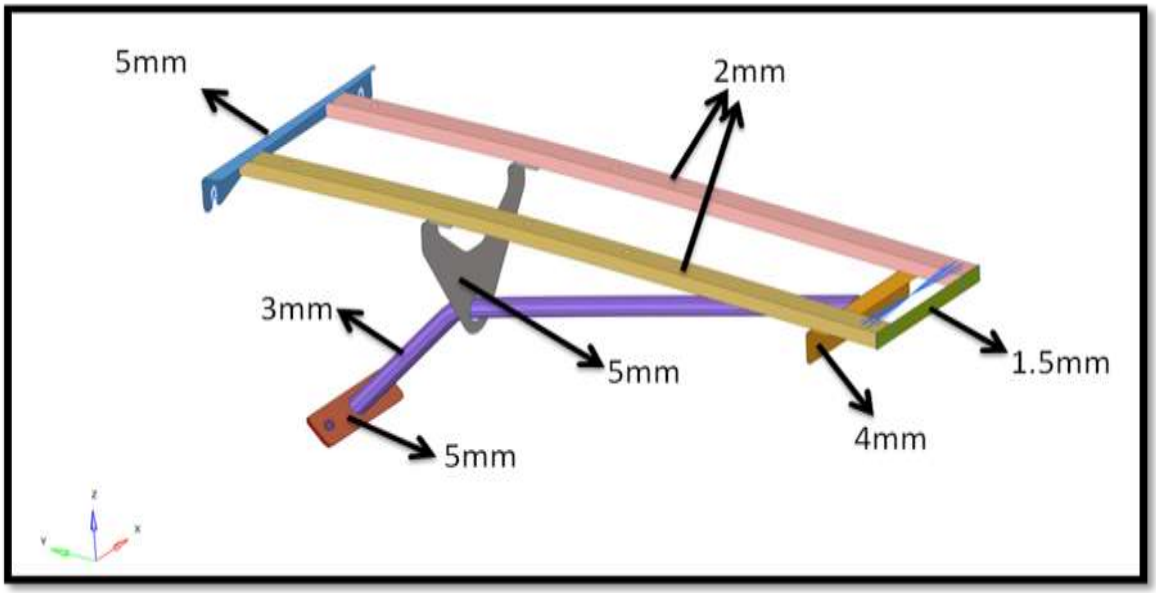
Önceki bölümde Şekil 1'de verilen Cantilever tipi yolcu koltuğu Hyperworks programında analiz edilirken ilk önce plastik koltuklar rijit kabul edilerek analiz boyunca plastik malzemelerde meydana gelen değişim ise sabit kabul edilerek göz ardı edilmiştir. Uygulanan kuvvet plastik koltuğun tutamak bölgesinden olup koltuğun arka yönünden ön yönüne doğru yani araç gidiş doğrultusundadır. Koltuğa uygulanan kuvvet 2000 N olup, aracın ani freni esnasında koltuğun arkasındaki yolcunun frenle birlikte ivmelenmesiyle ön koltuğa uyguladığı kuvveti temsil etmektedir.

Plastik koltuk rijit kabul edildikten sonra araç gidiş doğrultusunda uygulanan 2000 N büyüklüğünde kuvvet programda tanımlanmıştır ve sonlu elemanlar modeli Şekil 2'de gösterildiği üzere elde edilmiştir.



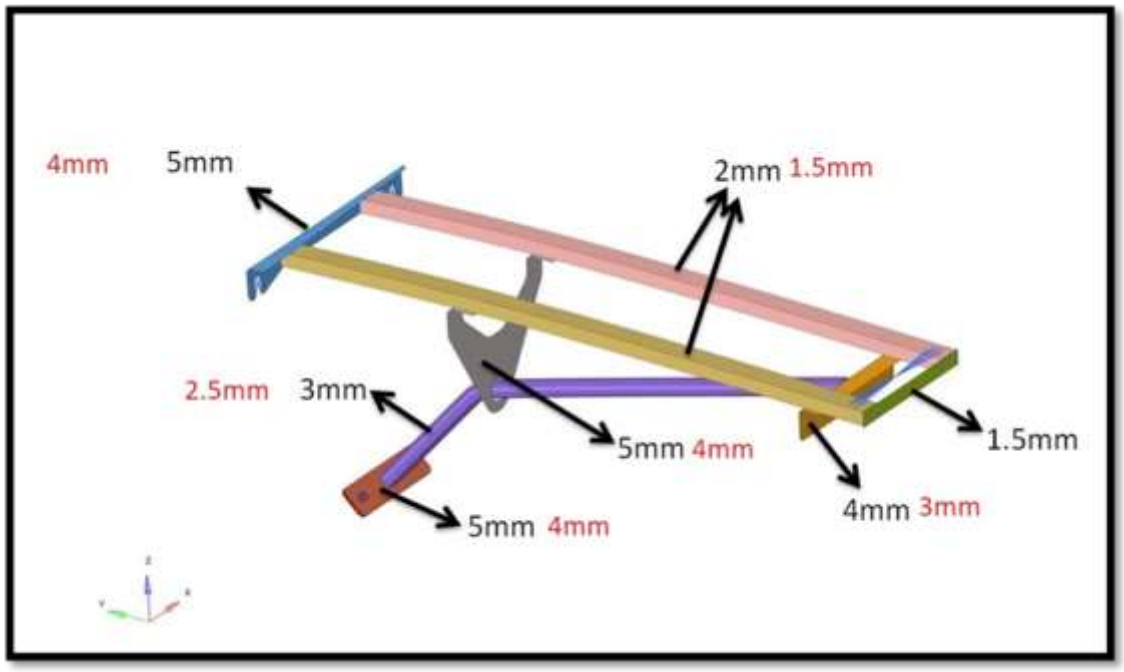
Şekil 2. Analiz Modeli

Şekil 2'de belirtilen analiz modeli ile birlikte 3 tip farklı analiz çalışması yapılmıştır. Bilgisayar üzerinde simüle edilen çalışmaların ilki olan 1. çalışmada saç parçalar DD11, boru ve profil malzemeleri E235 malzemeden oluşmaktadır. Koltuk şasesindeki parçaların kalınları ise Şekil 3'te gösterilmiştir.



Şekil 3. 1.Çalışmadaki Malzeme Kalınlıkları

Sonraki aşama olan 2. çalışmada ise saç parçalar S420MC, boru ve profiller ise DP600 malzemeden oluşmuştur. En son yapılan 3. çalışmada ise saç parçalar için S550MC, boru ve profiller ise DP600 malzemeden oluşmaktadır. Tüm çalışmaların ilk aşamasında başlangıç değerleri olarak malzeme kalınlıkları aynı tutulmuş daha sonra Şekil 4'te gösterildiği gibi saç parçalarda malzeme kalınlığı 1mm, profillerde ve boruda ise 0.5mm olacak şekilde kalınlıklarda azaltma yapılarak 2. ve 3. analizler tekrarlanmış ve daha sonra elde edilen bu sonuçlar karşılaştırılmıştır.

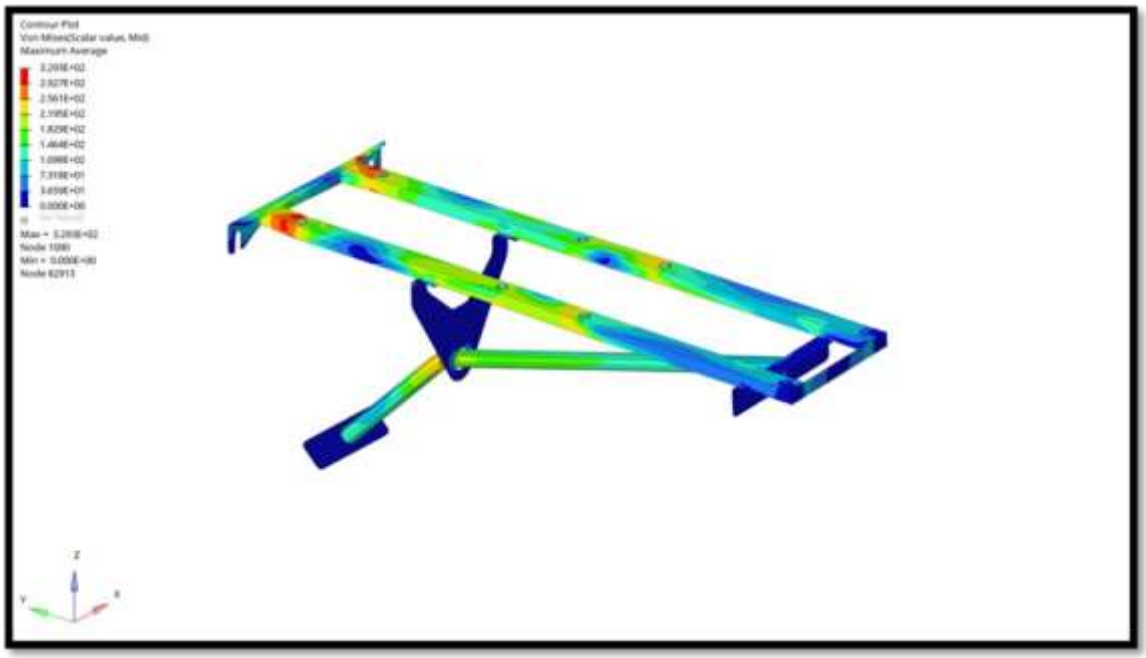


Şekil 4.Kalınlık Azaltılmış Analiz Modeli

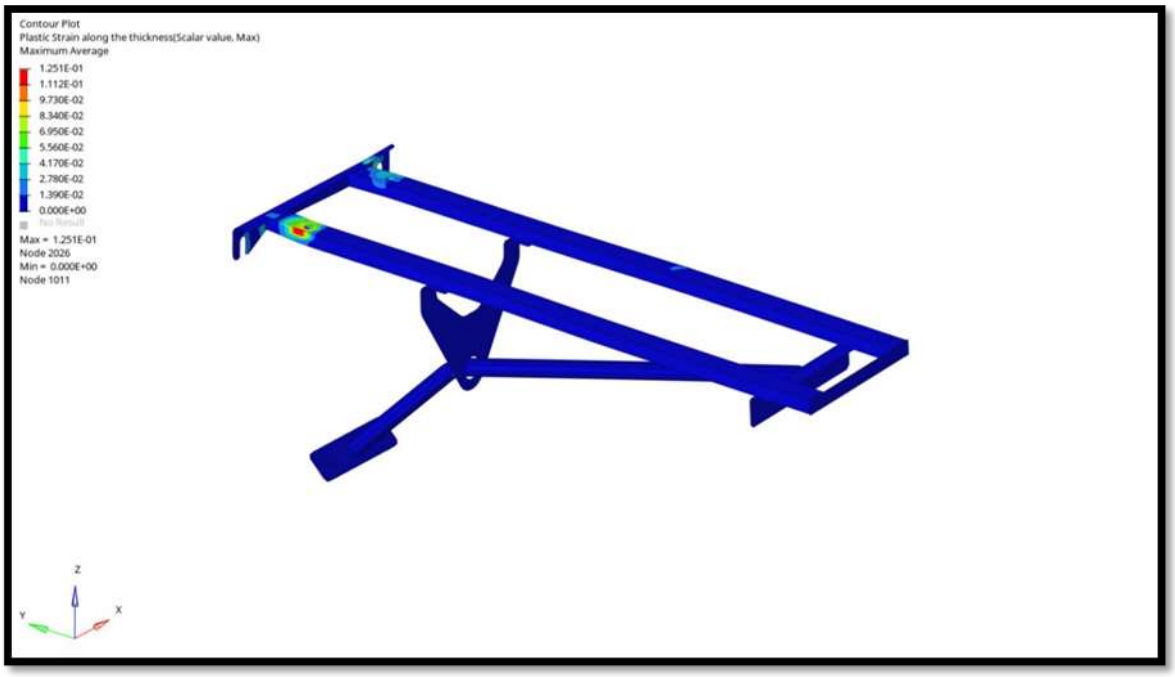
3. SONUÇLAR

Yukarıda Şekil 3 ve Şekil 4'de belirtilen farklı malzeme ve kalınlıklarla yapılan analizlerle, şasenin uygulanan kuvvet karşısındaki maksimum stress ve maksimum plastik deformasyonları incelenerek birbirleri ile kıyaslanmıştır.

1. analizde, şasede meydana gelen maksimum gerilme 329 MPa olarak bulunmuştur. E235 malzemenin akma sınır değerini aştığından şasede kalıcı deformasyon meydana gelmektedir. Ayrıca şasede oluşan maksimum plastik deformasyon değeri de %12.5 olarak elde edilmiştir.

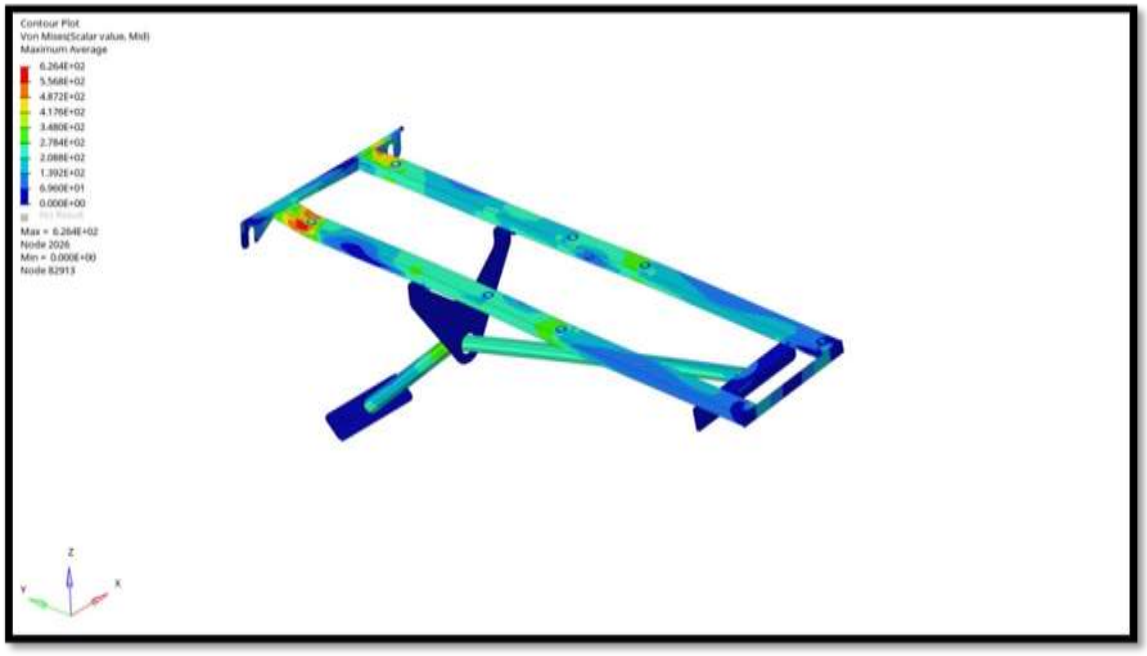


Şekil 5. 1.Analiz çalışması Maksimum Stres Grafiği

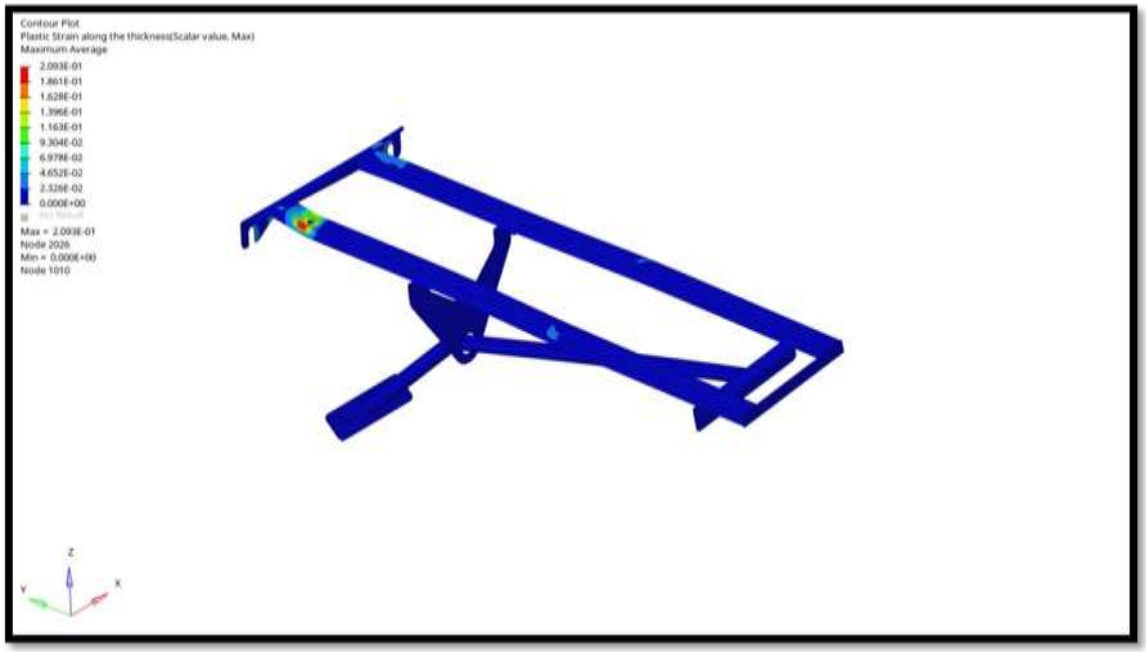


Şekil 6. 1. Analiz Çalışması Maksimum Strain Grafiği

Kalınlığı azaltılarak yeniden S420MC-DP600 malzemeler tanımlanarak analizi yapılan 2. çalışmada 2000N kuvvet Şekil 4'te gösterildiği gibi ilk çalışmadakine benzer şekilde araç gidiş doğrultusunda uygulanmıştır. Şasede meydana gelen maksimum gerilme 626 MPa olarak bulunmuş ve DP600 malzemin akma sınırını aştığı için şasede kalıcı deformasyon meydana gelmiştir. Ayrıca şasede oluşan maksimum plastik deformasyon %20 olup DP600 malzemenin uzama miktarını aştığı için profillerde yırtılma söz konusudur.

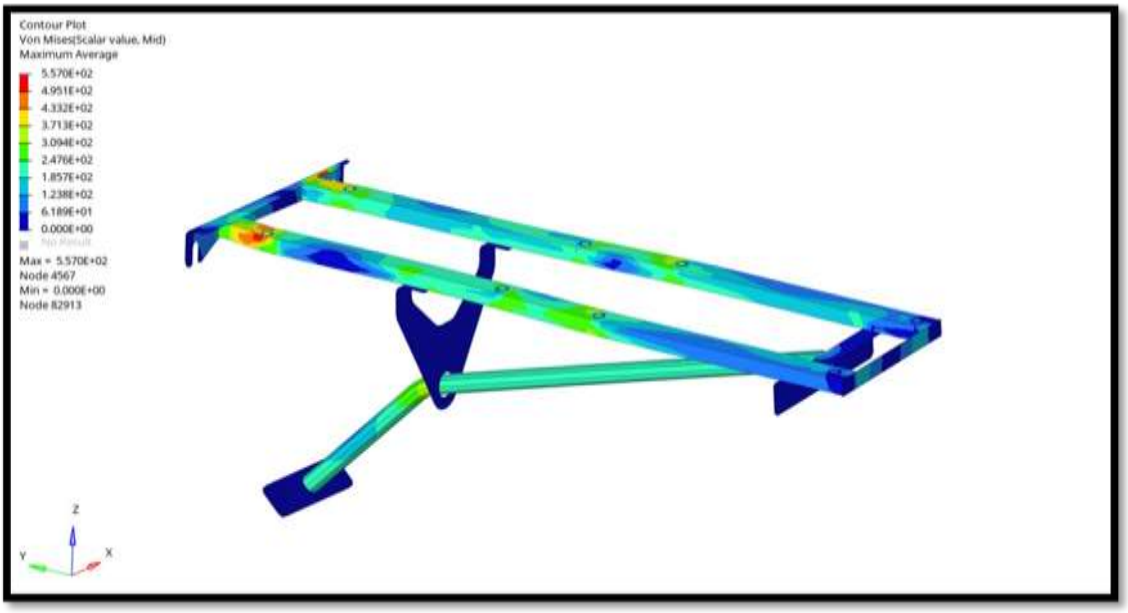


Şekil 6. 2. Analiz Çalışması Maksimum Stress Grafiği

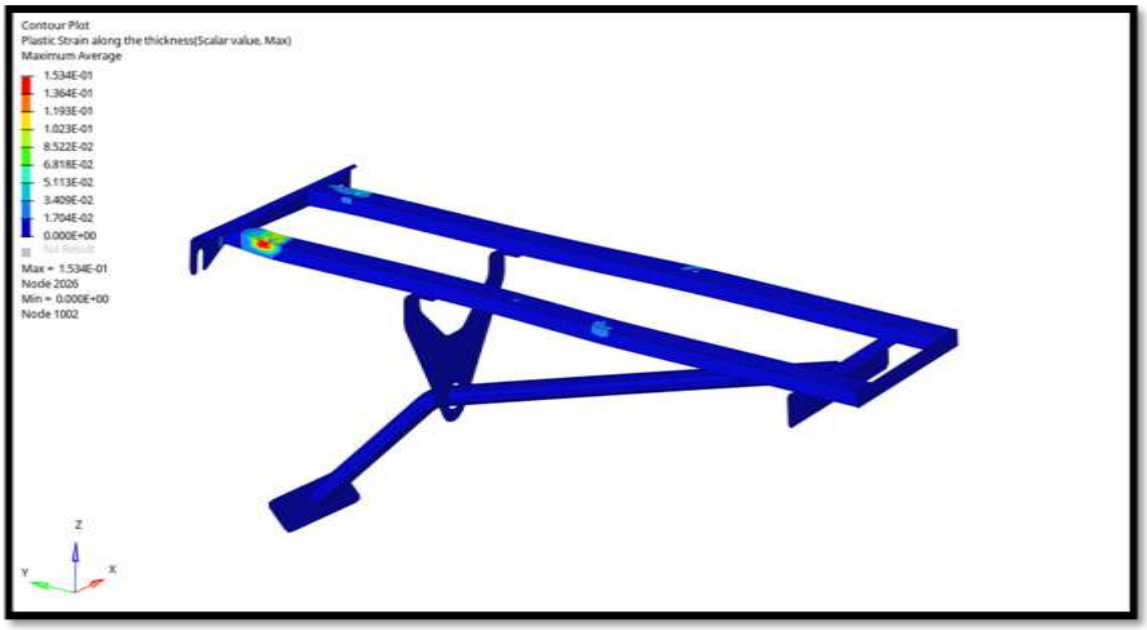


Şekil 7. 2. Analiz Çalışması Maksimum Strain Grafiği

En son yapılan 3. çalışmada ise belirtildiği üzere S550MC-DP600 malzemeler, 1. çalışmada olduğu gibi 2000 N kuvvet uygulanarak yapılmış ve şasede maksimum gerilme 557 MPa olarak bulunmuştur. Elde edilen gerilme değeri DP600 malzemenin akma sınırını aştığı için kalıcı deformasyon meydana gelmiştir. Ayrıca şasede meydana gelen maksimum plastik deformasyon ise %15 olup malzemelerin uzama miktarlarını aşmamıştır.



Şekil 8. 3. Analiz Çalışması Maksimum Stress Grafiği



Şekil 9. 3. Analiz Çalışması Maksimum Strain Grafiği

Tüm analiz sonuçları karşılaştırıldığında en iyi sonuç 3.analizde elde edilmiştir. 2. analizde malzemede yırtılma hasar durumu söz konusu olduğundan değerlendirmeye katılmamıştır. 3. analizde ise herhangi bir yırtılma söz konusu olmayıp şasede meydana gelen kuvvet sonrası esneme durumu, mevcut seri şaseye göre daha iyi performans göstermiştir.

Tablo 3. Analiz Sonuçları

	1. Analiz Çalışması (SERİ DİZAYN)	2. Analiz Çalışması (Kalınlık Azaltılmış)	3. Analiz Çalışması (Kalınlık Azaltılmış)
	(DD11/S235)	(DP600/S420MC)	(DP600/S550MC)
GERİLME	329 MPa	626 MPa	557 MPa
ESNEME	22.9 mm	38 mm	19.4 mm
MAX. STRAIN	12.50%	20,0%	15,0%

Ağırlık analizi incelendiğinde ise 3. analizdeki kalınlık azaltımı uygulandığında şasede ortalama %20 civarında bir ağırlık azalışı söz konusudur.

Tablo 4. Ağırlık Kıyaslaması

	1. Analiz Çalışması (SERİ DİZAYN)	3. Analiz Çalışması (Kalınlık Azaltılmış)	FARK (%)
AĞIRLIK (kg)	5.38	4.28	20.4%

ÖZET

Kauçukları mühendislik malzemesi haline getirmek için uygulanan vulkanizasyon prosesinde, parça geometrisine en çok etkiyen parametrelerden birinin sıcaklık olduğu bilinmektedir. Gerekli hal değişimi için parçalar kalıp içerisinde yüksek sıcaklıklara çıkarıldıktan sonra soğumaya bırakıldığında kauçuk üzerinde iç gerilmeler başlar ve geometriyle de ilişkili olarak parçalar şekil değişikliğine zorlanmaktadır. Vulkanizasyon prosesinden çıkan titreşim sönümleme elemanlarında farklı doğrultuda farklı kauçuk yapıları olduğunda ya da dış boruları plastik olmaları durumunda ürünlerin montajlarını etkileyecek derecede sıkıntılar ortaya çıkabilmektedir. Bu çalışmada dış borusu plastik olan maçalı bir burçta meydana gelen ovalite problemi, sonlu elemanlar metodu kullanarak termal analiz ile giderilmesi ve tasarımın doğrulanması üzerine çalışılmıştır. Bu yöntem ile ovalite problemi ile karşılaşabileceğimiz parçalarda termal analiz çıktılarına göre ovalite miktarları belirlenip bu çıktılar ışığında tasarım optimizasyonları yapılarak ovalite problemi ortadan kaldırılmıştır. Bu sayede son kullanıcı tarafında yaşanan ovalite kaynaklı, parçaların ilgili salıncak yuvasına montajı esnasında gerçekleşen problemler ortadan kaldırılmış, hurda oranları azaltılmış ve maliyette iyileştirme yapılmıştır. Parçanın mesh yapısı MSC APEX programında, termal analiz ve yapısal analizler MSC Marc programı kullanılarak yapılmıştır.

DETERMINATION OF OVALITY PROBLEM ON PLASTIC OUTER TUBES OF RUBBER MOUNTS AFTER VULCANIZATION

ABSTRACT

It is known that temperature is one of the most influential parameters on the geometry of the part in the vulcanization process applied to turn rubbers into engineering materials. Internal stresses begin on the rubber when the parts are brought to high temperatures in the mold for the necessary change of state and then left to cool and in relation to geometry, parts are forced to change shape. After the vulcanization process, if the anti-vibration elements have different rubber structures in different directions or if the outer tubes are plastic, problems may arise that will affect the assembly of the products. This work focusses on the prediction of the ovality problem of anti-vibration bushings of which has plastic outer tube and core by thermal analysis. In the parts where we may encounter the ovality problem, the ovality are determined according to the thermal analysis outputs with this method and the ovality problem is eliminated by making design optimizations according to these outputs. In this way, the problems were eliminated that occurred during the assembly of the parts to the control arm, the scrap rates were reduced and the cost was improved. MSC Apex (pre-processing) and MSC Marc (solver) were used for modelling the rubber during design validation phase.

Keywords: Thermal Analysis, Ovality, Natural Rubber, Anti-Vibration Bushing, Finite Element Analysis

1. GİRİŞ

Taşıt süspansiyon sistemleri, iyi bir sürüş, gerekli yol tutuş performansı, dönüş esnasında direksiyon kontrolünü sağlayan ve aktarma organlarının birbirleri arasındaki etkileşimlerini dengede tutmaya yarayan alt sistemlerdir. Bu alt sistemler hızlanma, frenleme, viraj alma, bozuk zeminde ilerleme gibi farklı çalışma şartlarında gerekli konforu ve

güvenliği sağlamalıdır. Daha çok salıncaklarda kullanılan kauçuk bazlı burçlar da süspansiyon sistemlerinin önemli birer üyesi olmakla birlikte gerekli olan bu gereksinimleri yerine getirmede önemli bir rol oynarlar.

Kullanılan bu burçlar araçta yoldan gelecek ani kuvvetlere karşı yaşam döngüsü devam ettirebilmeli, aynı zamanda montajının yapıldığı yerde kendini muhafaza edebilmelidir. Burada öne çıkan birincil etken parçaların çakıldığı veya montajının yapıldığı yuvaya ait geometrik kriterlerdir.

Wang ve arkadaşları yaptıkları çalışmada; Amortisör için kauçuk burç üzerinden hareket ederek, doğrusal olmayan sonlu elemanlar yazılımı ABAQUS kullanarak her yöndeki sertlik ve çekme kuvvetini Sonlu Elemanlar Analizi ile hesaplamışlardır. (Wang, Shangguan, 2013).

Li ise deneysel bir çalışma gerçekleştirerek, arka teker süspansiyon sistemi için bir kauçuk burcun dört farklı yükleme altında davranışını incelemiştir. Bu yükleme şekillerinin eksenel, radyal, burulma ve yalpalama hareketlerini temsil edecek şekilde planlandığı görülmüştür. (Li, L., 2014).

Andre yaptığı çalışmada, kauçuk malzemesinin vulkanizasyon öncesi ve sonrası sıcaklığa bağlı davranışları üzerine bir çalışma gerçekleştirmiştir. (Andre, Wriggers, 2005). Bu çalışmadan kauçuğun vulkanizasyon sonrası büzülme-çekme davranışı ile ilgili tasarım ve analiz aşamalarında yararlanılması beklenmektedir.

Kauçuk bağlantı elemanları; çelik, alüminyum ve plastik üzerine kauçuk enjeksiyon yöntemi ile üretilmektedir. Doğal kauçuk iç yapısında bulunan polimer zincirleri arasında vulkanizasyon işlemi ile çapraz bağlar oluşturulmakta ve kauçuğun mekanik özellikleri iyileştirilmektedir. Kauçuğun üretimi sırasında kauçuk ısıtılarak vulkanizasyon işlemi gerçekleştirildiği için sonrasında soğurken kauçuğun hacmi küçülmektedir. Bu sebeple maçalı parçalarda bir yönde daha fazla kauçuk olduğu için ovalite problemi ortaya çıkmaktadır. Şekil 1'de örnek bir maçalı burç gösterilmiştir. Dış borusu çelik ve alüminyum olan burçlarda da ovalite meydana gelmektedir fakat bu ovalite montaj açısından risk yaratmadığı için göz ardı edilebilmektedir. Dış borusu plastik olan burçlarda ise ovalite problemi çelik ve alüminyum malzemelere göre daha fazladır ve bu ovalite sebebiyle parçalar montaj problemi yaratmakta ve bu esnada hem kauçuk hem de plastik üzerinde deformasyonlar meydana gelmektedir. Bu deformasyonlar kauçuk üzerinde, parçanın çalışma koşulları altında altında çentik etkisi oluşturabilmekte ve yapının olması gerekenden daha kısa sürede ömrünü tamamlamasına sebebiyet verebileceği gibi plastikteki deformasyonlar da parçanın yuvadan çıkma riskini ortaya çıkarmaktadır.

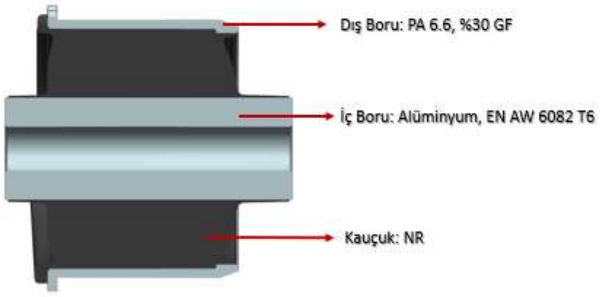
Şekil 1. Örnek bir maçalı burç

Bu çalışmada, kauçuk malzemeden imal edilmiş bir burcun modellenmesi için malzeme testleri yapılmış ve MSC Apex ve MSC Marc yazılımları vasıtasıyla sonlu elemanlar yöntemi ile burcun hiperelastik ve viskoelastik modelleri oluşturulup termal analiz yapılmıştır.

2. TASARIM, TESTLER VE SONLU ELEMANLAR ANALİZİ

2.1. Ürün Geometrisi

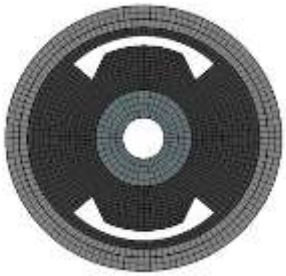
Çalışmada kullanılacak burca ait geometri Şekil 2'de gösterilmiştir. Buna göre ilgili salıncak burcu iç boru, dış boru ve kauçuktan oluşmaktadır. İç boru ve dış boru boyutları, aracın montaj yerine ve statik gereksinimlerine göre belirlenmektedir. Tasarlanan burç, monte edildiği yer göz önüne alındığında süspansiyon sistemine hareket serbestisi sağlamakla birlikte yoldan gelen titreşimleri sönümleyerek şasiye aktarmaktadır.



Şekil 2. Burç geometrisi

2.2. Mesh Yapısı

Sonlu elemanlar mesh yapısı MSC Apex programında Şekil 3'deki gibi yapılmıştır. Mesh yapısı hazırlanırken sonuçların doğruluğu için doğrusal ilerleyen bir mesh yapısı tercih edilmiştir. 2.5D Hex Mesh olarak atılan modelde 59.058 node ve 47.028 eleman yer almaktadır. Mesh atılırken elemanların birbirleriyle konuşması ve uygulanacak fiziksel harekete göre tasarlanmasına dikkat edilmiştir.



Şekil 3. Parçanın mesh yapısı

2.3. Sınır Koşulları

Burcun proses işleminde iç boru ve dış boruya yapıştırıcı uygulama yapılmakta ve vulkanizasyon işlemi gerçekleştirilmektedir. Bu nedenle burcun iç borusu ve dış borusu kauçuğa glue olarak tanımlanmıştır. Parçanın montaj koşullarına göre yapısal analizler için dış boru yuvaya çakılıymış gibi sabitlenmiş ve iç boruya yüzey atanıp serbest bırakılmıştır. İki adımlı analiz tasarlanmıştır. Birinci adımda termal veriler girilerek kauçuğun soğuması simule edilmiş, ikinci adımda da ön gerilmelere maruz kalmış burcun radyal (X,Y) ve eksenel (Z) yönlerde test edilmesi sağlanmıştır.

2.4. Malzeme Verileri

Kauçuk hiperelastik bir malzeme olduğu için çelik, alüminyum vb. malzemeler gibi young modulü ve poisson oranı yeterli değildir. Bu sebeple kauçuğun malzeme verilerini çıkarmak için Şekil 4'deki kesme ve basma numuneleri hazırlanarak Şekil 5'de gösterilen basma ve kesme test düzeneklerinde fiziksel testler gerçekleştirilmiştir. Testlerden elde edilen kuvvet-deplasman grafikleri boyutsuzlaştırılarak mühendislik stress-strain eğrisine çevrilmiş, sonrasında C10 ve C01 değerleri sonlu elemanlar programında hesaplatılmıştır.

Şekil 4. Basma-kesme test numuneleri

Şekil 5. Basma-kesme numunelerine ait test düzenekleri

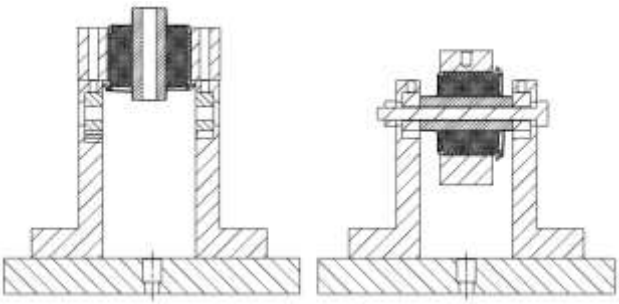
2.5. Termal Veriler

Vulkanizasyon prosesi sonrasında kalıptan çıkarılan burç hava ile soğumaya bırakılmaktadır. Malzemelerin ısıl genleşme katsayıları farklı olduklarından kullanılan hammaddelere göre vulkanizasyon sonrası ölçülerde farklılık oluşmaktadır. Kauçuğun ısıl genleşmesi 70x$10^{-6} \circ m / m \circ K$ iken alüminyum malzemelerde bu değer 22 x$10^{-6} \circ m / m \circ K$ çeliklerde 12 x$10^{-6} \circ m / m \circ K$ ve polyamid plastiklerde ise 110 x$10^{-6} \circ m / m \circ K$ 'dır. (URL1)

Bu değerler göz önüne alındığında vulkanizasyon sonrası soğuma sırasında plastik dış boruya sahip burçlar alüminyum ve çeliğe göre daha fazla ovalite problemi oluşturmaktadır. Bu sonuçları görebilmek adına malzemelerin ısıl genleşme değerleri sonlu elemanlar programına girilerek malzemelerin sıcaklıkla olan değişimleri incelenmiş ve çıkan sonuçlara göre tasarımlar optimize edilmiştir.

2.6. Statik Testler

Kauçuk malzemelerin farklı uzama oranlarında farklı karakteristik eğrileri vardır. (Wang, 1998), (Legorju-jago ve Bathias, 2002). Bu nedenle, ürünlerin hangi yükleme koşullarında çalışacağını bilmek ve uygun şekilde test etmek gerekmektedir. Ürünün statik testleri Zwick Roell test makinesinde gerçekleştirilmiştir Şekil 6'de Zwick Roell test kurulumu gösterilmektedir. Test makinesi 50 kN ve 600 mm kapasitelidir. Statik testler Şekil 7'da gösterilen test yönlerinde Tablo 1'de belirtilen parametrelerde gerçekleştirilmiştir.



a) b)

Şekil 6. Zwick Roell test kurulumu a) Eksenel (Z) b) Radyal (X,Y)

Şekil 6. X: Radyal 1.yön Y: Radyal 2.yön Z: Eksenel yön

Tablo 1. Statik test parametreleri

	X (Radyal 1)	Y (Radyal 2)	Z (Axial)
Ön Yük	100 N	100 N	100 N
Ön Şartlandırma Hızı	50 mm/min	50 mm/min	50 mm/min
Ön Şartlandırma Yükü	±4 mm	±4 mm	±5 mm
Ön Şartlandırma Çevrimi	3	3	3
Gecikme	10 sec	10 sec	10 sec
Test Hızı	10 mm/min	10 mm/min	10 mm/min
Test Yükü	±4 mm	±4 mm	±5 mm

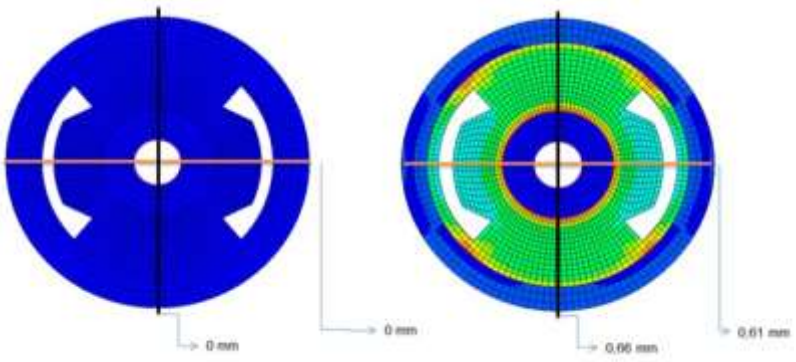
Burcun iç borusu, montaj yerini simule edecek şekilde ve kaymasını önlemek amacıyla cıvatalar ve somunlar kullanılarak sabitlenmiştir. Tablo 1'de verilen şartlandırma çevrimleri, Mullins etkisini ortadan kaldırabilmek için yapılmıştır. Bu nedenle kuvvet-yer değiştirme grafiği, tabi tutulan testin 4. döngüsüne dayanmaktadır (Mullins ve Tobin, 1969). Test armatürleri ve test ekipmanından kaynaklanabilecek boşlukları ortadan kaldırmak için 100 N ön yük uygulanmıştır. Test sonucunda kuvvet-yer değiştirme grafiği elde edilmiş ve statik sertlik (Ks) değerleri hesaplanırken grafiğin belli aralıktaki eğimine bakılmıştır.

$$Ks = \frac{\Delta F}{\Delta x} \tag{1}$$

3. HESAPLAMALAR VE SONUÇLAR

3.1. Termal Analiz Sonuçları

Öncelikle bu çalışmada kullanılacak Tasarım 1 olarak adlandırılan burca termal analiz yapılmıştır. Tasarım 1'in termal analiz sonuçları Şekil 7'de gösterilmektedir. Dolu yön Radyal 1 (X) ve boş yön Radyal 2 (Y) olarak belirlenmiştir.



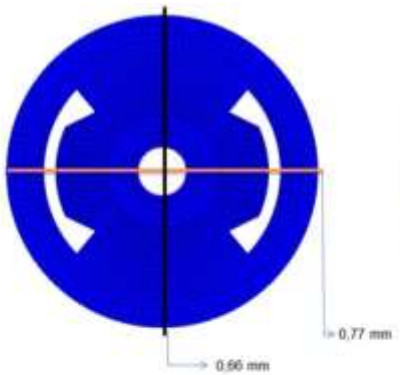
a) b)

	Analiz Öncesi (a)	Analiz Sonrası (b)
DOLU YÖN (mm)	Ø70,5	Ø69,84
BOŞ YÖN (mm)	Ø70,5	Ø71,11
Ovallik Değeri(mm)	Ovallik Değeri= 0	Ovallik Değeri= 1,27

c)

Şekil 7. Tasarım 1 termal analiz sonuçları a) Analiz öncesi görsel b) Analiz sonrası görsel c) Ölçülen değerler

Tasarım 1 sonucunda ortaya çıkan atıklık değerlerine göre alternatif tasarımlar yapılmıştır. Termal analizler bu alternatif tasarımlar için de tekrarlanmıştır. Şekil 8' de alternatif tasarımlardan biri olan Tasarım 2'ye ait termal analiz sonuçları gösterilmektedir.



a) b)

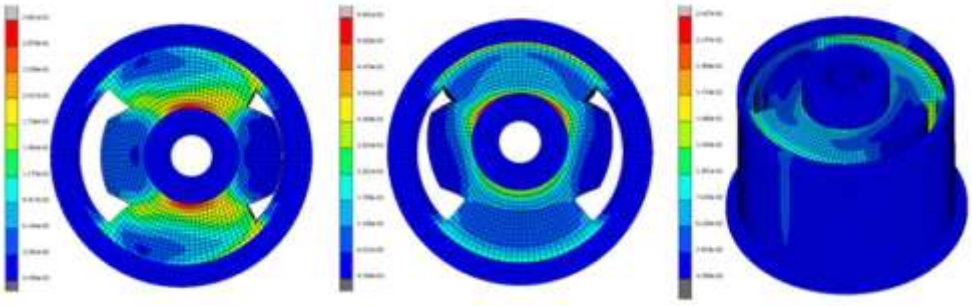
	Analiz Öncesi (a)	Analiz Sonrası (b)
DOLU YÖN (mm)	Ø72,4	Ø71,08
BOŞ YÖN (mm)	Ø69,2	Ø70,74
Ovallik Değeri(mm)	Ovallik Değeri= 3,2	Ovallik Değeri= 0,34

c)

Şekil 8. Tasarım 2 termal analiz sonuçları a) Analiz öncesi görsel b) Analiz sonrası görsel c) Ölçülen değerler

3.2. Yapısal Analiz Sonuçları

Termal analizlerden çıkan Tasarım 2'ye Tablo 1'de belirtilen test yöntemine göre ilgili yönlerde analizlere tabi tutulmuş ve analiz görüntüleri Şekil 9'da yapısal analiz sonuçları da Tablo 2'de gösterilmektedir.



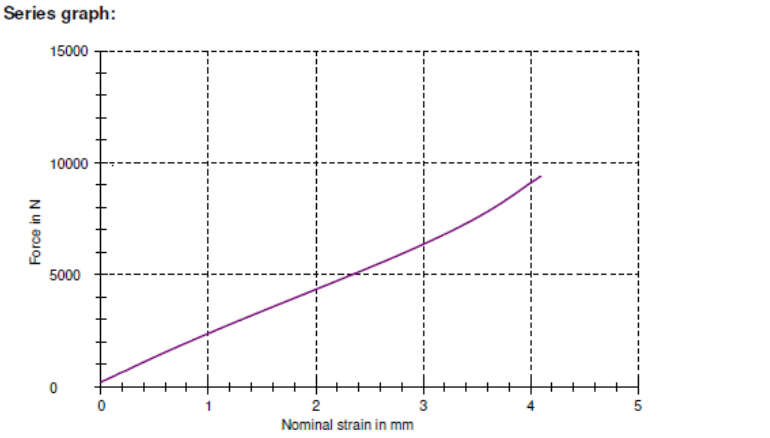
Şekil 9. Radyal (X, Y) ve Eksenel (Z) analiz görüntüleri

Tablo 2. Tasarım 2 yapısal analiz sonuçları

X (Radyal 1.Yön)	**SEA Sonucu**
65 ShA Ks-(0,5-1,5 mm) :	1945,7 N/mm
Y (Radyal 2.Yön)	**SEA Sonucu**
65 ShA Ks-(0,5-1,5 mm) :	521,5 N/mm
Z (Eksenel Yön)	**SEA Sonucu**
65 ShA Ks-(1-3 mm) :	310 N/mm

3.3. Prototip Ürün ve Ürün Test Sonuçları

Tasarım 2'ye ait prototip kalıplar tasarlanmış ve prototip parça üretimi yapılmıştır. Üretilen prototip parçanın radyal 1 (X) test sonuçları Şekil 10, radyal 2 (Y) test sonuçları Şekil 11 ve eksenel (Z) test sonuçları Şekil 12'de gösterilmektedir.

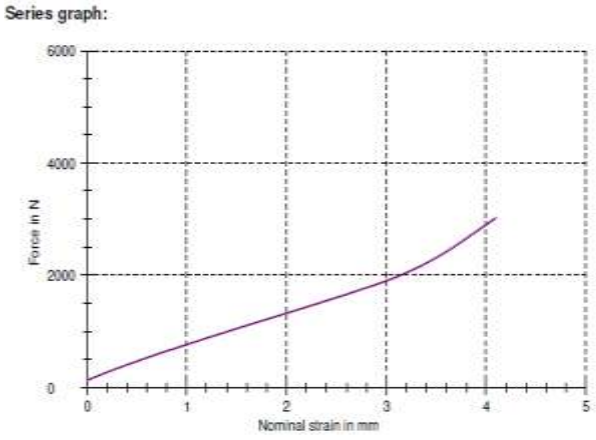


Results:

Legends	Nr	Ks(0,5-1,5 mm) N/mm	F at 0,5 mm N	F at 1 mm N	F at 1,5 mm N	F at 2 mm N	F at 2,5 mm N	F at 3 mm N
	1	2045,9	1321,54	2373,04	3367,40	4337,62	5315,14	6349,87

Şekil 10. Radyal 1.yön (X) test sonuçları

Şekil 10'da görüldüğü üzere tasarım 2'ye ait geliştirilen parçanın radyal 1.yöndeki kuvvet-deplasman verileri çıkartılmıştır. Grafikteki eğri karakteristiği incelendiğinde parçanın 3 mm deplasman miktarından sonra lineer olmayan bölgeye geçtiği görülmektedir. Kuvvet-deplasman eğrisinin lineer bölgesi belirlenerek radyal 1. yön için rijitlik hesaplaması yapılmıştır. Parçanın radyal 1.yön için rijitlik değeri 2045,9 N/mm olarak hesaplanmıştır.

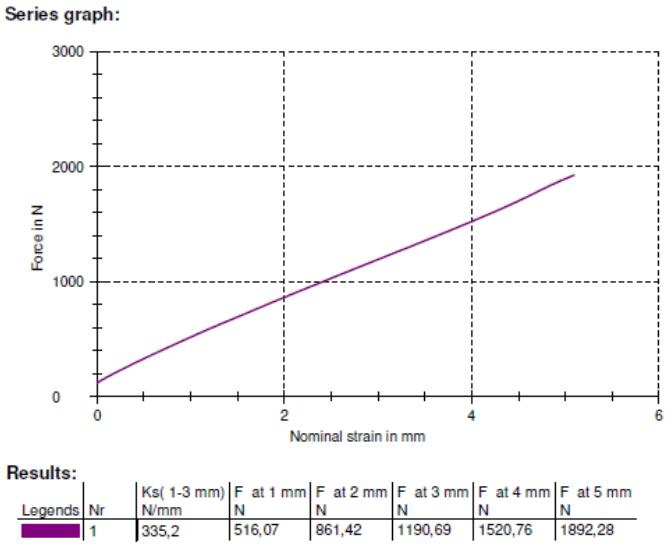


Results:

Legends	Nr	Ks(0,5-1,5 mm) N/mm	F at 0,5 mm N	F at 1 mm N	F at 1,5 mm N	F at 2 mm N	F at 2,5 mm N	F at 3 mm N
	1	581,1	466,24	763,75	1047,37	1322,25	1601,02	1898,31

Şekil 11. Radyal 2.yön (Y) test Sonuçları

Şekil 11'de görüldüğü üzere tasarım 2'ye ait geliştirilen parçanın radyal 2.yöndeki kuvvet-deplasman verileri çıkartılarak, kuvvet-deplasman eğrisindeki lineer bölge belirlenerek radyal 2. yön için rijitlik hesaplaması yapılmıştır. Parçanın radyal 2.yön için rijitlik değeri 581,1 N/mm olarak hesaplanmıştır.



Şekil 12. Eksenel Yön (Z) test sonuçları

Şekil 12'de görüldüğü üzere tasarım 2'ye ait geliştirilen parçanın eksenel yöndeki kuvvet-deplasman verileri çıkartılmış, grafiğin lineer bölgesi belirlenerek rijitlik hesaplaması yapılmıştır. Parçanın eksenel yön için rijitlik değeri 335,2 N/mm olarak hesaplanmıştır.

Tasarım 2'ye ait SEA ve reel test sonuçları Tablo 3'de karşılaştırılarak analiz verileri ile reel test sonuçları arasındaki sapmalar tespit edilmiştir.

Tablo 3. Tasarım 2'ye ait statik test ve analiz sonuçlarının karşılaştırılması

X (Radyal 1)	**SEA Sonuçları**	**Test Sonuçları**	**Fark**

Üretilen prototip parçalarda vulkanizasyon prosesi sonrasında parçanın görsel ve ölçüsel kontrolleri yapılmıştır. Yapılan kontroller neticesinde parçalarda herhangi bir problem görülmemiştir. Üretilen prototip parçaların görseli Şekil 13'te görülmektedir.

Şekil 13. Prototip ürün görseli

4. SONUÇLAR VE TARTIŞMA

Bu çalışmada plastik dış boruya sahip maçalı burçlarda vulkanizasyon sonrası oluşan ovalite probleminin önceden tespit edilebilmesi için termal analizler gerçekleştirilmiştir. Dış çap değeri Ø70.5 mm olarak belirlenen Tasarım 1'e yapılan termal analiz yüklemelerine göre, birinci adımdan sonra soğumaya bırakılan burca ait ölçüler Radyal 1 (X) yönünde 69.84 mm, Radyal 2 (Y) yönünde ise 71.11 mm gelmektedir. Ovalite değerinin analiz sonuçlarına göre Tasarım 1'de 1,27 olduğu görülmektedir. Tasarım 1'e ait yapılan prototip kalıptan elde edilen parçalara analizde yapılan kontroller tekrarlandığında elde edilen reel sonuçlar Radyal 1 (X) yönünde 69.10 mm Radyal 2 (Y) yönünde 72.15 olarak ölçülmüştür.

Tasarım 2'de burcun Radyal 1 (X) yönünde ölçüsü 72.4 mm, Radyal 2 (Y) yönünde ölçüsü ise 69.2 mm olarak tasarlanmıştır. Tasarım 2'nin termal analizi sonrasında ölçüleri; Radyal 1 (X) yönünde 71.08 mm, Radyal 2 (Y) yönünde ise 70.74 mm olarak ölçülmüştür. Sonuçlar incelendiğinde ovalite değerinin analiz sonuçlarına göre Tasarım 2'de 0.34'e düşürüldüğü görülmektedir. Tasarım 2'ye ait yapılan prototip kalıptan elde edilen parçalara analizde yapılan kontroller tekrarlandığında elde edilen reel sonuçlar Radyal 1 (X) yönünde 70,73 mm, Radyal 2 (Y) yönünde 70,50 mm gelmektedir. Sonuçlardan da anlaşıldığı gibi termal analiz verilerinden elde edilen geometrik sonuçlar ile fiziksel parça üzerinden elde edilen boyutsal sonuçlar birbiriyle örtüşmektedir.

Ayrıca, yapısal analiz verileri ile hesaplanan rijitlik değerleri ve fiziksel testler sonucu hesaplanan rijitlik değerleri karşılaştırması Tablo 3'te görüleceği üzere kauçuk burçlar için kabul edilebilir seviyede olduğu ve bu değerlendirmeler neticesinde bu tip burçlar için kauçuk verilerinin kullanılabileceği görülmüştür.

Bu çalışma sayesinde elde edilen verilere göre plastik dış boruya sahip burçlarda ovalite kaynaklı problemlerin önceden tespitine istinaden önemli çıktılar elde edilmiştir. Daha çok deneme-yanılma metoduyla çözülebilen problemler için mühendislik tabanlı sistem devreye alınarak olası zaman, hurda ve maliyet kayıplarının önlenmesi sağlanmıştır.

ÖZET

Titreşim sönümleyici burçlar, araçlarda süspansiyon parçalarının araç şasisine bağlantı noktalarında, aracın hareket halinde maruz kaldığı titreşim ve gürültülerin azaltılması ve sistemdeki kararsız davranışların telafi edilmesine yönelik özel olarak tasarlanırlar. Süspansiyon sisteminde montajının yapıldığı konuma göre birden fazla eksende harekete maruz kalırlar. Bu sebeple, burcun farklı eksenlerde farklı deplasmanlarda hareket etmeleri beklenir. Bu çalışma, sonlu elemanlarla farklı çalışma yönlerinde birden fazla sertlikte kauçuk içeren burçların geliştirilmesine odaklanmaktadır. Burç, farklı çalışma eksenlerinde farklı sertlik ve özellikte kauçuk parçalar içeren, farklı yönlerde ve farklı yer değiştirme değerlerinde hareket edecek şekilde tasarlanmış ve geliştirilmiştir. Bu sayede farklı çalışma eksenlerinde kendisinden beklenen yer değiştirme kriterlerinde hareket ederek üzerindeki titreşimleri, darbeleri ve gürültüleri absorbe edebilmektedir. Yapılan tasarım, sonlu elemanlar metodu ile yapısal analizler gerçekleştirilerek doğrulanmıştır. Pre-processing kısmında MSC/Apex programı, analizin gerçekleştirilmesi ise MSC/Marc programı yardımıyla yapılmıştır. Tasarımda kullanılan farklı karışıma sahip farklı sertlikteki kauçukların vulkanizasyon proses analizleri için Autodesk Moldflow programı kullanılarak kauçuk akış analizleri yapılmıştır.

DEVELOPMENT OF ANTI-VIBRATION BUSHING WITH MULTIPLE RUBBER HARDNESS IN DIFFERENT OPERATIONAL DIRECTIONS

ABSTRACT

Anti-vibration bushings are specially designed to reduce the vibrations and noises that the vehicle is exposed to in motion at the connection points of the suspension parts to the vehicle chassis and to compensate for the unstable behavior in the system. In the suspension system, they are subject to movement in more than one axis, depending on the location where they are mounted. For this reason, the bush is expected to move in different displacements on different axes. This work focusses on the development of bushings containing more than one hardness rubber in different working directions with the finite elements. The bushing was designed and developed to meet to move in different directions and at different displacement values which are containing rubber parts of different hardness and characteristics in different working axes. In this way, it can absorb the vibrations, impacts and noises on it by acting in the displacement criteria expected from it in different working axes. The design was verified by performing structural analyzes using the finite element method. MSC Apex and MSC Marc were used to modelling the rubber during design validation phase. Rubber flow anaylzes were performed with Autodesk Moldflow program to simulate vulcanization process of rubbers of different hardness with different mixtures.

1. GİRİŞ

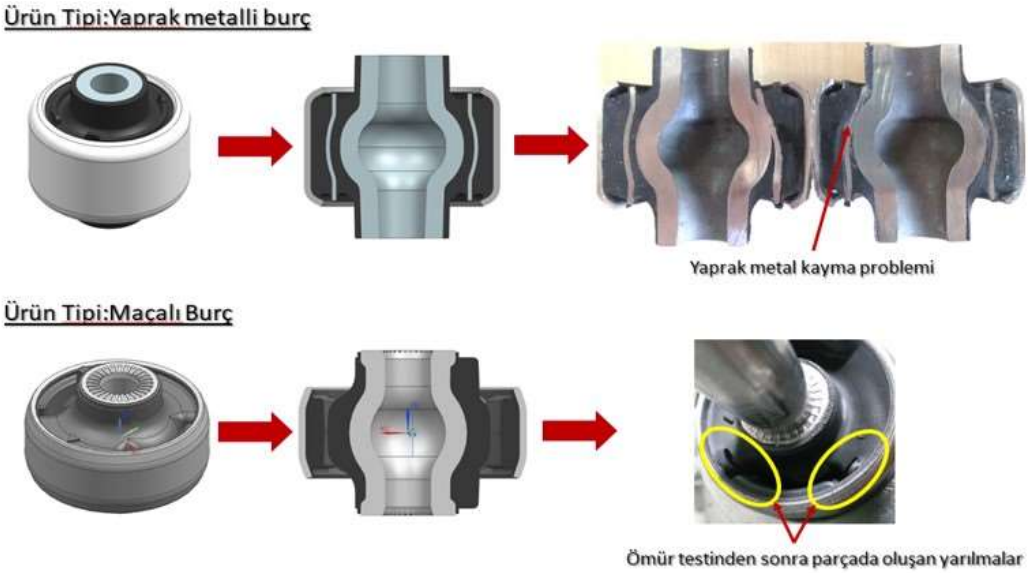
Taşıt süspansiyon sistemleri, iyi bir sürüş, gerekli yol tutuş performansı, dönüş esnasında direksiyon kontrolünü sağlayan ve aktarma organlarının birbirleri arasındaki etkileşimlerini dengede tutmaya yarayan alt sistemlerdir. Bu alt sistemler hızlanma, frenleme, viraj alma, bozuk zeminde ilerleme gibi farklı çalışma şartlarında gerekli konforu ve güvenliği sağlamalıdır. Daha çok salıncaklarda kullanılan kauçuk bazlı burçlar da süspansiyon sistemlerinin önemli

birer üyesi olmakla birlikte gerekli olan bu gereksinimleri yerine getirmede önemli bir rol üstlenirler. Kullanılan bu burçlar, araçta yoldan gelecek ani kuvvetlere karşı yaşam döngüsünü devam ettirebilmeli, aynı zamanda montajının yapıldığı yerde kendini muhafaza edebilmelidir. Burada öne çıkan birincil etken parçaların farklı eksenlerde farklı statik gereksinime ihtiyaç duymasıdır.

Li, deneysel bir çalışma gerçekleştirerek, arka teker süspansiyon sistemi için bir kauçuk burcun dört farklı yükleme altında davranışını incelemiştir. Bu yükleme şekillerinin eksenel, radyal, burulma ve yalpalama hareketlerini temsil edecek şekilde planlandığı görülmüştür. (Li, L., 2014).

Burçlarda, farklı yönlerde farklı rijitlik ihtiyaçlarını karşılama amacıyla iki farklı yöntem uygulanmaktadır: Bunlardan biri burcun maça boşluklu olacak şekilde tasarlanması, bir diğer yöntem ise kauçuk kısma ilave komponentler eklenmesidir. Her iki yöntemin de avantaj ve dezavantajları bulunmaktadır. Örneğin; burcun maça boşluklu olarak tasarlandığı koşulda, burç tekrarlı yükler altında çalışırken maça boşluğunun kauçuk üzerindeki zayıf olduğu bölgelerde yarılma ve yırtılmalar meydana gelmektedir. Bu sebeple parçanın servis ömrü beklentilerini karşılamakta zorlanılmaktadır. Kauçuk kısma ilave komponent eklenerek yapılan tasarımlarda ise hem ürün maliyeti artmakta hem de üretim prosesleri sırasında, bu ilave komponentlerin kalıp gözlerine yerleştirilmesinde zorluklar yaşanmaktadır. Bu yöntemin getirdiği diğer dezavantaj ise parça ağırlığının artmasıdır.

Yukarıda bahsedilen 2 yöntem için, görülen bu hata ve dezavantajlar Şekil 1'de kesitleri alınmış burçlarda detaylı bir şekilde gösterilmektedir.



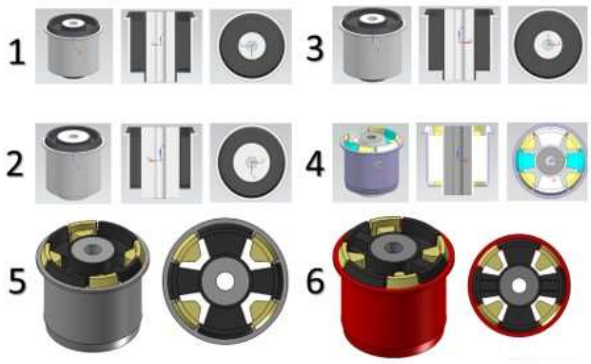
Şekil 1. Örnek bir maça boşluğuna sahip burç, yaprak sac tasarımı ve yaşanan sorunlar

Bu çalışmada, yukarıda bahsedilen problemleri ortadan kaldırmak amacıyla farklı eksenlerde farklı sertlik değerine sahip burç tasarımı yapılmıştır. Statik gereksinimleri yakalamak için ürünün bir çalışma yönünde 75 ShA kauçuk hamuru, diğer çalışma yönünde ise 70 ShA kauçuk hamur kullanılarak iki yöndeki statik gereksinimleri de karşılayacak burç tasarımı yapılmıştır. Burçtan beklenen statik gereksinimler için tasarım doğrulama fazında sonlu elemanlar yöntemi kullanılarak yapısal analizler gerçekleştirilmiş, farklı kauçuk sertliğine ait hamurların kalıplanabilirliği ve üretilebilirliğinin doğrulanması için ise akış analizleri yapılmıştır. Yapısal analizlerin gerçekleştirilmesinde pre-processing kısmında MSC Apex, çözücü için ise MSC Marc programından yararlanılmıştır. Akış analizlerinin gerçekleştirilmesinde ise Autodesk Moldflow programından faydalanılmıştır. Numune üretimleri yapılan parçaların fiziksel testleri yapılarak analiz sonuçları ile karşılaştırılmış akabinde ömür testi yapılarak parçanın servis koşullarındaki performansı değerlendirilmiştir.

2. MATERYAL VE METOT

2.1. Ürün Tasarım ve Doğrulama Çalışmaları

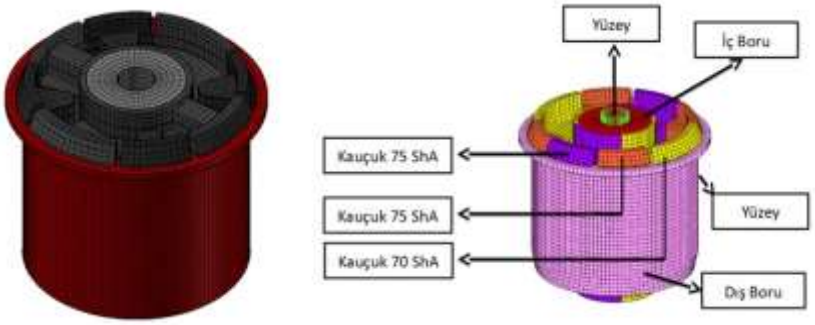
Çalışmada tasarımı gerçekleştirilen burcun tasarım varyasyonları Şekil 2'de gösterilmiştir. Montaj koşulları, üründen beklenen statik ve dinamik beklentileri karşılayacak şekilde tasarım dondurulmuştur.



Şekil 2. Tasarım varyasyonları

2.2. Sonlu Elemanlar Modeli

Sonlu elemanlar mesh yapısı MSC/Apex programında Şekil 3'de gösterildiği gibi yapılmıştır. Mesh yapısı hazırlanırken sonuçların doğruluğu için doğrusal ilerleyen bir mesh yapısı tercih edilmiştir. Eleman tipi 2.5D Hex Mesh atılan modelde 51.818 node ve 36.255 eleman yer almaktadır. Mesh atılırken elemanların birbirleriyle konuşması ve uygulanacak fiziksel harekete göre tasarlanmasına dikkat edilmiştir.



Şekil 3. Parçanın izometrik görünüşü ve mesh yapısı

2.3. Sınır Koşulları

Burcun proses işleminde iç boru ve dış boruya yapıştırıcı uygulaması yapılmakta ve vulkanizasyon işlemi gerçekleştirilmektedir. Bu nedenle burcun iç borusu ve dış borusu kauçuğa glue olarak tanımlanmıştır. Parçanın montaj koşulları dikkate alınarak; yapısal analizler için dış boru sabitlenmiş, iç boruya tanımlanan yüzey serbest bırakılmıştır. İki adımlı analiz tasarlanmıştır. Birinci adımda termal veriler girilerek kauçuğun vulkanizasyon sonrası soğuması simule edilmiş, ikinci adımda da ön gerilmelere maruz kalmış burcun radyal ve eksenel yönlerde karakteristikleri çıkartılmıştır.

2.4. Termal Veriler

Kauçuk malzemeyi mühendislik malzemesi haline getirmek için gerekli olan parametreler sıcaklık, süre ve basınçtır. Bu parametreler arasında sıcaklığın ürün üzerinde büyük etkisi vardır. Kauçukların non-lineer özelliklerine bağlı olarak, burç içindeki kümülatif histeritik enerji birikimi, mekanik özelliklerde çeşitli sıcaklıklarda önemli ölçüde değişmesine neden olabilir. (Dean vd.,1984)

Bu çalışmaya konu olan süspansiyon burcunda kullanılan tabii kauçuk malzemeyi elastomer hale getirmek için 130°C kalıp sıcaklığı kullanılmıştır. Kauçuğun davranışları veya süspansiyon bileşenlerinin modelleri hakkında yayınlanan araştırmaların çoğunda, dinamik çalışmalar altında parça üzerindeki termo-dinamik etkilerin özellikle histerisis üzerinde ciddi etki yarattığı bildirilmektedir. (Sayyaadi H, Shokouhi N.,2009)

Vulkanizasyon prosesi sonrasında kalıptan çıkarılan burç hava ile soğumaya bırakılmaktadır. Malzemelerin ısıl genleşme katsayıları farklı olduklarından kullanılan hammaddelere göre vulkanizasyon sonrası ölçülerde farklılık oluşmaktadır. Kauçuğun ısıl genleşmesi $70x10^{-6} \circ m / m \circ C$ iken alüminyum malzemelerde bu değer 22 $x10^{-6} \circ m / m \circ C$ çeliklerde 12 $x10^{-6} \circ m / m \circ C$ ve poliamid plastiklerde ise 110 $x10^{-6} \circ m / m \circ C$ dır. (URL1)

Bu değerler göz önüne alındığında vulkanizasyon sonrası soğuma sırasında plastik dış boruya sahip burçlar alüminyum ve çeliğe göre daha fazla ovalite problemi oluşturmaktadır. Bu sonuçları görebilmek adına malzemelerin ısıl genleşme değerleri sonlu elemanlar programına girilerek malzemelerin sıcaklıkla olan değişimleri incelenmiş ve çıkan sonuçlara göre tasarımlar optimize edilmiştir.

3. SONLU ELEMANLAR ANALİZLERİ VE TESTLER

3.1. Termal Analiz Sonuçları

Tasarlanan burca termal analiz yapılmıştır. Dondurulan tasarımın termal analiz sonuçları Şekil 6'da gösterilmektedir.

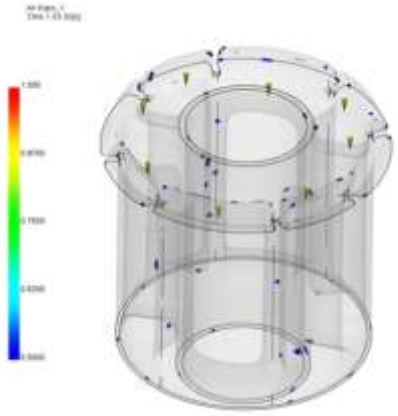
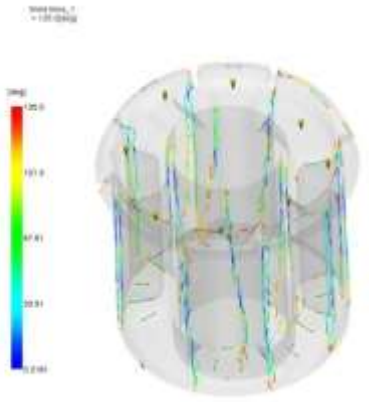
3.3. Kauçuk Kalıp Akış Simülasyonu

Değişken rijitliğe sahip burçta farklı rijitlik değerine sahip NR esaslı kauçuk reçeteler kullanılmaktadır. Kauçuk sertlikleri (rijitlikleri) içerisindeki katkı malzemelerinin oranı ile değişmektedir. Rijitlikler arasındaki fark çok büyük olmadığı sürece kalıp içerisinde malzeme davranışı birbirine yakın olmaktadır. Burada kalıplama açısından farkı oluşturan en önemli husus farklı giriş kanallarından (yolluklardan) aynı anda, kauçukların farklı gözlere gönderilerek birbirleri ile farklı kanallardan gelen kauçuğun birleşimini sağlamak sureti ile parçanın elde edilmesidir. Farklı giriş kanallarından aynı anda gönderilmesi durumu bu simülasyonda dikkate alınmış, rijitlik farkından doğan malzeme akış karakteristikleri farkı çok küçük olacağı düşünüldüğünden dikkate alınmamıştır.



Şekil 8. Gaz boşlukları

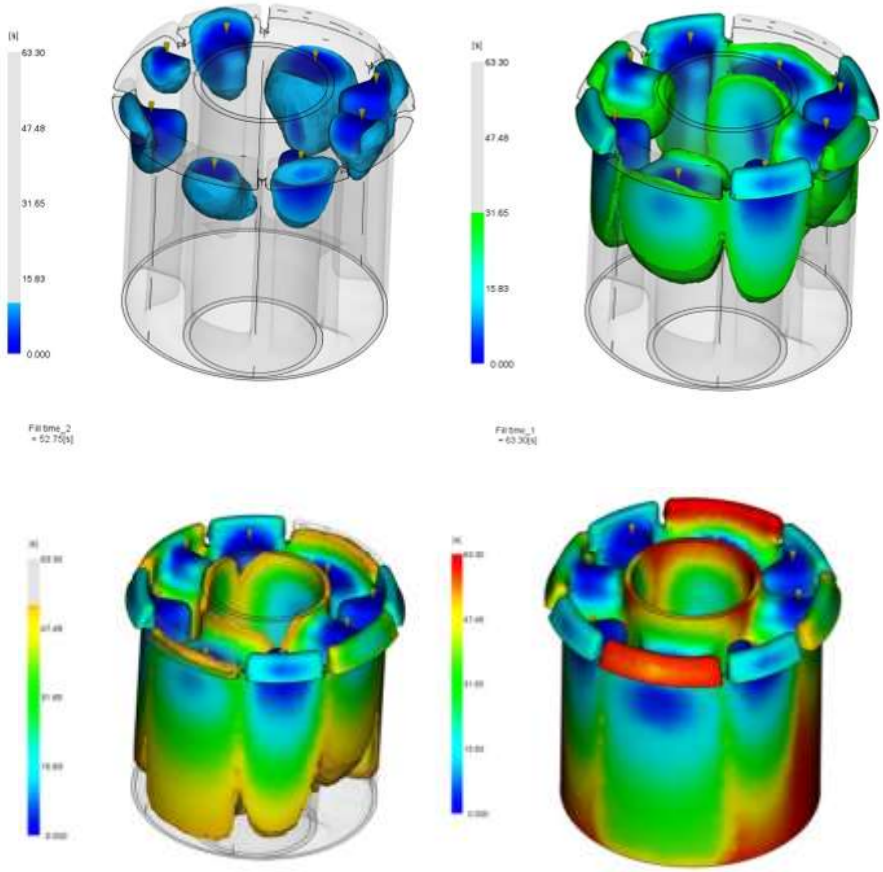


Şekil 9. Kaynak izleri

Çok noktadan yapılan enjeksiyon veya malzeme girişi doğal olarak kaynak izlerini ve gaz boşlukları oluşumunu tetiklemektedir. Şekil 8 ve Şekil 9'da bu durum görülmektedir. Bu problem proses parametrelerine müdahale ederek çözmek mümkündür. Bu parametrelerin başında kalıp, enjeksiyon sıcaklığı ve kalıplama basıncını yükseltmek gelmektedir. Dolayısı ile bu sorun proses parametrelerinin ayarlanması ile kalıp tasarımında herhangi bir değişikliğe gerek kalmaksızın sorun çözülmektedir.

3.4. Kauçuk Dolum Prosesi Simülasyonu

Dolum analizleri Şekil 10'da görülmektedir. Kalıbın her bir gözüne kauçuk malzeme aynı anda farklı giriş kanallarından giriş yapmaktadır. Görüleceği üzere kalıp boşluğunda dengeli olarak dolum gerçekleşmektedir. Giriş kanalının seviyesinden başlayan akış sonucunda, dolum en son en geniş kulağa sahip bölümlerde gerçekleşmektedir.



Şekil 10. Kalıp dolum analizleri

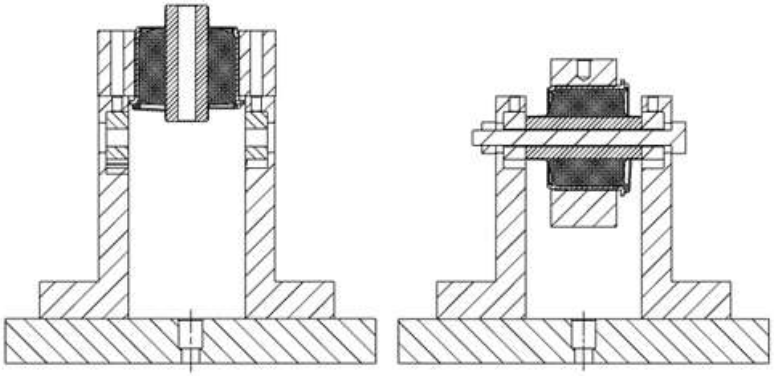
3.5. Prototip Numune Üretimi ve Kontrolleri

Kalıp tasarımı ve imalatı gerçekleştirildikten sonra proses çalışmaları yapılarak prototip parça üretimleri gerçekleştirilmiştir. Üretilen prototip parçalarda herhangi bir problem görülmemiştir.

Şekil 11. Üretilmiş prototip numune görüntüleri ve kesiti

3.6. Statik Testler

Kauçuk malzemelerin farklı uzama oranlarında farklı karakteristik eğrileri vardır. (Wang, 1998), (Legorju-jago ve Bathias, 2002). Bu nedenle, ürünlerin hangi yükleme koşullarında çalışacağını bilmek ve uygun şekilde test etmek gerekmektedir. Ürünün statik testleri Zwick Roell test makinesinde gerçekleştirilmiştir Şekil 12'de Zwick Roell test kurulumu gösterilmektedir. Test makinesi 50 kN ve 600 mm kapasitelidir. Statik testler Şekil 5'te gösterilen test yönlerinde Tablo 2'de belirtilen parametrelerde gerçekleştirilmiştir.



a)Eksenel Yön b)Radyal Yön

Şekil 12. Zwick Roell test kurulumu

Şekil 13. X:Radyal 1 yön, Y:Radyal 2 yön, XY: Radyal 3 yön, Z:Eksenel yön

Tablo 2. Statik test parametreleri

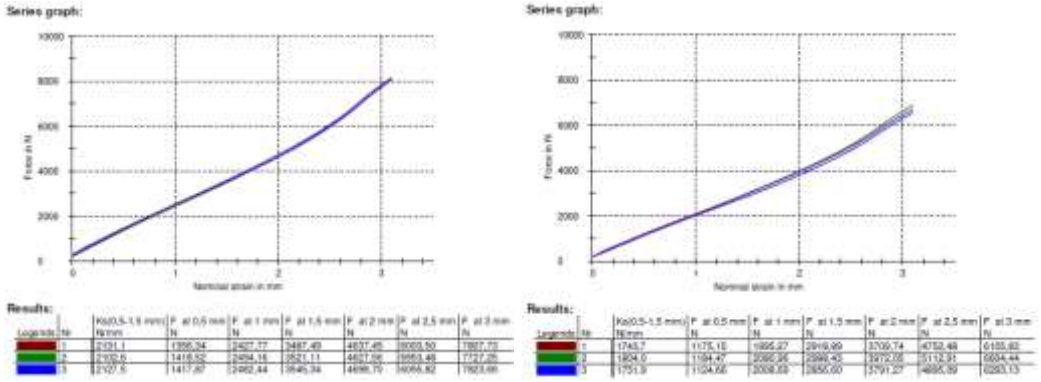
	X (Radyal 1)	Y (Radyal 2)	XY (Radyal 3)	Z (Eksenel)
Ön Yük	100 N	100 N	100 N	100 N
Ön Şartlandırma Hızı	50 mm/min	50 mm/min	50 mm/min	50 mm/min
Ön Şartlandırma Yükü	±3 mm	±3 mm	±7 mm	±5 mm
Ön Şartlandırma Çevrimi	3	3	3	3
Gecikme	10 sec	10 sec	10 sec	10 sec
Test Hızı	10 mm/min	10 mm/min	10 mm/min	10 mm/min
Test Yükü	±3 mm	±3 mm	±7 mm	±5 mm

Burcun iç borusu, montaj yerini simule edecek şekilde ve kaymasını önlemek amacıyla cıvatalar ve somunlar kullanılarak sabitlenmiştir. Tablo 2'de verilen şartlandırma çevrimleri, Mullins etkisini ortadan kaldırabilmek için yapılmıştır. Bu nedenle kuvvet-yer değiştirme grafiği, tabi tutulan testin 4. döngüsüne dayanmaktadır (Mullins ve Tobin, 1969). Test armatürleri ve test ekipmanından kaynaklanabilecek boşlukları ortadan kaldırmak için 100 N ön yük uygulanmıştır. Test sonucunda kuvvet-yer değiştirme grafiği elde edilmiş ve statik sertlik (Ks) değerleri hesaplanırken grafiğin belli aralıktaki eğimine bakılmıştır.

$$K_S = \frac{\Delta F}{\Delta x} \quad (1)$$

3.7. Ürün Test Sonuçları

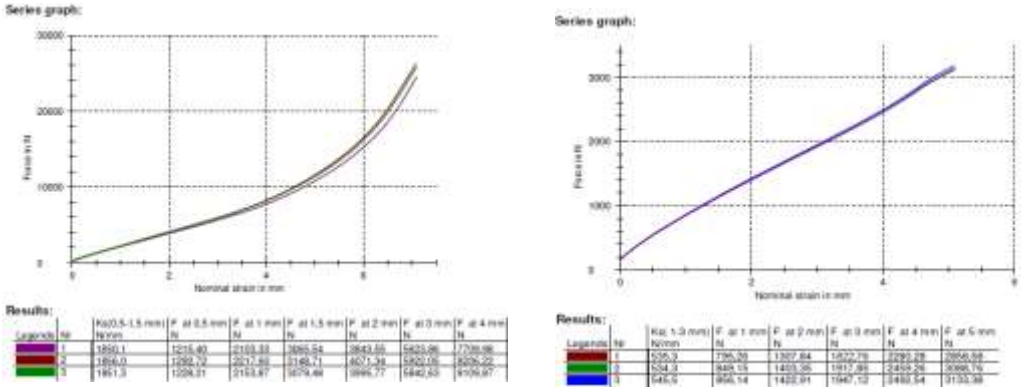
Tasarıma ait prototip kalıplar tasarlanmış ve prototip parça üretimleri yapılmıştır. Üretilen prototip parçaların Radyal 1.yön test sonuçları Şekil 14, Radyal 2.yön test sonuçları Şekil 14, Radyal 3.yön test sonuçları Şekil 15'de ve Eksenel yön test sonuçları Şekil 15'de gösterilmektedir.



a) b)

Şekil 14. a) Radyal 1.Yön (X) b) Radyal 2.Yön (Y) Statik Test Sonuçları

a) b)

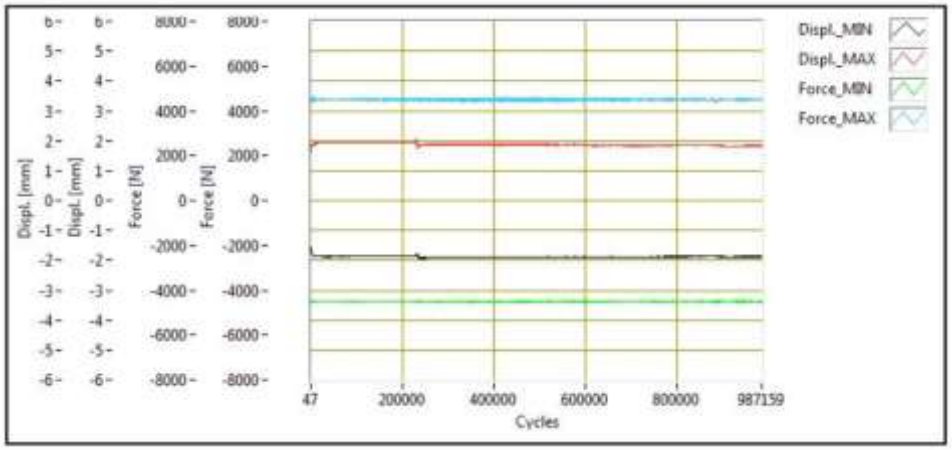


Şekil 15. a) Radyal 3.yön (XY) b) Eksenel yön (Z) Statik test sonuçları

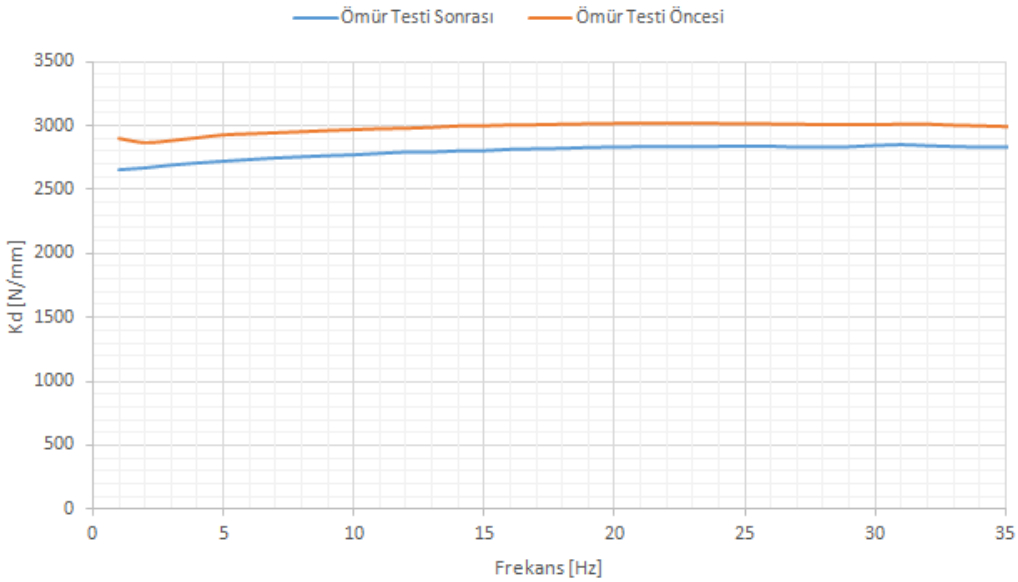
Şekil 14 ve 15'te görüldüğü üzere geliştirilen parçanın tüm ilgili yönlerdeki kuvvet-deplasman verileri çıkartılmış, rijitlik değeri hesaplamaları eğrilerin lineer bölgeleri belirlenerek yapılmıştır.

3.8. Dayanım Testleri ve Performans Kayıp Ölçümleri

Üretilen prototip parçalar ±4,5 kN, 4Hz ve 1 milyon çevrim olacak şekilde ömür testi yapılmıştır. Ömür testi Dynamess tek eksenli ±10 kN, ±6 mm genlik, 0-35 Hz frekans kapasitesine sahip ömür test cihazında yapılmıştır. Ömür testi sonucunda herhangi bir sorun tespit edilmemiş ve parçada yarılma, yırtılma vb. deformasyonlar görülmemiştir. Test sonuçları Şekil 16 ve Şekil 17'de verilmiştir.



Şekil 16. Yük tekrar eğrileri



Şekil 17. Frekansa bağlı olarak burcun dinamik rijitlik değişimi

4. SONUÇLAR VE TARTIŞMA

Bu projede farklı yönlerde farklı statik gereksinime ihtiyaç duyan bir burç geliştirilmiştir. Bu burcu tasarlarken klasik olan 2 farklı yöntem yerine (maça boşluklu yapı ve ilave komponentli tasarım) iki farklı yön için farklı sertlikte kauçuklar kullanılmıştır. Farklı yönde farklı rijitliğe sahip burcun statik gereksinimlerini karşılamak için tasarımlar yapılmıştır. Her bir tasarım için sonlu elemanlar analizi yapılarak istenen değerlere ulaşılıp ulaşılamadığına bakılmıştır. Altıncı iterasyon sonucunda hedeflenen statik gereksinimleri karşılayan bir burç tasarımı oluşturulmuştur. Yapısal olarak tasarımı sonlu elemanlar analizleri ile doğrulan nihai tasarım burç, üretilebilirlik açısından da analiz edilmiş ve değerlendirilmiştir. Kalıp akış simülasyonunda, kalıpta parçadaki gaz boşlukları, doldurma ve kaynak izlerinin oluşumları incelenmiş ve kalıp tasarımı da bu kapsamda dondurulmuştur. Analiz verilerine göre doğrulanan kalıp tasarımı sonrası kalıp imalatı gerçekleştirilmiştir. Prototip parçaların üretiminde kauçuk hamurlara ait reometre raporları ile yaklaşık olarak belirlenen vulkanizasyon parametreleri ile prototip parçalar kalıplanarak üretilmiştir. Yapılan tasarım doğrulama çalışmalarının bir sonucu olarak tek iterasyonda hatasız parça üretimi gerçekleşmiştir. Elde edilen numuneler kullanılarak, parçaların ölçüleri ve sertlikleri kontrol edilmiştir. Boyutsal ve fiziksel olarak hedeflenen değerlerin yakalandığı görülmesi nedeniyle, bu numuneler kullanılarak parçaların statik testleri gerçekleştirilmiştir. Statik test sonuçlarında kuvvet-deplasman davranışında tasarım değerleri ile uyumlu sonuçlar elde edilmiştir. Ayrıca, numuneler ömür testlerine tabi tutulmuştur. Dinamik yükleme altında gerçekleştirilen ömür testlerinde numunelerde hasar oluşmadığı ve hedeflenen ömür performansı değerlerinin sağlandığı görülmüştür.

Tasarıma ait sonlu elemanlar analizleri ve reel test sonuçları Tablo 3'de karşılaştırılmıştır. Sonuçlardan da görüldüğü gibi analiz değerleri üretilen parçanın sonuçları ile uyumlu olup sapma değerleri çok düşük bir aralıktadır.

Tablo 3. Statik test ve analiz sonuçlarının karşılaştırılması

X (Radyal 1.yön)	**SEA Sonuçları**	**Test Sonuçları**	**Fark**

70-75 ShA Ks-(1-3 mm)	520,8 N/mm	538,3 N/mm	+%3,4

Bu çalışma sayesinde burcun farklı yönlerde farklı deplasman değerlerinde hareket edebilme ve farklı eksenlerdeki statik gereksinimleri karşılamak üzere farklı çalışma eksenlerinde farklı sertliklerde ve karakteristikte kauçuk kısımlar içeren bir burç geliştirilmiş, bu gereksinimleri karşılayabilecek diğer 2 yönteme alternatif oluşturmuştur. Bu sayede mevcut durumda yaşanan kauçuk üzerinde yarılma, yırtılma gibi parça ömrüne etkiyen dezavantajlar elimine edilmiştir. İlave komponent kullanımı da geliştirilen bu üründe ihtiyaç dahilinden çıkartılmış ve üretimde yaşanan proses zorluklarının önüne geçilmiş, proje maliyetleri de düşürülmüştür.

5. TEŞEKKÜR

Bu çalışma TÜBİTAK-TEYDEB 1501 Sanayi-Ar-Ge programı 3192344 nolu projesi kapsamında gerçekleşmiştir. Yazarlar, verilen destekten dolayı TÜBİTAK'a ve YAMAS A.Ş 'ye teşekkürlerini sunar.

ÖZET

Toplu taşıma sektörü gelişmekte olan ülkeler için oldukça önemli bir ulaşım seçeneğidir. Bu araçlarda yakıt tasarrufu sağlayarak karbon emisyonunun düşürülmesine yönelik çalışmalarda yolcu, sürücü ve hostes koltukları önemli bir potansiyele sahiptir. Bu koltuklardan konfor ve kullanım amaçlarına hizmet etmeleri beklenirken aynı zamanda daha az yer kaplama, modüler tasarıma sahip olma gibi farklı avantajlara da sahip olmaları istenmektedir. Bu çalışma kapsamında şehirlerarası yolcu otobüslerinde kullanılan hostes koltukları ele alınmıştır. Yapılan tasarımsal değişiklikler ile daha hafif ve daha az yer kaplayan bir hostes koltuğu geliştirilmiştir. Sonlu elemanlar analizleri ile doğrulanan tasarımın prototip imalatı gerçekleştirilmiş ve standartlara uygun olarak testlere tabi tutulmuştur. Sonuç olarak yapılan tasarımsal değişiklikler sayesinde yaklaşık olarak %12 daha hafif ve 800 cm^2 daha az yer kaplayan yenilikçi bir muavin koltuğu geliştirilmiştir. Ortaya çıkan koltuk güvenlik testlerinden başarı ile geçmiştir.

Anahtar Kelimeler: Hostes koltuğu, Otobüs, Hafifletme, Sonlu elemanlar analizi

DEVELOPMENT OF CO-DRIVER SEAT WITH ROTATING MECHANISM FOR INTERCITY PASSENGER BUS

ABSTRACT

The public transportation sector is a very important transportation option for developing countries. Passenger, driver and co-driver seats have an important potential in the studies aimed at reducing carbon emissions by saving fuel in these vehicles. While these seats are expected to serve their comfort and usage purposes, they are also required to have different advantages such as occupying less space and having a modular design. Within the scope of this study, co-driver seats used in intercity passenger buses are discussed. With the design changes, a lighter and less space-saving co-driver chair has been developed. The prototype of the design, which was verified by finite element analysis, was manufactured and tested in accordance with standards. As a result, thanks to the design changes, an innovative co-driver seat has been developed that is approximately 12% lighter and takes up 800 cm^2 less space. The resulting seat has successfully passed the safety tests.

Keywords: Co-driver seat, Bus, Weight reduction, Finite element method

1. GİRİŞ

Avrupa Birliği 2020 yılı itibarıyla hala %94 oranında petrol bazlı yakıt tüketimine ihtiyaç duymaktadır. Bu durum dünya genelinde de benzerlik göstermektedir. Artan dünya nüfusu ile birlikte ulaşım talebi de artmakta ve karbondioksit (CO_2) emisyonu ile mücadele etmek giderek zorlaşmaktadır. Paris iklim anlaşmasına göre küresel ısınmanın endüstri devrimi öncesine kıyasla 2 °C'nin altında tutulabilmesi için özellikle ulaşım sektöründe önemli atılımların yapılması gerekmektedir. Bu konuda taşıtların ağırlıklarında hafifletmeler ve elektrikli araçların yaygınlaşması gibi temiz enerji kaynaklarına yönelimin yanı sıra ulaşımın her alanında getirilecek tüm pratik çözümler oldukça değerlidir [1].

Taşıtlardaki enerji tüketiminin yaklaşık %70'i ağırlık ile ilgili sebeplerden kaynaklandığı için enerji verimliliğini arttıran bu teknolojilerin arasında taşıt ağırlığında hafifletme en verimli ve en hızlı geri dönüş sağlayan teknolojilerden biridir [2]. Hafifletme ile aracın yol tutuşu artmakta frenlemesi ve hızlanması için gerekli kuvvetler azalmaktadır. Özellikle toplu taşıma araçlarında yapılacak olan iyileştirmelerin karbon emisyonu üzerinde olumlu etkisi daha belirgin olacaktır.

Toplu taşıma sektörü gelişmekte olan ülkeler için oldukça önemli bir ulaşım seçeneğidir. Bu alanda otobüs, midibüs, minibüs gibi karayolu taşıtları ön plana çıkmaktadır. Avrupa Komisyonunun koordinasyonunda yapılan bir araştırma sonucu olarak Türkiye en fazla toplu taşıma aracı kullanan ülke konumundadır [3]. Bu veri, ülkemizde ve global ölçekte toplu taşıma araçlarında yakıt tasarrufu sağlayan teknolojilerin kullanımının ne denli önemli olduğunu göstermektedir.

Toplu taşıma araçlarında yakıt tasarrufu sağlayarak karbon emisyonunun düşürülmesine yönelik çalışmalarda otobüslerde yer alan yolcu, sürücü ve hostes koltukları önemli bir potansiyele sahiptir. Yapılan çalışmalarda öne çıkan alan ise farklı malzeme ve tasarım teknikleri ile koltukların hafifletilmesi gelmektedir. Literatürde birçok çalışmacı farklı yöntemler ile koltuk ağırlıklarının hafifletilmesine yönelik çalışmalar yürütmüş ve farklı oranlarda hafifletmeler sağlamıştır. Özcanlı ve Dede (2018) yüksek alaşımlı çelik malzeme kullanarak koltuk ağırlığında hafifletme elde etmişlerdir [4]. Birçiçek ve ark. Ağır vasıtalarda kullanılan koltuklarda metal yapı yerine kompozit yapı kullanarak performanstan kayıp yaşamadan yaklaşık 1.5 kg'lık bir hafifletme elde etmişlerdir [5]. Ren ve ark. (2017) cam elyaf takviyeli termoplastik prepreglerden oluşan ve poliüretan köpük ile doldurulmuş çözgülü örme ara kumaştan oluşan bir sandviç yapı kullanarak koltukta hafifletme sağlamışlardır. Yenilikçi hafif tasarımla, koltuğun kütlesi, geleneksel seri üretime ait referans koltuğa göre %57'ye kadar azaltılabilmiştir [6]. Yuce ve ark. (2014) yolcu koltuklarında farklı malzeme kullanımı ve çeşitli tasarımsal değişiklikler ile %20 oranında hafifletme sağlamışlardır [7]. Yine Yuce ve ark. Yolcu koltuğu ayaklarında topoloji optimizasyonu sonucunda %45'e varan bir hafifletme sağlamışlar ve bu tasarımın prototip imalatını gerçekleştirip FMVSS 210 standartlarına uygun olarak test edip doğrulamışlardır [8]. Yapılan literatür araştırmasından da görülebileceği üzere taşıt koltuklarının hafifletilmesinde uygun malzeme, uygun üretim tekniği ve tasarım optimizasyonlarının kullanılması ile önemli oranlarda hafifletmelerin elde edilebileceği görülmüştür.

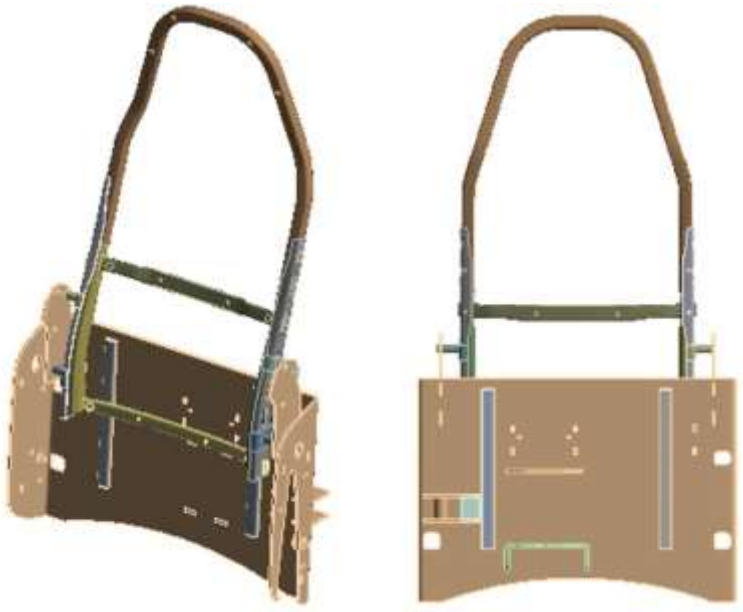
Toplu taşıma araçlarında kullanılan koltukların sadece hafif olması müşteri beklentileri ve taşıt için konfor alanının sağlanması açısından yeterli olmamaktadır. Toplu taşıma araçlarının iç hacimlerinin verimli kullanılması ve aynı zamanda kullanılan tüm koltukların performans ve kaliteden ödün vermeden hafifletilmesi tüm koltuk üreticilerinin temel hedefleri arasındadır. Bu çalışmada şehirlerarası yolcu otobüslerinde kullanılan hostes/muavin koltuğu olarak adlandırılan koltuklarda tasarımsal revizyonlar sonucunda daha hafif ve otobüs içinde alan tasarrufu sağlayacak bir muavin koltuğu geliştirilmiştir. Ortaya çıkan yeni tasarım sonlu elemanlar analizleri ile doğrulandıktan sonra prototip imalatı gerçekleştirilerek ECE R14 normlarına uygun olarak emniyet kemer çekme testi ve ömür testlerine tabi tutulmuştur.

2. MATERYAL VE YÖNTEM

Bu çalışmada M3 sınıfında yer alan 30-55 adet yolcu taşıma kapasitesine sahip bir otobüsün hostes/muavin koltuğu ele alınmıştır. Muavin koltuklarının araç içi lokasyonu şoför mahali ve yolcu giriş kapısı arasıdır. Muavin koltukları Şekil 1'de gösterildiği gibi sade bir tasarımdan meydana gelebildikleri gibi dönme, geri yatırma vb. hareket mekanizmalarına sahip olup masaj, ısıtma/soğutma, aydınlatma, tablet ve şarj üniteleri gibi pek çok donanımı da barındırabilmektedirler.

Şekil 1. Muavin/Hostes koltuğu örneği

Yenilikçi tasarım ile tekrardan tasarlanan muavin koltuğu öncelikle sonlu elemanlar analizi ile doğrulama çalışmalarına tabi tutulmuştur. Bu kapsamda ANSYS programının Static Structural Analysis modülü kullanılarak koltuğun arkalık iskeleti üzerine ECE R14 regülasonuna uygun olarak yükleme gerçekleştirilmiş ve koltuk üzerinde oluşan gerilme ve deformasyon değerleri incelenmiştir. Şekil 2'de analizde kullanılan koltuğun CAD datası verilmiştir.



Şekil 2. Sonlu elemanlar analizlerinde kullanılan koltuğun CAD görüntüsü

Koltuğun üzerinde araca bağlanan kısımları tanımlanmış ve bu bölgelerden koltuk sabitlenmiştir. Koltuk sırtlık bölgesinden ECE R14 regülasyonunun gerektirdiği kuvvet uygulanmıştır. Koltuk yapısında ortalama 4 mm boyutlarında kartezyen elemanlar kullanılarak 66648 eleman ve 59045 noddan oluşan bir ağ yapısı elde edilmiştir (Şekil 3).

Şekil 3. Sonlu elemanlar analizlerinde kullanılan sınır şartları

Tasarımı tamamlanan koltuğun prototipi üretilmiş ve bağlı olduğu araç sınıfına uygun olarak ECE R14 standartlarına uygun olarak emniyet kemer çekme testi uygulanmıştır. Bu test standardında çekme kuvveti Şekil 4'te verildiği gibi emniyet kemeri üzerinden uygulanarak koltuğun bağlantı mekanizması üzerindeki deformasyonlar kontrol edilmektedir [9].

Şekil 4. ECE R14 Emniyet kemer çekme testi şematik görüntüsü

ECE R14 regülasyonuna uygun olarak gerçekleştirilen testlerde koltuğun ağırlığına bağlı olarak belirlenmiş olan 458-689 kgf arasında değişen kuvvetler altı farklı bölgeden pistonlar yardımıyla prototip koltuk üzerine uygulanmıştır. Yaklaşık 6.5 saniye boyunca uygulanan bu kuvvetlerle koltuk üzerindeki deformasyonlar incelenmiştir.

Prototip koltuğun ayrıca döner mekanizması da ömür testlerine tabi tutularak doğrulanmıştır. Bu kapsamda FKT Koltuk Sistemleri bünyesinde yer alan özel test cihazı kullanılmıştır. Pnömatik bir tahrik aparatına sahip test cihazı sayesinde koltuğun dönme mekanizması üzerine 2500 çevrimli periyotlarda 10000 dönüş yaptırılarak üzerinde oluşan deformasyonlar incelenmiştir.

3. BULGULAR VE SONUÇLAR

Bu çalışma kapsamında otobüslerde yer alan muavin koltuğunun tasarımı, sonlu elemanlar analizleri ve prototip imalatı gerçekleştirilerek ilgili regülasyonlara uygun olarak doğrulaması gerçekleştirilmiştir.

Mevcut hali ile sabit bir ayak yapısına sahip olan muavin koltuğunda döner dişli mekanizması kullanılarak hem hafiflik hemde katlanabilirlik özelliği kazandırılmıştır (Şekil 5). Koltuğun tasarımında gerçekleştirilen iyileştirmeler neticesinde, hareket mekanizmasında bulun 4 adet dişli ile 82°'lik dönme işlemi senkronize olarak yapılabilir hale gelmiştir. Sabit ayak yapısı yerine döner dişli mekanizması kullanılarak yaklaşık %12 civarında bir hafiflik elde edilmiştir. Dişlilerin teknik özellikleri ise Tablo 1'de verilmiştir.

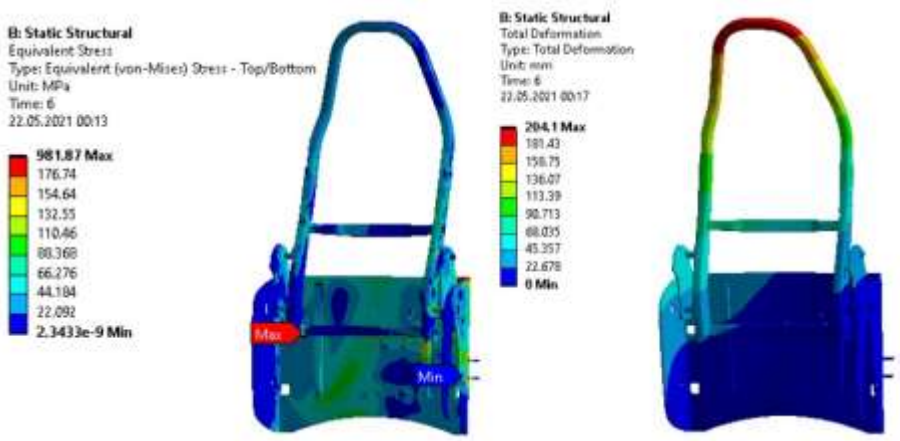
Şekil 5. Döner dişli mekanizmasının görüntüsü

Tablo 1. Döner dişli mekanizmasındaki dişlilerin özellikleri

Diş Sayısı (z)	10
Modül	4
Diş dibi çapı (mm)	30
Diş üstü çapı (mm)	48
Bölüm dairesi çapı (mm)	40
Diş kalınlığı (mm)	8

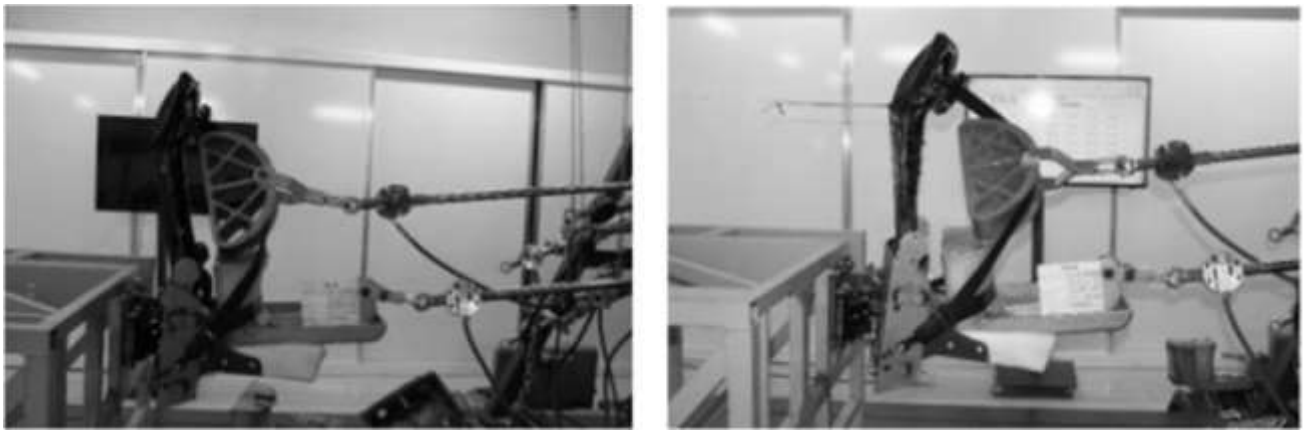
Koltuğun tasarımında yapılan iyileştirmeler sayesinde elde edilen 82° dönüş kabiliyeti görevliye şoför ve yolcularla daha rahat ilgilenme ve irtibat kurma imkanı sunmaktadır. Katlanır sele (oturak) sayesinde de 800 cm^2 alan tasarrufu sağlanabilmiştir.

Tasarımı tamamlanan koltuğun sonlu elemanlar analizi yardımı ile ECE R14 şartlarına uygun olarak analizleri gerçekleştirilmiştir. Koltuk iskeleti üzerinde ortaya çıkan maksimum eşdeğer gerilme ve toplam deformasyon miktarları incelenmiştir. Yapılan analiz sonucunda koltuk iskeletindeki gerilme değerlerinin malzemenin akma dayanımının altında kaldığı görülmüştür. Maksimum gerilme olarak görülen 980 MPa değer ise çok küçük bir alanda mesh yapısı nedeni ile gözlenmiştir. Toplam deformasyon değeri incelendiğinde ise maksimum 204 mm 'lik bir deformasyonun beklenildiği gibi arkalık kısmının en uç noktasında oluştuğu görülmüştür (Şekil 6).



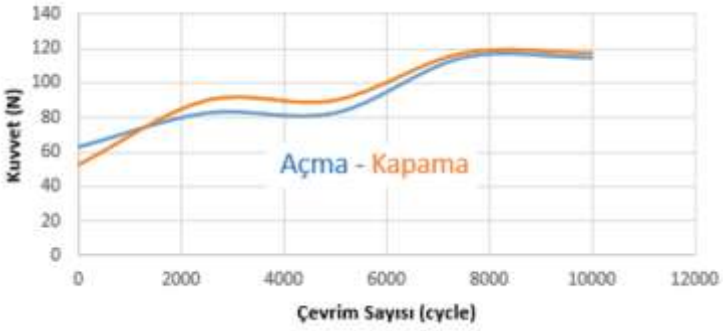
Şekil 6. Sonlu elemanlar analizi sonucu maksimum eşdeğer gerilme ve toplam deformasyon sonuçları

Analiz sonucunda doğrulanan muavin koltuğunun prototip imalatı gerçekleştirilmiş ve testler ile doğrulama aşamalarına geçilmiştir. Bu kapsamda prototip koltuğa öncelikle ECE R14 regülasyonuna uygun olarak emniyet kemer çekme testi uygulanmıştır. Yapılan testler sırasında 35 kg ağırlığa sahip koltuğa ECE R14 normlarına uygun olarak 458-689 kgf arasında değişen kuvvetler 6 farklı bölgeden pistonlar yardımıyla uygulanmıştır. Yaklaşık 6,5 sn. boyunca uygulanan bu kuvvetlerle koltuğun dayanım performansı sınanmıştır (Şekil 7). Regülasyon gereği maksimum yer değiştirmenin 336 mm olması gerekmektedir. Yapılan test sonucunda maksimum 210,94 mm'lik deformasyon olduğu gözlenmiştir. Bu sonuç koltuğun ECE R14 regülasyonuna uygun olarak yapılan testleri başarı ile geçtiğini göstermektedir.



Şekil 7. FKT Test Merkezi - ECE R14 Emniyet Kemeri Çekme Testi

Ayrıca döner mekanizmanın ömür testleri de gerçekleştirilmiştir (Şekil 8). Yapılan testlerde Pnömatik tahrikli bir piston yardımı ile 10000 dönüş gerçekleştirildiğinde koltuk yapısı üzerinde herhangi bir kalıcı deformasyon, çatlak oluşumu ya da fonksiyon kaybı gözlenmemiştir.



Şekil 8. FKT Test Merkezi – Ömür Testi

4. DEĞERLENDİRME

Bu çalışmada tasarımsal revizyonlar sonucunda daha hafif ve otobüs içinde alan tasarrufu sağlayacak bir muavin koltuğu geliştirilmiştir. Mevcut muavin koltuğunda sabit ayak yerine döner dişli mekanizması kullanımı sayesinde yaklaşık olarak %12 daha hafif ve 800 cm2 daha az yer kaplayan yenilikçi bir muavin koltuğu geliştirilmiştir. Ortaya çıkan yeni tasarım öncelikle ECE R14 normlarına uygun olarak sonlu elemanlar analizleri ile doğrulanmış, sonrasında prototip imalatı gerçekleştirilerek emniyet kemer çekme ve ömür testlerine tabi tutulmuştur. Yapılan sonlu elemanlar analizleri sonucunda 204 mm'lik bir toplam deformasyon gözlenirken bu değerin testlerde 210 mm civarında olduğu gözlenmiştir. Bu sonuçlar analizlerde kullanılan modelin doğrulama amacı ile kullanılabileceğini göstermektedir. Ayrıca, prototip koltuk uygulanan ömür testlerini de herhangi bir fonksiyonellik kaybı ve hasar oluşmaksızın başarı ile geçerek seri imalata hazır hale gelmiştir.

Yapılan tüm testlerden geçer not alan koltuk her ne kadar şehirlerarası ulaşımda kullanılacak olsa da şehir içi toplu taşıma araçlarında da kullanım potansiyeline sahiptir. Özellikle kalabalık metropollerde sürdürülebilir ulaşım küresel ölçekte önemli bir sorun haline gelmiştir. Bu soruna çözüm olarak Hollanda-Amsterdam şehir içi ulaşım modeli motorize olan ve olmayan araçların birlikte kullanıldığı güzel bir örnektir. Yukarıda bahsedilene benzer veya daha gelişmiş hareket serbestliği ve alan tasarrufuna sahip olan koltuklar yaygınlaştıkça özel araç kullanımı yerine bisiklet vb. araçlarla birlikte toplu taşıma kullanımı tercihi artabilir. Bu da yeşil enerjiye geçiş sürecinde küresel iklim krizinin çözümüne yapıcı katkı verirken mega şehirlerdeki trafik sorununa azaltıcı yönde etki edebilir.

ABSTRACT

The uniformity of a tire shows the dynamic mechanical properties of the tires. Many measurement standards and test conditions have been defined and accepted by vehicle and tire manufacturers. Among them, variation of strength, change in geometry and mass change are the main parameters in these standards for the tires. In this work, we will focus on comfort concept in vehicles related with tire and tire forces affecting the vehicle dynamics. The producers performing measurements of uniformity on tires with the aim of identifying tires, which do not meet the standards accepted by the market. Tire manufacturers always try to improve the levels of tire uniformity to get more performance from product and to meet the demands of the vehicle manufacturers.

During the production of a tire, ach imperfection generates a deviation with respect to an ideal tire. These differences lead to a non-uniformity in the tire. A poor uniformity of the tire will produce a variation of forces applied by the tire to the vehicle. These force variations will be constant for each revolution of the tire. Cause of this periodicity, the tire will generate constant vibrations depends on the speed value. Thus, these vibrations effect plastic and acoustic comfort of the vehicle. For a long term, the discomfort will start to increase and create deformation on the vehicle parts. Therefore, comfort concept and tire forces should be known and kept within the limits defined by uniformity standards.

Keywords: Tire uniformity, tire parameters, vehicle comfort, vehicle dynamics

1. INTRODUCTION

Tires are the only element of contact between vehicle and road. Being that, they are the first elements of the suspension system, which have to absorb road roughness. Comfort can be divided into two subgroups as plastic and acoustic comfort. Ride comfort is mainly affected by the distribution of weight between sprung and unsprung masses. Generally, a body fluctuates less if the sprung mass is higher. For better understanding, an illustration can be seen in Fig. 1.

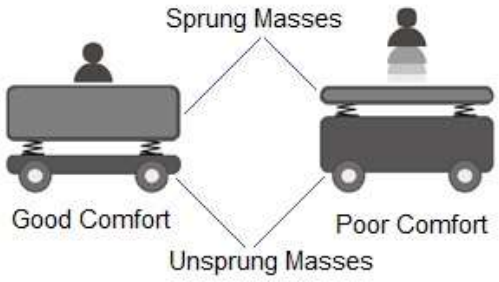

Figure 1. Comfort situation depends on sprung and unsprung masses

"Ratio between sprung and unsprung masses" is defined as the ratio between the total weight of the unsprung masses and the total weight of sprung masses. The higher the ratio means the greater comfort and dynamic stability. Generally, minimum expectation from this ratio is to be greater than five.

1.1. Plastic Comfort

Plastic comfort is the property of the tires to absorb road roughness minimizing the transmission of the various disturbances to the passengers inside the vehicle. They are mainly determined by the tire construction, in particular sidewall height and structural stiffness. In Fig. 2, some tires are shown that have different sidewall height.

Figure 2. Tires with various sidewall height

Generally, harder sidewall means more rigid structure and it causes lower plastic comfort. The driver will feel an added sense of directness of steering response with a sharp grip. Softer sidewalls have more comfort since they can absorb road roughness. The driver will feel a softer, but more comfortable, steering response. Plastic comfort is directly influenced by ultimate vibrations due to a tire not properly "balanced". A proper balancing can usually eliminate these sources of vibration.

1.2. Acoustic Comfort

Acoustic comfort is the property of tires, which can roll, at any speed, with the lowest possible noise emission. Car and tire producers can offer vehicles in which the ride, even at high speeds is very quiet with an accurate design and testing. This noise reduction is obtained with acoustic insulation of the engine and of the exhaust system, an appropriate vehicle aerodynamic and an appropriate tire design. Investigations on tire design have shown us three main noise sources caused by tire. These are tread element vibration, carcass vibration and air resonance & pumping as shown in Fig. 3.

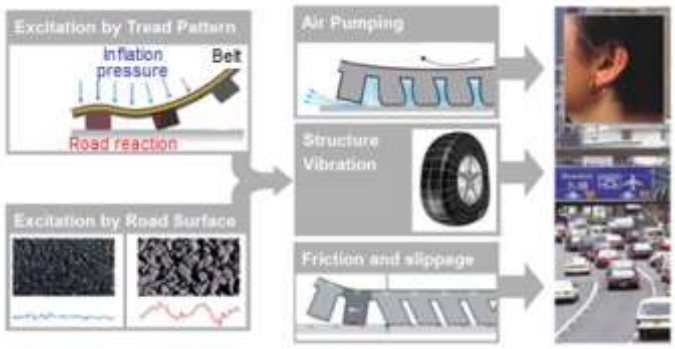

Figure 3. Noise sources caused by tire

Tread element vibration is produced by the collision between the tread blocks and road or the roughness of road. On the other hand, carcass vibrations are generated in the carcass as the tire interacts with the road macro texture. And air-resonance & pumping are another noise sources because of the air captured by the tread elements, etc.

Acoustic comfort is affected directly by many external factors like road conditions. The road, depending on the type and condition of the asphalt, contributes to the generation of noise. The new self-draining asphalts though increasing wet safety transmit more noise. While designing a tire, noise is also an important element taken into consideration and tread patterns are developed that can minimize rolling noise emissions. Tread patterns characterized by geometric blocks have been replaced with patterns characterized by smoother lines and grooves that are appropriately dimensioned to minimize noise without impairing wet performance. In Fig. 4, tire design patterns are shown.

Figure 4. Tire tread design patterns

The shape of tread grooves is one of the elements contributing to a good level of acoustic comfort. Grooves with sharp edges cause more noise emissions than grooves with smoother edges. To minimize rolling noise emissions, one can

exploit the concept of variable pitch sequence, in which the blocks vary in length along the circumferential direction. The larger the number of pitches, the larger the acoustic comfort. The sipes in tread blocks have effect on the acoustic comfort since they "act" on the frequencies of the noise emissions. Nowadays noise, as noise emissions, has become increasingly important as an objective evaluation performance characteristic. It is considered as a form of environmental pollution. The current situation as well as psychological trend is to reduce pollution cause of vehicle noise emission as much as possible. Therefore, car producers place great attention in the noise performance of the tire.

2. TIRE FORCES

Tire forces are classified into three groups as radial force, lateral force and longitudinal force. Directions of the forces are shown in Fig. 5.

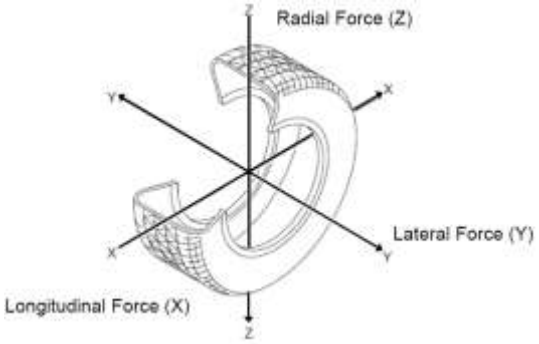

Figure 5. Tire forces

Within these forces, radial and lateral forces are more effective on comfort and vehicle dynamics.

2.1. Radial Force

Radial Force is the representation of the vertical force generated by the tire in contact with the road.

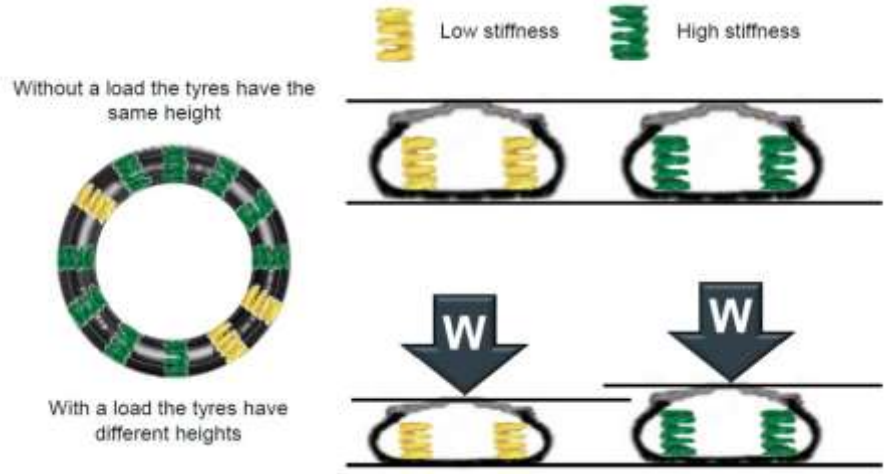

Figure 6. Tire force variation basics

The force variation of a tire can be represented, for ease of understanding of the concept, by the use of springs. Springs with different stiffness generate different thrust forces. The greater the stiffness, the greater the thrust. Without application of a load a tire may not exhibit non-uniformity. Thus in Fig. 6. the representation of forces by means of springs, there will be springs of different force which have the same height. With the application of a load W, tires with different vertical stiffness react differently.

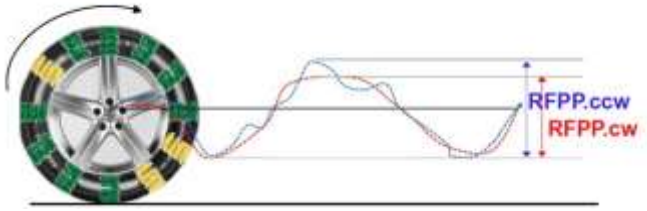

Figure 7. Tire radial force variation

During use, a tire is subject to a load (weight of the car). Rotating, the tire transmits its non-uniformity to the car via force variations. The radial force variation during a complete revolution of the tire with constant control conditions (conformation pressure, load, contact surface, distance from center of the wheel and road, etc.) from the maximum to the minimum point is called RFPP. For complete control the tire, it is measured in both the clockwise and the counter-clockwise direction. The RFPP value measured in the clockwise direction is called RFPP.cw while the RFPP value measured in the counter-clockwise direction is called RFPP.ccw as shown in Fig. 7. The RFV value attributed to the tire corresponds to the worst (greater) value of the two measurements.

These variations can also be increased. In particular, frequency ranges related to the speed of rotation of the tire, combining with frequency ranges of other rotating vehicle components and increase the overall negative impact on the behavior of the vehicle itself. The evaluation of such non-uniformity is measured as “force variation”, that is the load or force which should be applied to the tire to obtain a constant deflection or compression around its circumference. Radial force variations are generally speed dependent. A very accurate balancing of the tire and rim assembly is needed, as an unbalance of only a few grams could result in force variations at high speeds in the same order of magnitude as the force variations of the tire itself. Changing the load or inflation pressure will change the force variations. According to tire type, maximum limit of the RFV is changing between 110 N and 330 N. From car line to SUV line the limit is increasing.

2.2. Lateral Force

A perfect tire will follow a straight-line course during its revolution. In reality, this does not happen and the tire will tend to follow a non-straight course, thus generating lateral force. The lateral force variation during a complete revolution of the tire with constant control conditions (pressure of conformation, load, surface contact ...) from the peak to the trough is called LFPP or LFV.

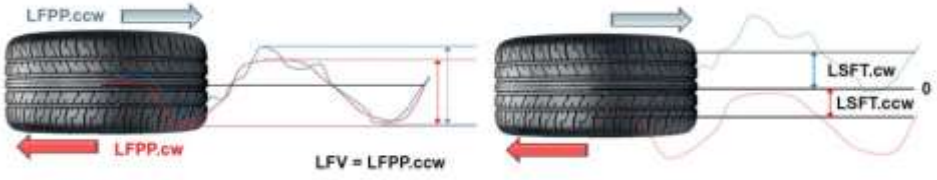

Figure 8. Tire lateral force variation and lateral shift

The LFPP in practice represents the amount of force that the tire will exert upon contact with the road to deviate from a straight-line course during a complete rotation. For proper evaluation of the tire the LFPP value should be measured in both directions. The lateral force peak to peak values will be defined as LFPP.cw for the measurement made in a clockwise direction and LFPP.ccw for the measurement made in a counterclockwise direction. The tire will be attributed with the worst result of the two measurements. From a physical point of view, the LFPP values are measured with values of different media. Depending on the direction of rotation, the tire shows different central values. When the tire is measured on the control machine, a stabilization period elapses before the mean value of the lateral force is calculated. The mean lateral force is called lateral shift or LSFT as shown in Fig. 8. For a perfect tire, it is not sufficient to have a low lateral force variation (LFV), but it is also important to check the mean lateral force values for both directions of rotation. The LSFT values are analyzed on two parameters as conicity and ply steer. According to tire type, maximum limit of the LFV is changing between 80 N and 150 N. From car line to SUV line the limit is increasing. Comparing with the RVF, we can easily see that, the LFV limits are narrower that RFV.

2.2.1. Conicity

A non perfect tire shows not equal LSFT values in clockwise and counterclockwise directions. The mean value of the difference between the two measurements will indicate the mean lateral force generated by the casing. This parameter is defined as "conicity". Conicity is easily associated to the effect produced by a tire with a truncated conical shape.

Figure 9. Tire conicity and effect of force

Depending on the geometry of the tire, a force will be generated towards the apex of the cone and will be independent of the direction of the tire. By definition, conicity is a force component that does not change direction with the direction of rotation as shown in Fig. 9. The same type of effect can be achieved by applying camber to the car. For this reason, conicity is often referred to as "pseudo camber". Conicity is noticeable primarily on the front axle of the vehicle, this being the steering axle that gives direction to the car. On the rear axle will cause a slight off-set that causes a misalignment between the front and rear axles. This effect has practically no impact on ride comfort. A car subject to a "pulling" effect will force the driver to continuously correct the steering, resulting in reduced driving comfort. Pulling effect is shown Fig. 10.

Figure 10. Pulling effect of tire conicity

The causes that lead to conicity problems in a tire can be grouped as geometric problems, different diameters of the left and right sides of the tire. Vertical rigidity problems, differing vertical rigidity on left and right sides of the tire. Tire build problems, effects from assembly in the building area or effects from vulcanization. Problems on works in process, components that are asymmetric or show different thicknesses. According to tire type, maximum limit of the “Conicity” is changing between ±70 N and ±90 N. From car line to SUV line the limit is increasing.

2.2.2. Ply Steer

The mean variation of lateral deviations is called Ply Steer. The value is calculated by measuring the sum of LSFT.cw and LSFT.ccw and taking the mean value. Being a project value, it is generally is not selected in control machines. This component of lateral force variation describes the influence of a tire in generating forces that could steer a vehicle from a straight path. Ply steer, by definition, is a force component that changes the direction of reverse rotation, when measuring the tire lateral force variations. For this reason, ply steer is often referred to as "pseudo slip".

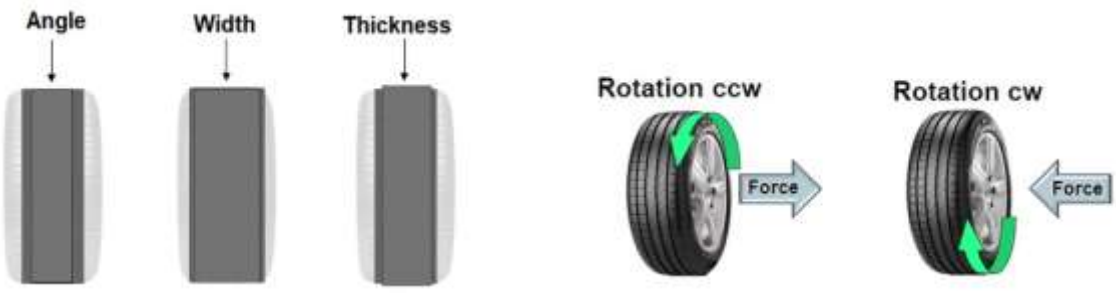

Figure 11. Causes of ply steer and its effect of force

Ply Steer is a force that is relative to the tire direction of travel. This is the reason why it is a force component that changes direction with variation of the direction of travel. Ply steer is a characteristic that is defined in the design phase and depends mainly on the belt characteristics. Cause of ply steer and its effect of force is shown in Fig. 11. increasing.

CONCLUSION

Within this work, we have seen that vehicle comfort, in addition to vehicle design, also depends on some tire parameters. These tyre parameters are affected from design and operational factors of the tire.

As a design factors, tire construction and tread design are very important. As operational factors, wheel speed, tire load, tire inflation pressure, pavement surface and steer angle are also affect the vehicle comfort. To get desired comfort and vehicle dynamics, tires should be produced within the defined tire standards. Additionally this work purposed to create an information for intelligent tire sytems that try to collect data from tire sensors about tire conditions and tire forces. In future works, these collected data and this investigation can be used to by tire and vehicle dynamics researchers to improve the ride comfort.

ACKNOWLEDGEMENTS

This investigation has been supported by Pirelli Otomobil Lastikleri R&D center. All uniformity control machines test results and documentations have been used while preparing this work with permission of the company.

ABSTRACT

The manual coating process for automotive weather-strip is quite complex and many factors affect the coating performance. In order to efficiently develop and improve manual coating application, it is crucial to analyses the several factors affecting their performance. Therefore, design of experiment is a functional statistic method that is used to perform operations effectively.

The aim of this study is to determine how the manual application conditions affects the coating coverage, thickness and the most importantly the coating curing level which are linked with the coating performance. For this purpose, the influence of spray distance to part, spray gun movements, part temperature before coating and after coating on the performance of coating were studied. The effect of these factors on the coating performance was determined by using a 2-level factorial experimental design on Minitab 17. As a consequence, the mathematical model is obtained through analysis of factors and determine the importance of the main effects of variables as well as their interactions on the coating performance.

Keywords: spray coatings, manual application, coating performance, weather-strip seal, design of experiment

1. INTRODUCTION

Automotive weather-strip seal (see in Figure 1) is typically composed on EPDM (ethylene propylene diene monomer) rubber due to its superior heat and ozone resistance. Additionally, low friction and high abrasion resistance are the key requirements for an automotive sealing system. Nevertheless, EPDM presents high friction in contact with glass during application. In order to reduce the friction behavior and increase the abrasion performance between rubber and the substrate (glass), an offline (manual) or online (in extrusion) coating applications are used quite widely in sealing systems. Therefore, Ginic-Markovic et al. define the polyurethane (PU) water-based coating as the most ideal coating type for application to the automotive EPDM substrate [1, 2].

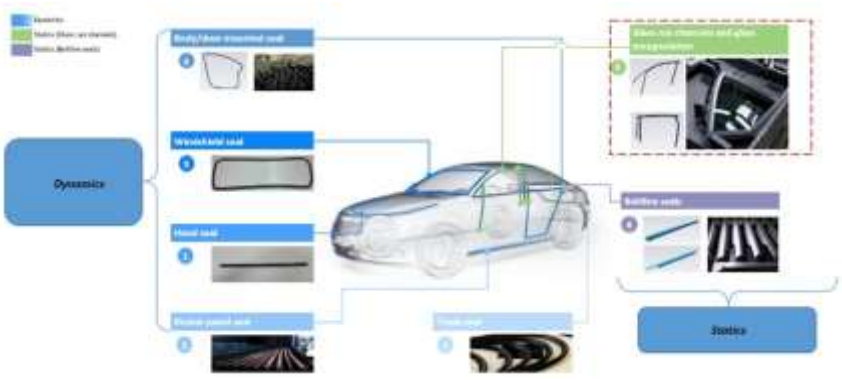

Figure 1. Sealing systems in a vehicle

Coating material is used for improving hydrophobicity, preventing or retarding the wear on surfaces of profiles as well as enhancing the appearance in addition to its high friction and abrasion performance. Key properties of coating material are controlled friction values, abrasion and wear reduction, noise reduction and suppression, chemical resistance, waterproofing and stain resistance, weathering, freeze release and easy fitting.

Coatings are applied during production with spraying method onto the rubber surface followed by curing in an industrial heat process [1]. In order to achieve high performance provided by the PU coating, it is important to ensure that the coating is applied to the EPDM substrate as required and cures properly. In manual coating application, covering the substrate surface homogeneously and providing the required dry film thickness (DFT) are the main building blocks to be considered. Basic image of a coated material is shown in Figure 2. After the spray application, the substrate surface temperatures before and after the coating are checked to ensure that the curing level is appropriate.

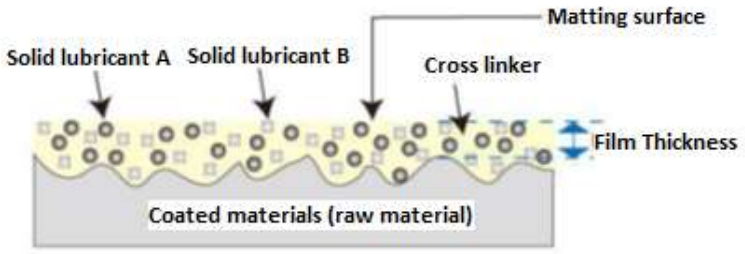

Figure 2. Coated material

In the manual coating process for automotive sealing systems, many factors affect the coating performance. To efficiently develop and improve manual coating application, it is crucial to analyze the various factors that affect their performance. Therefore, in this study, experimental design was evaluated as a functional statistical method used to perform operations effectively. Basically, this study is focused on the spraying method and cure behavior of the coating using statistical design of experiment methodology.

Statistical design of experiments (DoE) is powerful approach to optimizing chemical and also industrial process [3]. Typical type of DOE is given in Figure 3. This approach determines not just the main effects of each factor but also the interactions between the factors.
In DoE method, process variables are first screened to determine which are important to the response variables. Second step is the optimization, when the best settings for the factors are determined [4]. Thus, the objective of this study is to apply the design of experiments technique on manual coating application conditions in a process of automotive industry. For this purpose, the effect of following inputs on the coating performance was studied by using 2-level factorial experimental design on Minitab 17;

A. Spray distance to parts,
B. Spray gun movements (number of cycles),
C. Before surface temperature
D. After surface temperature

Coating coverage, DFT, curing level and gloss were selected as response variables which are linked with the coating performance. Room and inside coating cabin temperatures were noted as covariates in DOE.

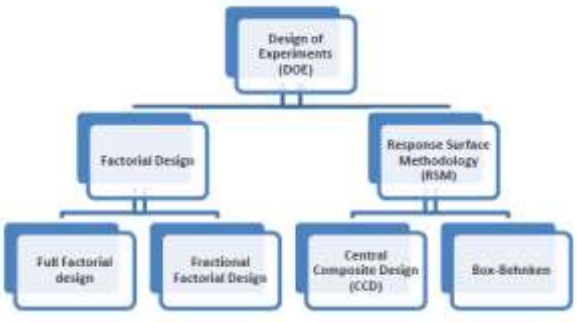

Figure 3. Type of design of experiments [5]

2. EXPERIMENTAL PROCEDURE

Process trials are performed on coating cabin including infra-red (IR) heaters and via Devilbiss GTI Pro Lite spray gun with 1.8 mm nozzle size given in Figure 4. Sponge EPDM rubber substrate is used. Spray pressure, pulverization and

air pressure of spray gun is adjusted as manual by pattern formation study (Figure 5) and kept stable as possible. PU water-based coating is used in the study.

Figure 4. Images of used coating cabin and spray gun

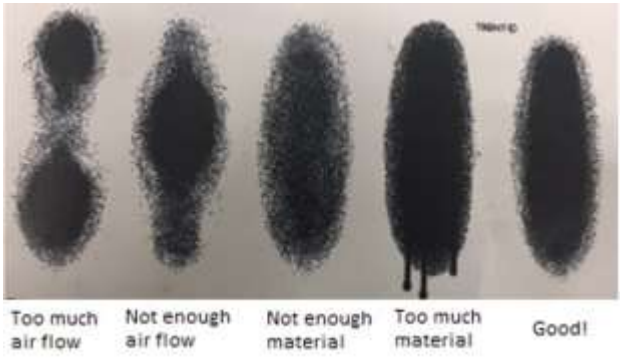

Figure 5. Spraying pattern scale

Two DoE plans are created using statistical package program: Minitab 17. For each factor, low, mean and high values were determined and DoE plans were created consequently. DoE methods are performed as screening experiment to determine the boundary conditions of coating thickness. DoE studies include 4 factors, 22 runs, 2 blocks and 6 center points.

Factors and levels of 1st DoE are given in Table 1.

Table 1. DoE plan of 1st study

Factor	Name	Low level	Mean level	High level
A	Spray distance, cm	10	20	30
B	Number of cycles	4	7	10
C	Before coating temp, °C	40	70	100
D	After coating temp., °C	150	165	180

In 1st DoE, A and B factors are adjusted and applied as manual. C and D factors are obtained by trial-error method and part peak temperatures inside the cabin were measured with Thermax® temperature stickers. Therefore, process set conditions of 1st DoE study (Infrared, IR level and time) are determined and given in Table 2.

Table 2. Process set conditions of 1st DOE study

Process step	IR, %	Time, sec	Surface temp., °C
Before coating application	65	10	40
	65	20	70
	65	22	100
After coating application	65	80	150
	65	83	165
	65	90	180

In 2nd method, the levels of factors A and B were revised and recreated according to the results of 1st DoE experiment. The factors and levels are given in Table 3.

Table 3. DoE plan of 2nd study

Factor	Name	Low Level	Mean Level	High Level
A	Spray Distance, cm	20	25	30
B	Number of cycles	3	5	7
C	Before Coating Temp, °C	40	70	100
D	After coating temp., °C	150	165	180

A and B factors are adjusted and applied as manual. C and D factors in the 1st study was checked by repeating the process conditions. However, the temperatures were obtained off spec. Therefore, the process conditions were re-adjusted to achieve the determined surface temperatures. Process conditions of 2nd study (%IR and time) are given in Table 4.

Table 4. Process set conditions of 2nd DOE study

Process step	IR, %	Time, sec	Surface temp., °C
Before coating application	65	10	40
	65	20	70
	65	22	100
After coating application	65	40	150
	65	60	165
	65	65	180

3. MEASUREMENTS AND EQUIPMENT USED

Measurements performed were used as a tool for researching the coating performance. Coating coverage and DFT are analyzed by Zeiss Optical Microscope under UV light. Curing test is used to determine the degree of cure of the coating with a specified solvent using SDL Atlas M238BB Crock-meter. The gloss measurements (60°) are realized by BYK micro-gloss Glossmeter.

4. RESULTS AND DISCUSSION

After the coating operation was performed, the profiles were conditioned for 24 hours under 23±2 °C before being tested. In experiments, DoE steps are applied according to Run Order and coverage, dry film thickness, curing, gloss analyzes are performed and results are given in Table 5.

Table 5. DoE results of 1st study

As a result of 1st study, DFT values were changed between 12 and 22 microns (Figure 3). Targeted DFT for used polyurethane coating must be 9-15 microns, therefore new 2nd DoE plan were created as defined in Table 6 according to thickness values of contour plot graph in Figure 5. Levels of A and B factors have been revised so that it is within the required coating thickness range. It is predicted that spray distance should be changed between 20 to 30 cm, and number of cycles should be changed between 3 to 7 cm in order to obtain targeted DFT of 9-15 microns. Consequently 2nd DoE plan were created accordingly.

**1: Full coverage, 0: Poor coverage*

*** 1, 2: Not OK, 3, 3.5: Conditionally OK, 4, 4.5, 5: OK*

As a result of 2nd DoE study, it was obtained targeted coating thickness values of 9-15 microns with determined input levels of spray distance and cycle, as seen in contour plot graph given in Figure 6.

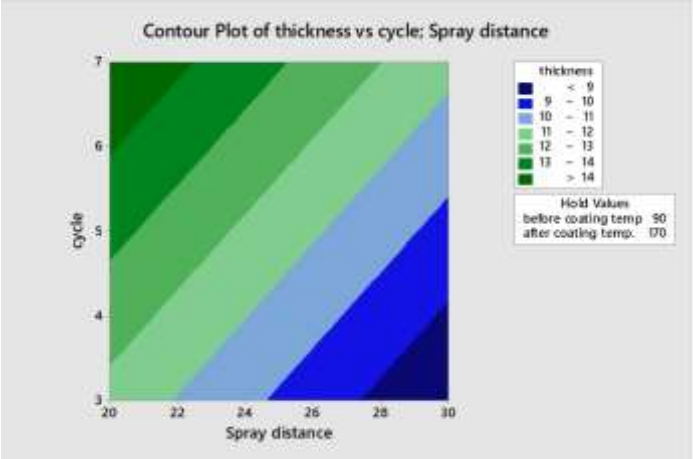

Figure 6. Contour plot of thickness vs cycle; spray distance of 2nd study

In order to reach minimum gloss, maximum curing level, 12 microns targeted thickness and maximum coverage; optimum process conditions were obtained as follows (see in Figure 7);

A. Spray distance : 20 cm
B. Number of cycles : 4
C. Before coating temp : 80 °C
D. After coating temp. : 170 °C

Above optimum conditions are valid when cabin temperature is 30 °C.

Even if the targeted levels were reached in coverage, thickness and gloss when these optimum conditions were applied, the same relationship could not be achieved for the coating curing level. The reason for this can be thought of as the vulcanization level of the sponge EPDM is not sufficient. If the sponge injection does not cure under sufficient conditions, it affects coating performance.

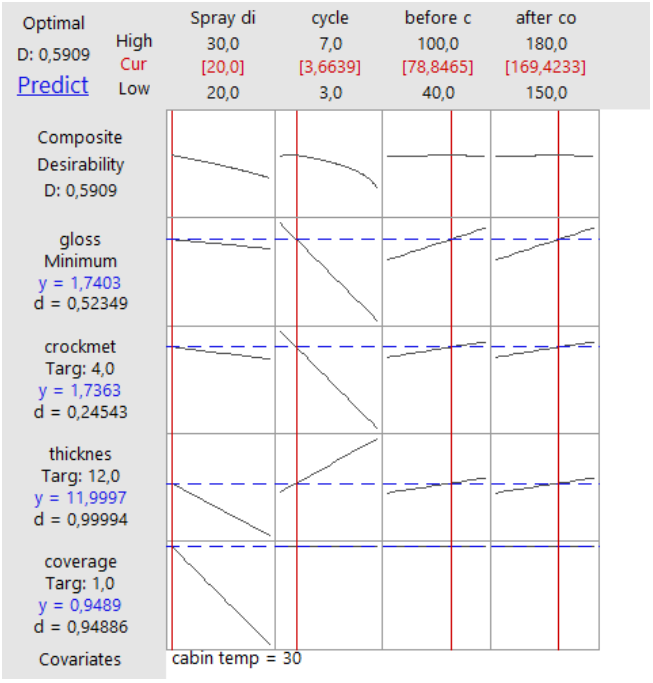

Figure 7. Optimum process conditions

5. CONCLUSIONS AND RECOMMENDATIONS

In this study, the effects of coating application conditions on coating performance by using design of experiment method was investigated. As a result of DoE studies, optimum process values for coating application was obtained as follows when cabin temperature keep stable as 30 °C;

A. Spray distance : 20 cm
B. Cycle : 4
C. Before coating temp : 80 °C
D. After coating temp. : 170 °C

Within the scope of this study, following recommendations are determined to perform coating process efficiently;

- Spray gun adjustment: spray pressure & air pressure need to be measure in order to obtain homogeneous coverage and required DFT.
- The necessity of temperature control system: Surface temperatures in the coating process must be kept under control with the PID controller system.
- Set up a regulator system for screening and controlling spray and air pressure.
- Need to be make sure rubber vulcanization conditions.

TYPE OF GEOMETRY PARAMETERS IN TIRE UNIFORMITY

Semih Öngir[1], Hüseyin Metin Ertunç[2]

ABSTRACT

A tire, in addition to not generating vibration problems, must not have structural and aesthetic problems. Geometry control serve to identify aesthetic problems and to ensure the integrity of the tire in use. Even if the geometry is not directly associated with vibration problems, the market perceives geometric non-uniformities as vibration problems. This association exists because tire specialists are able to "see" geometry problems but are not capable of measuring the stiffness parameters (or forces) of a tire (only some machines are capable of measuring stiffness parameters, but not with methods that can be associated with those performed on the uniformity control machines currently in the factories). A correlation can exist between geometry and forces. This correlation is high on tires that show high values of radial runout, so complaints about vibration problems often also show geometric problems.[1]

In this work we will focus on tire geometry parameters, their limits according to standards and their effect on vehicle. Also we will investigate the measurement methods of these parameters. Recently research show us geometry parameters are not effected by pressure, force and speed changes during the usage.[2]. For these reason geometry parameters problems have to be fixed during the production. Purpose of this work is increase the knowledge of the tire parameters and combine the know how with automotive sector. Knowing type of geometry parameters in tire uniformity controls will serve all players in this area.

Keywords: Tire geometry, tire geometry control, tire geometry measurements

3. INTRODUCTION

One of the most important point in tire uniformity is geometry of the tire. To get comfortable ride on the vehicle, tires have to be in uniformity limits, defined by standards. Before using the tires on the vehicle, they have to be controlled with uniformity control machines.[2] Generally, these controls are made in tire production area. To make these controls, first we have to know, which parameters are effect the tire. Then we can fix the problems on the tire, depends on the measurement results.

4. GEOMETRY

Geometry parameters of the tire can be investigated mainly as radial runout, spot, bulge & depression, lateral runout, and wobble.

4.1. Radial Runout

A tire must be geometrically circular and concentric with respect to its axis of rotation. It must show the least possible variation in the rolling radius. The variation between the minimum radius and the maximum radius measured during a single revolution of the tire is defined radial runout (RRO). It is shown in Fig. 1.

Figure 1. Radial runout on tire

An excessively high radial run-out value has a negative effect on comfort, in the form of vertical vibrations on the steering wheel and the vehicle chassis. The RRO value can be measured with a measuring instrument by rotating it slowly around the circumference of the tire, which is mounted on a rim and inflated to operating pressure. Different systems exist for the measurement of radial runout. The measurement techniques have become increasingly precise, with greater adjustability and greater scope for analysis of the information. Some measurement methods are shown in Fig. 2.

Figure 2. Measurement systems for radial runout

The phenomenon potentially caused by RRO can be reduced so as not to create vibrations to the driver through "matching" between tire and rim. The tire can be mounted on the rim so that a "defect" in the tire is offset against one in the rim, thus creating a geometrically more correct assembly. During assembly, it is necessary to check the correct position of the tire bead relative to the edge of the rim. If the tire bead is not equidistant at all points, a vibration may occur, caused by eccentricity (runout) deriving from the assembly of tire/rim. According to tire type, maximum limit of the RRO is changing between 0.8 mm and 1.3 mm. From car line to SUV line the limit is increasing. [1]

4.2. Spot

Analyzing the RRO signal of three tires represented in Fig. 3. It can be seen that all the signals are within the selection limits. This analysis, however, is not sufficient to define a tire as compliant to geometry requirements. From a qualitative point of view, although signal number three is within the RRO tolerance limit, it proves to be non-compliant and may create anomalies in use.

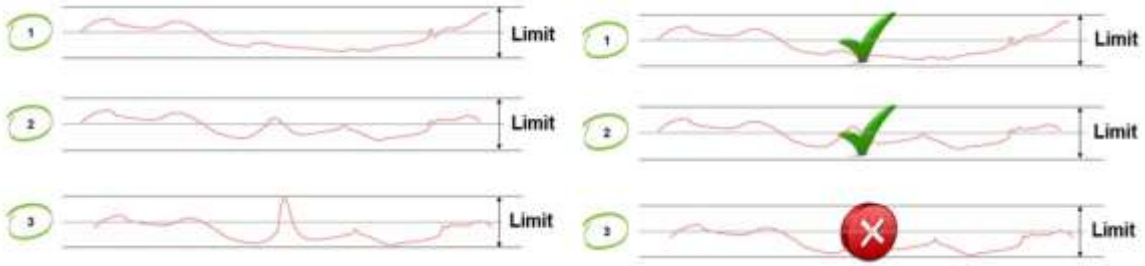

Figure 3. Sample RRO signals for three tires

In fact, the signal of tire number three shows a peak. A localized geometric peak can generate a noticeable vibration on the car. To remedy this type of problem, a control called as “spot”. In Fig. 4, comparison spot and RRO signal can be seen.

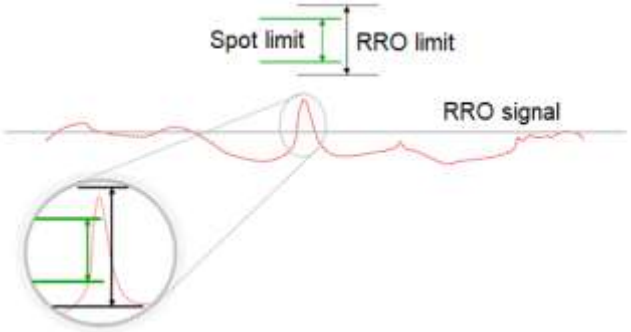

Figure 4. Comparison Spot and RRO signal

The “spot” checks the RRO value not for the 360° of the tire, but for a limited window. This window will be mobile and will cover the entire RRO signal of the tire. The applicable limit for this type of analysis will be narrower than that of the RRO. According to tire type, maximum limit of the “spot” is changing between 0.5 mm and 0.8 mm. From car line to SUV line the limit is increasing. [1]

4.3. Bulge & Depression

A geometric control on sidewall is made to check the tire integrity. The most critical part of a tire for this type of defect is the sidewall. Bulge and depression controls are implemented to try to identify the tire's structural problems, linked mainly to the assembly phase. In a revolution of the tire, controls are made to check whether localized irregularities are present on both sidewalls. Localized irregularities that show outward protrusions are called “Bulges”. Localized irregularities that show inward protrusions are called “Depressions”. Both parameters are shown in Fig. 5.

Figure 5. Comparison Spot and RRO signal

Bulge and depression parameters have the main scope of identifying structural problems in the casing or problems that may compromise its integrity. These controls are intended mainly to identify problems caused by fabric inserts and open or surmounted sidewalls. To make the control of bulge and depression more effective, the tire is inflated to a higher pressure than the operating temperature in such a way that defects will be amplified as shown in Fig. 6.

Figure 6. Amplified defect signals for bulge and depression

Using high pressure, greater than tire specification pressure, allows you to amplify the tires defects during the inspection cycle, which makes it possible to detect. The SOL laser is capable of giving a topographic mapping of the surface of the tire; it is also possible to use suitable filters to eliminate the problem deriving from the lettering. In Fig. 7, bulge and depression measurement with SOL sensor is shown. According to tire type, maximum limit of the Bulge & Depression is changing between 0.9 mm and 1.1 mm. [1]

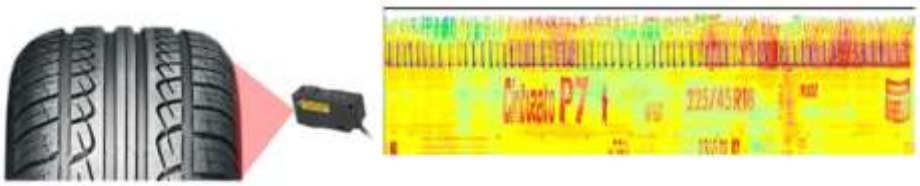

Figure 7. Measurement of bulge and depression

4.4. Lateral Runout

A tire is checked to see if the sidewall shows geometric variations that could lead to aesthetic problems. Both sidewalls of the tire are checked over an entire revolution as shown in Fig. 8.

Figure 8. Lateral runout on tire

The peak-to-peak measured values of the upper side of the casing are called LROPP.up, while for the lower side is called LROPP.dwn. The greater of the LROPP.up and LROPP.dwn values are called LRO. Although it is conceptually correct to check the variability of the sidewall of a tire, from a practical point of view there is no need for a selection based on this parameter.

The sidewall analysis is made through the calculation of the first harmonic value of LRO signals (LRO.up and LRO.down) and calculating the peak to peak of 1HLRO.up and 1HLRO.dwn. The greater of the peak-to-peak values for 1HLRO.up and 1HLRO.down is called 1HLRO. The 1HLRO identifies a maximum point and a minimum point set at 180° between them. In practice, it identifies the inclination of on sidewall with respect to an ideal plane perpendicular to the axis of rotation.

As previously stated, the end user or the tire specialist associates a geometrical problem with a comfort problem. An excessive LRO value can cause a “shaking” effect on the chassis, characterized by alternating left/right swinging of the steering wheel. The oscillation of the steering wheel only occurs at specific speeds, depending on individual car characteristics, because it depends also on the section width of the tire, the type of suspension and the steering system.

It has to be always checked the correct position of the bead centering rib with respect to the rim flange; if the centering is not correct at one point around the circumference this means that the tire bead is not perfectly seated, and rotation of the wheel will cause steering wheel shimmy. According to tire type, maximum limit of the LRO is changing between 0.9 mm and 1.1 mm. From car line to SUV line the limit is increasing. [1]

4.5. Wobble

As indicated earlier, the LRO checks whether the tire sidewall has an inclined surface, but the analysis is performed independently on each single sidewall of the tire.

Figure 9. Wobble on tire

This analysis could be insufficient to rule out problems (for lateral geometry problems) on a tire. The “wobble” parameter allows you to check the combined effect of the geometry of the sidewalls. The “wobble” is calculated starting with the measurement of the lateral runout signal for both sides (LRO.up and LRO.down curves). A subtraction must be made between the two LRO.up and LRO.dwn curves. The subtraction must take account of the angular position. The curves must be acquired having the same start and end point. The LRO.delta curve will be obtained. The first harmonic (1HLRO.delta) is calculated on the LRO.delta curve. The peak to peak of the 1HLRO.delta curve is the “Wobble”. It is shown in Fig. 9. Regardless of tire type, maximum limit of the “wobble” is 0.9 mm. [1]

CONCLUSION

To get more comfortable ride, we have to produce more rigid tires and we have to know all tire parameters to fix related problems caused by them. For this reason geometry parameters on tires has been investigated. Most effective geometry parameters are founded as radial runout, spot, bulge & depression, lateral runout, and wobble. For this reason these parameters have been investigated in detail. This investigation will be helpful guide for tire and vehicle producers while making a research on tire and vehicle dynamics.

ACKNOWLEDGEMENTS

This investigation has been supported by Pirelli Otomobil Lastikleri R&D center. All uniformity control machines test results and documentations have been used while preparing this work with permission of the company.

ABSTRACT

Nowadays, using Single or Two Speed Transmission Systems in electric vehicles is one of the trends in the commercial electric vehicle industry, because of their efficiency and performance properties. Single or Two Speed transmission systems are lighter, more efficient, and have a simpler design. The driving range is a big issue for electric vehicles. This study aims to maximize the driving range by making design and layout changes for single or two-speed transmission systems of SmartforFour electric vehicles. The performance parameters for optimization are chosen as gear ratio and gear type for the first optimization stage. These parameters are used as design variables for the optimization study. Initial gear ratio values of the SmartforFour are calculated by the data of the vehicle and theoretical formulas. Boundary conditions in optimization processes are acceleration, maximum speed values of the vehicle, and the dedicated slope value of the road. Optimization study is carried out by using the genetic algorithm in Simcenter Amesim and optimum gear ratio values for single speed and two-speed transmission are obtained. By using optimized gear ratios, the transmission systems are designed in a KISSSoft gear design software. As a result of this study, the driving range is increased between 1.8% and 8.6% in single-speed and two-speed transmission systems.

Keywords: Electric Vehicle, Powertrain, Optimization, Single Speed Transmission

1. INTRODUCTION

Electric traction vehicles are firstly introduced in 1888 by German engineer Andreas Flocken. The First system had a simple and not efficient small electric motor (URL 1). For a long time, electric cars have not appeared in the industry, because of some limitations. These limitations are especially about battery development and electric motor physical properties. These limitations caused internal combustion engine industry domination. Because of the domination of internal combustion engines, transmission systems evolved with internal combustion engine development.

In the last decade, the percentage of electric vehicle sales increased when compared with internal combustion engine vehicle sales (URL 2), (URL 3). Increased performance values of electric motors, battery systems, and emission regulations are reasons for this situation. The change in the power sources of the vehicles also led to the change and simplification of the powertrain components. For instance, because of the electric vehicle traction system's torque-rpm-efficiency properties, the transmission system has to be simpler and more compact. The main reason for this evaluation of transmission systems is electric motors do not need regulation like internal combustion engines and also there is no regulatory requirement for different revolution values (Hofman and Dai, 2010).

Transmission systems are mainly used to regulate the speed of the engine. Also, layouts and the design of transmission directly affect the driving range by this regulation. Therefore, it affects directly electric vehicle performance (Lange and Küçükay, 2020). To increase driving range, the design of the powertrain needs to be compact and more efficient, so the amount of gear sets needs to be less. For that reason, engineers developed systems called single-speed and two-speed transmissions for electric vehicles. In these transmission systems, gearset design requires a balance between maximum speed, performance, and range (Walker continued, 2013). Especially the range is commonly most studied topic in these systems.

Nowadays, the range of electric cars can reach up to 622 km with a new electric motor called synRM and for this motors simple, basic powertrain systems. This new type of simple and more efficient system is called single-speed or two-speed transmission. But in the electric vehicle industry single-speed transmission is more common when compared with two-speed transmission (Lange and Küçükay, 2020). Mainly, single-speed powertrain systems have sub-components. They are open-differential, idle gear, pinion gear, main gear, bearings, gearbox housing. This system has a one-speed transmission to provide the required torque for electric vehicles as shown in Figure 1. This system is also called a reducer, it reduces motor speed and increases torque. Furthermore, some types of small cars and micro-mobility use single-speed transmission. Most small vehicle systems using hub-type gear reduction as shown in Figure 1. For this study, a small vehicle powertrain is selected to optimize.

Figure 1. Tesla Single Speed Transmission (URL 5)

When the future trends for electric vehicles are investigated, it can be said that vehicle systems are in evolvement. With these investigations, a new type of electric vehicle is invested, which is called Smart Cars. The sales of these cars are increasing year by year. When the sales are compared, the graph shows that sales of Small Smart cars are increasing (Figure 2). Thus, the new trend of the mobility sector is more compact and more environmentally friendly vehicles.

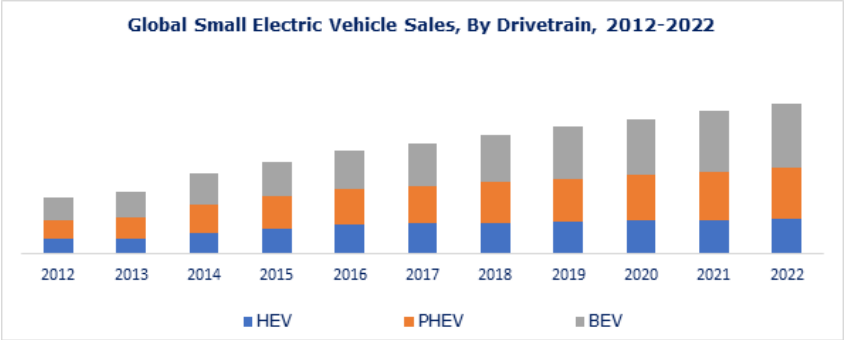

Figure 2. The global Small Electric Vehicle Market stood at 4.08 million units in 2016 and is expected to grow at a CAGR of over 8%, in volume terms, to reach 6.54 million units by 2022. (URL3)

2. OPTIMIZATION OF GEAR RATIO

2.1. Task Definition

The task of this paper is to design optimum single-speed and two-speed transmission systems with considering driving range as objective. To create these systems, firstly SmartforFour vehicle is selected as an investigation vehicle. Technical data for SmartforFour researched in literature. With technical data of the SmartforFour, the 1-D model of the vehicle is created in Simcenter Amesim program. This model helps to predict computer-based real-life situations. Then, formulas from the literature are used to find initial values of minimum and maximum gear ratios, and these values are integrated into the model. The 1-D Model aims to optimize the gear ratio in dedicated range for the SmartforFour. This range is related to the mathematically calculated gear ratios and manufacturing limitations. The gear ratio is optimized in the 1-D model with a range for gears. The optimization algorithm type of the process is the genetic algorithm. In literature, the manufacturable gear ratio range is 3 to 15 (Lange and Küçükay, 2020), (Walker continued, 2013). Because of that, in the optimization process minimum and maximum interval limits are 3 and 15.

With optimized gear ratios, the gearset layout, gear geometries, and types for one-speed and two-speed transmission systems are designed. In this design, SmartforFour vehicle electric motor's torque and rpm values are considered. While designing in the KISSSoft Gear Design program, the program considers material properties and contact areas for gears. By this analysis and design, geometries are generated and exported as CAD data.

2.2. System Defining

System defining methodology is firstly about defining technical properties of SmartforFour vehicle. The technical specifications of the vehicle are required for modeling the vehicle in a computer-based modeling program. These features are given in Table 1.

Table 1. Technical Specifications of SmartforFour Electric Vehicle (URL 4)

Engine Type	Electric
Maximum power - Output	60 kW
Maximum torque	160 Nm
Electric engine 1 type	Permanent magnet AC synchronous motor
Drive wheels - Traction - Drivetrain	RWD
Average energy consumption	13 kWh / 100 km
Battery Type	Lithium-ion
Battery capacity	17,6 kWh
Top Speed	130 km/h
Acceleration 0 to 100 km/h	12.7 s
Wheelbase	249.4 cm
Length	349.5 cm
Width	166.5 cm
Height	155.4 cm
Front Axle	146.9 cm
Rear Axle	142.9 cm
Front Tyres - Rims dimensions	165/65 R15
Rear Tyres - Rims dimensions	185/60 R15
Curb Weight	1200 kg
Acceleration 0 to 100 km/h	12.7 s

The 1-D Model of the SmartforFour is defined with technical specifications and components of the vehicle. The model is shown in Figure 3. This model helps to create a computer-based real-life vehicle model. This vehicle model contains driver behaviors, environment situations, vehicle control unit, electric motor, and battery components. These components are enough to predict real-life situations.

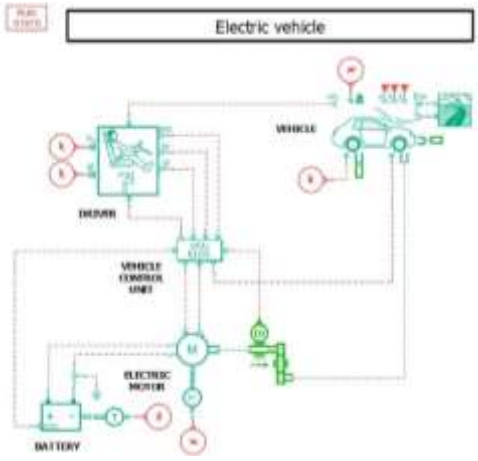

Figure 3. 1-D Modelling of the SmartforFour

When the literature investigated, the transmission system of SmartfourFour is a single-speed transmission, but there is no data about the gear ratio of this system. To create a system for gear ratio optimization, the initial values of the

minimum and maximum gear ratios are calculated from the following equations. Maximum gear value named considering by maximum torque requirement for dedicated slope. Minimum gear value named considering by maximum speed requirement. (Naunheimer continued, 2010), (Li continued, 2020), (Spanoudakis continued, 2020):

$$i_{A,max} = \frac{r_{dyn} * m_f * g\,[f_r * cos(\alpha_{st}) + sin(\alpha_{st})]}{T_{M,max} * n_{tot}} \quad (1)$$

$$i_{A,min} = \frac{3 * 6\frac{\pi}{30} * N_{M,max} * r_{dyn}}{V_{max}} \quad (2)$$

where, i_A is gear ratio, r_{dyn} is dynamic tire radius, m_f is vehicle mass, f_r is rolling resistance coefficient, α_{st} gradient angle, $T_{M,max}$ motor torque at maximum rpm, n_{tot} is powertrain efficiency, $N_{M,max}$ the maximum rotation speed of the motor, V_{max} the maximum speed of the vehicle. r_{dyn}, m_f, $T_{M,max}$ and V_{max} values are taken from Table 1. For the rough road condition f_r is chosen as 0.014. For a permanent magnet AC synchronous motor $N_{M,max}$ chosen as 1200 rpm at maximum torque. α_{st} and n_{tot} are selected as 16.7˚ and 0.76, respectively from the literature (Naunheimer continued, 2010).

These values are interval limits for gear ratio optimization. For single-speed transmission, optimization limits are calculated as maximum and minimum gear values. Thus, optimization limits for single-speed transmission are 5.06 and 7.73 respectively. On the other hand, because of the two-speed transmission layout, optimization limits are different values when compared with the one-speed transmission. For two-speed transmission systems, the first gearset is providing the required speed, the second gearset is providing the required torque. For the first gearset limits are, calculated maximum gear value and gear ratio value for minimum gear ratio producibility limitation. Moreover, for second gearset limits are minimum calculated gear ratio and gear ratio value for maximum gear ratio producibility limitation. Thus, for the first gearset optimization limits are 3.26 and 7.73, for the second gearset optimization limits are 5.06 and 15 respectively. More detailed information about gear ratio bounds can be found in literature (Walker Continued, 2013). The calculated initial values of minimum and maximum gear ratios and producibility limitations are given in Table 2.

Table 2. Calculated Minimum-Maximum Gear Ratios

	First Gear		Second Gear	
Transmission Type	Minimum	Maximum	Minimum	Maximum
One-Speed	5.06	7.73	-	-
Two-Speed	3.26	7.73	5.06	15.0

2.3. Methodology

As seen in literature, the most common algorithm which is used in 1-D Models is the genetic algorithm (McDonald, 2012), (Walker continued, 2013). For this reason, the 1-D Model of SmartforFour has been optimized by using the genetic algorithm as an optimization technique. This optimization process aims to maximize the range for the same battery usage. Parameters of the optimization process are; Population size, Reproduction ratio (%), Maximum number of generations, Mutation probability (%), Mutation amplitude, and seed. The values chosen for these parameters are 100,80,20,10,0.2,1 respectively.

By using optimized minimum and maximum gear ratio values, other geometric properties of gears are defined by KISSSoft Gear Design. While defining geometric properties of gears, the boundary conditions are maximum torque and maximum rpm that come from the electric motor. In literature, there are common types to create a layout for transmission systems which is about gear constructions and gear contacts (Sorniotti continued, 2011). With these relations and calculated geometric properties of gears, the computer-based three-dimensional model of the transmission systems is designed.

2.4. Results

The optimum values for min-max gear ratios obtained as a result of the optimization study using the genetic algorithm are given in Table 3.

Table 3. Optimized Max-Min Gear Ratios

Transmission Type	First Gear	Second Gear
One-Speed	6.6	-
Two-Speed	4.1	13

In the literature parameters to define gear model, gear ratios, and optimization are enough to create a CAD model. With these optimized gear ratios and results of the optimization processes, transmission systems are defined in three-dimensional geometric models as shown in Figure 4. These systems are for one-speed transmission planetary-spur gear set, one-speed transmission planetary-helical gear set, and two-speed helical transmission. As a result of these processes, gear ratios, gear measurements, and transmission constructions are designed for these systems. (Shen continued, 2017).

Figure 4. Three-Dimensional Geometric Model of The Gears; a) PSosT b) HtsT c) PHosT

The main aim of the study is range increase is achieved with optimized gear ratios and gear geometries. As shown in Figure 5, after the gear optimization for the Two-Speed First Gear ratio, the displacement is increased from 10080 meters to 10256 meters. This is a nearly 1.8% increase in the vehicle range.

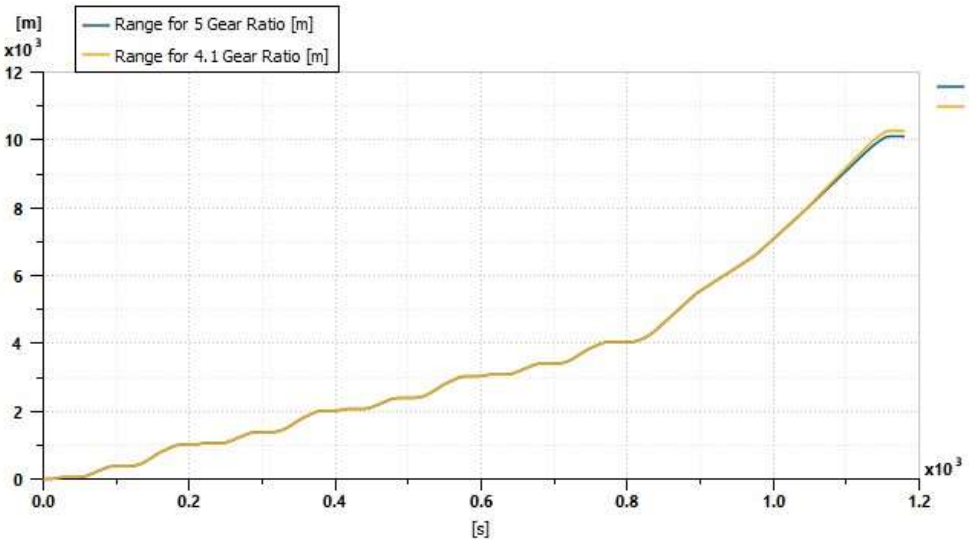

Figure 5. Displacement Difference Between 4.1 and 5 Gear Ratio for One-Speed System

After gear ratio optimization for One-Speed First Gear Ratio, the range is increased from 10080 meters to 10550 meters. This relation is shown in Figure 6. The percentage of this range increase is nearly 4.7%.

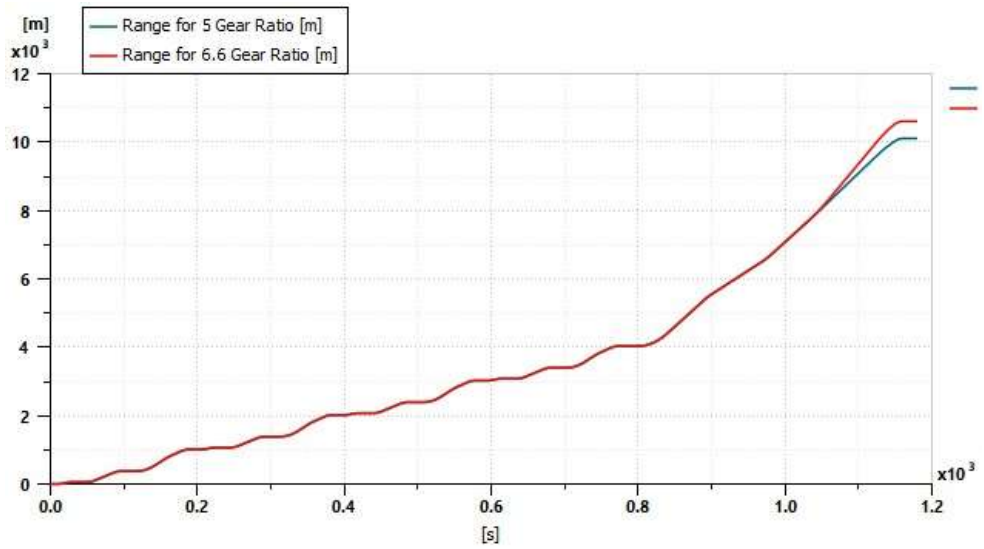

Figure 6. Displacement Difference Between 5 and 6.6 Gear Ratio for Two-Speed System

The two-Speed Second Gear ratio range difference that is shown in Figure 7 is from 10080 meters to 10950 meters. This increase of the range is nearly 8.6%. As seen all these three ranges increased results, the optimizations can be considered as successful.

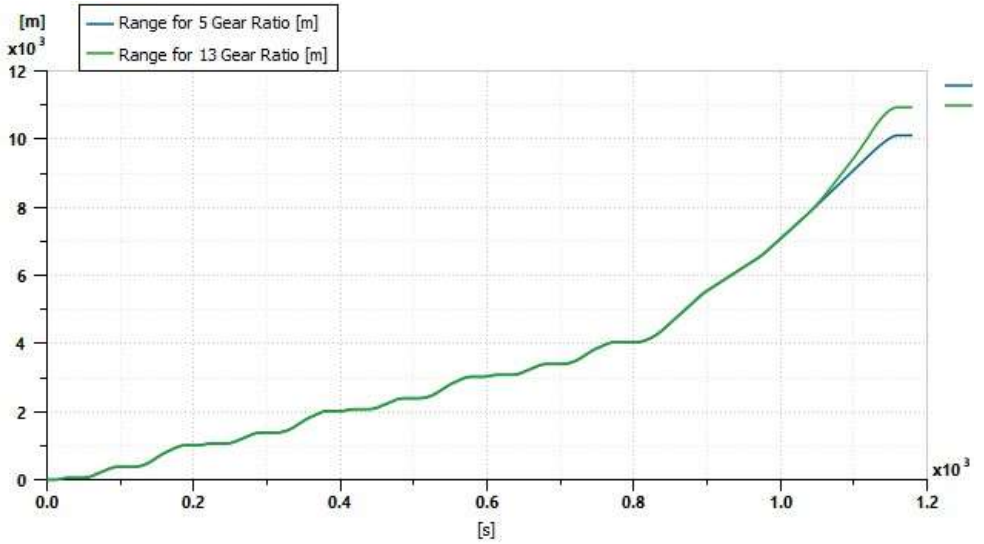

Figure 7. Displacement Difference Between 5 and 13 Gear Ratio for Two-Speed System

3. CONCLUSIONS AND RECOMMENDATIONS

This paper has considered the transmission system from many aspects and made it better from the initial design through continuous improvement. The subject of the paper included electric traction vehicles to the new type of transmission systems. These subjects included computer-based 1D modeling processes, contact and material analysis processes, geometrical optimization processes, and geometric CAD data generation.

With these processes, the gear ratios are calculated with mathematical formulas. After that, the system and calculated numbers are optimized in the light of efficiency and sustainability. There are two benefits of the study, which are increasing the performance criteria of the system and geometrically minimizing the transmission's measurements. After

these optimization processes, the gear ratio of the system is defined. By using optimized gear ratios, the gearset's CAD data generated. With these gear designs, the system has become producible and balanced in a mechanical way.

Simulation results of the project have shown that high efficiency in the transmission systems for smart cars' can be achieved in a theoretical way. On the other hand, what to be noticed about this paper is, there is no production yet in a real way, there are all computer data. The future plan of this paper is real-time production and making real-time efficiency measurements, but there is no guarantee about real-time situations will be all in the planned way that is shown in this paper. All the production procedures are considered, and all the geometric data are checked in computer-based programs, but the paper suggests that the test product must be produced at the beginning of the production.

ACKNOWLEDGEMENTS

This study is handled under the project named "Designing and Parameter Optimizing One and Two-Stage Shift Systems for to use in Electric Vehicles". This project is supported by TUBITAK (The Scientific and Technological Research Council of Turkey) with project number 1139B412000935 under the "TÜBİTAK 2209 - B Industry Oriented Research Project" program.

ÖZET

İçten yanmalı motorlarda hacimsel verim (volumetrik verim), aynı devirde bir motorun gücündeki artışı karakterize eden ana parametredir. Supapların çalışma özellikleri (açılma ve kapanma süreleri, kalkma yüksekliği, kam profilinin tasarımı) hacimsel verimi etkileyen parametreler arasındadır. Ancak her devir için aynı parametreleri kullanmak, farklı hacimsel değerler ifade etmektedir ve motorun çalıştığı devir için en uygun hacimsel verim değerini karşılamamaktadır. Bu sebeple, değişen motor hızına bağlı olarak supap çalışma parametrelerinin de değiştiği Sürekli Değişken Supap Zamanlaması (CVVT) gibi farklı teknikler geliştirilmiştir. Bu çalışmada, literatürde ilk defa piezonun uzama özelliğinden faydalanılarak içten yanmalı motoruın emme supabının direkt olarak tahrik edildiği deneysel bir yöntem kullanılmıştır. Piezonun mikron mertebelerindeki uzamasını supap kalkma miktarı mertebelerine çıkarmak için hidromekanik büyütücü kullanılmıştır. Tasarlanan bu hidromekanik büyütücüyü hareket ettirecek piezo eyleyiciyi çalıştırmak için de bir elektronik kontrol ünitesi ve yüksek gerilim güç kuvvetlendiricisi tasarlanmış ve daha sonra tamamen dijital çözüm geliştirilmiştir. Piezo ve hidrolik büyütücü sistemin içten yanmalı motor üzerinde çalıştırılması bu çalışmada açıklanmıştır.

Anahtar kelimelers: Piezo, piezo eyleyici, sürekli değişken supap zamanlaması, yüksek güçlü piezo sürücü

APPLICATION THE ELECTRONIC DRIVER OF PIEZO ACTUATOR USED FOR CONTINUOUSLY VARIABLE VALVE TIMING ON AN ENGINE

ABSTRACT

Volumetric efficiency in internal combustion engines is the main parameter that characterizes the increase in power of an engine at the same speed. The operating characteristics of the valves (opening and closing times, lift height, cam profile design) are among the parameters that affect the volumetric efficiency. However, using the same parameters for each revolution means different volumetric values and does not meet the most appropriate volumetric efficiency value for the running engine rpm. For this reason, different techniques have been developed, such as Continuously Variable Valve Timing (CVVT), in which valve operating parameters also change depending on the changing engine speed. In this study, for the first time in the literature, an experimental method in which the intake valve of the internal combustion engine is directly driven by utilizing the elongation property of the piezo was used. A hydromechanical magnifier was used to increase the elongation of the piezo in micron ranges to valve lift levels. An electronic control unit and high voltage power amplifier were designed to operate the piezo actuator to move this hydromechanical amplifier, and then a completely digital solution was developed. The operation of the piezo and hydraulic enlarger system on the internal combustion engine is explained in this study.

Keywords: Piezo, piezo actuator, continuous variable valve timing, high-powered piezo driver

1. GİRİŞ

İçten yanmalı motorlar, otomotiv sektörü için günümüzde gelişmesini sürdüren, güç aktarma sisteminin önemli bir bileşenidir. İçten yanmalı motora sahip araçlar genellikle düşük ve orta devirlerde, kısmi yüklerde çalışmaktadır (Duan ve ark, 2017). Bu durum içten yanmalı motorlarda yüksek pompalama kayıplarına sebebiyet vermektedir (Fu ve ark, 2013). Yani buji ateşlemeli motorlarda güç kontrolü gaz kelebeği ile yapıldığı için basınç düşüşüne bağlı olarak bu kayıp daha belirgin olmaktadır (Hong ve ark, 2004).

Pompalama kayıplarını düşürebilmek için kullanılan yöntemlerden bir tanesi de supabın çalışma parametrelerinin kontrol edilmesidir. Bunun için literatürde birçok Değişken Supap Zamanlaması (VVT) teknikleri kullanılmıştır. Temel olarak bu tekniklerde; supabın hareketini sağlayan kama avans veya gecikme vermek (Yoshita ve ark, 1996), motorun belirli devir bölgeleri için farklı kam profilleri kullanarak supabın açılma miktarı ve açık kalma süresini değiştirmek (Melcher, 2001), her devir ve her supabın açılıp kapanma durumlarını kontrol eden Sürekli Değişken Supap Zamanlaması (CVVT) gibi teknikler kullanılmıştır.

Supap hareketini kontrol etmek için kullanılacak yöntemlerden birisi de piezonun çalışma prensibinden yararlanmaktır. Elektriksel alana maruz kalan piezo malzemenin uğradığı deformasyon sonucu meydana gelen uzama etkisinin hidrolik büyütücü ile supap hareketine denk gelen mesafelere ulaştırıldığı, Prof. Dr. Ali Sürmen'e ait patentli tasarım daha önceki çalışmada detaylıca anlatılmıştır (Surmen ve ark, 2019). Bunun dışında literatürde birçok farklı patent ve akademik çalışma bulunmaktadır (Rudolf ve ark, 1984), (Clifford ve ark, 2003), (Gatecliff ve ark, 2004), (Joshua, 2006).

Benzer amaçla yapılan çalışmada, sistem bant genişliğini artırmak için önerilen, içinde selonoid aktörlerin piezoelektrik sütunlar ile birlikte yer aldığı elektro hidrolik supap tahrik sistemi, 12.4 mm maksimum supap açıklığı oluşturabilecek yeterliliğe ve 500 Hz'e kadar bant genişliği frekansa sahiptir (Brader ve Rocheleau, 2004). Bu mekanizmada kontrol sisteminden gönderilen elektriksel sinyal piezo-elektrik kütlenin genişlemesine sebep olmaktadır. Bu lineer genişleme, katı bir mafsal mekanizması aracılığıyla supaba iletilir. Bu yöntemin tercih edilme sebebi; çalışma frekansını ve verimi koruyarak piezo-elektrik kütledeki deplasman sınırlamalarını gidermektir. Bu mekanizma kullanılarak piezo-elektrik sütun 30 μm dan 150 μm'ye kadar büyütülebilir ki bu da supap tahriki için yeterli bir uzunluktur.

Üst üste tabakalar halinde bulunan piezo-elektrik malzeme sütunları aracılığıyla verilen elektriksel impuls supabın yer değiştirme hareketine çevrilmesi ve mikron mertebesindeki bu yer değiştirme miktarının, supabın simetri eksenine dik ve birbirine paralel olarak yerleştirilen piezo-elektrik elemanlara (2 adet) elektriksel impuls uygulanmasıyla, malzemede görülen uzama miktarının hidrolik üniteye içerisinde hidrolik akışkan bulunan kanallar vasıtasıyla iletildiği ve burada büyütülerek yeterli supap açma kapama miktarının elde edildiği çalışma ise patentlerde yer alan önemli bir çalışmadır. İçten yanmalı motorlarda optimum şartlar gözetilerek karakterize edilmiş piezo-hidrolik tahrik sistemi de bu kapsamda iyi bir alternatif olarak değerlendirilebilmektedir. Bu çalışmada; piezo-elektrik malzemedeki uzama miktarı hidrolik ünitede bulunan akışkan üzerinde temelde sıvıların kaldırma prensibi ve Pascal prensibine dayanarak bir çeşit hidrolik yükseltici ünitede büyütülerek, istenen açma kapama miktarı elde edilmiştir (Anmelder, 2014).

Tersinir piezo-elektrik etkiye dayanarak oldukça özgün bir kademesiz değişken supap mekanizması tanıtıldığı bir diğer buluş ise proje kapsamında tasarlamak istediğimiz sistem ile pek çok benzerlik taşımaktadır (URL1). Bu sistem genel olarak, bir gerilim dönüştürücü, strok çarpanı, yağ doldurma aparatı, supap ünitesi vb. elemanlardan oluşmaktadır. Herhangi bir gerilim sinyali girdisi tek çipli program kontrolüyle (single-chip program control) gerçekleştirilmektedir. Böylece her devir için yeterli ve optimum supap açıklığı elde edilmiş olur. Bu sayede sistem, supap zamanlaması, supap kalkma miktarı gibi birçok değişken supap hareket parametresi ayrı ayrı ve rahatça kontrol edilmesine imkan verir.

Bu çalışmada içten yanmalı motorun çeşitli devirlerde en iyileştirilmiş volumetrik verim eğrilerini elde edebilmek için deneysel çalışmalar yapılmıştır. Bu amaçla sadece emme supabına Sürekli Değişken Supap Zamanlaması (CVVT) yöntemini uygulayarak çeşitli devirlerde elektrik motoru ile tahrik ederek soğuk çalışma yapılmıştır. CVVT için literatürde ilk defa piezo eyleyici deneysel olarak doğrudan tahrik amacıyla kullanılmıştır. Supabı açıp kapatmak için motor krankının dönüş açısı ile senkronize elektriksel kontrol işaretini üretip kuvvetlendirerek Piezo-eyleyiciye uygulamak gerekmektedir.

2. MATERYAL VE METOD

Bu çalışmada kullanılan piezo eyleyicinin çalışma noktası tayini, sürücü devresi kontrol ünitesi, yüksek gerilim güç kuvvetlendirici ve tam sayısal çözüm ile ilgili detaylar önceki çalışmada bulunabilmektedir (Dirim ve ark, 2020).

2.1. Gömülü Yazılım Geliştirme

Programda pin tanımlamaları yapılan tamamlayıcı PWM çıkış sayacı yeniden kurulan modu seçilmiş ve sayıcıda 0'dan 1000 değerine saymaktadır. İkinci bir sayıcı kanalı artımlı enkoder modunda 0-719 arası değer üretecek şekilde ayarlanmıştır. Ana döngüde sayıcılar aktif edildikten sonra sadece enkoder sinyali ile belirlenen adrese karşılık gelen çıkış tablosu değeri PWM üretecine aktarılır. Enkoder sıfır sinyali (Z-darbesi) motor kalkış hareketinin algılanması için ve sayıcı kontrolünde kullanılmak üzere fiziksel harici kesme sinyaline bağlanmıştır. Bir bitlik yazılımsal bayrak aracılığı ile kesme alt programında enkoder ve PWM kanalları aktif edilir. Test sırasında emme supabı hareketinin değiştirilmesi (daha önceden girilen farklı eğri tabloları arasında geçiş veya eğrinin bir yöne ötelenmesi) bilgisayar aracılığıyla gönderilen verinin alındığına ilişkin kesme altprogramında işletilir.

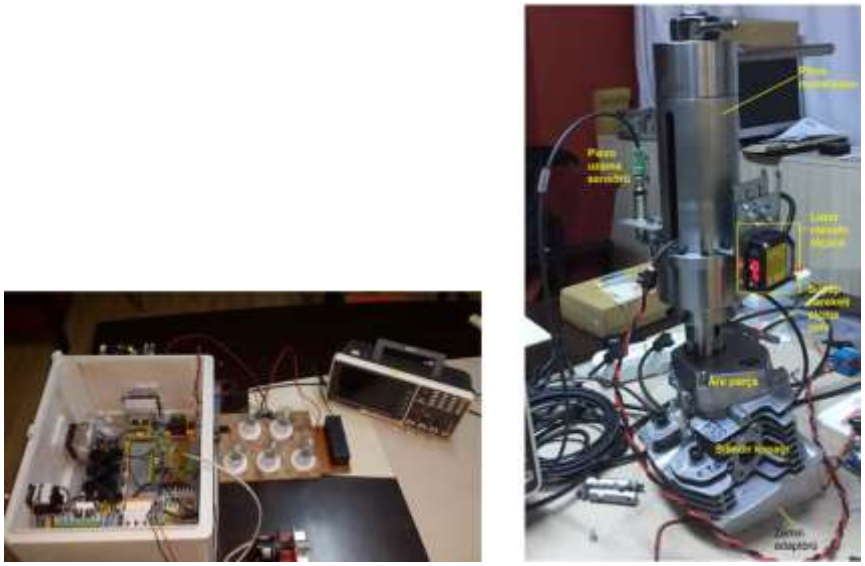
2.2. Emme Supabı Açma Eğrisine Ait Sinyal Örneklerinin Hazırlanması

Emme supabının 10 derece aralıklarla ölçülen kam mili açısına karşılık gelen deplasman değerleri kullanılan darbe genişlik modülasyonu (PWM) üreteci (Timer PWM counter) sayıcı değeri olan 0-1000 aralığına getirilmiştir. Emme supabının hareketi yaklaşık 320 derecelik bir aralıkta tamamlanmaktadır. Sinyal üreteci için bu aralıktaki örnek sayısı (33) yetersiz kalarak sinyalde bozulmalar oluşturmuştur. Sinyaldeki bu bozulmaların önüne geçmek üzere mekanik hareket örnek sayısı Matlab programında iki farklı interpolasyon metodu ile on kat arttırılmış, karşılaştırma sonucu Spline (şerit) interpolasyon yöntemi seçilmiş ve elde edilen sonuç tablolar gömülü yazılıma aktarılmıştır (Şekil 2.1).

Şekil 2.1 a) Düşük örnek sayısı b) Spline uygulandıktan sonra elde edilen emme supabı açılma eğrisi osiloskop görüntüleri

2.3. Kontrol Sistemi ve Uygulamada Karşılaşılan Problemlerin Giderilmesi

Piezosuz (yalancı/dummy piezo ile) testler yapılırken tasarım ve üretim çalışmaları tamamlanmak üzere olan sürücü ve kontrol ünitesinin söz konusu çalışmaları tamamlanmış ve hidro-mekanik modül ile entegre edilir hale getirilmiştir. Önce piezo hidro-mekanik modüldeki kovanına yerleştirilmiş, daha sonra da sürücü ve kontrol devresi ile elektriksel bağlantıları yapılmıştır (Şekil 2.2). Daha sonra detaylı bir şekilde anlatılacağı üzere önce düşük gerilimlerle başlayarak piezonun (karakteristik maksimumu 1000 V'tur) hidro-mekanik modülün çıkış pimini (supap sapını itecek olan modül çıkış pimi) ittirmesi ve itme miktarı gözlenmeye çalışılmıştır.

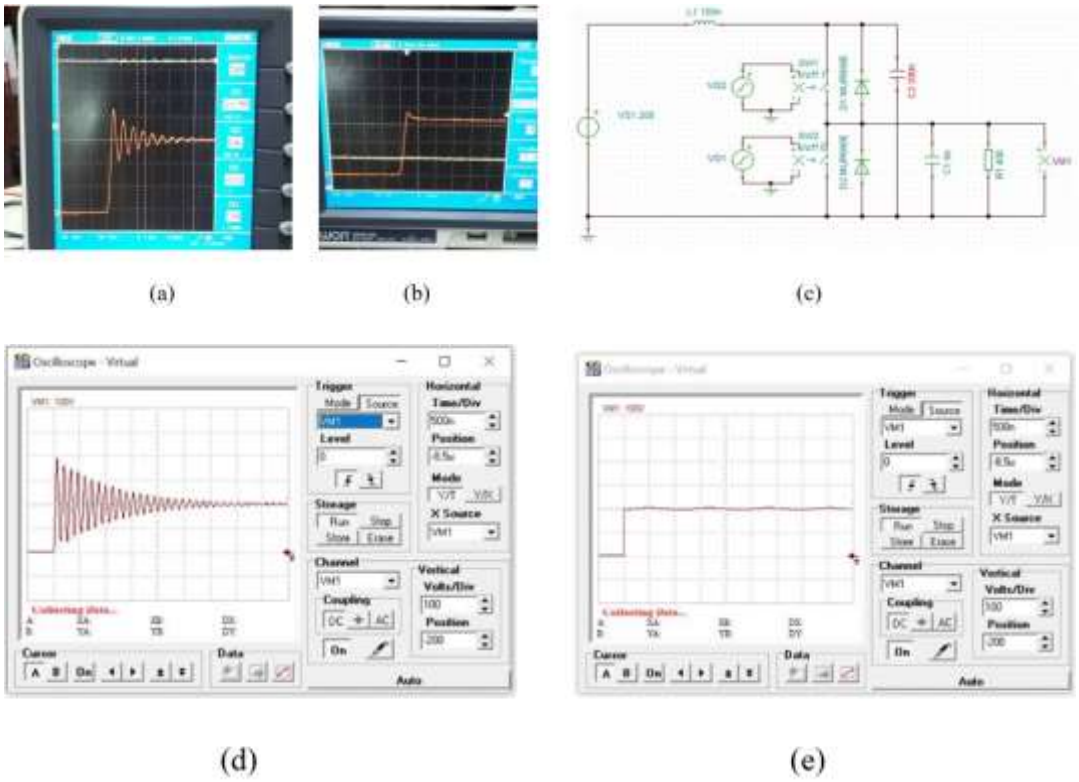


Şekil 2.2 a) Piezo sürücü ve kontrol sistemi b) Motor kafasına monte vaziyette hidrolik modül-piezo komplesi

Burada özellikle şunu ifade etmek gerekir ki piezonun hareketi ile çıkış piminin hareketi arasında, hidrolik sızdırmazlık keçesinin etkisinden ve sistemdeki ara boşluklardan kaynaklandığı değerlendirilen önemli bir hareket kaybı olmaktadır. Bu hareket kaybının anlamlı bir çıkış değeri elde edilmesini engellememesi için mutlaka sisteme bir ön gerilme uygulamak gerekmektedir. BTÜ'deki dinamik test cihazında piezosuz yapılan çalışmalarda bu ön gerilme kuvvetinin 2200 N civarında olduğu tespit edilmiştir. Piezonun montajından sonra ise pimin ilk hareketi gözle görülünceye kadar piezoya üsten mekanik olarak ön gerilme uygulanmıştır. Bu gerilmenin bu kez 400-600 N civarında gerçekleştiği görülmüştür. Bu ön gerilmenin çok dar bir aralıkta olduğu ve belli bir sınırın altında hareketin başlamadığı, o sınırın az bir miktar üstüne çıkıldığında ise supabın açık kaldığı görülmüştür. Denemeler sırasında sürücü ve kontrol sisteminde bazı problemler oluşmuştur. Bu problemler ve giderilmeleri için yapılan çalışmalar aşağıda izah edilmiştir.

2.4. Class-D Kuvvetlendirici Güç Katı Çıkışında Çınlama

Piezo sürücü devresi çıkış katında PWM işaretleri yükselen kenarlarında oldukça yüksek genlikli çınlama titreşimleri (ringing) görülmektedir (Şekil 2.3.a) Çınlama oluşmasının temel nedeni besleme kaynağı çıkışı ile Class-D güç çıkış katı besleme noktası (üstteki IGBT tansistorun kollektor ucu) arasındaki iletkenin oluşturduğu düşük değerli endüktans ile çıkışa indirgenmiş kapasitenin oluşturduğu LC rezonans devresidir. Tina-9 spice simülatöründe kurulan güç katına ilişkin devre Şekil 2.6.c'de gösterilmiştir. Bununla yapılan simülasyon ile bu sönümlü titreşimler elde edilip Şekil 2.3.d' deki gibi sanal osiloskop üzerinde gösterilmiştir.

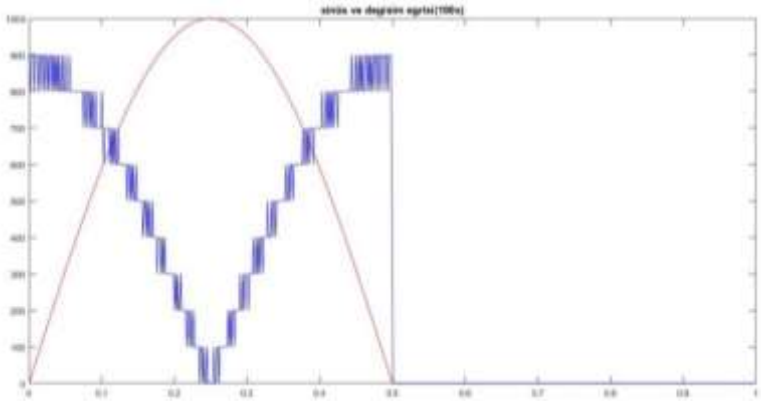


Şekil 2.3 a) Class-D güç katı çıkışında, yükselen kenarda oluşan çınlamanın gerçek devreye bağlı osiloskop üzerindeki görüntüsü b) Class-D kuvvetlendirici (Piezo sürücü devresi) çıkış güç katındakiTotem-pole bağlı IGBT transistörlerin besleme uçları arasına 330 nF değerinde bir kondansatör bağladıktan sonra çınlama sönümlü osilasyonlarının bastırıldığı gerçek osiloskop görüntüsü c) Tina-9 simulatöründe çizilen Class-D kuvvetlendirici güç katı devresi (IGBT transistörler gerilim kontrollü anahtar olarak verilmiştir) d) Yukarıdaki devreye ait C2 dekuplaj kapasitesi 0 olduğundaki simulasyonun sanal osiloskop görüntüsü e) C2 dekuplaj kapasitesi değeri 330 nF olduğunda çınlamanın söndüğünü gösteren simulasyon sonucuna ait sanal osiloskop görüntüsü

Sonuç olarak gerçek kuvvetlendirici (piezo sürücü) çıkışındaki IGBT yarım köprü besleme uçlarına en yakın noktaya bağlanan C2 =330 nF kapasitesi ile salınımların bastırılmış olduğu Şekil 2.3e'de sanal osiloskop ve Şekil 2.3b'de gerçek osiloskop üzerinde görülmektedir.

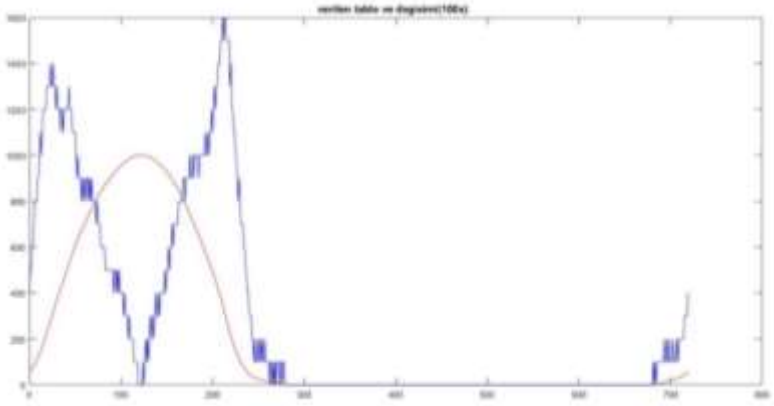
2.5. IGBT Yarım Köprü Çıkış Katı Gerilimini Yükseltirken Karşılaşılan Problemler

350 V DC besleme gerilimine kadar güç katı çıkışında elde edilen işarette kayda değer bir bozulma meydana gelmemektedir. 350 - 400 V DC besleme gerilimi aralığında ve üzerine çıkıldığında yarım köprü güç katı çıkışındaki darbe genişlik modülasyonlu işarette, kare dalganın yükselen kenarlarında ani yükselen iğne darbeler (spike) oluşmaktadır. 430 V DC besleme geriliminde bu iğne darbelerin genlikleri, en yüksek değeri elde edilmek istenen işaretin şekline bağlı olarak, 70 V ila 250 V arasında değişmektedir. Elde edilmek istenen işaretin her noktasındaki eğimine bağlı olan bu değişim aslında işaretin türevi olup tablodaki ardışık örnekler arasındaki değişimin miktarına bağlı olmaktadır. Yarım sinüs eğrisine (pozitif alternans) ait tablo kullanıldığında iğne darbelerin genlikleri 70 V civarında olurken (Şekil 2.4), orijinal kam supap açma eğrisine ilişkin tablo kullanıldığında, tablo adımları arasındaki fark sinüs eğrisi tablosuna göre daha büyük olduğundan 250 V değerlerine kadar artmaktadır (Şekil 2.5).



Şekil 2.4 Yarım sinüs eğrisine ait ardışık örnekler arasındaki değişim grafiği

Bu iğne darbeleri engellemek üzere IGBT lerin kollektör ve emetör arasına RDC bastırma devresi bağlanmıştır. D-Sınıfı kuvvetlendirici çıkışında kullanılan alçak geçiren LC filtrenin sönümlü titreşimler üretmesinin önüne geçmek üzere Şekil 2.6'da gösterildiği üzere filtre girişine seri bir R direnci (4,7 Ohm / 50W) bağlanmıştır.



Şekil 2.5 Orjinal kam eğrisine ait ardışık örnekler arasındaki değişim grafiği

2.6. Gömülü Yazılım ve Sistemde Yapılan İyileştirmeler

İlk kurguda enkoder referans girişi üst ölü noktaya göre en erken açılan test setine referans olarak düşünülmüştür. Piezo ön gerilme değeri, dinamik çalışma karakteristikten kaynaklanan ve sistemin motor bloğuna monte edilmeden önce gözlenlenemeyen silindir içerisindeki pistonların oluşturduğu karşıt kuvvetler nedeniyle farklı devirlerdeki gecikme ve açık kalma sürelerinde Uygulanan gerilim ile supap hareketinde farklılıklar oluşmuştur. Özellikle açık kalma sürelerinin bahsedilen harici parametrelere bağımlı değişimi, test için gerekli hareket grafiği örneklerini içeren veri tablolarıyla çalışılamayacağını göstermiştir.

Bu durumda gömülü yazılım ve sistemde değişikliğe gidilerek osilaskopta gözlemleme amaçlı harici bir üst ölü nokta (ÜÖN) sensörü ilave edilmiştir. Test işaretlerine göre dar aralıklarla değişen farklı açık kalma sürelerine ait sinüs fonksiyonu tabanlı yeni veri setleri oluşturulmuştur. Yapılacak deneylerde veri seti en geniş açık kalma süresine sahip hareket başta olacak şekilde sıralanmıştır. Böylece ilgili her devir için uygulanan gerilime göre oluşan supap hareketinin

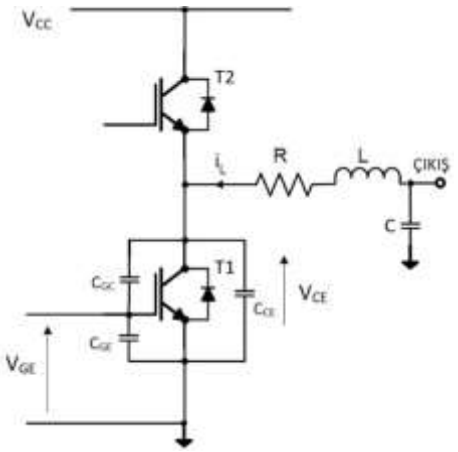
başlangıç ve açık kalma süreleri parametre alınarak açık kalma süresine göre eğri seçimi ve başlangıç açışına göre öteleme yapılarak yapılacak testin sübap hareketi grafiğiyle eşleşmesi sağlanabilmiştir.

2.7. Kendiliğinden İletime Geçme Problemi (Self turn-on phenomena)

IGBT yarım köprü güç katının besleme gerilimi arttırıldığında üstteki IGBT iletime geçirildiğinde alttaki IGBT'nin kendiliğinden iletime geçmesi problem ortaya çıkmaktadır. Şekil 2.6'da görüldüğü gibi alt taraftaki T1 IGBT transistoru üstteki T2 transistorun iletime geçmesi anında CGC Miller kapasitesi ve CGE kapı-emetör kapasitesi ile bölünen gerilimin kapı eşik gerilimi seviyesini aşması sonucunda T1 transistoru de istenmeyen şekilde iletime geçer. T2-T1 yarım köprüsü üzerinden aşırı akım akmasına neden olur. Bu olaya kendiliğinden iletime geçme (veya Miller shoot-through; Miller atışı) adı verilmektedir.

Masa üstü denemelerde 400 V besleme gerilimi üstüne çıkıldığında benzer problemle karşılaşılmış ve güç çıkış katına ait IGBT'lerin her ikisinin birden iletime geçmesi sonucu devreden aşırı akım akması transistörlerin patlayarak bozulmasına neden olmuştur. Bu olayın nedenleri araştırıldığında aşağıdaki olgularla karşılaşılmıştır. Kullanılan IGBT elemanları, oluşabilecek yanma ve bozulma ihtimalleri dolayısı ile piyasadan hemen temin edilebilen, istenilen gerilim, akım, iletime ve kesime geçme süreleri en uygun olan Fairchild firmasının FGA25N120 ürünü seçilmiştir. Bu IGBT veri sayfalarından alınan VGE(th) kapı eşik gerilimi Cies ve Cres giriş ve geribesleme eşdeğer kapasiteleri üzerinden yapılan hesaplamalar, kapı devresinde paralel bağlı 3700 pF değerinde ek bir kondansatörün de bulunduğu göz önüne alındığında, yarım köprü devresindeki IGBT'lerin 350 V dan sonra kendiliğinden iletime geçebileceğini göstermiştir. Bu problemin çözümü için IGBT üreten firmaların uygulama notlarında belirtilen ve akademik araştırma makalelerinde söz edilen yöntemler taranmış ve simülasyon ile test edilmiştir.

Bu yöntemlerin birincisi kapı devresine paralel kondansatör bağlayarak giriş kapasitesini arttırmak ve Miller bölünme etkisini yani CGE/(CGE + CGC) değerini azaltmaktır. Eklenen kapasite değeri bölen parantezi içine ilave olmaktadır. İkinci yöntem kapı ve emetör uçlarını, IGBT kılıfına en yakın noktaya yerleştirilecek bir mosfet ile kısa devre ederek kesim durumundaki kapı gerilimini sıfırda tutmayı garantilemektir. Üçüncü yöntem ise IGBT kapı sürücü devresinin besleme geriliminin tek kutuplu besleme yerine çift kutuplu besleme (+/- 15 V) olarak uygulanması ve Miller etkisi ile oluşan kapı geriliminin negatif besleme gerilimi ile aşağıya doğru çekilerek kapı eşik geriliminin altında kalmasını sağlamak suretiyle kendiliğinden iletime geçmesini engellemektir (URL2).



Şekil 2.6 D-sınıfı kuvvetlendirici güç çıkış katı yarım köprü devresi ve çıkış filtresi

Birinci yönteme ilişkin devre simülasyonu göstermiştir ki, kapı devresine paralel kondansatörün ilavesi kapı sürme akımının artmasına neden olmaktadır. İkincil olarak gözlemlenen bir husus ilave edilen kapasite nedeniyle kapı devresinde oluşabilecek parazitik osilasyonlardır ki tepe değerleri kapı eşik gerilimini geçtiğinde yarım köprü üzerinden aşırı akım akmasına sebep olmaktadır. İkinci yöntem uygulanırken kapı-emetör arasını kısa devre edecek mosfetin mümkün olduğu kadar IGBT nin kılıfına en yakın bölgeye monte edilmesi gerekir. Bu durumda bu mosfetin anahtarlama karakteristiği, kapısına uygulanacak işaretin parazitik gerilimlerden uzak olması, iletken yolların endüktansının etkilerinin en azda kalması gibi devre topolojisine bağlı olmaktadır. Ayrıca IGBT kapı devresinin kılıf içinde kalan endüktansı üzerinde CGC geri besleme kapasitesinden Miller etkisi ile akan akımın yükselme eğimi dolayısı ile oluşan gerilimi bu mosfetin kısa devre edemeyeceği göz önünde bulundurulmalıdır. Üçüncü yöntemde IGBT kapı sürücü devresi iki kutuplu gerilim (+/- 15 V) ile beslenmektedir. Bunun anlamı ise kesim durumunda IGBT kapısına emetör referans olmak üzere negatif gerilim uygulanmasıdır. Bu durumda IGBT kılıf yapısı içinde Miller etkisi ve kapı iletkeni endüktansında oluşan gerilimlerin referans noktası -15 V besleme gerilimi olacağından kapı-emetör

gerilimi, kapı eşik gerilimi VGE(th) değerini aşamayacağından IGBT kendiliğinden iletime geçemeyecektir. Yukarıda açıklanan yöntemler ve simülasyonları incelenmiş, üçüncü yöntemin kullanılmasına karar verilmiş ve uygulanmıştır. Bu yöntem uygulanmadan önce 400 VDC besleme gerilimleri civarında yarım köprü güç katı IGBT leri kendiliğinden iletime geçme probleminden dolayı arızalanırken üçüncü yöntem uygulandıktan sonra 620 VDC besleme gerilimi altında herhangi bir problem oluşmamıştır. Tekrarlanan testlerde bu besleme gerilimi değerlerinde çoğunlukla 4-5 mm civarında nadiren 6 mm'ye ulaşan çıkış mili hareketi alınabilmiştir. Böylece ilk defa piezo ile gerçek bir supap sisteminin sürülebileceği görülmüş ve sistemin motor kafasına montajı aşamasına gelinmiştir.

Piezo-Hidrolik modül komplesi motor kafasına monte edildikten sonra 620 VDC besleme geriliminde daha önce kapağa monte edilmeden yapılan deneme testleri tekrarlanmıştır. Kapağa monte edilme öncesi elde edilen değerler mertebesinde çıktılar elde edilebilmiştir. Ancak 4 mm nin üzerindeki değerler istikrarlı bir şekilde elde edilemediğinden, sistem ayarlarının her denemede 4 mm alacak şekilde yapılmasına ve 4 mm nin deneyler boyunca sabit kalkma miktarı değeri olarak kabul edilmesine karar verilmiştir. Keza 620 VDC besleme geriliminde elde edilen 4 mm açma yüksekliği deneylerin yapılabilmesi için yeterli görüldüğünden besleme geriliminin 620 VDC den daha büyük değerlerinin denenmesi daha sonraya bırakılarak motor laboratuvarındaki uygulamalara geçilmesine karar verilmiştir.

3. BULGULAR

Şekil 3.1'de gösterilen laboratuvar deneyleri öncesinde, deneylerde kullanılacak "içten yanmalı motor - elektrik motoru" deney standında (setinde), elektrik motoru fan tarafı miline 1/2 oranında trigger kayış ve dişlileri ile eksantrik milini modelleyen enkoder bağlanmıştır. Bu enkoder elektrik işaret çıkışı diferansiyel olacak şekilde seçilerek elektromanyetik girişimden etkilenmemesi (en az oranda etkilenmesi) sağlanmıştır. Ayrıca içten yanmalı motor mili kaplin tarafına endüktif yaklaşım sensoru bağlanıp mil üzerine delinen bir delikle pozisyonu üst ölü noktada buluşacak şekilde ayarlanıp krank mili üst ölü nokta işareti elde edilmiştir. Bundan sonra içten yanmalı motor üst kapağı sökülüp emme supabına ait manivela (külbütör) ve itici tij sökülüp dışarı alınmış ve piezo eyleyici tahrikli hidrolik büyütücü sistemi kapağın olduğu yere, büyütücü çıkışındaki itici çubuk emme supabı üzerine gelecek şekilde monte edilmiştir.

Şekil 3.1 Deney düzeneği komplesi (Motor kontrol paneli sol altta)

Piezo eyleyici- büyütücü sistemi çıkış milinin hareket mesafesi, buna dik bağlı çubuğu gören lazer mesafe okuyucu tarafından 0,01 mm çözünürlükle okunmaktadır. Deneyler öncesinde ön yükleme ve sistemdeki boşlukları almak amacıyla piezo üzerindeki cıvata gevşek duruma getirildikten sonra lazer okuyucu sıfırlanacak ve ön yükleme cıvatası dikkatlice sıkılırken lazer okuyucu ekranı gözlenecektir. Ekrandaki değişme 0,05 mm civarına kadar yükseldiğinde sistemdeki boşlukların alınmış olur. Deneylere başlamadan önce yapılan bu ayar statik boşluk alma ayarıdır.

Deneyler esnasında deney standı elektrik motoruna motor sürücü panosundan enerji verilerek bilgisayar ekranına girilen devir sayısına belli sürede hızlanarak gelmesi temin edilmektedir. Böylece elektrik motoruna akuple içten yanmalı motor soğuk olarak istenilen devirde çalıştırılmış olur. Motor tahrik edilirken krank milindeki oyuğa bakan endüktif yaklaşım şalterinden üst ölü nokta (ÜÖN) işareti alınıp diğer işaretlerle senkronize şekilde izlenmek üzere 4 kanallı osiloskop girişlerinden birine uygulanmaktadır. Elektrik motorunun kuyruğuna bağlı trigger kayış ile 1/2 oranında tahrik edilen enkoderden sıfır darbesi eksantrik mili referans işareti olarak ve 720° sayma darbeleri A ve B çıkışlarından alınıp elektronik kontrol sistemindeki mikroişlemci işaret girişlerine gönderilmektedir. Bu enkoderin sıfır darbesi osiloskop girişlerinden bir diğerine uygulanır. Lazer mesafe okuyucu analog çıkışı da osiloskop girişlerinden birine

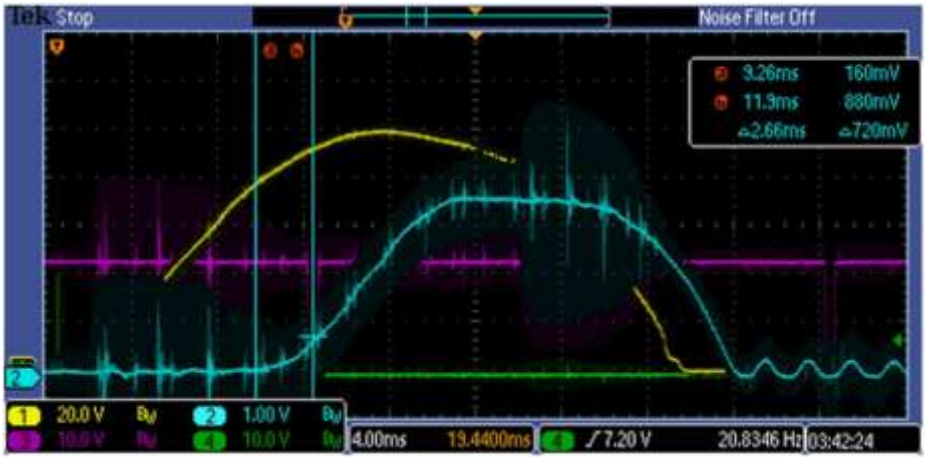
bağlanmıştır. D-Sınıfı kuvvetlendirici filtre çıkışından sonra piezo eyleyiciye uygulanan elektrik işareti aynı zamanda paralel olarak (kuvvetlendirici çıkışının sadece kapasitif yüklenmesini engelleyip rezistif yüklenmesini de sağlamak amacıyla) seri bağlı beş adet 40 W gücündeki enkandesan lambaların enerji almasını sağlamaktadır. Çıkış geriliminin 1/5'i seri bağlı lambalardan en alttaki üzerinden alınarak osiloskobun boşta kalan son girişine gönderilir. Böylece deney düzeneği ve elektriksel bağlantıları tamamlanmış olur.

1500 d/d dönüş hızı ile yapılan deneyde öncelikle ön yükleme ayarının dinamik durumda emme supabı açıklığına etkisi incelenmiştir. 2 mm hatveli ön yükleme cıvatasını sıkma yönünde birkaç derece döndürerek dinamik durumda 3,9-4,0 mm civarında bir hareket miktarının elde edildiği lazer mesafe sensorundan gelen analog işaretin osiloskopta değerlendirilmesi sonucunda görülmüştür. Ancak piezo eyleyiciye uygulanan elektriksel işaret (sinüs işaretin sadece pozitif alternansı) ile büyütücü çıkışından alınan hareket miktarına tekabül eden lazer okuyucu analog çıkışının osiloskop üzerindeki görüntüleri incelendiğinde, elektrik işaret ile büyütücü mekanik çıkışı arasında önemli miktarda açısal bir faz farkı olduğu ve bunun ön yükleme kuvveti ile hissedilir miktarda değiştiği gözlenmiştir. Ön yükleme kuvveti arttırıldığında aradaki açısal fark azalmaktadır (Şekil 3.2).

Şekil 3.2'de görüldüğü üzere büyütücü çıkışına ait deplasman eğrisinin (mavi) piezo eyleyiciye uygulanan elektriksel işaretten farklı olarak trapezoidal olduğu gözlenmiş, bunun açıklaması olarak belli bir deplasmandan sonra kuvvetler dengesinin sağlandığı noktada mekanik hareket imkanının kalmadığı düşünülmüştür. Bu sınırlı yük uygulamasının nedeninin 1000 V gerilimde 100 µm genlik ifade eden sarı eğriye karşılık, uygulanabilen gerilimin 620 V olması muhtemeldir.

Piezo eyleyici sürücü ünitesinde çıkış işaretine ait tablolar eksantrik enkoderinden gelen referans işareti ile mikroişlemci tarafından okunmaya başlar. Bu durumda elektriksel çıkış işaretini sola kaydırabilmek için referans işareti daha da solda olmalıdır. Elektrik-mekanik arasındaki bu önemli miktardaki açısal fark nedeniyle eksantrik referans işaretinin ÜÖN işaretinden 40°-50° önce olması, istenen emme supap açık kalma süresini (açısını) sağlayamadığından, eksantrik referans işareti (enkoder sıfır darbesi) ÜÖN işaretinden 175° öncesinde gelecek şekilde enkoder açısal pozisyonu değiştirilmiştir. 1500 ve 2000 d/d devir sayılarında motorun soğuk haldeki volumetrik verim deneyleri bu eksantrik referans değeriyle yapılabilmiş olmasına karşın 2500-3000 d/d devir sayılarındaki soğuk deneyleri aynı eksantrik referans değeriyle (175°) gerçekleştirmek mümkün olmamıştır. Bu nedenle deneyler yüksek devir sayılarında yapılmaya başlandığında eksantrik referans değerini 225° civarına getirmek gerekmiştir. 2500 d/dak'da bu değerle elde edilebilen elektriksel ve gerçekleşen sinyallerin osiloskop görüntüleri Şekil 3.3'de verilmiştir.

Şekil 3.2 1500 d/dk piezo eyleyiciye uygulanan elektrik işaret (sarı), ÜÖN işareti (mor), eksantrik referansı (yeşil) ve büyütücü çıkış deplasmanı (mavi)



Şekil 3.3 2500 d/dk elektriksel (sarı) ve mekanik deplasman (mavi) arasındaki açısal gecikmenin artışı görülmektedir

4. TARTIŞMA

Bu alt başlık altında elde edilen değerlerin motor tekniği ve performansı açısından ne derece gerçekçi olduğu mevcut sistem özellikleri ve parametrik kısıtlar da göz önünde bulundurularak değerlendirilecektir. Öncelikle;

- yanmanın olmadığı soğuk şartlarda çalışıldığını,
- gerilimin kullanılan piezonun hedeflenen çalışma değeri olan 1000 V'a çıkarılamadığını, 620 V civarında kalındığını
- dolayısıyla orijinal emme supabı kalkma değeri olan 7,6 mm'ye çıkılamadığı, 4,0 mm civarı değerler elde edilebildiğini
- makine dinamiği bakımından sistem karakterizasyonunun yapılmadığı bir tasarımla çalışıldığından özellikle 3000 devir seviyelerine gelindiğinde klasik gömülü değerlerle istenen açma kapama açılarının tutturulmasının çok zor olduğunu bir durum özeti olarak tekrar sunmakta fayda vardır.

5. SONUÇ VE ÖNERİLER

Bu çalışmada ortaya çıkan problemler ve bunların deney sonuçlarını en düşük seviyede etkilemesi için alınan tedbirlerden bahsedilmiştir. Çalışmanın en başından en sonuna problemler sıralanıp bunlarla ilgili yapılanlar ve proje raporunun sunulmasından sonra yapılması planlanan çalışmalar özetlenmiştir.

Çözülmesi gereken en önemli problemlerden birisi de çalışma devrini artırmaktır. Projenin iddiası piezoların yüksek frekans özelliğini kullanmak dolayısıyla çok yüksek motor devirlerinde bile motoru supap zamanlamasını gecikmesiz değiştirebilmektir. Piezonun frekansı (rezonans frekansı 7 kHz) çok yüksek bir frekanstır. Ancak deneylerin tek silindirli bir motorda yapılması maliyetler açısından zorunludur, fakat 7200 d/dak gibi hedef aldığımız yüksek devirde çalışabilecek tek silindirli ve bizim amacımıza uygun yapısal modifikasyonlar uygulanabilecek tek silindirli bir motor bulunabileceği de düşünülmemiştir. Dolayısıyla diğer hiçbir yapısal problemimiz olmasa da bu motorla çıkılabilecek devir maksimum 4000 d/dak civarıdır (max. güç. devri 3600 d/dak). Kaldı ki ürettiğimiz hidromekanik modülün sistem ataleti çok yüksek olmuştur ve bu devirlere de çıkılamamıştır. Frekanslardan bahsederken 4 zamanlı motorda supap tahriki için gerekli frekansın motor devrinin yarısına karşılık gelen bir frekans olacağını unutmamak gerekir. Kullanılan piezoya yük altında olmaksızın 100 Hz uygulanmıştır. Bu 200 Hz lik bir çalışma frekansı yani yüksüz 12000 d/dak'yı kaldırabilecek bir frekanstır. Ancak kritik frekans eşiğini piezonun rezonans frekansı değil, hareketli sistemin tümünün rezonans frekansı üzerinden değerlendirmek gerekir. İşte bu anlamda proje bitiminden sonra yapılacak iyileştirmelerden birisi önce sistem kütlelerini mekanik dayanımdan taviz vermeksizin olabildiğince azaltmak, sonra da sistemin dinamik bir modelini yaparak rezonans frekansını belirlemektir. Böylece sistemin bütünü ile çıkabileceğimiz en yüksek motor devri konusunda bilgi sahibi olunabilecektir.

Projenin deneysel kurgusunda açı değişikliklerinin motor durdurulmadan yapılması öngörülmüştür. Ancak motor deneyleri sırasında supap açılarını değiştirip uygulanacak yeni kalkma eğrisini yüklediğimizde, elektromekanik uyumluluğun kaybolduğu görülmüştür. Yani bu değişim, ilk değerlerle çalışan önceki çevrimden yeni değerlerle çalışacak olan sonraki çevrime yetişememektedir. Bu uyumsuzluk kendini osiloskop ekranında supap kalkma eğrisinde

anormal bir faz kayması şeklinde göstermektedir. Bunu değişim sinyalinin motor hızına yetişememesi gibi esasında çözümü çok da zor olmayan bir problemden kaynaklandığı değerlendirilmiştir. Ancak diğer problemlerde olduğu gibi zaman mülahazalarıyla çözüm için zaman harcanmamasına ve motorun durdurulup tekrar çalıştırılması arasında değişikliğin yapılmasına karar verilmiş ve deneylere bu şekilde devam edilmiştir. Gerçek bir "sürekli değişken supap zamanlamasından" bahsedebilmek için çalışma esnasında bu geçişin rahatlıkla yapılabilmesi gerekir. Devam edecek olan çalışmalarımızda çözülmesi gereken problemlerden biri de budur.

Yukarıdaki 3., 5. ve 6. Problemlerin hepsinin (hatta kısmen 4. Maddedeki de) dinamik problemler olduğu ve büyük ölçüde gereksiz derecede hantal imal edilmiş hidrolik modül hareketli bileşenlerinde kaynaklandığı söylenebilir. Onun için piezoyu takip eden metal hareketli parçaların kütleleri en aza indirilmeden sistemin ulaşabileceği dinamik sınırları (sistemsel kısıtlarını) belirlemek mümkün değildir. Dolayısıyla bu konu özellikle halledilecek konu olarak öne çıkmaktadır.

TEŞEKKÜR

Bu bildiriye esas olan çalışmaları 216M241 nolu 1003 projesi kapsamında desteklediği için TÜBİTAK'a teşekkürlerimizi arz ederiz.

ABSTRACT

Brake Pads consist of several different ingredients including fibers, abrasives, solid lubricants, fillers, and binders to satisfy various functionalities. The selection of these ingredients is critical to obtain multiple properties that require throughout the usage of the brake pad simultaneously. Among these ingredients, solid lubricants provide a smooth sliding without compromising friction coefficient and can help to build a strong tribofilm on the interface to enhance the tribological performance of the brake systems. This study experimentally investigates the performance of six different combinations of graphite, metal sulfurs, and metal fluorides as solid lubricants in brake systems. The properties of the used solid lubricants were first characterized using scanning electron microscopy, thermogravimetric analysis, X-ray diffraction, and particle size distribution analysis. Tribological properties of brake systems containing 15% solid lubricants in total were investigated via the Krauss test, and friction properties and wear rates were evaluated.

Keywords: brake pads, solid lubricants, coefficient of friction, wear rate.

1. INTRODUCTION

Brake pads consist of complex composite systems to be able to provide consistent friction and wear performance under varying working conditions throughout their lifetime (Jang and Kim, 2000). This composite system includes fillers, reinforcing fibers, abrasives, binders, and solid lubricants. The ratio and type of the individual components are mostly determined based on experience or trial-error approaches. Considering a large number of alternative materials choices, the performance of brake systems can be enhanced by improving the composition of individual components (Martinez and Echeberria 2016).

One of the critical components of brake pads is solid lubricants. These lubricant materials are solid at working temperatures and can provide better thermal ranges compared to liquid lubricants. Solid lubricants are commonly employed in brake pads to reduce wear rates by generating a tribofilm on the surface between the brake pad and disk, reducing brake-induced vibrations by providing smooth sliding, and regulating the coefficient of friction (Kim continued, 2007; Österle and Dmitriev 2016). Depending on their thermal and tribological properties, graphite, metal sulfides, and metal fluorides are commonly used solid lubricant materials in brake systems (Kalel continued, 2020; Pérez and Echeberria 2019; Allam 1991; Antonyraj and Singaravelu 2019). During usage, the friction converts kinetic energy into thermal energy thus, high temperatures are experienced. The experienced high temperatures cause the oxidation of solid lubricants and a thin tribofilm is obtained. This tribofilm enhances the wear performance of the brake pad by protecting the inner body. Depending on the solid lubricant composition, the quality of this tribofilm can be improved (Gudmand-Høyer continued, 1999).

Various studies have focused on the performance of solid lubricant systems in the brake pads. For instance, Jang and Kim investigated the effect of antimony trisulfide and zirconium silicate and showed that antimony trisulfide stabilizes the coefficient of friction and, zirconium silicate improves fade performance (Jang and Kim, 2000). Cho et al. investigated the effect of three different solid lubricants (graphite, antimony trisulfide, and molybdenum disulfide) on a brake dynamometer and showed that antimony trisulfide had superior friction stability and fade performance compared to other investigated materials (Cho continued, 2006). Ram-Prabhu compared 3 different solid lubricants and concluded that molybdenum disulfate showed a better tribological performance than graphite and hexagonal boron nitride (Prabhu, 2015). Kim et al. investigated various combinations of graphite and antimony trisulfide and concluded that the best performance can be obtained when the brake pad includes has 6% graphite and 3% antimony trisulfide (Kim continued, 2007). Vijay et al. compared premixed tin disulfide + iron disulfide with antimony trisulfide and claimed that premixed

sulfides showed better performance in terms of friction and wear properties under chase tests (Vijay continued, 2021). The above studies and many others identified that the choice of solid lubricants strongly affects the performance of brake pads, and the coexistence of different solid lubricants improves the performance of brake systems. Although many studies have focused on a mixture of solid lubricants in the brake pads, numerous uninvestigated solid lubricant combinations may provide better tribological performance.

This study provides a comparative experimental analysis of six different brake pads containing varying combinations of graphite, antimony trisulfide, zinc sulfide, molybdenum disulfide, and calcium fluoride. First, solid lubricant powders were characterized using scanning electron microscopy, thermogravimetric analysis, X-ray diffraction, and particle size distribution analysis. Then, solid lubricant mixtures were combined with identical brake pad combinations with an 85% weight rate, and brake pads with six different combinations were fabricated from the mixtures. The tribological performance of the prepared brake pads was evaluated using the Krauss test.

2. MATERIALS AND METHODS

2.1. Materials

The base combination of the brake pads used in the study is manufactured following the recipe of the heavy-commercial vehicle brake pads, property of Eren Brake Lining INC. These pads are produced from asbestos-free and copper-free fillers, reinforcing fibers, abrasives, and binders. First, the base components of the brake pad were mixed with a high-speed mechanical mixer (MTI) with 750 rpm. 85 w% base materials and 15 w% solid lubricants were measured with a precision scale and mixed with a lab-scale mechanical mixer (Eirich EL1) with 1000 rpm. The particle size distribution of used solid lubricants was measured using a particle size analyzer (Mastersizer 3000, Malvern). The average diameters of the used solid lubricants and their amount in the prepared samples are listed in Table 1. Briefly, all the samples contain 5 weight% graphite, and two solid lubricants with 5% in total pad mass were added to the base combination. After ensuring homogeneous distribution, the samples were pressed at 165°C with 300 kgf/cm2 using a hot press for 300 seconds. To ensure complete bonding of individual components, the pressed samples were sintered in an oven at 165°C for 8 hours. The obtained sample size was about 85 ×52 ×13 mm. To obtain uniform thickness, the sintered samples were grounded after sintering.

Table 1. Weight percentages of the solid lubricants in the produced samples

Sample ID	Graphite **(w.%)**	**Sb_2S_3 (w.%)**	**ZnS (w.%)**	**MoS_2 (w.%)**	**CaF_2 (w.%)**

S3	5	0	5	5	0
S4	5	5	0	0	5
S5	5	5	0	5	0
S6	5	5	5	0	0

Bulk density of the overall mixture was determined before pressing following ASTM D1895, Ash content was determined as described in ASTM D3171, Acetone extraction was utilized based on ASTM D494 and moisture ratio was obtained using ASTM D3171. After sintering, Rockwell hardness (HRR) of samples was obtained per SAE J2654, Compressibility was determined based on ISO 6310, and density of samples was determined following ISO 15484 standards. The obtained results are listed in Table 2.

2.2. Experimental Conditions

The manufactured samples were tested under a constant interval type drag test Krauss friction tester following ECE R R90 regulation Annex 9 2.2.2.2 and 3.2.2 under constant velocity. Among these two regulations, Annex 9 2.2.2.2 is to for light-weight vehicles whereas Annex 9 3.2.2 is for heavy weight vehicles. 2 brake pads were simultaneously attached to the experimental setup which includes a gray cast-iron disc with 277 mm outer diameter. The disc and samples were burnished until stable friction was obtained. The samples were then exposed to the test schedule determined based on ECE R90. First, the friction and wear performance of brake systems were analyzed under constant torque for 14 cycles, and their responses were recorded with a data acquisition system. Following the constant torque tests, the performance of a new set of brake pads under constant pressure was evaluated. The detailed experimental schedules under both constant torque and constant pressure conditions are given in table 3. In each cycle, the brake was activated for 5 seconds, and the following brake application was applied 10 seconds apart. The initial velocity before the brake applications was 650 rpm. The temperature values during the experiments were measured using a

thermocouple mounted nearby the interface, the wear loss was measured by weighting the pads before and after experiments. Similarly, the initial and final thicknesses of the samples were recorded. The collected temperature, coefficient of friction, pressure, torque, and wear values were used for further analyses.

3. RESULTS AND DISCUSSIONS

Figure 2 shows the experimental results for all the six samples listed in Table 1. To elaborate, Figure 2.a and 2.b show the change in friction coefficients and temperatures with applied brakes during the fade test under constant torque, and figure 2.c and 2.d shows the behavior of coefficient of friction and disk temperatures with applied brakes under constant pressure. Both figures include temperature and coefficient of friction behavior of samples after the burnishing period. In constant torque tests (Figure 2.a, and 2.b), the highest coefficient of frictions was observed in sample 4 and sample 5. On the other hand, sample 2 and 6 showed the lowest coefficient of friction, and the lowest variation of coefficient of friction (the best fade performance) under the investigated conditions was observed in sample 2. The observed temperature profiles for the fade test were quite similar for the investigated materials. For the tests under constant pressure (Figure 2.c and 2.d), the highest operation coefficient of friction was obtained from sample 4. For both cases, the lowest friction coefficient was observed in sample 6. It should be noted that the results for sample 3 in constant pressure experiment showed different temperature behavior, (Figure 2.d) and it was excluded from the further comparisons.

Further characterization of the relationship between pressure, applied torque, temperature, and coefficient of friction were analyzed for sample 1 and sample 2. Figure 3 shows how the coefficient of friction varies under the investigated conditions and the coefficient of friction increases with increasing torque, where is it proportionally decreases with increasing pressure. Thus, the relationship between the coefficient of friction and pressure is consistent with the literature (e.g., Gil continued, 2016; Ma, de Rooij, and Schipper 2010).

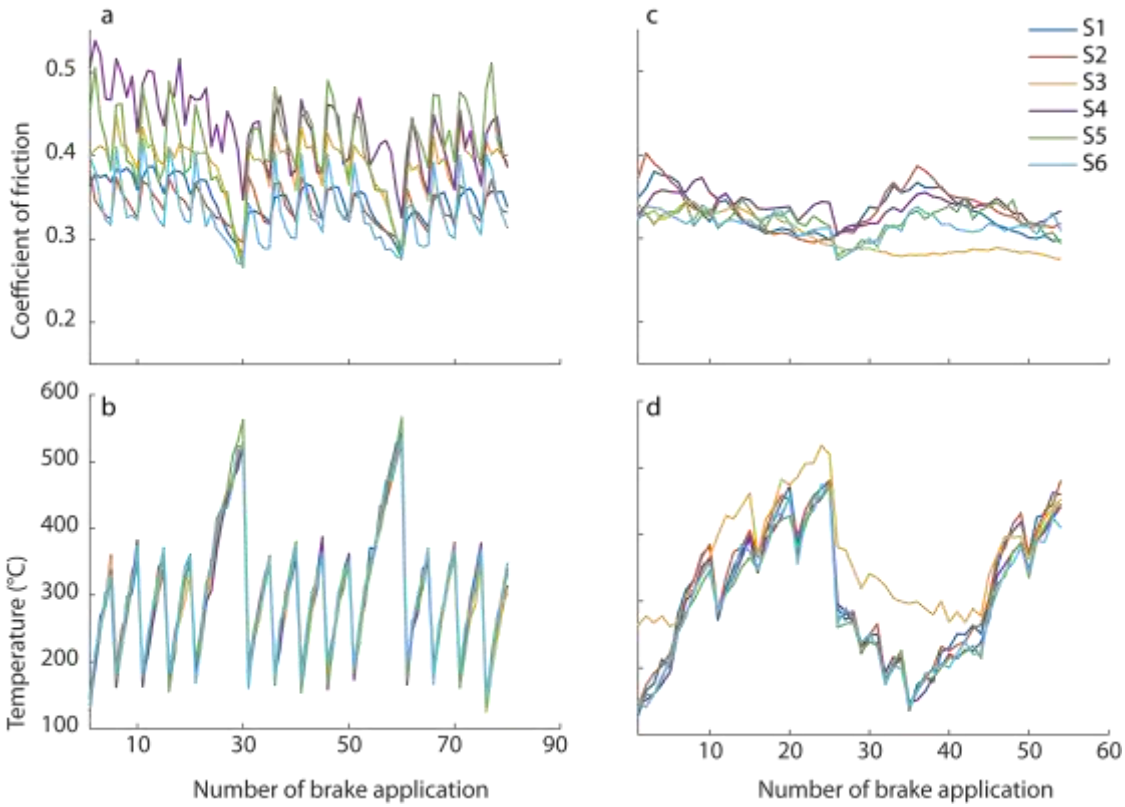

Figure 2. Krauss test results for all the samples: (a) The coefficient of friction with respect to brake application, (b) disc temperature versus brake application under constant torque, (c) the coefficient of friction with respect to brake application, (d) disc temperature versus brake application under constant pressure

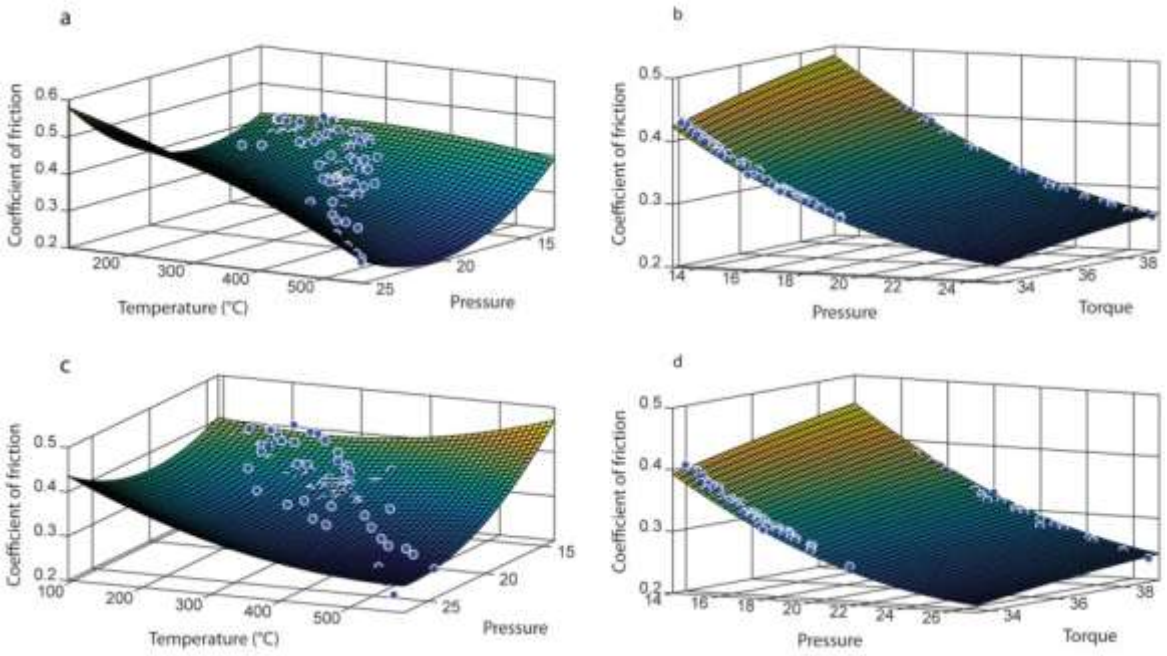

Figure 3. The behavior of friction coefficient in sample 1 as a function of (a) temperature and pressure, (b) as a function of pressure and torque; in sample 2 (c) as a function of temperature and pressure, and (d) as a function of pressure and torque, respectively. (A second-order polynomial fitting is used.)

The fade characteristics of the samples were further analyzed. To this end, the performance of the samples under constant torque case was investigated and the cycle 5 and 10 listed in Table 3 resulted in a considerable amount of temperature increase. The change in the coefficient of friction and the temperatures in these zones are given in figure 4. The lowest experienced coefficient of friction variation was observed in sample 2, while sample 5 showed the highest variation in coefficient of friction. Antimonium trisulfide-containing samples (S4, S5, S6) showed an irregular relationship between temperature and coefficient of friction. This was probably due to the strong oxide thin tribofilm formation in these materials. Sample 4 interestingly showed stable friction coefficients until 450 °C, after this temperature level, it showed a rapid decrease in the coefficient of friction indicating the loss of stability of tribofilm after these temperature ranges.

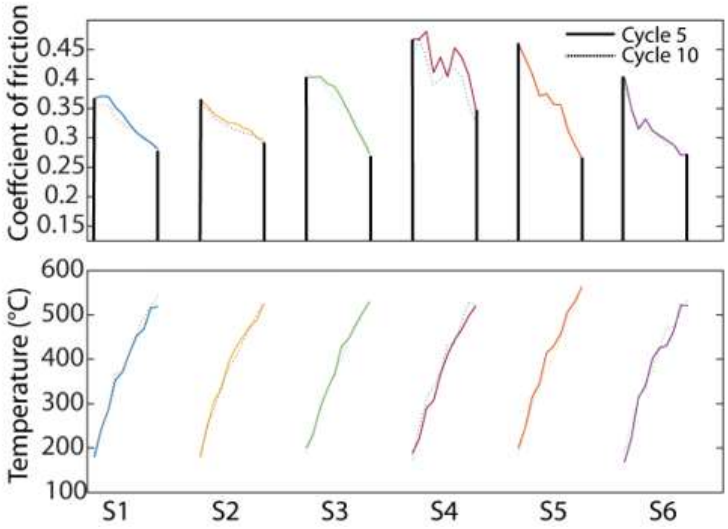

Figure 4. Fade performance of the samples for cycles 5 and 10 in table 3 under constant torque.

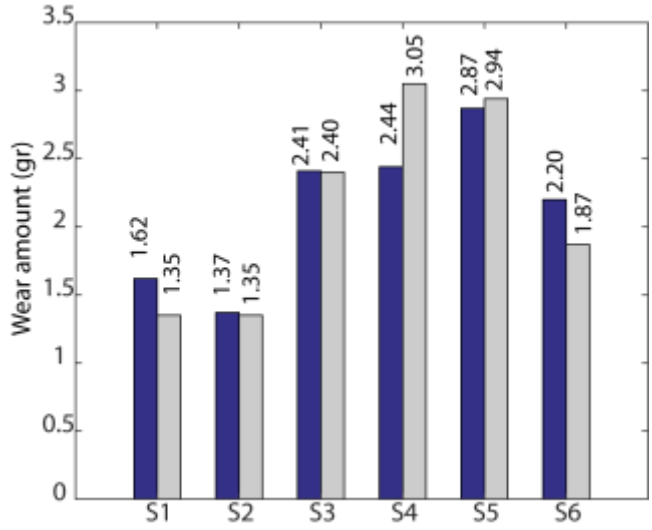

Figure 5. The amount of wear loss of the samples during the constant pressure Krauss tests

In addition to the friction coefficient, the total material loss due to wear during the Krauss test was calculated by measuring the initial and final mass of the brake pads. Figure 5 shows the amount of wear during the constant pressure test. The lowest wear was observed in sample 2 followed by sample 1. Both these samples include zinc sulfide in their ingredients.

Taking together, the combination of graphite, zinc sulfide, and calcium fluoride provided the lowest amount of wear and highest stability with increasing temperatures. Overall, the study showed that the combination of different solid lubricants significantly affects the performance of brake pads.

4. CONCLUSIONS AND RECOMMENDATIONS

In this study, we investigated the combined effect of four different solid lubricants (antimony trisulfide, zinc sulfide, molybdenum disulfide, and calcium fluoride) on the performance of brake pads. To this end, six different samples containing 5w% graphite and two different solid lubricants with 5% from each were fabricated with the same remaining composition and under the same manufacturing conditions. Their tribological performance was evaluated using a Krauss test following the experimental plan suggested by ECE R90 regulation. The coefficient of friction, disc temperatures, and wear rates were further analyzed. The following conclusions were drawn based on the experimental findings.

- The choice of solid lubricants plays an important role in obtaining favorable tribological properties in designing brake pads.
- Among the investigated combinations, sample 2 which includes 5w% graphite, 5w% zinc sulfide, and 5w% calcium fluoride as solid lubricants showed the best performance in terms of wear rate and stability with an average 0.372 operation coefficient of friction.
- Sample 4 was found to be producing the highest coefficient of friction for both the experimental cases, followed by sample 5 under constant torque and sample 3 under constant pressure.

ACKNOWLEDGEMENTS

We gratefully acknowledge the support of the Eren Brake Lining INC. in all aspects of the study. Furthermore, we greatly appreciate Ahmet Nazim and Ahmet Senocak of Gebze Technical University for their assistance in obtaining SEM images and Thermogravimetric analysis.

ABSTRACT

Increased pressure on the lightweight requirements in automotive industry force the automotive OEMs and their suppliers to research new methods and materials in the product development cycle. This study focuses on the comparison between Ethylene Propylene Diene Monomer (EPDM) and Thermoplastic elastomers (TPE) on the acoustic performance as both are the most commonly used materials in automotive sealing systems. More specifically, the dynamic and mechanical properties of different test setup were determined experimentally. In these experimental studies, the mechanical properties of the materials were determined with a dynamic mechanical analysis (DMA) test device. From these test outputs, the glass transition temperatures, loss modulus, storage modulus and tan delta values obtained. These data obtained made by temperature scanning. Besides, the acoustic properties were determined experimentally and numerically. In acoustic analysis, the materials first subjected to sound transmission loss performance tests in the 4-microphone impedance tube test setup. The frequency-dependent sound transmission loss values of the materials cut in the same cross-sectional dimensions measured. In the subsequent CAE study, the results of the impedance tube test system, whose materials modeled with MSC Actran software, verified. In these analyzes, the frequency-dependent sound transmission losses of the models obtained and compared with the experimental results for each material. The results from this numerical and experimental investigations show the TPE materials have different acoustic characteristics compared to EPDM materials. The research reveals the relationship between the main design parameters and functional characteristics such as frequency ranges of acoustic performance, sound transmission loss factors, which will play a key role on the design cycle for automotive sealing systems.

Keywords: Sound transmission loss, vehicle sealing profiles, thermoplastic elastomer, vehicle acoustics

1. INTRODUCTION AND MAIN SECTIONS

The expectation of comfort has become an indispensable element in modern life. This requirement is one of the results of the necessity of keeping the quality of human life high in every living environment. Accordingly, the search for comfort in modern transportation vehicles has become an important quality parameter. In order to provide this comfort and quality indicator in vehicles, isolation materials are used in certain areas of the vehicles to isolate the passenger area of the vehicle from outside as much as possible. These areas and materials generally determine the elements to be prevented from entering the passenger area. For example, the type of material to be used as insulation determines the source of heat in the exhaust line, while the sources of noise are determined in the door structure and on the vehicle floor.

Weather-strips are essential parts to control noise levels in the vehicle interior. Elastically properties of the rubber parts are utilized to reduce aeroacoustics noise around the vehicle emitting via an airborne transfer path. Even there not any air leakage through the interior cabin, Sealing systems are required to have a good insulation performance to prevent mid and high-frequency noise ingress. Sealing elements are manufactured from polymer-based raw materials. These are mainly EPDM and TPE materials.

Polymers have high flexibility capabilities thanks to their long polymeric chains. These abilities allow for high deformability. Thanks to these capabilities, it is actively used in design studies in multiple sectors. According to the mechanical responses of polymer materials at high temperatures, they are studied in two main groups, thermoplastic and

thermoset materials. In terms of the physical concept of polymer chains, thermoreversible, that is, soften when heated and harden when cooled and process completely reversible, thermoplastics are a material that can be used in many industries [1].

Thermoplastics present elastic behavior equivalent to that of vulcanized (chemically cross-linked) established elastomers. Such materials correspond a large group of polymers, called TPEs [2].The thermorevesible capabilities makes TPEs ideally suited for high-efficient thermoplastic processes, such as melt extrusion and injection molding. This easy manufacturability of this material makes them popular raw material for many components [3]. When the usage areas of TPE materials are examined, their use is observed in many industries such as automotive, construction, electronics, and medical. Even more, it is noted in market research that these amounts of use will increase over the years for many industries (Mordor Intelligence, 2019).

TPE sealing materials, which are an effective solution in the topics such as weight and cost reduction, one of the trends of the century in automotive sector, have been the subject of many academic and industrial researches . EPDM materials, on the other hand, still remain an important raw material in the sealing systems industry. These two materials fulfill the performance characteristics that expected of a sealing system within their dynamic, mechanical properties. These two materials, which have different behaviors as chemical and physical properties, naturally exhibit different performances[3].

Figure 1. Thermoplastic Elastomer (TPE) Market: Revenue (%), by Application, Global, 2019 and 2024 [4]

It is an important requirement for companies to be able to respond to this need by conducting R&D processes for automotive manufacturers. Since the improvements in the noise source are limited by criteria such as ergonomics, performance and cost, the most efficient way is to avoid high-frequency wind noise in the transmission path, namely the acoustic isolation of the cabin. Sealing profiles used in vehicles for the isolation of all environmental factors are also one of the most important parts for preventing wind noise. A well-designed gasket should have a high sound transmission loss (STL).

In this study, the sound transmission loss behaviors of different raw materials, TPE (SEBS) and EPDM, which are important for sealing elements, were analyzed experimentally and numerically (FEM). Experimental test groups created in this direction consist of samples with similar mechanical properties from each material group. Firstly, while the test group members were subjected to impedance tube tests experimentally, the dynamic properties of the materials that would form the material model in the FEM model were obtained with the help of an ise dynamic mechanical analyzer (DMA) test device. The FEM model created with the obtained material data was solved with MSC Actran software and compared with the experimental data. This study aims to investigate the geometry-independent sound transmission loss capabilities of the raw material differences of the sealing elements and to model the FEM.

2. MATERIALS AND METHOD

Material and method details used in the study are specified under two main subheadings. While the first of these is the grouping and material details of the sealing elements that make up the test set, the second includes the details of the methods of test and verification studies used in the study.

2.1. Test Materials

The materials to be analyzed in the sound transmission loss tests were tested in 1o different materials, TPE and EPDM in two main groups. The materials in the experiment set were grouped as different hardness and density. TPV group materials contain materials of the same density but different hardness values within their own group. SEBS group includes materials with different hardness and density. The group also includes SEBS sponge material. The EPDM group contains a sponge material and two similar compact materials with different formulations. The materials are coded according to their groups. The table specifies a set of experiments.

Table 1. Experiment sets

Type	Hardness	Density g/cm3	Exp. Set code	Sample code
TPV	40 ShrD	0,96	E1	T40_096
TPV	68 ShrA	0,96	E2	T68_096
TPV	55 ShrA	0,97	S1	T55_097
TPV	65 ShrA	0,97	S2	T65_097
SEBS	70 ShrA	1,13	M2	S70_113
SEBS	70 ShrA	1,2	M4	S70_120
SEBS	80 ShrA	0,6	E3	S80_060
EPDM	-(sponge)	0,62	D1	Ena_062
EPDM	65 ShrA	1,2	D2	E65_120
EPDM	65 ShrA	1,2	D3	E65_120_2

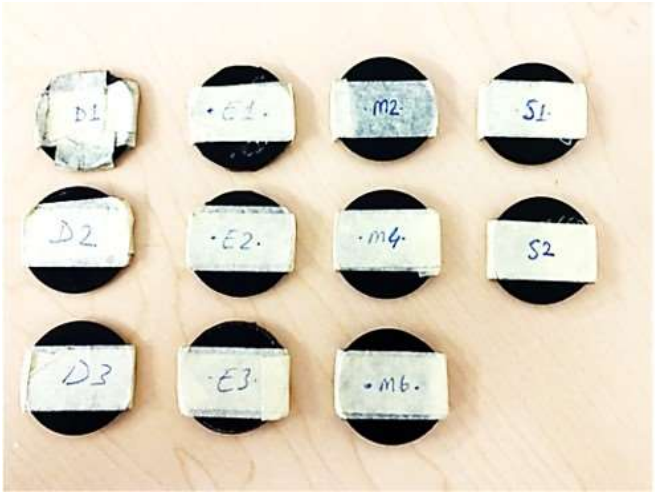

Figure 1. Experiment sets

2.2. Test Methods

Test materials were experimentally subjected to two tests. The first of these is the DMA tests, in which the dynamic mechanical behavior of the materials will be determined. The data obtained from these tests were then used to determine the material properties in the creation of the FEM model. Since polymer-based materials show viscoelastic properties, they have both viscous and elastic capabilities depending on the temperature. These properties affect the dynamic mechanical properties.

Viscoelastic materials show time dependency for the strain stress relations compared to elastic material. For the uniaxial status this relation can be represented as;

$$\sigma(t) + \sum_{k=1}^{K} b_k \frac{d^k \sigma}{d t^k} = E_0\, \varepsilon(t) + \sum_{j=1}^{J} E_j \frac{d^j \varepsilon}{d t^j} \tag{1}$$

For Dynamic loading harmonic stress and strain function can be represented as $\sigma(t) = \sigma_0 e^{i\omega t}$ ve $\varepsilon(t) = \varepsilon_0 e^{i\omega t}$ then equation will be in the form of;

$$\sigma_0 = \frac{\varepsilon_0 \left(E_0 + \sum_{j=1}^{J} E_j (i\omega)^j\right)}{1 + \sum_{k=1}^{K} b_k (i\omega)^k} = \frac{\varepsilon_0\, E_0 \left(1 + \sum_{j=1}^{J} a_j (i\omega)^j\right)}{1 + \sum_{k=1}^{K} b_k (i\omega)^k} \tag{2}$$

Which will lead to the following equations after mathematical expression .

$$\sigma_0 = (E' + iE'')\, \varepsilon_0 \tag{3}$$

In this expression E and E' is called as storage and loss modulus respectively. For viscoelastic material sthese modulus depends on excitation frequency under the dynaic loading . If we consider that acoustic excitation is also dynamic loading material characteristics will be changed in each frequency. Complex modulus of the viscoelastic material will be in the form of :

$$\tilde{E}^* = E'(\omega)\big(1 + i\eta(\omega)\big) \tag{4}$$

Whereas η is loss factor which is ratio of loss modulus to storage modulus.

$$\eta(\omega) = \frac{E''(\omega)}{E'(\omega)} \tag{5}$$

Material used in sealing system are viscoelastic materials. Viscoelastic materials behave between elastic and viscous phenomena. Linear viscoelasticity means the stress/strain ratio depends only on frequency (time) and temperature. DMA which used in this study is a test equipment which mechanically deforms the materials under different temperature or frequency and measures the response. Storage modulus (elastic property) and loss modulus (viscous property) of the materials are measured and reported as elastic coefficient (E) and tan delta [5].

The materials were subjected to acoustic performance tests in the second part. In these tests, sound transmission loss analyzes were performed. Thee sound transmission ability of a material is a performance criterion proportional to the ability of the material to absorb the sound energy of the noise source. The loss of sound transmission is measured by the ratio of sound source side energy ratios and receiver side sound energy of the material [3].

$$TL(\beta, f) = 10\, log \frac{W_{in}(\beta,f)}{W_{out}(\beta,f)} \tag{6}$$

β is the angle of incidence of the sound wave over the surface of the given partition
f is the frequency of the considered sound wave
$W_{in}$is the sound power incident at the source side
W_{out} is the sound power radiated at the opposite side of the partition.

Since sound is examined as a wave phenomenon, loss of sound transmission is examined depending on frequency. In other words, the frequency range performance of the isolation type to be selected should be taken into consideration in the frequency band. Loss of sound transmission values are an important material criterion that this study will use in material selection, detailed explanation is shared later in the study.
Another experimental test, the impedance tube, was used to experimentally determine the sound transmission loss of materials. These test kits consist of precision testing tubes that are equipped with microphones and sound sources. Material samples are inserted into the tube. A loudspeaker in the tube then emits precisely quantified sound, and the microphones measure the sound pressure level at specific locations along the length of the tube. The software then calculates the normal incident acoustic properties of the material based on frequency response functions measured between the various measurement locations.

These tests were performed under the test conditions specified in ASTM E2611 standard. In line with impedance tube theory, a sound source is mounted at one end of the impedance tube, and a sample of the material is placed in a holder. The loudspeaker generates broadband, stationary random sound waves that propagate as plane waves. The plane waves hit the sample in the holder with part of the waves reflected back into the source tube, part absorbed by the material and part passing through the material to the receiving tube. The portion of the plane waves that pass through the material then encounter the end of the receiving tube where some of the waves are reflected and some exit the tube. By measuring the sound pressure at four fixed locations (two in the source tube and two in the receiving tube) and calculating the complex transfer function using a four-channel digital frequency analyzer, it is possible to determine the transmission loss of the material [6].
The sound waves transmitted from the sound source to the sample, reflected from the sample, transmitted to the second tube over the sample and reflected back from the terminator of the second tube are shown as A, B, C and D respectively. In practice, these sound waves are intertwined and the sound waves need to be separated in order to determine the acoustic parameters.

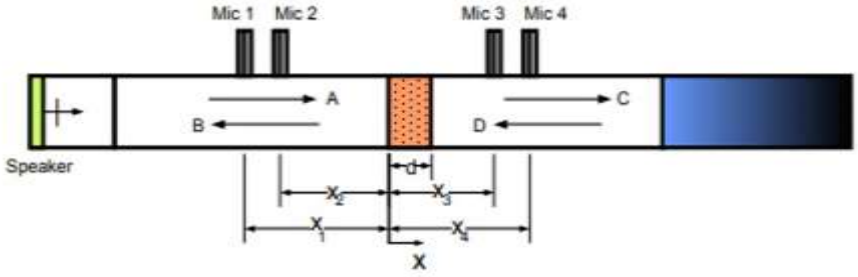

Figure 2. The method is described in ASTM E2611 [6].

The tests incluedes With 30 mm inner diameter tube, the sound transmission losses of the materials were measured between 200 Hz and 6400 Hz. The measurement, signal processing parameters were determined in sequence:

- The ambient temperature was 22 ºC at the time of test.
- Frequency Resolution: 2 Hz
- Number of Averages: 48
- Measurement Duration: 20 seconds
- Buffer Size: 16384 Samples

Finally, the impedance tube is modeled in the FEM environment. The aim here is to verify the ability of different raw materials to be modeled with FEM. In this direction, all impedance tube scenarios were analyzed with the help of MSC Actran software. The image of the MSC Actran model is shared in the figure.

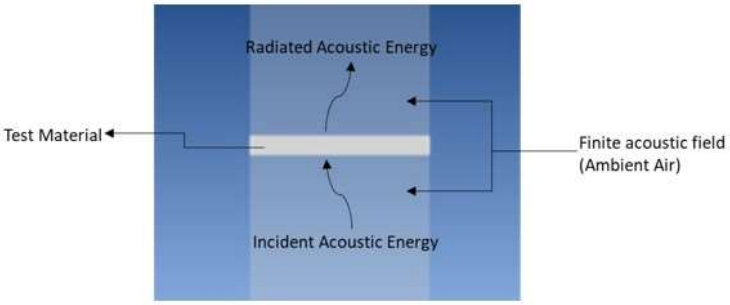

Figure 3. MSC Actran Model.

3. RESULTS

Firstly, the DMA test data of the materials were analyzed and elastic characteristics were extracted for each material. DMA result graphs for a sample are shared as in the graph below.

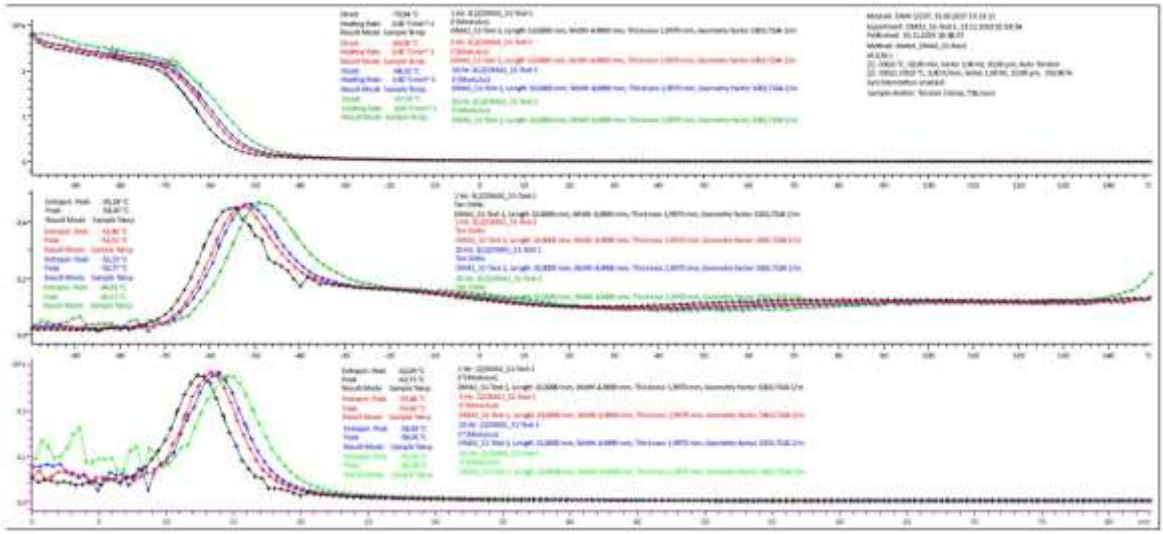

Figure 4. DMA Results

The impedance test results are graphed according to material classes and different materials with same physical properties. The test results are indicated by graphs below.

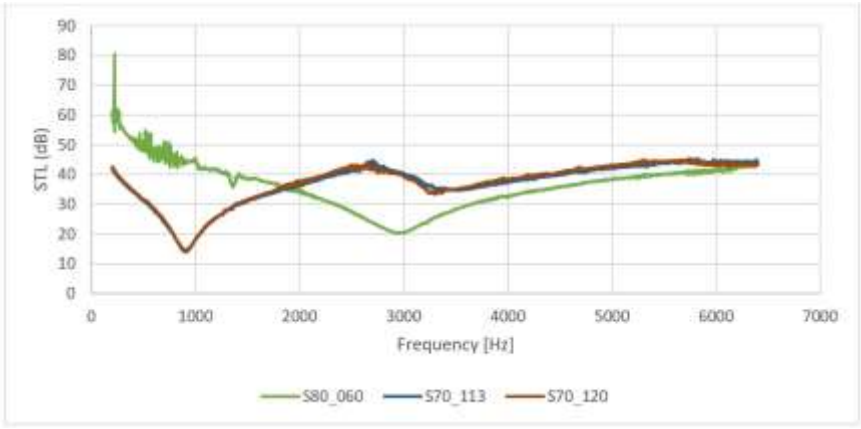

Figure 6. Experiment data for SEBS materials.

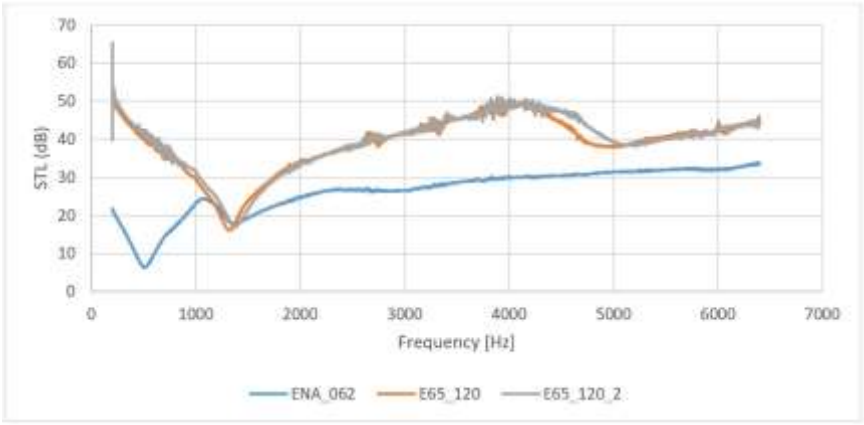

Figure 7. Experiment data for EPDM materials.

Finally, a sample of TPE and EPDM samples from the result graphs where the results of the FEM results and the results of the experimental test data overlap are shared as follows.

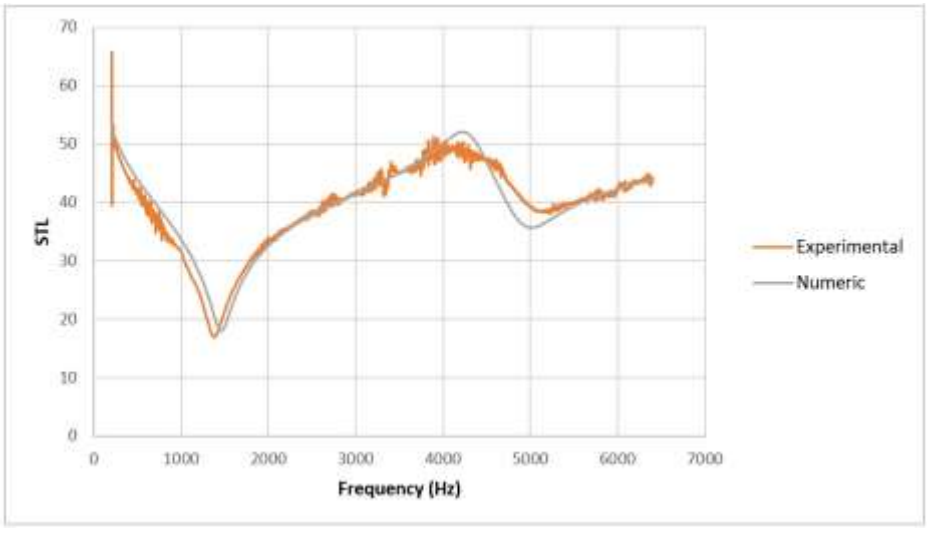

Figure 8. Experiment & FEM results for EPDM(D2) material.

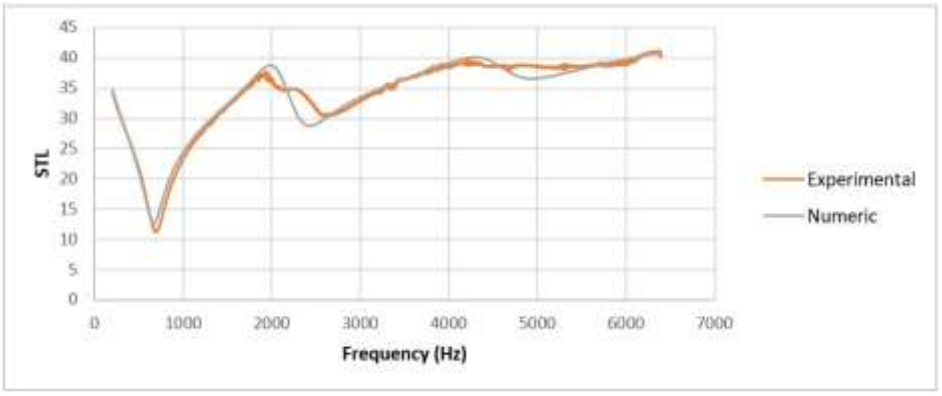

Figure 9. Experiment & FEM results for TPE(S2) material.

4. CONCLUSION

In this study, it is aimed to analyze the sound transmission loss performances of different materials under similar conditions. In the experiment sets, material types, material densities and material hardness were selected as independent sampling parameters. Materials were selected in such a way that the thickness of the materials to be tested was in the closest range available for production and supply. These thickness differences will be taken into consideration in the evaluation of the results.

In the first inferences of the study, the materials (TPV) with the same density limits gave different results according to their hardness. As a result, as the hardness increased of TPV plates having the same density, higher loss of sound transmission performance was observed in higher octave bands (Fig. 10). It can be assumed that the difference in the first mode in E2 and S2 materials with similar hardness and density is caused by the difference in sample thickness. The E1 with the highest hardness performed 55% better in the first resonance mode than the least rigid S1 material.

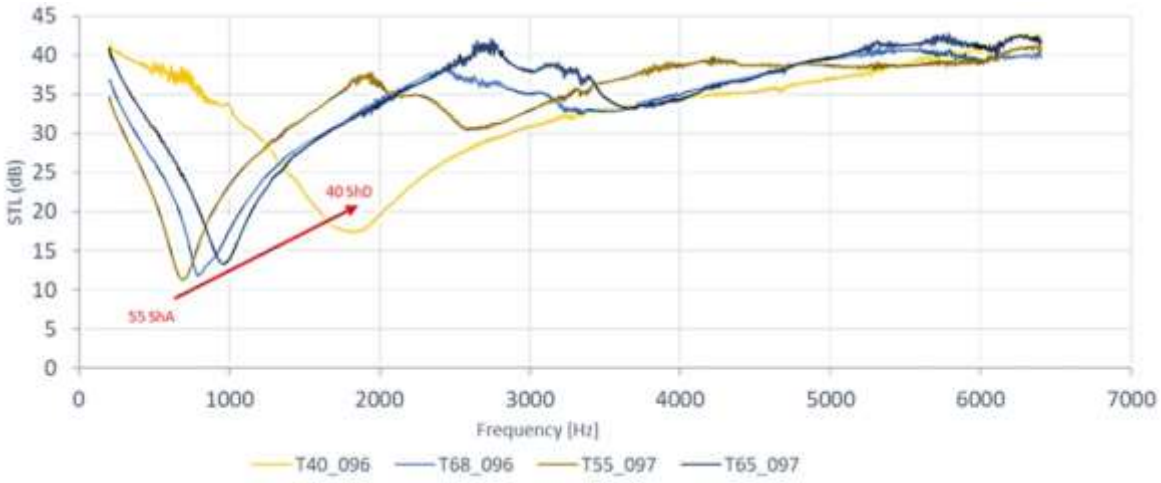

Figure 10. Experiment data for TPV materials.

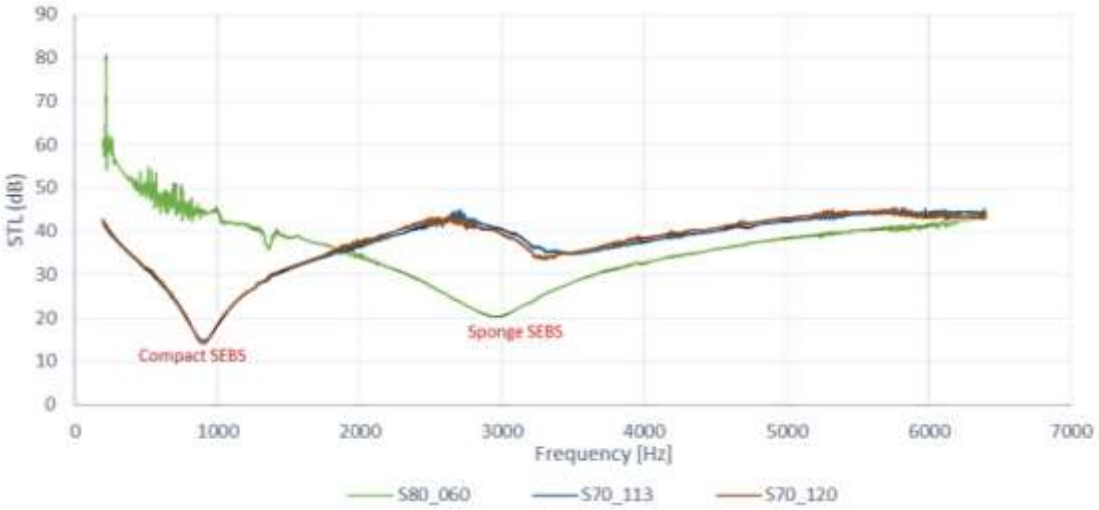

Figure 11. Experiment data for SEBS materials.

When examine the results of SEBS materials results, while compact SEBS materials exhibit STL performance at lower frequencies, Sponge SEBS material has been observed in the first mode of higher octave bands (Fig. 11). The criterion that sponge SEBS material has a higher thickness should not be forgotten in this analysis.

When the results of similar density materials are examined, it is observed that SEBS and EPDM materials give close STL values. But the materials exhibited these values in different octave bands. The first resonance mode of the SEBS was observed in the near 900 Hz, while the first modes of compact EPDM were observed in the near 1300Hz (Fig. 12).

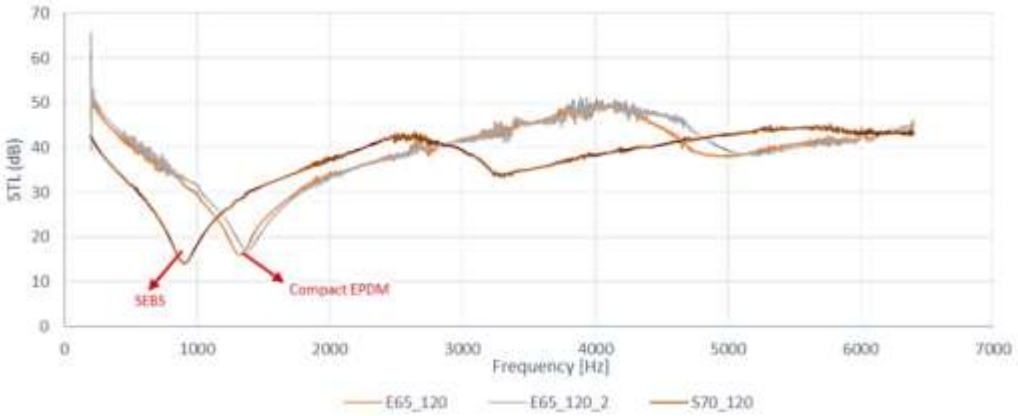

Figure 12. Comparative graph of different materials (SEBS -EPDM) with similar density.

In addition to the analysis of the performance of the materials, outputs were also obtained on how the materials affect STL behavior:

- Results were obtained in such a way that validation was obtained in FEM and experimental data in all models.
- In order to observe the STL characteristics of TPV and SEBS materials, the materials exhibited their first mode at close frequencies considering the materials having similar hardness.
- The increase in hardness values shifts the first resonance mode to high frequencies, for TPV materials.
- The increase in density in SEBS materials shifts the first resonance mode to high frequencies.
- In first frequency mode of the two sponge materials SEBS shows the first resonance mode at higher frequencies than EPDM.

ÖZET

Bu deneysel çalışmada, saf poliamid-66 (PA) ve öğütülmüş kolemanit (KOL) dolgulu PA kompozit malzemelerin, tribolojik özellikleri, KOL dolgu miktarına bağlı olarak çalışılmıştır. Saf PA66 malzemesinin tribolojik özelliklerine, KOL dolgu miktarının etkisi hala belirsiz durumdadır. Bu kapsamda, alışıla gelmiş özelliklerden farklı özelliklere sahip aşınma direnci büyük (yüksek) mikro partikül dolgulu yeni bir PA/KOL kompozit malzeme elde etmek amaçlanmıştır. Bu amaçla, saf PA ve ağırlıkça yüzde 12,5, 15, 17,5, 20 oranlarında KOL dolgulu PA kompozit malzemeler kullanıldı. Saf ve kompozit malzemelere, TS ISO 7148-2 standardına göre yağlama olmaksızın, sabit 30 N yük, sabit 150 d/d kayma hızı ve değişken (120 m, 360 m, 720 m) kayma mesafesi şartlarında pim – disk (Pin–on–Disc) aşınma testi uygulandı. Deneysel sonuçlar, saf PA malzemenin ve/veya PA/KOL kompozit malzemenin, tribolojik özelliklerinin, KOL dolgu miktarına bağlı olduğunu gösterdi. Artan kayma mesafesine bağlı olarak artan KOL dolgu miktarının saf PA malzemesinin maksimum sürtünme kuvvetini ve ortalama sürtünme katsayısını küçülttüğü ve aşınma oranını düşürdüğü tespit edilmiştir.

EFFECT OF GROUND COLEMANITE FILLED CONTENT ON THE TRIBOLOGICAL PROPERTIES OF POLYAMIDE 6.6 MATERIAL

ABSTRACT

In this experimental study, tribological properties of pure polyamide-66 (PA) and ground colemanite (KOL) filled PA composite materials were studied depending on the amount of KOL filler. The effect of the amount of KOL filler on the tribological properties of pure PA66 material is still unclear. In this context, it is aimed to obtain a new PA/KOL composite material filled with microparticles with high (high) wear resistance, which has different properties than the usual ones. For this purpose, pure PA and PA composite materials with KOL filled at 12.5, 15, 17.5, 20 percent by weight were used. Pure and composite materials, according to TS ISO 7148-2 standard, without lubrication, under constant 30 N load, constant 150 rpm sliding speed, and different (120 m, 360 m, 720 m) sliding distance conditions pin – disc (Pin–on– Disc) wear test was performed. Experimental results showed that the tribological properties of pure PA material and/or PA/KOL composite material depend on the amount of KOL filler. It has been determined that the amount of KOL filler that increases due to the increasing sliding distance reduces the maximum friction force and average friction coefficient of the pure PA material and reduces the wear rate.

Key words: Polyamide 6.6, Colemanite, Composite, Wear, Pin-on-disc

1. GİRİŞ

Günümüzde üretim sektörünün artan ihtiyaçları ve kullanılan malzemelerden beklenen düşük ağırlık, yüksek dayanım gibi özelliklerin artması sonucunda metal malzemeler dışındaki malzemeleri kullanma ihtiyacı artmıştır. Polimer malzemelerin metallere göre düşük mekanik ve tribolojik özelliklerinden dolayı kullanım alanı kısıtlı olsa da kimyasal ve/veya fiziksel modifikasyonla mukavemet arttırıcı katkı ve dolgu malzemeleri sayesinde, düşük ağırlıkları ve yüksek korozyon dirençlerinin yanı sıra kazandıkları, yüksek aşınma direnci ve düşük üretim maliyeti sebebiyle kullanım alanını genişleterek otomotiv, inşaat ve havacılık gibi birçok sektörde kullanılmaktadır [1-2]. Polimer malzemelere kalsiyum karbonat ($CaCO_3$), talk ve baryum sülfat ($BaSO_4$) gibi mineral katkı maddeleri eklenerek nihai ürün maliyetleri ve ürün kalitesi iyileştirildiği bilinmektedir [3]. Önemli bir kullanım alanına sahip olan poliamid ise diğer polimerlerle kıyaslandığında daha üstün mekanik özelliklere, yüksek kimyasal ve aşınma direncine sahiptir [4]. Bu üstün özellikler poliamidin moleküler zincirlerinde bulunan hidrojen bağlarından dolayıdır [5]. Her geçen gün kullanım alanını artıran bor mineralleri ve ürünleri; cam, seramik, temizleme ve beyazlatma, yanmayı önleyici madde, tarım, nükleer uygulamalar, tekstil ve metalürji gibi pek çok sanayi kolunda kullanılmaktadır [6]. Bu çalışmada kullanılan kimyasal bileşimi $Ca_2B_6O_{11}.5(H_2O)$ olan öğütülmüş kolemanit en yüksek bor içeriğine sahip bor minerallerinden biri olup, Türkiye kolemanit minerallerinin dünyadaki en büyük rezervlerine sahiptir [7]. Ayrıca tribolojik çalışmalar incelendiğinde borik asit, üleksit ve boraks ilaveli polimer matrisli malzemelerde daha kararlı sürtünme katsayısı elde edildiği bildirilmiştir [6].

Bu çalışmayla ilgili literatürde; Koyunbakan ve arkadaşları PA6 polimerine farklı oranlarda karbon elyaf eklendiğinde aşınma oranının azaldığını gözlemlemiş ve PA6 kompozit malzemenin sürtünme katsayısını etkileyen en önemli parametrenin yük olduğunu tespit etmişlerdir [8], İpek ve arkadaşları, %3 olarak kullanılan bor oksit katkısının fren balatasındaki sürtünme katsayısını %18 oranında arttırdığını tespit etmişlerdir [9], Başar ve arkadaşları balata malzemesine %4 ilave edilen kolemanit ve boraksın en iyi (en yüksek) sürtünme katsayısı değerini verdiğini, bunun yanında malzemeye kütlece %4'den fazla kolemanit ve boraks katkısının sürtünme performansını olumsuz etkilediğini (azalttığını) gözlemlemişlerdir [10], Ünal ve arkadaşları, kayma mesafesi arttırıldığında poliamid 66 (PA66), alifatik poliketon (APK), polioksimetilen (POM), ultra yüksek moleküler ağırlıklı polietilen (UHMWPE) ve %30 cam elyaf takviyeli polifenilen sülfür (PPS+30%GFR) kompozit malzemelerinin aşınma oranlarının azaldığını gözlemlemiştir [11].

Bu deneysel çalışmada, saf poliamid 6.6 (PA) polimerine ağırlıkça %12,5, %15, %17,5 ve %20 oranlarında öğütülmüş kolemanit (KOL) dolgu maddesi ilave edilerek elde edilen PA/KOL kompozit malzemelerin pin-on-disk test cihazında, kuru (yağlama olmayan) ortam şartlarında, seramik bilye ile sabit hız ve sabit yük altındaki sürtünme davranışları test edilmiştir. Farklı oranlarda ilave edilen öğütülmüş kolemanit dolgu miktarının, farklı kayma mesafesine bağlı olarak poliamid malzemesinin sürtünme davranışına etkileri araştırılmıştır.

2. MALZEME VE YÖNTEM

2.1. Poliamid 6.6

Bu çalışmada, ticari ismi Stabamid-26 AE 1 (Rhodia Operations) olan ve Tablo 1'de fiziksel özellikleri verilen poliamid 6.6 polimeri matris malzemesi olarak kullanıldı.

Tablo 1. Poliamid 6.6 fiziksel özellikleri (Rhodia Operations)

Erime sıcaklığı	260°C
Katılaşma sıcaklığı	220°C
Dökme yoğunluğu	0,6 – 0,7 g/cm³
Yoğunluk	1,14 g/cm³

2.2. Öğütülmüş Kolemanit

Eti Maden İşletmeleri Genel Müdürlüğünden 45 mikrometre elek altı (alt elek) parçacık boyutunda temin edilen, $Ca_2B_6O_{11}.5(H_2O)$ kimyasal bileşimine ve öğütülmüş kolemanit (KOL) ticari adına sahip mineral dolgu maddesi olarak kullanıldı. Öğütülmüş kolemanit, 2,42 g/cm³ yoğunluğa ve 45 mikrometreden küçük parçacıkların % 75 – 85 oranında olduğu bir parçacık içeriğine sahiptir (EYS FRM-ETİ-00 10 /20/5/2014-02). Bazı kimyasal bileşimlerinin içeriği B_2O_3 için %40, CaO için %27, SiO_2 %6.5, Al_2O_3 için % 0.40, MgO için %3, SiO_2 için %1.5 ve As için 35 ppm'dir (EYS TBL ETİ 01 /24.08.2015/00).

2.3. Partikül Boyut Dağılım Analizi

Öğütülmüş kolemanitin (KOL) partikül boyut dağılımı ölçümünde (analizinde), bir bilgisayar destekli Hydro2000MU (5,6 sürüm) yazılımı ve seri numarası MAL101630 olan Mastersizer 2000 (Malvern Instruments Ltd., UK) cihazı kullanıldı. 45 mikrometre elek altı (alt elek) parçacık boyutuna sahip öğütülmüş kolemanitin tanecik boyutu dağılımı ölçümünden elde edilen bazı fiziksel özelliklerinin değerleri Tablo 2'de verilmiştir.

Tablo 2. Öğütülmüş kolemanit fiziksel özellikleri (Mastersizer 2000)

Ortalama Partikül Çapı (D50 %)	14,008 µm
Top Cut (D90%)	49,094 µm
Özgül yüzey alanı	1,32 m^2/g

2.4. Kompozit Malzeme Hazırlama

PA/KOL kompozit malzemelerin üretilmesinde, vida oranı (L/D) 45, vida boyu (L) 1125 mm olan çift vidalı ekstrüder (Coperion Werner ve Pleiderer ZSK 25 P8.2 E WLE) kullanıldı. Farklı ağırlıkça yüzde 12,5, 15, 17,5 ve 20 oranlarında, kompozit hammaddeler üretimi, sabit ekstrüzyon parametrelerinde ve vida devir hızı 900 rpm (d/d), besleme bölgesinden kafa (matris) bölgesine doğru kovan bölgesi sıcaklıkları 170˚C - 230˚C, anma üretim kapasitesi 30 kg/sa ve su banyosu 30oC olan sabit ekstrüzyon ayarlarında gerçekleştirildi. Granül halde elde edilen her bir PA/KOL kompozit hammaddeler sıcaklığı 50˚C olan fırında 4 saat kurutuldu.

2.5. Çok Amaçlı Deney Parçası Üretimi

Saf PA ve PA/KOL kompozit hammaddelerin enjeksiyon kalıplama ile şekillendirilmesinde, vida çapı (D) 46 mm ve vida oranı (L/D) 20 olan enjeksiyon makinesi (Haitian Plastics Machinery HTF 90W) kullanıldı. TS EN ISO 294-1 standardı dikkate alınarak gerçekleştirilen enjeksiyonla üretim işleminde, 235˚C meme sıcaklığı, 230˚C – 225˚C – 220˚C zone sıcaklıkları, 1400 bar enjeksiyon basıncı, 700 – 500 bar ütüleme basıncı, 45 – 20 m/dak enjeksiyon hızı, 5 – 12 m/dak ütüleme hızı ve 60 s bekleme süresi ile 30˚C kalıp soğutma suyu sıcaklığında sabitlenmiş enjeksiyon parametreleri kullanıldı.

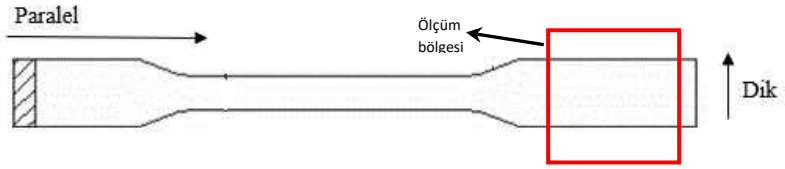
ISO 3167'e göre Tip 1A çok amaçlı deney parçalarına, direkt olarak (doğrudan doğruya) TS EN ISO 294-1'e göre bir T yolluklu ve iki kaviteli (oyuklu) tip A ISO çekme kalıbında 216 mm x 10 mm x 4 mm ölçülerinde üretildi. Üretilen çok amaçlı deney parçaları, tertemiz bir yapıyla beraber bir tarafı kaygan bir diğer tarafı kaygan olmayan üst yüzeylerine sahiptir. Çok amaçlı deney parçaları, deneylerden önce, TS EN ISO 291 standardına uygun olarak şartlandırıldı.

2.6. Yoğunluk Ölçümü

Yoğunluk numunesi olarak ilgili standart dikkate alınarak çok amaçlı deney parçalarının orta bölgesi (middle region) dışında kalan ve enjeksiyon girişine (gage region) en uzak bölgesinden, disk testere ile kesilen 10 mm x 20 mm x 4 mm ölçülerine sahip numuneler kullanıldı. Yoğunluk deneyleri, TS EN ISO 1183-1 standardına göre maksimum kapasitesi 210 g, ölçme hassasiyeti 0,1 mg ve yoğunluk ölçme seti (kiti) olan bir terazide (Sartorius CP224S) gerçekleştirildi. Yoğunluk ölçümlerinde ilgili standartta belirtilen A (daldırma) metodu ve saf su (daldırma sıvısı) kullanıldı. Deney süresince saf su sıcaklığı sürekli olarak ölçülerek ilgili sıcaklıktaki saf suyun yoğunluğuna bağlı olarak saf PA ve PA/KOL kompozit malzemelerin yoğunlukları tespit edildi. Yoğunluk deneylerinde her bir ortalama değerin tayini için en az 3'er adet numune kullanıldı.

2.7. Pürüzlülük Ölçümü

Pürüzlülük deneyleri, Mitutoyo Marka SJ 301 Model yüzey pürüzlülük ölçüm cihazı kullanıldı. Yüzey pürüzlülük ölçümleri TS EN 10049 ve TS 2040 EN ISO 1302 standartlarına göre 22˚C±1˚C ortam sıcaklığında gerçekleştirildi. Yüzey pürüzlülük ölçümü yüzey bölgesi olarak şekil 1'de gösterilen çok amaçlı deney parçalarının orta bölgesi (middle region) dışında kalan ve enjeksiyon girişine (gage region) en uzak bölgesinden, disk testere ile kesilen 10 mm x 20 mm x 4 mm ölçülerine sahip numunelerin kaygan tarafı kullanıldı. Bu kapsamda her bir ilgili pürüzlülük numune parçasında, enjeksiyon kalıplama doğrultusuna paralel ve dik yönlerde olacak şekilde en az 3'er (üçer) yüzey pürüzlülük ortalaması (Ra) değeri ölçüldü.



Şekil 1. Pürüzlülük ölçüm bölgesi

2.8. Young's Modülü Ölçümü

Testler 5 kN kapasiteli, üzerinde Clip-on statik ekstansometre (INSTRON 2630-111) bulunan ve bilgisayar destekli Bluehill yazılımı kurulu INSTRON Universal (4411 H 4240) çekme basma test cihazında gerçekleştirildi. Young's Modülü için 1 mm/dak çekme hızı ve çeneler arası 115 mm, ekstansometre ayakları mesafesi 50 mm olan sabit parametreler kullanıldı. Testlerin tamamı sıcaklığı 22°C ±1°C, nemi %50±10 ortam koşullarında gerçekleştirdi. Her bir ortalama deneysel değer için en az 5'er adet deney numunesi kullanıldı ve ilgili deneysel verilerin en yüksek ve en düşük sonuçları çıkarılarak istatistiksel olarak değerlendirildi.

2.9. Aşınma deneyi

Aşınma deneyleri, NANOVEA markalı bilgisayar kontrollü aşınma test cihazıyla, pin-on-disk (ASTMG99) metoduna göre yapıldı. Aşınma deneyleri TS ISO 7148-2 standartlarına uygun 23˚C ±1˚C ortam sıcaklığında ve kuru ortam şartlarında gerçekleştirildi. Aşınma numunesi olarak ilgili standart dikkate alınarak, çok amaçlı deney parçalarının orta bölgesi (middle region) dışında kalan ve enjeksiyon girişine (gage region) en uzak bölgesinden, disk testere ile kesilen 20 mm x 20 mm x 4 mm ölçülerine sahip numuneler kullanıldı. Kütle kayıplarını hesaplamak amacıyla, aşınma (sürtünme) testi öncesinde her numunenin deney öncesi kütleleri ($M_ö$) ölçme hassasiyeti 0,1 mg terazide (Sartorius CP224S) gerçekleştirildi. Bu kapsamda aşınma deneyleri, Tablo 3'te belirtilen parametreler ile yapıldı.

Tablo 3. Deney parametreleri

Bilye Malzemesi	Bilye Çapı (mm)	Dönme Yarıçapı (mm)	Kayma Hızı (rpm)	Test Yükü (N)	Kayma Mesafesi (m)
Seramik	6	6	150	30	120 360 720

Testlerin ortalama sonuçlar verebilmesi için numunelere 120 m, 360 m ve 720 m kayma mesafelerinde en az 3'er adet test uygulandı. Testler sonrasında deney sonrası kütleler (M_s) hassas terazide ölçülüp kütle kayıpları;

$$M_s - M_ö = \Delta M \quad (1)$$

denklemi ile hesaplandı.

Denklem (2) ve (3) kullanılarak hacim kaybı (ΔV) ve aşınma oranı (k) hesaplandı.

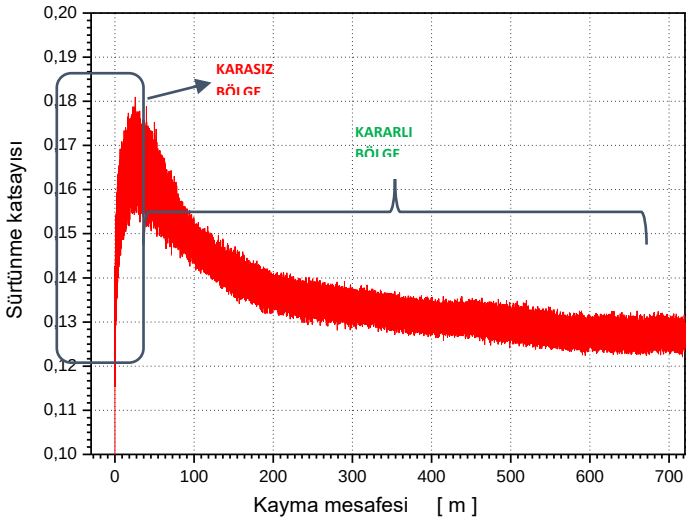
$$\Delta V = \frac{\Delta M}{d} \times 1000 \quad (2)$$

$$k = \frac{\Delta V}{F \cdot L} \quad (3)$$

Burada; ΔV: hacim kaybı [mm^3], M_s: deney sonrası kütle [g], $M_ö$: deney öncesi kütle [g], d: yoğunluk [g/cm^3],

k: Aşınma oranı [mm^3 / N · km], F: test yükü [N], L: kayma mesafesi [m]'dir.

Kompozit malzemenin sürtünme katsayısının katkı oranına ve kayma mesafesine göre değişimini görmek için TS ISO ISO7148-2 standardı madde 12.2 Test Sonuçları kısmında belirtildiği şekilde, kararsız bölge analizden çıkarılarak kararlı bölgedeki değişim incelendi



Şekil 2. Sürtünme katsayısı için kararlı ve kararsız bölgeler

Deney sonuçları incelendiğinde her bir kayma mesafesi için deney başlangıcındaki %10'luk kayma mesafesi kararsız bölge olarak analizden çıkarılıp sonuçlar incelendi. Şekil 2'de sürtünme katsayısı için kararlı ve kararsız bölgelerin kayma mesafesine göre konumu verilmiştir.

3. DENEY SONUÇLARI

3.1. Yoğunluk Sonuçları

Yoğunluk değerlerinin verildiği Tablo 4'te incelendiğinde artan dolgu miktarı ile orantılı olarak beklenen şekilde yoğunluk değerinin de arttığı görüldü. Beklenen şekilde çıkan sonuç kompozit malzeme üretiminin homojen olduğunu göstermektedir.

Tablo 4. Yoğunluk ölçümleri

Numune	Yoğunluk (g/cm³)
Saf PA	1,1400 ± 0,0003
yüzde 12,5 KOL dolgulu PA kompozit	1,2980 ± 0,0002
yüzde 15 KOL dolgulu PA kompozit	1,3290 ± 0,0002
yüzde 17,5 KOL dolgulu PA kompozit	1,3610 ± 0,0003
yüzde 20 KOL dolgulu PA kompozit	1,3920 ± 0,0005

3.2. Pürüzlülük Sonuçları

Pürüzlülük ölçüm sonuçlarının verildiği Tablo 5'te incelendiğinde, enjeksiyon yönüne paralel olarak alınan ölçümlerde ortalama pürüzlülük değeri artan kolemanit dolgu miktarıyla orantılı olarak artarken enjeksiyon yönüne dik olarak alınan ölçümlerde ise ortalama pürüzlülük değerlerinin kolemanit dolgu miktarından etkilenmediği görüldü.

Tablo 5. Pürüzlülük ölçümleri

Numune	Enjeksiyon yönüne	
	Paralel Ra (µm)	Dik Ra (µm)
Saf PA	0,10±0,02	0,16±0,05
yüzde 12,5 KOL dolgulu PA kompozit	0,17±0,05	0,16±0,03
yüzde 15 KOL dolgulu PA kompozit	0,19±0,06	0,16±0,03
yüzde 17,5 KOL dolgulu PA kompozit	0,21±0,08	0,16±0,05
yüzde 20 KOL dolgulu PA kompozit	0,23±0,04	0,16±0,03

3.3. Young's Modülü Sonuçları

Young's Modülü ölçüm sonuçlarının verildiği Tablo 6 incelendiğinde, artan dolgu miktarı ile birlikte Young's Modülü değerinin de arttığı görüldü. Saf malzemeye kıyasla kompozit malzemenin Young's modülü değeri en az %54 oranında, en yüksek %80 oranında arttığı tespit edildi.

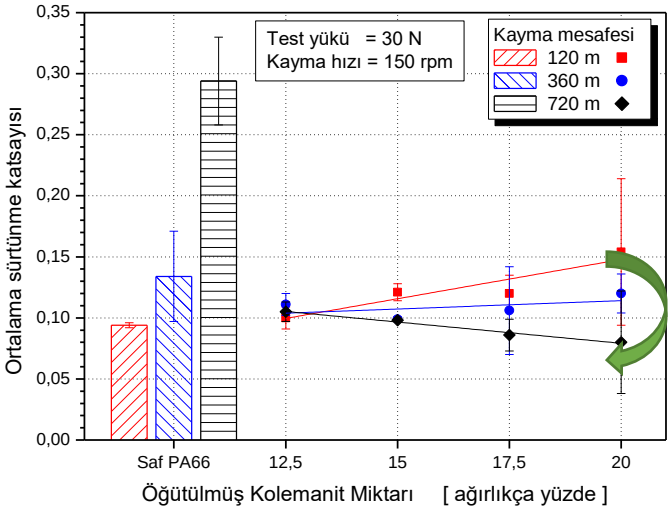
Tablo 6. Young's Modülü ölçümleri

Numune	Elastisite Modülü (N/mm²)
Saf PA	2807,334
yüzde 12,5 KOL dolgulu PA kompozit	4333,169
yüzde 15 KOL dolgulu PA kompozit	4345,004
yüzde 17,5 KOL dolgulu PA kompozit	4891,674
yüzde 20 KOL dolgulu PA kompozit	5065,269

3.4. Aşınma Deneyi Sonuçları

3.4.1 Sürtünme Katsayısı

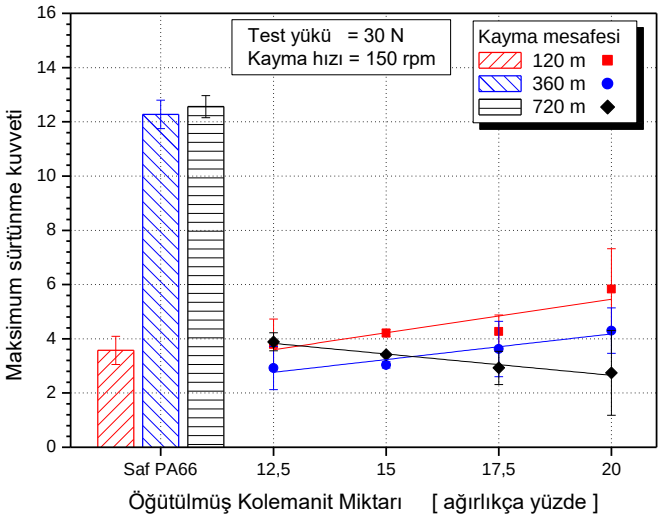
Aşınma (sürtünme) deneyi sonrası elde edilen ortalama sürtünme katsayısı değerlerinin bir araya getirildiği Şekil 3 incelendiğinde artan kayma mesafesi ile saf PA malzemesinin ortalama sürtünme katsayısı artarken, kompozit malzemenin sürtünme katsayısının azalma eğilimi gösterdiği tespit edildi.



Şekil 3. Kayma mesafesine ve kolemanit dolgu miktarına göre ortalama sürtünme katsayısı

3.4.2 Sürtünme Kuvveti

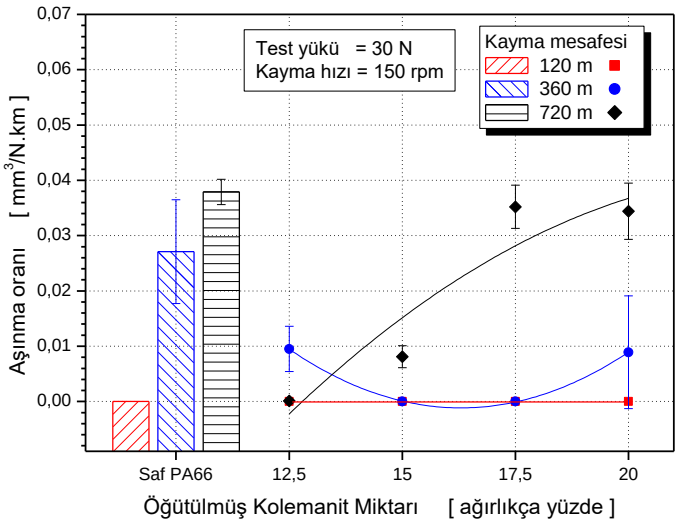
Aşınma deneyi sonrası elde edilen maksimum sürtünme kuvveti değerlerinin verildiği Şekil 4 incelendiğinde maksimum sürtünme kuvveti değerinin saf PA malzemesi için 720 m kayma mesafesinde olduğu görülürken kompozit malzeme için 720 m kayma mesafesinde artan dolgu oranıyla birlikte maksimum sürtünme kuvvetinin azaldığı tespit edildi. 120 m ve 360 m kayma mesafesinde ise artan dolgu oranıyla birlikte maksimum sürtünme kuvveti değerinin arttığı belirlendi.



Şekil 4. Kayma mesafesine ve kolemanit dolgu miktarına göre maksimum sürtünme kuvveti

3.4.3. Aşınma Oranı

Kütle kaybından hesaplanan aşınma oranı değerlerinin verildiği Şekil 5 incelendiğinde PA ve PA/KOL kompozit malzemelerin tümü için 120 m kayma mesafesinde aşınma oranı sıfır iken kayma mesafesi 360 m olduğunda aşınma oranının saf PA malzemesinde yaklaşık 0,03 mm^3/N.km civarında, PA/KOL kompozit malzemelerde ise 0,005 mm^3/N.km civarında olduğu tespit edildi. Kayma mesafesi 720 m olduğunda en iyi sonucu ağırlıkça yüzde 12,5 KOL dolgu miktarına sahip PA/KOL kompozit malzeme gösterirken artan dolgu miktarıyla birlikte aşınma oranının da arttığı tespit edildi.



Şekil 5. Kayma mesafesine ve kolemanit dolgu miktarına göre aşınma oranı

4. SONUÇ VE ÖNERİLER

Yapılan deneysel çalışma sonucunda;

- Eklenen her bir KOL dolgu oranı seviyesinden PA malzemesinin özelliklerinin etkilendiği belirlendi.
- Artan kayma mesafesi ile saf PA malzemesinin ortalama sürtünme katsayısı artarken, PA/KOL kompozit malzemenin sürtünme katsayısının azalma eğilimi gösterdiği tespit edildi.
- Maksimum sürtünme kuvveti değeri saf PA malzemesi için 720 m kayma mesafesinde olduğu görülürken kompozit malzeme için 720 m kayma mesafesinde artan dolgu oranıyla birlikte maksimum sürtünme kuvvetinin azaldığı tespit edildi.
- Aşınma oranı PA ve PA/KOL kompozit malzemelerin tümü için 120 m kayma mesafesinde sıfır iken 360 m olduğunda PA saf malzemede yaklaşık 0,03 mm^3/N.km civarında, PA/KOL kompozit malzemelerde ise 0,005 mm^3/N.km civarında olduğu tespit edildi.
- Kayma mesafesi 720 m olduğunda en iyi sonucu 12,5 KOL dolgu miktarına sahip PA/KOL kompozit malzeme gösterirken artan dolgu miktarıyla birlikte aşınma oranının da arttığı tespit edildi.

PA/KOL çalışmaların da;

- KOL maddesinin daha küçük ve/veya daha büyük ortalama tane boyları,
- Farklı kaplama maddeleri,
- Farklı kaplama miktarları,
- Farklı kaplama yöntemleri ,
- Farklı kompozit üretim yöntemleri kullanılarak ve
- Farklı üretim parametreleri tercih edilerek devam ettirilmesinin faydalı olacağı düşünülmektedir, önerilmektedir.

TEŞEKKÜR

Yazarlar, PA/KOL kompozit hammaddelerin üretilmesinde yardımcı olan EMAŞ Plastik Sanayi ve Ticaret A.Ş.'ye ve çok amaçlı deney parçalarının enjeksiyon kalıplama yöntemiyle elde edilmesinde katkılarından dolayı AKSU Tost Makinaları Sanayi ve Ticaret Ltd Şti.'ye teşekkür eder.

ABSTRACT

Along with the developments in digital technology, there have been developments in smart cities and smart grids, and with the developments in digital technology, there have been developments in smart cities and smart grids, and smart vehicles. The security vulnerabilities of autonomous vehicles have been investigated for comfortable, reliable, and time-saving travel and transportation. Cyber-attacks have 3 different purposes: to control the system by preventing the administrator from controlling the system, to cause delays in system operation, and to render the system completely inoperable. In this study, 10 different attacks are examined to show that control can pass from the user to the attacker. The analyzed attacks are GPS Spoofing, Buffer overflow, exploit attacks, Man-in-the-Middle attack, Malware attack, DDoS attack, Proxy/Socks attack, Sybil Attack, OBD Attack, and Arp Spoofing attack. In general, attacks are made on the processor where sensor information is collected in autonomous vehicles. The use of wireless connections in autonomous vehicles has revealed many vulnerabilities. To reduce attack vulnerabilities in the processor; The tasks required by the processor should be reduced. Studies, some tools, and measures that will facilitate the security processes of users have been examined. Nmap, Maltego, and Metasploit tools that can detect unauthorized movements and foreigners in the system have been examined. In addition, measures to be taken against the weaknesses that may occur in newly designed vehicles are given in this study.

Keywords: Cybersecurity, Autonomous vehicles, Cyber Threats, Cyber Attacks.

1. INTRODUCTION

For years, automobiles are one of the dreams that people want to buy. Recently, people have been wasting a lot of time in traffic due to traffic jams and human-induced driving effects. In order to prevent this, it is thought that cars will become autonomous. Autonomous systems have been developed extensively for cars. They will develop together with automobiles in other vehicles. The first known example of an autonomous car was seen in 1925(Feng, 2019; Green, 1925). In autonomous technologies, the communication and decision mechanisms of vehicles are mostly managed via wireless. In 2004, the DARPA Grand Challenge was announced(Kendi, 2017). At first, vehicles were designed for the military field. In the following years, major automobile companies competed in the DARPA Grand Challenge for cars. As a result of Google's investments in autonomous vehicle technology in 2010, companies such as Ford, Toyota, and Volvo started to test their vehicles with Google (Nennioğlu & Köroğlu, 2018). Almost 90% of traffic accidents are caused by driver faults as shown Figure 1 (TÜİK, 2018). This situation is shown in Figure 1. The development of autonomous vehicles will also help us to prevent driver faults.

In this study, primarily autonomous levels of vehicles, autonomous architectures, attacks on autonomous vehicles; New architectural design criteria against exploits, Buffer overflow, GPS Spoofing, DDoS-DoS Attacks, Man-in-the-Middle, Proxy/Socks, ARP Spoofing, Malware, Sybil Attacks, OBD Attack and them; Privacy/Anonymity, Availability, Authorization, Data confidentially, Data Integrity, Authentication, and traceability/revocation are examined.

2. AUTONOMOUS VEHICLES

Autonomous vehicles consist of 6 levels in themselves (Bezai et al., 2020). Level names of autonomous cars: Level 0; Non-Autonomous Vehicles, Level 1; Driving Assistance Vehicles, Level 2; Partially Autonomous Vehicles, Level 3; Conditionally Autonomous Vehicles, Level 4; Highly Autonomous Vehicles, Level 5; They are called Fully Autonomous Vehicles. All autonomous levels are shown Table 1.

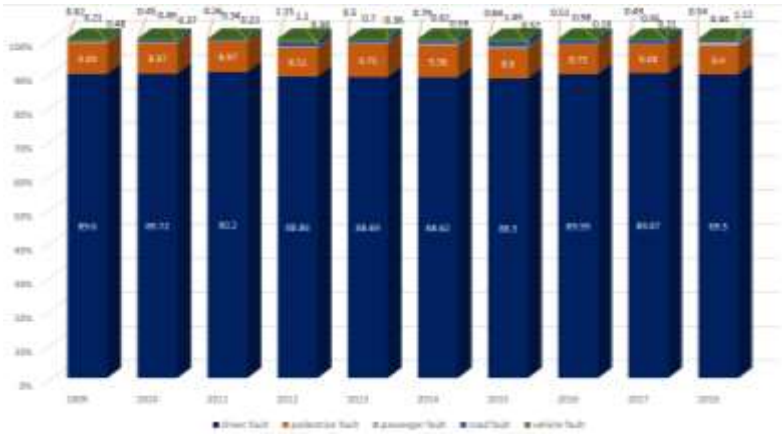

Figure 1: Percentage Data Of Fault

2.1. Manual Control Vehicles

In vehicles with manual control, the sensors do not affect while driving. Driving control is entirely in the hands of the driver.

2.2. Driving Assistance Vehicles

Driving assistance support is transmitted to the driver. Driving control is in the hands of the driver. It has used, such as adaptive cruise control, headlight angle sensor.

2.3. Partially Autonomous Vehicles

It works with driver control. Driving can be transferred to the system. The driver can intervene in the system at any time. For partially autonomous vehicles, asks to hold the steering wheel by drivers.

2.4. Conditionally Autonomous Vehicles

They have more sensors than the level of Partially Autonomous Vehicles. The controls are left entirely to the vehicle's brain. They are designed in such a way that the factors that will occur due to environmental factors are notified to the herd in advance.

2.5. Highly Autonomous Vehicles

In High Autonomous Vehicles, the destination is reported to the vehicle. Control is not expected from drivers. The vehicle can park itself. Can navigate alternative routes to congested traffic routes.

Table 1: Autonomy Level

Category	Autonomy Level	Human Intervention	Domination Control
Traditional	0 Manual Control Vehicles	Yes	Manually Used tools
Smart	1 Driving Assistance Vehicles	Yes/No	Machine-assisted human-use vehicles
Smart	2 Partially Autonomous Vehicles	Yes/No	People make the decisions, the use is in the vehicle
Autonomous	3 Conditionally Autonomous Vehicles	Yes/No	The means by which people make the final decision
Autonomous	4 Highly Autonomous Vehicles	Yes/No	People make decisions except in emergencies
Autonomous	5 Fully Autonomous Vehicles	No	People only report emergencies

2.6. Fully Autonomous Vehicles

All necessary sensors are fully equipped in the vehicle. It can move in the desired route without human intervention.

2.7. Autonomous Vehicle Architecture

The vehicle architecture includes radar, lane tracking system, lidar sensor, infrared camera, GPS, inertial measurement device, wheel encoder, odometry, computer vision system, braking, speed control unit, and steering controllers(Naranjo et al., 2009; Raiyn, 2018). There may also be differences in the sensors used according to the autonomous levels of the vehicles. However, the control center has to establish a connection with the traffic via wireless (Gomes, n.d.). Vehicle communication brain architecture is shown in Figure 2.

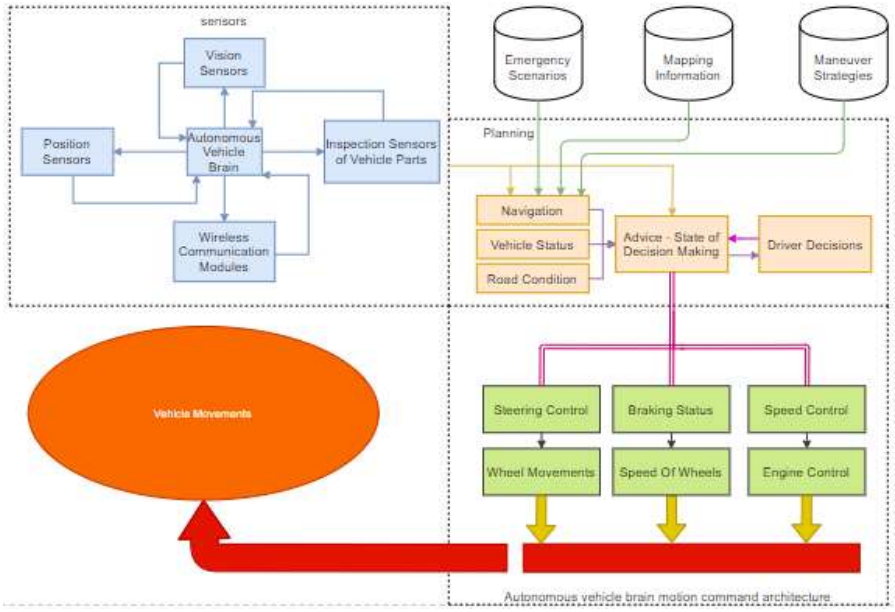

Figure 2: Autonomous Vehicle Brain Commication Architecture

3. CYBERATTACK METHODS AND RISKS IN AUTONOMOUS VEHICLES

Cyber-attacks are aimed at stopping, shutting down, or completely crash the system. Cyber attacks can be made over wired and wireless connections. In this section, possible attacks are examined. Possible attacks: Exploits, BufferOverFlow, GPS Spoofing, DDoS-DoS attack, Man-in-the-Middle Attack, Proxy/Socks, ARP Spoofing, Malware, Sybil Attack, and OBD Attack (MURATOĞLU, 2020). Table 3 shows the hierarchy of cyberattacks. The level of expertise required for attacks is shown in table 4. The effects of the attacks are shown in Table 5.

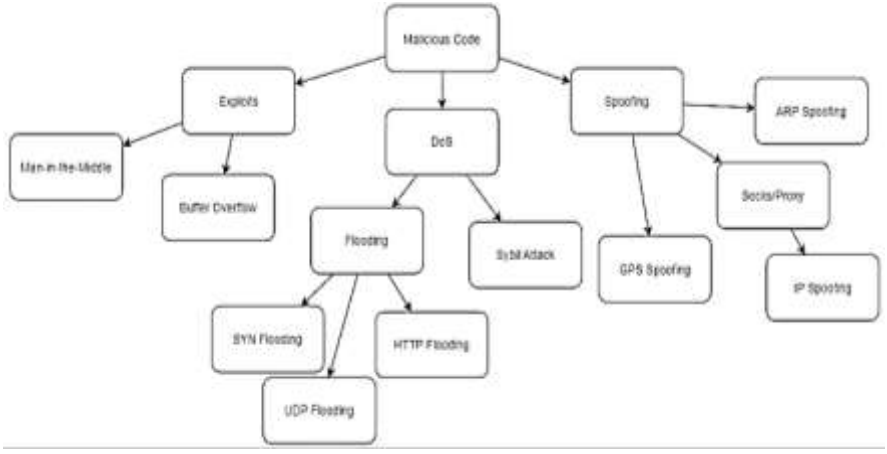

Figure 3: Autonomous Vehicles Cyber Threats

3.1. Exploits

Points of exploitation of security vulnerabilities are called "exploit". Although it is intended to directly infiltrate the system, it is used to show the extent of the risks that security holes will provide us. With exploits, system passwords can be seen and information about systems can be obtained. Exploits prevent the system from working normally and convince the system that it is working normally by sending code from outside and are generally used for unauthorized access (Gelernter et al., 2017; Marquez, 2010).

3.2. BufferOverFlow

It is a type of vulnerability arising from excessive memory in the system. There are areas on the memory where static and dynamic variables are kept. It arises due to data loading above the capacity of these fields. With the changes to be made in the shellcodes in the system, the system control can be completely passed to the attacker(Kumar et al., 2009).

3.3. GPS Spoofing

It is a type of attack that reproduces the signals in the system by copying the radio waves and sends these signals to the system. The system accepts the incoming signals regardless of their accuracy. The use of attacks is also shaped according to the GPS wavelength used in the attacks(Haider & Khalid, 2017). These attacks are costly and hardware-requiring types of attack. It is possible to attack with 2 techniques. These techniques are covert capture and overt capture techniques (Çuhadar, 2017).

Table 2: Bandwidth for DDoS-DoS Attacks

Attack Types	**100 MB (pps, packet per second)**	**1000 MB (pps)**
SYN Flood	200.000 pps	2.000.000 pps
UDP Flood	400.000 pps	4.000.000 pps
Http Flood	32.000 pps	320.000 pps

3.4. DDoS-DoS Attacks

This attack type, which stands for Denial of Service, sends too many request packets to the system to be attacked. The system receives too many requests, causing it to be unable to respond. It is possible to increase the signals in 2 different ways. The first method is the botnet. It is used as an abbreviation of the robot network. The second method is DoS servers. It is possible to attack in 3 different ways. Attack types are SYN Flood, UDP Flood, HTTP Flood attacks. Bandwidths of these attacks are given in Table 2.

3.5. Man-in-the-Middle

Each system has its own logical and physical operators. These are MAC and IP protocols. These protocols are designed for security purposes. At the same time, it is aimed to prevent confusion in internet surfing. The openness here is that someone else uses our IP and MAC addresses. IP and MAC protocols used by others can see our information. The victim and the server can be listened to easily and are available to be manipulated. Every packet that the server sends to the victim passes through the attacker's terminal (Gelernter et al., 2017). Traffic routes are shown in Figure 4.

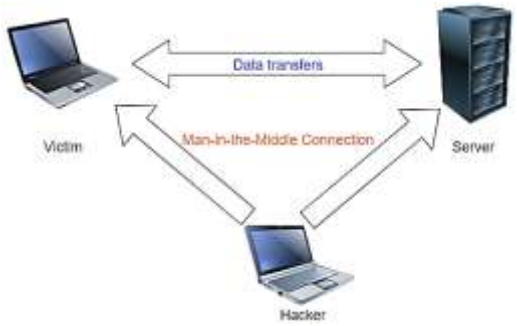

Figure 4: Man-in-the-Middle Attacks

3.6. Proxy/Socks

Proxy usage is made for IP hiding. It is generally used for those who do not want to share IP. It has 3 common uses. These are 4, 4a, and 5 uses. The use of each is unique. The most common is the use of 4. It only supports IPv4, and a 32-bit IP address can be specified as the destination address. 4a can be used with an addition to 4. Useful if you do not have a DNS server that can resolve an IP address. 5 has IPv6, hostname support, UDP forwarding, and enhanced authentication support (Graham, 2011).

3.7. ARP Spoofing

Figure 5: ARP Request Packets Sends To Victims

Figure 6: ARP Response Packets Sends To Hacker

ARP is used to route IP traffic over ethernet. The working logic is that the terminal that wants to connect to the server creates its IP, MAC addresses, and destination IP, and MAC addresses as ARP packets. An ARP packet is sent to the users via Ethernet by the attacker. Users connected to Ethernet receive this package. Users with the appropriate IP and MAC address for the received packet return. The user with the appropriate content for the incoming package provided feedback. With this feedback, the victim to be used in the system is determined (Şimşek, 2020; ŞİMŞEK, 2019).

3.8. Malware

Malware is a general name given to malicious software. It is short for the phrase Malicious software. Malware that harms the system, stops it, leaks information, manipulates or is prepared to use it (Vassallo & Manaugh, 2018).

3.9. Sybil Attack

The attacker sends false signals to the attacked system, destabilizes the system with fake identities, and wants to take control. They cause the system to not work correctly by showing the vehicles that are not in the traffic as if they exist (Newsome et al., 2004).

3.10. OBD Attack

It is the process of infiltrating the system by wire through the diagnostic port. The system can be controlled by reprogramming the operating system of the system (MURATOĞLU, 2020).

Table 3: Skill Table Required For Hacking

Parameters				
Scoring	**3**	2	1	0
Ability	Novice	Technician	Hacker, Automotive Expert	Expert Team in Many Fields
Availability of Information	Public information	Information is available for maintenance or customers.	Information for Production available	The information available to ECU suppliers
Accessibility	Permanent access with Untrusted Networks	Permanent access with private networks or partial access with untrusted networks.	Physical permanent access or partial access with private networks	Only physically accessible
Required equipment	IT devices available to everyone	Private IT devices open to everyone	Personally, registered IT devices	Multiple Custom Design, Proprietary IT devices

Table 4: Examples of Threats and Risk

Possible Attacks	**Threats**	**Risk**
Known exploits in OS or remote control	Rootkit or Trojan installation	Loss of ECU control
Known exploits in OS or BufferOverFlow	Deleting Software Tools	It is the reduction of ECU control
Man-in-the-middle Attack	Eavesdropping to the Password to be Used Secretly	Capturing the Necessary Connection
Compromise and DDoS Attack between ECU and Web Server	Stopping the system to interrupt incoming data	Stopping the ECU
Man-in-the-middle	Sending manipulative data to	Pre-prepared maintenance data

attack in communication	Web Server	causes unnecessary maintenance
Malware and Sending data to too many ECUs at the same time	Temporarily disables OS or apps	It causes a decrease in system functions and a decrease in storage areas.
Known exploits in OS or BufferOverFlow	Unauthorized access to data	Access to Usage or Configuration of ECU
Man-in-the-middle attack in communication	Unauthorized Access to Transferred Data	Specific Access Usage Data
GPS Spoofing	Changing incoming GPS data	Causes changes in the route to be set
Proxy/Socks	Allows attacker to remain anonymous	The attacker's address cannot be determined correctly by the system
ARP Spoofing	Allows attacker to remain anonymous	The system cannot correctly identify the attacker

4.CYBER ATTACK DETECTION TOOLS

We have some tools to show us the vulnerabilities in the system for attacks. Our tools to detect attacks are shown in Table 5.

Table 5: Cyber Attack Detection Tools

Intrusion Detection Tools	Detection Methods	Data Provided to Us
Nmap	By scanning the ports connected to IPs, information about port openings is obtained. Ports, where attacks can be made, can be detected.	It gives us the values of Open, Closed, Filtered, and Unfiltered according to the openness of the ports.
Maltego	It extracts the mapping of IP routes by mapping the ports that the system is connected to in IP routers.	It provides us with the connection paths of the system. All external links are represented by IP paths.
Metasploit	It allows us to listen to the system listening paths in the database and the paths that can be connected to the system.	The vulnerabilities of the system are presented to us.

4.1. Nmap

There are 65,532 ports known in the systems. Nmap is a popular tool used to scan these ports. If certain intervals are not specified in the scans, the most used 1000 ports are used(AKYILDIZ, 2013; Altınkaynak, 2020). Port, State, and Service information are taken as output.

- Port indicates the protocol using the port number.
- Service specifies the service names running on the port.
- State indicates whether the port is open, closed, or filtered.
  - Open: indicates that the port is accessible.
  - Closed: indicates that the port is accessible but cannot be modified.
  - Filtered: means that the filtering port is blocked by the filtering mechanism. There is no information about whether the port is open or closed.
  - Filtered: means that the filtering port is blocked by the filtering mechanism. There is no information about whether the port is open or closed.
  - Open|Filtered: port may be open or filtered. This situation has not been resolved.

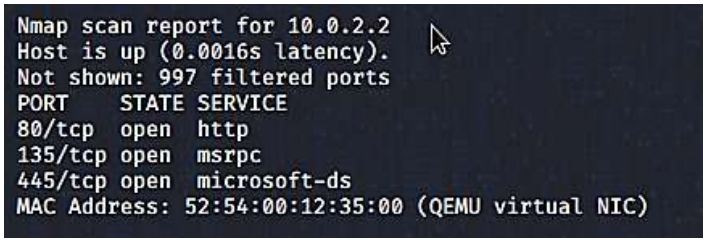

Figure 7: Nmap Screen After Scanning

4.2. Maltego

It is important to know about the systems to be attacked. It is necessary to have enough information about the system by collecting passive and active information about the systems(Çelik, 2020). passive information; It is the information that is fixed on the internet of the system about which information is requested to be collected. Search engines, social networking platforms, whois and DNS query sites, and sites that collect personal information can provide us with this information. Active information; IP is the acquisition of DNS and subdomains through servers and service providers. Maltego is the tool that provides us with the active and passive information of the system. It was developed by Paterva in the Java programming language. Free and commercial versions are available. It is used by experts in the field of security and those who want to improve themselves in this field to collect and analyze open-source information(ADIR, 2019).

4.3. Metasploits

It is an open-source platform developed in 2003 that facilitates the discovery and control of security vulnerabilities in its system. Metasploit 2.0 is coded in Perl, Metasploit 3.0 is coded in Ruby. It provides us with security vulnerabilities of services or applications running on the systems. It has 1400+ exploits, 800+ auxiliary modules, 400+ payloads, 30+ encoders, and 8 nobs on its framework. Attack, eavesdropping, and vulnerability detection can be done with available tools(Kennedy et al., n.d.).

Metasploit Framework has its database. There is information such as what the openings are and how they are used. To facilitate the use of openings, their use is also explained. There are some modules such as information gathering, detection of vulnerabilities, passing through security points without authorization. The methods that will provide ease of use are(Jaswal, 2014):

- Exploits: System vulnerabilities that will cause the system to run out of service by using the vulnerabilities found in the targeted system. Exploits attacks are the use of methods that will cause the system to be out of use as a result of the use of all vulnerabilities that do not work in the system or are described as bugs.
- Encoder: It is the encryption process necessary for bypassing security points in the system.
- Payload: These attack codes written to listen to system connections. You can listen and monitor system connections such as webcam, speaker, Bluetooth connections, wireless. Changes can be made to the system after the attack.
- Auxiliary: These are the attacks made on the system to gather information before the attack. Service detection, port scans, vulnerability scans, and tools used for all clients are available under this title.
- Nops: Bits that occupy memory to learn “Not Operation” memory locations. Their purpose is to detect intrusions and deceive systems. The program progress flow can be changed and jumped to a random place (Graham, 2011).

Metasploit's unique filing system features;

- Data: Data can be manipulated and modified by Metasploit.
- Lib: It is the main build library of the framework system.
- Plugins: It is a plugin that can use all the features of the framework.
- Tools: These are the tools that handle the operations on the command line according to the location.
- External: External sources are 3rd party software and source codes.
- Documentation: These are the documents used to inform the Framework.

5. AUTONOMOUS VEHICLE NEW DESIGN SECURITY MEASURES

5.1. Data Security

Data security in autonomous vehicles is important with the development of technologies on vehicles. There is a need for new designs to increase the security measures according to new technologies in new vehicles. Some recommendations are made for security measures. These recommendations are shown in figure 8. Demonstrated safety precautions; Secure Communication, Security Monitoring, Anti Malware, Secure Cloud Computing, User in- Vehicle authentication, Isolation, IPS, Patch Management, Firewall.

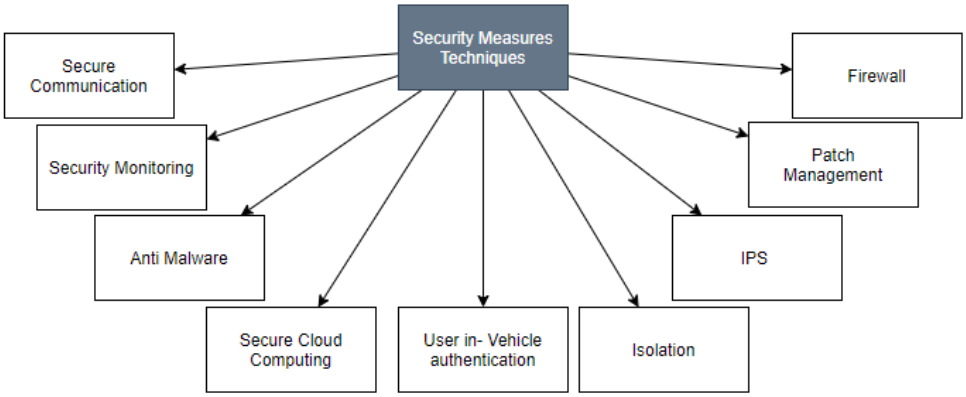

Figure 8:Security Measures Concept Tree

6. RESULTS

The study aims to evaluate how to eliminate the cyberattacks that threaten the use of autonomous technological vehicles and especially automobiles. In general, attacks made by using vulnerabilities arising from the processors on which the system is running are taking control of the system, stopping and shutting down the system. For attacks to be carried out, there must be a wireless connection. Since it is not possible to have a wireless connection for the system to work, the system must be used in a controlled manner by the user. The system architecture requires a processor. The system is susceptible to cyber attacks due to its structure. Other parts in the system; position sensor, vision sensor, vehicle parts sensors, and wireless communication modules. All these sensors are used with the openings arising from their use. Necessary precautions should be taken for use and the entire system should be inspected at regular intervals. Since the attacks are usually aimed at the processors of the cars, they should be. checked whether the updates that may come to the system come from known sources. Updates or calibration updates from unknown sources should not be done. Intervention outside the user should not be allowed. It can be supervised by system experts, enthusiasts, those who want to improve themselves in this field, and users. For this, there are tools (tools) that provide system control. Unknown IPs that will appear in system scans due to IP usage should be disabled to infiltrate the system via a wireless connection. Since it is thought that the systems will always have a wireless connection, scanning and intrusions in this area should be rejected. When it is thought that there is an intervention in the system, system files should be checked and harmful software should be deleted from the system when detected. In the use of the system, the inspection phase should not be skipped. Movements that are known to be foreign or whose identity is unknown should not be allowed in the system.

The work of anti-virus companies and experts working in this field will be aimed at reducing the share of the processor in control since the cyber attacks are aimed at the processor. In this way, the use of the processor in cyberattacks will be reduced. Risks in trader vulnerabilities will decrease as its share in control decreases. These studies will cause attackers to look for new attack methods. In this way, it will not be possible to attack the systems with known methods for a long time. In this study, precautions and techniques to be taken in newly designed vehicles against cyber-attacks are also discussed. Thanks to these techniques, it is aimed to protect companies in terms of financial and corporate reputation, to prevent theft of information and accidents of vehicles. In addition, it is aimed to be beneficial for future academic studies and institutions that will work in this field.

ABSTRACT

Batteries and voltage source inverters (VSI) are most important components for electric vehicles. Three phase voltage source inverters are being commonly used in automotive industry to provide power for AC motor using the DC battery chemical energy. Output link of the VSI's are extensively studied because electric vehicle current usage is depending on dynamic torque demand and AC power is not smooth as DC power. However, DC-link voltage ripple is also vital phenomenon to design electric vehicle system and control of energy transformation with using VSI's. DC voltage ripple must be analyzed to define capacity of DC link capacitor on VSI. Besides that, when controlling electric vehicle if DC Voltage ripple is over its limits, durability of control system can be deteriorated. Validation is required for DC voltage ripple on different conditions during electric vehicle development activities. In this study DC voltage ripple on the DC link of the inverter is investigated. Ripple's dependencies on the modulation methods, switching frequency, load, and battery management system conditions such as temperature and state of charge are examined, an optimized calibration approach is suggested.

Keywords: Electric vehicles, DC voltage ripple, inverter control, vehicle tests, PWM Control

1. INTRODUCTION

Day by day, requirements from both customers and authorities in the automotive industry are getting challenging due to safety and emission regulations. To overcome those challenges, manufacturers are developing new technologies and methodologies for various disciplinaries. As one of the requirements is to lower the emissions, manufacturers are shifting to electrification where the vehicle's power is generated by an electric machine at least in one level of its operation. Reports of Advanced Propulsion Centre UK states that, electric powertrains are an important component of electric vehicles, which are gaining popularity as a result of new restrictions limiting the usage of ICE-powered vehicles in the short and medium term to minimize particulate and CO2 emissions [1].

Today in xEV applications, due to their high power/weight ratio and controllability AC motors are widely being used where they are powered by DC power sources (HV Batteries). Hence to maintain power flow, an AC-DC power conversion is a must between battery and AC motors. The three-phase voltage source inverter (VSI) is de facto standard in power conversion systems. As a power conversion method, researches on pulse width modulation (PWM) control strategies have been conducted intensively. Various modulation techniques have been proposed and analyzed to improve the inverter's performance and discussed by Holmes [2]. However, most of the studies and papers only focused on the AC-side (outlet) of the inverter while DC-Link performance is not analyzed extensively.

To minimize the current values, electrified powertrain systems are aiming to increase DC voltage as much as possible to lower conduction losses and heat generation. Rapid changes in the DC current and switching of power semiconductor devices creates ripples in the DC voltage. To filter out the ripple, one of the solutions is utilization of DC-link capacitor. Even tough DC link capacitors can filter out the ripple, to minimize capacitor size and protect ECUs from dramatic voltage change in short amount of time, controlling the ripple is crucial. To be able to control ripple, dependencies of voltage ripple in a vehicle must be investigated in detail.

At 2017 in a study carried out by Vujacic et al, [3] DC ripple is investigated based on operation point to use in DC link capacitor design. Through the paper detailed experimental investigation of instantaneous DC link voltage switching ripple have been conducted. In the study, non-ideal DC source is used with the acceptance of its impedance to be much

higher than the capacitor's. Ripple is analytically defined as a function of the phase angle, amplitude of the output current and modulation index. However, that study is done only for relatively low power and speed applications. Later in 2019, the study is widened to cover for automotive applications (high speed and high-power applications) [4]. But still the new study is focused on determining the ripple experimentally. This exiguousness is later covered by Mantzanas et al., in 2020 by deriving a mathematical expression for the current ripple [5].

However, all those studies suggest only estimation to the ripple value for the simultaneous operation condition and does not investigate or mention controlling the ripple. Different modulations techniques or voltage values, switching frequencies are not included. No controlling or prediction on the ripple is performed, instead, after system operates, using mentioned signal values, ripple is calculated. In previous studies, laboratory setups and model-based tests are used as development environment, on-vehicle tests and studies are not available. In the vehicle, ripple is affected by many other factors such as harness and DC-DC converters.

In this study, diversely to the previous studies, DC ripple is aimed to be optimize. Here DC ripple is not just a resultant phenomenon but also a key performance indicator that needs to meet the target. During the experiments a real battery with all non-ideal behaviors are used, the controlled experimental environment is kept however, all the components are used with their actual working behaviors. Also, during the study, both inverters and batteries impacts on the DC ripple is investigated extensively. For test data, a battery electric vehicle, equipped with synchronous e-machine that has interior permanent magnet in the rotor (IPM) has been used. A 3-channel high sample rate (up to 1 MHz) external measurement device is connected between the battery and inverter to measure DC voltage, current and power values. The vehicle tests are held on a proving ground and vehicle dyno under controlled external conditions. Undermentioned test maneuvers are performed to investigate impacts of following variables on the DC link voltage ripple,

- Load
- Used PWM method
- Used PWM frequency
- DC Link voltage (Battery's state of charge)
- Battery cell temperature

After the analysis, various dependencies are found. Outcomes are generated and supported with measurement data. Nonetheless, due to intellectual property concerns, used data are post-processed and normalized with hardware's maximum ripple capacity under full load, meaning 1.0 peak-to-peak voltage ripple is the limit. Additionally, motor speed and motor torque are also normalized and shown in results as percentage value. The result data show, ripple has affected significantly from operating conditions and with a refined calibration it can be minimized.

2. DC VOLTAGE RIPPLE DEPENDENCY ANALYSIS

On this study, DC Voltage theoretical background is investigated. Afterwards, the factors which has impact on DC Voltage ripple are tested on battery electrical vehicles. Vehicle conditions effects on DC voltage is analyzed such as SOC and test maneuvers. Results are investigated and ripple calibration effects are optimized based on test results. To begin with, below in Figure-1 field-oriented control strategy for the IPM is schematically given.

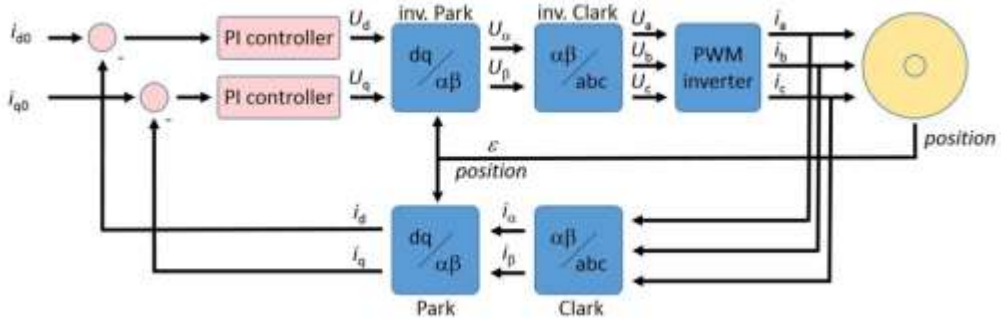

Figure 112. *Field Oriented Control Schema of an IPM [6]*

In field-oriented control, magnetic and electrical fields are controlled to generate requested torque. The "PWM inverter" section shown in the above figure generates switching patterns which causes the ripple. While investigating the ripple based on explained parameters, they are grouped into; environmental conditions which calibration engineer can control on test environment but cannot be controlled during the end-user operation, and controllable parameters which are

engineer's tools to meet targets via optimization. As shown in below figure the control parameters are PWM frequency and the utilized modulation method. While, they can be constant for whole operation zone, for optimized power-train applications, those parameters should be variables depending on the uncontrollable factors where they will be the inputs of decision-making process. Below a schematic is given in Figure-2 which states the controllable variables, environment conditions, the target output, and the workflow.

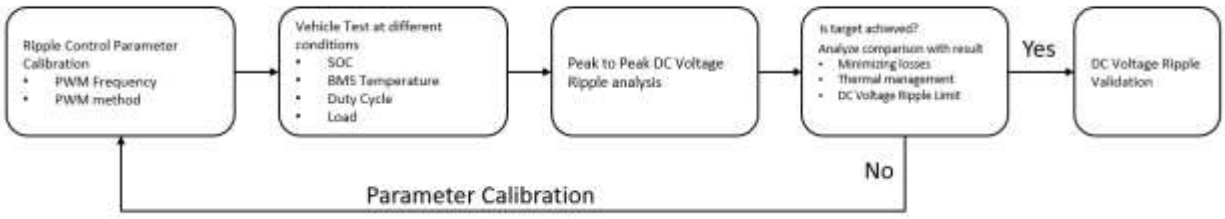

Figure 2. *DC Ripple Optimization Workflow*

2.1. DC Voltage Ripple Calculation

The residual periodic variation of the DC voltage within a power supply is known as ripple in electronics. After rectification or inversion, the waveform is not fully smoothed, it results in this ripple. Ripple voltage comes from the unsmooth high frequency voltage deviations from the generation and commutation of DC electricity [7].

To calculate DC voltage ripple, a fixed window size must be determined. For that window maximum and minimum voltage values are subtracted from each other to have peak to peak ripple values as shown in Figure-3 below.

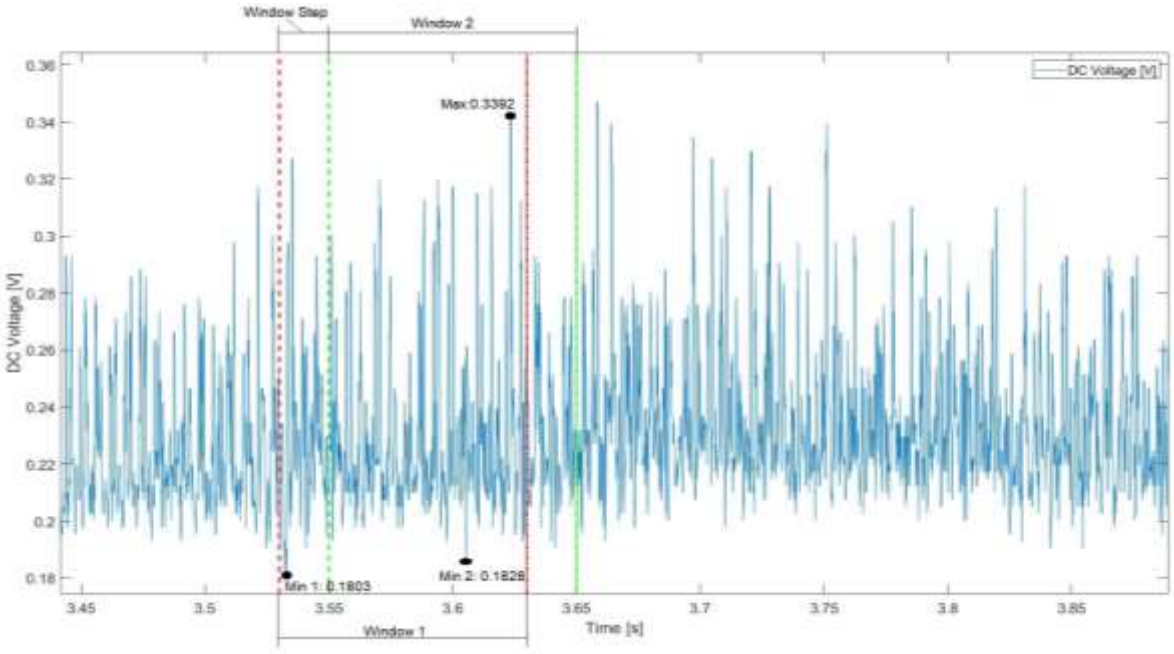

Figure 3. *Peak to peak Ripple Analysis Method*

This calculation method provides to consider all voltage difference in short time which are defined by window size and window step size. Formula is applied for all time base high sampled voltage measurement as shown in equation 1.

$$V_{peak2peak} = \max(Voltage)_{inwindow} - \min(Voltage)_{inwindow} \quad (1)$$

However, all those studies suggest only estimation to the ripple value for the simultaneous operation condition. They do not investigate or mention any details about controlling the ripple. Different modulations techniques or voltage values, switching frequencies are not included. No controlling or prediction on the ripple is performed, instead, after system

operates, using mentioned signal values, ripple is calculated. Additionally, in previous studies, as development environment, laboratory setups and Simulink models are used, and no on-vehicle study is conducted. In the vehicle, DC voltage ripple is affected by many other factors such as harness and DC-DC converters [8].

2.2. Test Setup And Measurement Methods

DC Voltage Ripple vehicle investigation tests are conducted either in a private test track where pedestrians are not allowed to enter or on climate-conditioned vehicle dynamometer where external conditions are controlled such as ambient temperature and wind speed. On the test track, maximum speed was limited to 180 kph, while same limit is applied in vehicle dynamometer for consistence. The test track had elliptical shape where its lengths is 2.5 km in straight lines and 6.5 km in total. Test runs are completed between 11:00 to 15:00 o'clock to avoid air conditions variations. Two different cycle is selected to test DC Voltage ripple which are full load acceleration and nominal load acceleration to maximum speed. Below in Figure-4 the schematic of the test track is shown.

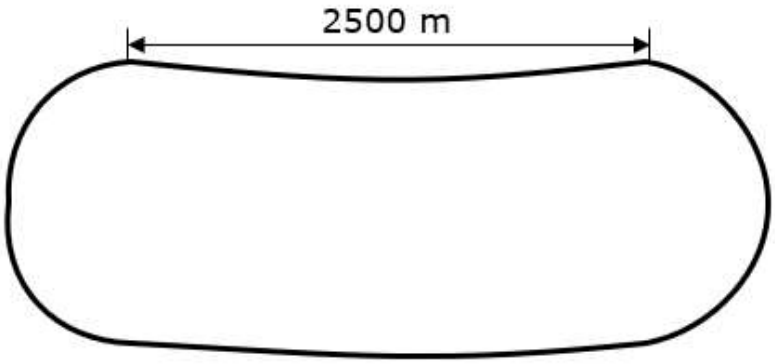

Figure 4. *Test Track Schema*

During tests, a rear wheel driven battery electric vehicle is used. Vehicle was equipped with a single ratio reduction gear transmission. The vehicle is installed with 150 kW permanent magnet synchronous AC motor and powered by 58 kWh battery with 420km WLTP range. Vehicle's curb weight is measured approximately 1650 kg including the mounted measurement devices and development equipment. To measure required signals, an ETAS box with ethernet cable extension is used. Relevant internal signals such as vehicle speed, acceleration pedal position, modulation index, switching frequencies of IGBTs, torque and e-machine rpm are measured (between 1ms to 100ms based on the signal) via mentioned ETAS box, beside all CAN-log. For BMS temperature, NTC sensors are equipped inside the battery pack for development purposes, also, a 3 channel power analyzer is positioned at the DC inlet of the inverter which is set to 2 μs (500 kHz) sampling time, for DC voltage, current and power measurement.

Vehicle tests are planned to cover all DC Voltage ripple dependency and totally 36 tests are run. During tests, vehicle data and external sensor data are recorded with ETAS toolbox. Except the tests runs where the PWM control strategy is specified, all the test runs are done where modulation method is decided based on the load on the system and this procedure is named as "Mixed" in the Table-1. The requested load is determined with modulation index while the mixed PWM control strategy combines the Continuous Space Vector Modulation (SVM) for the loads where modulation index is lower than the threshold and Discontinuous PWM Single update (DPWM SU) for the rest. Furthermore, to investigate effects of update strategy a discontinuous PWM Double Update technique is tested in tests number 5, 27, and 36. Also, for any other test run, all variables are kept same to prevent any cross-effects between the investigated properties. Test details are explained on Table-1 below.

Table 1. Test Matrix

Test No:	Rated Load	PWM Control Strategy	Modulation Frequency [kHz]	SOC [%]	Average Battery Temperature [°C]
1	Half Load	Mixed	9	Half	23
2	Full Load	Mixed	9	Half	23
3	Half Load	SVM	9	Half	23
4	Half Load	DPWM SU	9	Half	23

5	Half Load	DPWM DU	9	Half	23

21	Full Load	Mixed	6	Half	23
22	Full Load	Mixed	7	Half	23
23	Full Load	Mixed	8	Half	23
24	Full Load	Mixed	10	Half	23
25	Full Load	SVM	9	Half	23
26	Full Load	DPWM SU	9	Half	23
27	Full Load	DPWM DU	9	Half	23
28	Full Load	Mixed	5	High	23
29	Full Load	Mixed	6	High	23
30	Full Load	Mixed	7	High	23
31	Full Load	Mixed	8	High	23
32	Full Load	Mixed	9	High	23
33	Full Load	Mixed	10	High	23
34	Full Load	SVM	9	High	23
35	Full Load	DPWM SU	9	High	23
36	Full Load	DPWM DU	9	High	23

The data taken from the vehicle are investigated in the time domain. For time domain analysis ripple calculation is performed inside a time window whose duration is preselected. If the duration is selected too long, then ripple will be affected by the voltage drop due to varying currents, leading too large ripple values. Likewise, if the duration is selected less than the switching period, the voltage will not have the chance to vary, leading too low ripple values. Based on the requirements from microcontroller developer and datasheet of DC link capacitor, 50 millisecond time window is decided. Inside the analysis window maximum voltage value out of approximately 25.000 sampling points is subtracted from the minimum and ripple is calculated. Average of the other values such as motor speed is taken and assigned to ripple values. Then, analysis window is shifted 10 millisecond (~5000 sample point) and new window is analyzed as explained.

3. TESTS AND DATA ANALYSIS

Test details and ripple calculation methods are described on this study. Regarding vehicle test data, investigation for each dependency analysis is required to optimize ripple performance on the electric vehicle. On this section, vehicle test results are reported based on load rate, PWM control strategy, modulation frequency, battery SOC and battery temperature.

3.1. Ripple And Acceleration Load Rate Investigation

Dynamic power on electrified powertrains causes DC Voltage ripple. Main factors of dynamic power are torque demand and consequently, motor speed and motor torque operations. Torque demand signal is created by vehicle control unit via acceleration pedal position. Therefore, torque demand and limitation values are parameterized as two

different value for this study to observe load rate relevant ripple characteristics on Figure-5 below. Initially, acceleration maneuver with full pressed acceleration pedal test is conducted without any parameter changes and it is called as full load test. At the second test driver torque demand is limited to half. As a result, vehicle acceleration characteristics changed, and results are plotted based on motor speed.

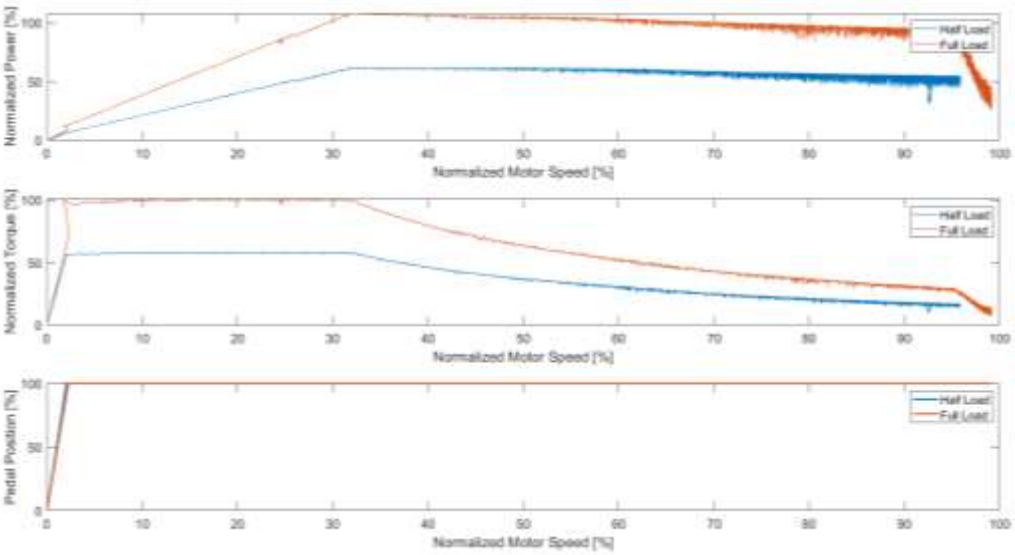

Figure 5. Half Load – Full Load Test Comparison

DC Voltage value is also affected by applied load on vehicle. Ripple characteristics on the half load and full load tests can be seen also in Figure-6 below. At half load test maximum ripple value is observed as 0.41 V_{p2p} around 0.52 normalized rpm but at the full load tests maximum ripple value increased to 0.79V_{p2p} and it is shifted to 0.42 normalized rpm. It is obviously seen that ripple characteristics are increased parallel to the power increase in the powertrain.

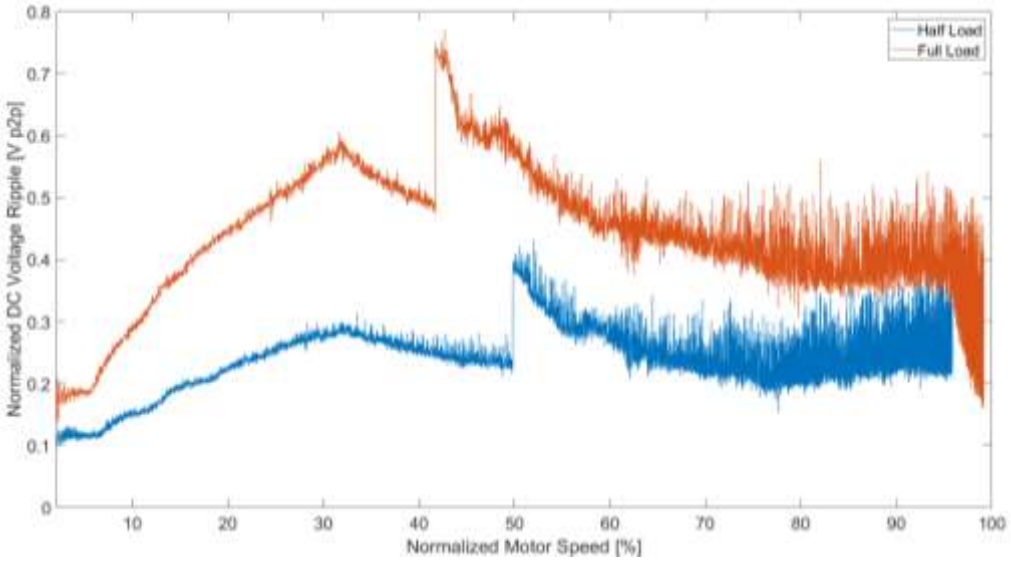

Figure 6. Half Load – Full Load Ripple Comparison

3.2. Investigation Of Control Strategy Effects On Ripple Characteristics

In a BEV, the e-machine is driven by the power electronic component which is VSI in many cases. The control strategy of the e-machine hence the vehicle's power is implemented inside the inverters ECU. Inside the inverter semiconductors such as IGBT's or MOSFET's are switched on and off rapidly in a determined sequence to generate correct output waves. Due to their superior advantageous such as better controllability, low total harmonic distortion and easier implementation, in automotive applications carries based PWM techniques are used [9].

In this study, two types of carrier-based pulse-width modulation techniques, space-vector modulation (SVM) and Discontinuous Pulse-Width Modulation (DPWM), are investigated. In DPWM method, single update (SU) and double update (DU) methods are utilized separately where in double update the third IGBT status updated with a frequency twice of the switching frequency. Results are plotted below in the Figure-7.

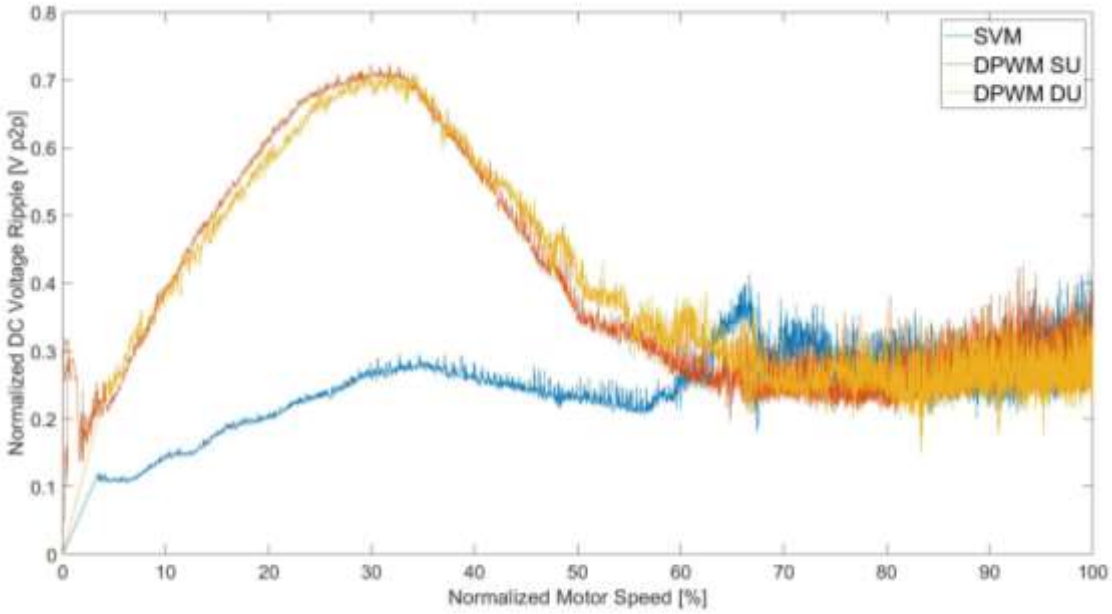

Figure 7. Different Modulation Techniques Ripple Comparison

Those results show in rpm zone between 0-0.5 normalized rpm values space vector modulation results in lower ripple, keeping all other variables same. After approximately 0.3 normalized rpm, ripple in DPWM starts decreasing with almost a constant slope until 0.5 normalized rpm. After that point, the slope is reduced to almost zero until maximum speed. As the ripple in SVM keeps increasing from 0 to 0.7 normalized rpm, around 0.65 normalized rpm the ripple for all three methods are getting almost equal. Later ripple in SVM has the tendency to be larger than the DPWM. The significantly higher ripple for DPWM in lower rpm zone can be explained with the disturbance coming from not switching third-IGBT On the other hand, this not switching IGBT leads a decrease in the switching loss and heat generation, leading the necessity of a fine calibration between modulation methods.

3.3. Investigation Of SOC Effects On Ripple Characteristics

Inlet voltage of the VSI inside the BEV is determined by the SOC of the battery pack in the vehicle. With increasing state of charge, available voltage is also increasing. During the analysis SOC levels which are read from CAN are group in 3 levels such as,

- 10-15% SOC as “LOW”
- 45-55% SOC as “HALF”
- 90-100% SOC as “FULL”

The results are obtained as given in the Figure-8.

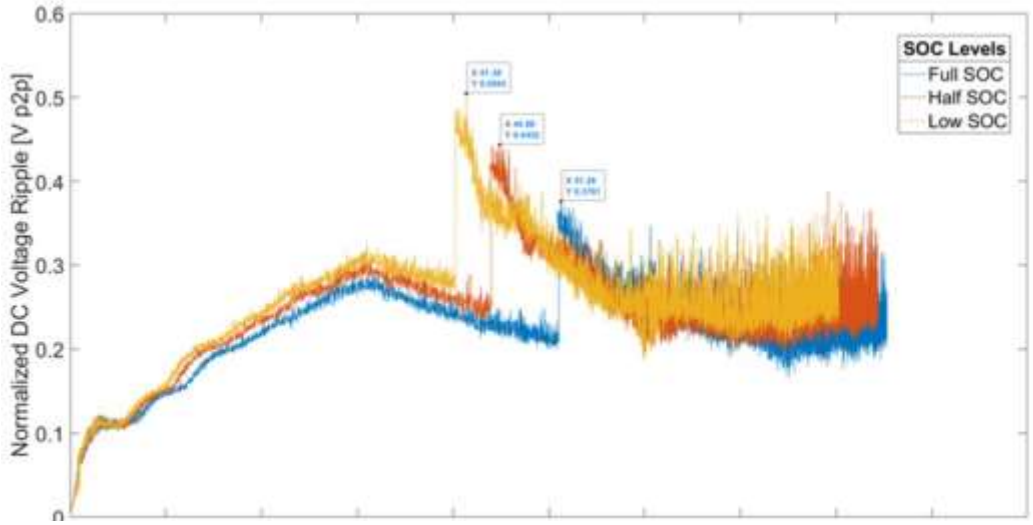

Figure 8. SOC Effects on DC Voltage Ripple

This results shows, when the modulation technique changes, it has similar effects on all SOC levels for ripple jump. But, lower SOC shifts, modulation technique switch to the lower rpm values. In other words, modulation method change occurs at lower rpm values. Also from the results, it is seen that for relatively low speed there is no difference on ripple between various SOC levels. The devation starts after approxiamtly 0.12 normalized rpm. At low SOC, maximum 0.50 V_{p2p} is observed at 0.41 normalized rpm, while at half SOC 0.44 V_{p2p} ripple occurred at 0.44 normalized rpm and at full SOC 0.38 V_{p2p} happened at 0.51 normalized rpm. For whole speed range low SOC test run had more ripple both in maximum and average values. It is seen that incresing real SOC (i.e. higher DC inlet voltage) led lower ripple in DC voltage.

3.4. Investigation Of Battery Temperature Effects On Ripple Characteristics

A simplified equation for DC link inlet voltage is given in Eq-2 below.

$$V_{inlet} = V_{battery} - iR \tag{2}$$

where $V_{battery}$ is the battery outlet voltage, i is the current and R is the resistance of the battery and cable section. As results from section 3.3. shows, increasing the inlet voltage decreases the ripple. So for the worst case analysis and to test the limitations, inlet voltage is aimed to be as low as possible. Hence initially battery resistance was tried to be maximized. For a Lithium-ion battery decreasing temperature results in higher battery internal resistances and limits the energy capacity [10]. To investigate the trade off vehicle is conditioned inside a -15°C climate chamber and half load test manuevers is performed. Results are shown in below Figure-9.

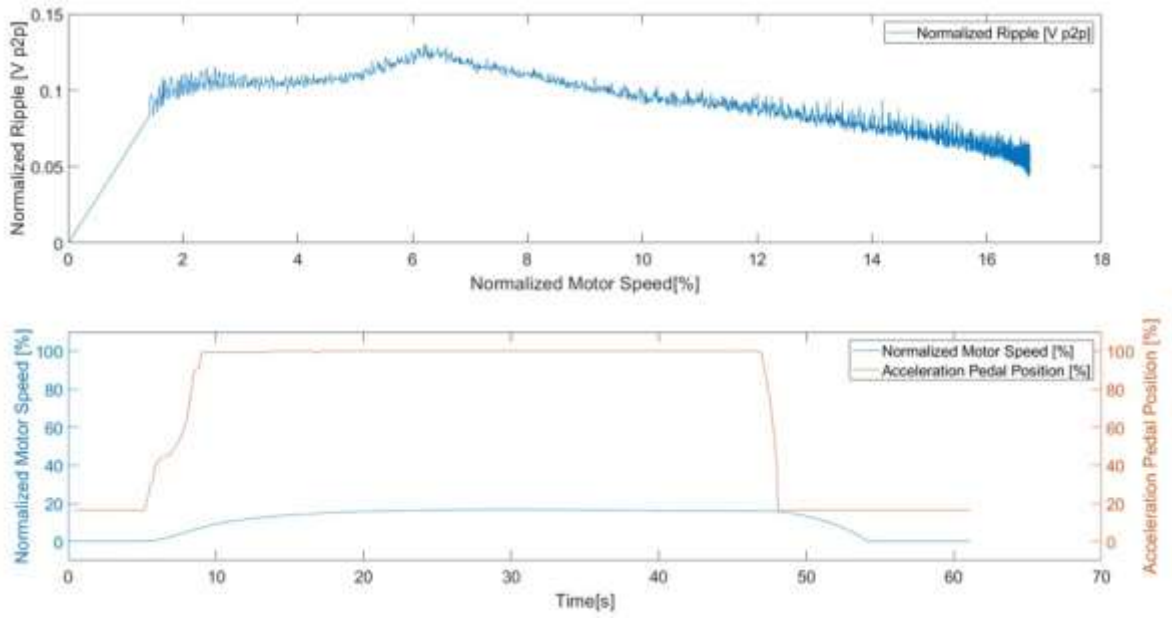

Figure 9. Ripple Calculation on -13°C Battery Temperature Test

With -13°C average cell temperature during the test, vehicle performance is limited dramatically. With fully pressed pedal (100%), vehicle accelerated up to 0.18 normalized rpm, than derating functions limit the current to protect the battery from high current drain at cold temperatures beside batteries own chemical limitations. After 20 seconds vehicle started to slow down due to resistive forces. Even the battery resistance is incresed and battery voltage dropped, due to realtively low current values, voltage drop from battery cells to inverter is negligiable. Under those limitations; low DC power availability, derating funcitons, only 0.13 V_{p2p} ripple is observed at 0.16 normalized rpm as maxima. Later, higher temperature test cases are performed as results are shown below in Figure-10.

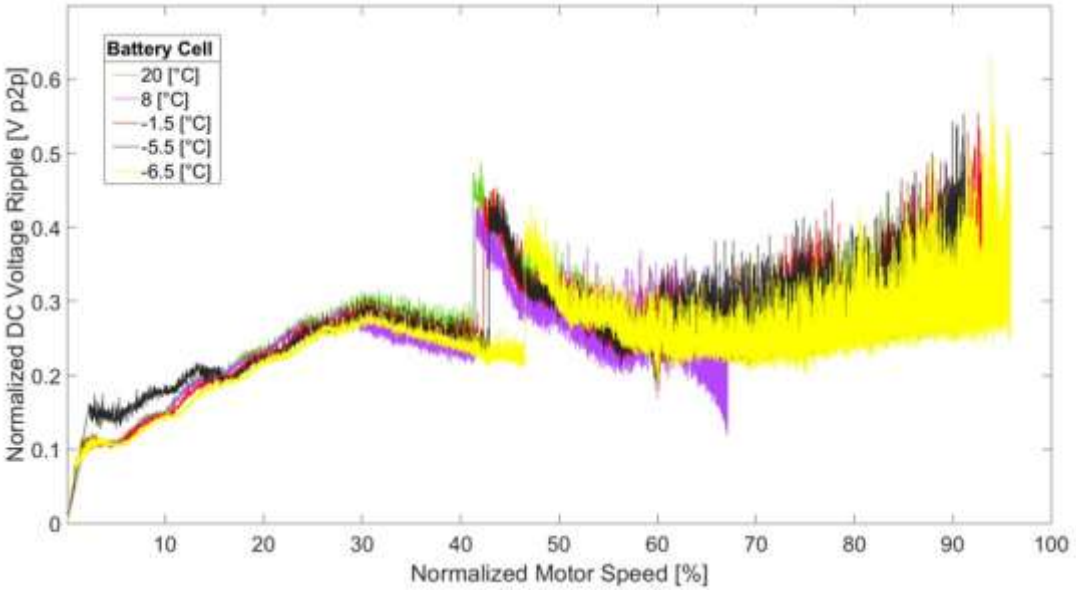

Figure 10. Battery Temperature Effects on DC Voltage Ripple

Results shows, at 20 degree, maximum 0.51 V_{p2p} ripple is observed at 0.41 normalized rpm. For 8°C this value is seen as 0.43 V_{p2p} ripple at 0.42 normalized rpm. For -1.5 and -5.5 V_{p2p} ripple are observed same with the value of 0.46 at 0.450 and 0.453 rpm respectively. At -6.5°C, maximum 0.42 V_{p2p} ripple is observed at 0.48 normalized rpm. These results shows, even though temperature affects the battery resistance, due to performance limitaitons and battery characteristics, ripple is not affected significantly. On the other hand, modulation technique switch point shifted to higher rpm values with the decreasing temperautre.

3.4. Investigation of Switching Frequency Effects on Ripple Characteristics

Switching frequency of VSI is one of the most important parameters. It affects the efficiency on both the inverter and e-machine. Below the results for various switching frequecy test runs are shown in Figure-11.

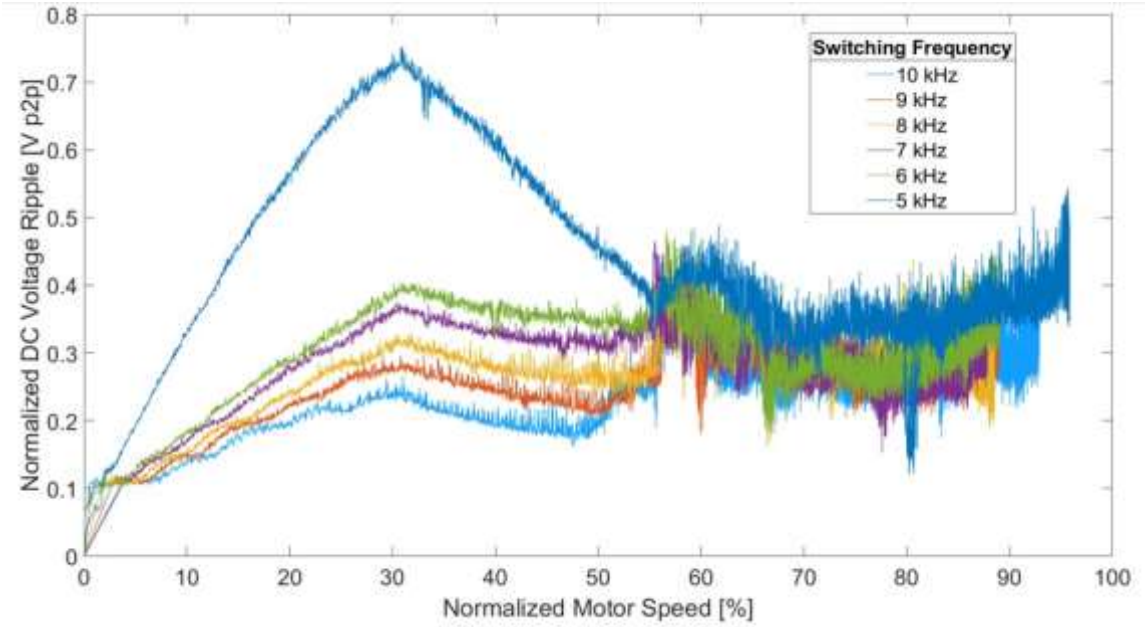

Figure 11. Switching Frequency Effects on DC Voltage Ripple

Switching frequencies are investigated with space vector modulation as modualiton methods with mentioned time steps. At low e-machine rpm, low ripple is observed regardless of the switching frequency. At each test run, a local maxima is observed at appx 0.3 normalized rpm which is the corner point of e-machine, outlying the 5 khz test run. Only in 5 kHz test run, a global maximum is observed. Around 0.55 normalized rpm, measured ripple values are gathered together around 0.4 normalized ripple value. However, the disturbance is significantly increasing after that point for all frequenies. For 6 kHz at 0.53 normalized rpm 0.48 V_{p2p}, for 7 kHz at 0.52 normalized rpm 0.46 V_{p2p}, for 8 kHz at 0.55 normalized rpm 0.44 $V_{p2p,}$ for 9 kHz at 0.56 normalized rpm 0.40 V_{p2p} and eventually for 10 kHz at 0.56 normalized rpm 0.36 V_{p2p} ripples are evaluated. That analsysis shows ripple is decreasing with incerasing frequency in the investigated scope.

4. CONCLUSION

Experimental vehicle tests have been conducted, and 36 test data are measured to investigate for the goal of this study. Different optimization parameterization approach is tested to investigate ripple dependency. All parameter sets are applied to inverter controller for dependency test one by one and test data are measured for each. MATLAB code is created for data mining and investigation. Results of the MATLAB code, optimum ripple performance for each condition are investigated. It is obviously shown that battery temperature, load rate of acceleration, battery SOC have direct effects on DC Voltage ripple for different conditions. On the other hand, control parameters such as switching frequency, PWM method selection can directly affect ripple characteristics too. As a main goal of this study, control parameters on different conditions are optimized to provide best ripple performance on all conditions.

Below in the Figure-12, effects of control parameters at different environmental conditions are shown. Using all information and outcomes from the vehicle tests and theoretical background, optimized calibration is suggested as in following.

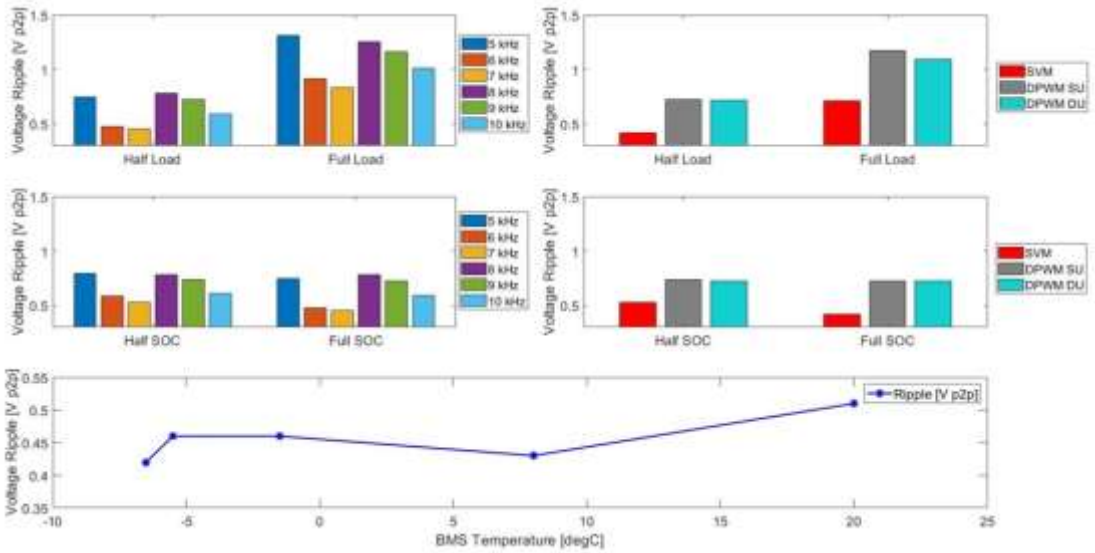

Figure 12. Evaluation of Parameter Dependency

When the power on the powertrain increases due to higher load request, ripple is increasing for each modulation strategy. To optimize the ripple behavior, 7 kHz switching frequency with SVM is suggested for the tested battery, inverter, and e-machine setup as base operation. Moreover, to the ripple optimization, a relatively lower frequency set point can decrease the heat generation on the inverter and cover the additional losses of SVM over the DPWM. To prevent any failure on the system due to over voltage ripple, SVM should be utilized as much as possible, however when the thermal load becomes unsustainable, modulation strategy must switch to DPWM. When the load request is high on the system, to meet the performance requirement DPWM strategy should be utilized to prevent overheating. However, when the pedal demanded torque is high at low rpm zones, thermal stability is no more concern in comparison to ripple. Hence SVM should be used until speed is approaching corner point of the e-machine to avoid overshooting the HW ripple limit. After corner point is exceeded, to lower the heat generation DPWM should be selected as soon as ripples are below HW ripple limit. This selection can be done via a calibratable that is calibrated based on the project specs to switch from SVM to DPWM. This switch parameter should decide the modulation technique based on the load on the system. During the operation of the BEV, with the decreasing SOC level, DC voltage ripple is increasing. To balance the increase, as inversely proportional to the SOC decrease, switching frequency should be increased to 7 kHz and SVM should be utilized more. On the other hand, while SOC is high, to prevent overheating the system DPWM strategy can be hold even lower speed zones. If battery pack is cold without any performance limitations, to lower the ripple, same strategy with the SOC decrease should be applied.

Beside the optimization of the DC voltage ripple, power losses of whole powertrain components such as, the inverter, e-machine and the gearbox must be considered during the development. For the future researches regarding DC voltage ripple on electric vehicles, application software of inverter must have additional control algorithms to have better durability of system such as DCDC voltage status, regenerative mode status etc. In addition, machine learning or fuzzy logic algorithms can be also implemented to system for improve used switching method. Design o experiment (DoE) methodology can be used in further studies for more inclusive optimization. Besides dependencies of DC voltage ripple, DC voltage ripple mathematical model can be developed, and it can be validated with vehicle tests.

ABSTRACT

Increasing environmental concerns and the limited energy density of the current Lithium-Ion battery technology attracts the industry and academia's attention to the control strategies and drivetrain architectures that can further help to reduce the energy efficiency of electric vehicles. On-board and in-wheel configurations bring additional benefits such as independent torque variation over centre-driven ones with a cost of high price. In this perspective, in this study, the energy benefit analysis of independent toque variation based control strategy has been studied for a fully electric tracked vehicle. Throughout the analysis, the nonlinear characteristics of each drivetrain component were modelled through 3D maps. The simulation studies have been tried to be carried out for the whole operating range of the vehicle. The analysis has shown that vehicle lateral dynamics significantly affect the energy consumption of electric vehicles. Furthermore, the results can be used directly during the design of the independent torque based controller design.

Keywords: Energy benefit analysis, torque vectoring, power consumption, electric tracked vehicle

1. INTRODUCTION

The growing environmental concerns caused by increasing vehicle emissions by 25% in the last 30 years have triggered the electrification of off-road vehicles [1]. That is mainly because internal combustion engines of off-road vehicles are the primary source of nitrogen oxides (NOx) and particulate matter (PM10) [2]. Therefore, the electrification of these vehicles plays a vital role in reducing energy usage and reducing emission levels. Moreover, at zero speed, the electric motor can deliver the maximum available torque, which translates into excellent launch capabilities of the vehicle. However, the main drawback of an electric vehicle is its energy storage system, which is the battery pack. The inadequate energy density of the battery, which is ten times less than fossil fuel, has a direct impact on the vehicle range [3].

Several studies have been carried out in the literature on the development of torque distribution allocation for in-wheel and on-board electric vehicles [1-14]. Some of the studies mainly consider the torque distribution considering only the longitudinal vehicle dynamics. In contrast, others have taken into account the lateral vehicle dynamics and reduction of energy consumption due to the possibility of individual control of each EM.

The first group of studies only considered the longitudinal dynamics together with drivetrain losses. In this perspective, Torinsson *et*. al proposed two different control strategies based on online and offline optimization techniques. The simulation results have shown that through developed optimization algorithms, a reduction of up to 3.9% in energy consumption for fixed distribution ratio and equal tyre-to-road friction utilization can be obtained [4]. Chen *et.* al proposed and compared real-time adaptive, Karush–Kuhn–Tucker (KKT) -based and rule-based energy-efficient control allocation (EECA) technics for longitudinal speed tracking control problem. The simulation and experimental results have proven that adaptive and Karush–Kuhn–Tucker-based ones have less consumption than the rule-based approach for rear-wheel-drive vehicle [5]. Moreover, the KKT-based EECA method is presented by formulating a nonlinear cost function for the front and rear-wheel is driven EVs. The simulation results have shown that the developed method is faster than other methods without any dependency on initial conditions [6]. Yuan *et.* al developed a EM consumption based online optimization for torque distribution. In this method, EM which is working on low torque region is disconnected from the axle via clutch. As a result of this, power consumption of EM is decreased 27% and energy economy improved 4% for New European Driving Cycle (NEDC) [7].

Building more environmentally friendly vehicle systems relies on understanding the root cause of the powertrain losses and lateral dynamics considering the powertrain architecture. In fulfilment of that, Chen *et.* al have presented a low-level adaptive EECA with a high level sliding mode control (SMC) structure considering propulsive and regenerative efficiency of motor for four in-wheel driven drivetrain configuration. The simulation and experimental results presented that the designed method have a lesser power consumption than pseudoinverse control allocation (CA) technic [8]. Kobayashi *et.* al have suggested a direct yaw torque control (DYC), including minimization of tyre slip loss on contact patches for four-wheel driven EV. Simulation results have shown that the developed method reduced power consumption of the vehicle due to dynamic steering response in the acceleration and deceleration when cornering [9]. Sun *et.* al have offered a DYC considering energy saving during quasi-steady-state steering for four in-wheel driven EV. In this work, offline optimization is made for torque distribution during continuous driving and steering, and it is shown that the proposed method made up to 10% energy economy compared to other techniques [10]. Edrén *et.* al have compared front axle steering (FAS), rear-axle steering (RAS) and all-wheel steering (AWS), considering actuator limitations in the six different EV configuration. The simulation results show that the combination of fully distributed torque vectoring and RAS structure provides a 10% reduction in energy consumption [11]. Zhai *et.* al have presented a hierarchical control combining energy efficiency and steering stability, making multi-objective optimization for four in-wheel-driven EVs. The simulation results have shown that the developed method saved energy 23.68% with enhanced vehicle steering stability [12]. Nishiara and Higashino have investigated the optimization of power consumption caused by tire slippage and developed a DYC algorithm for four in-wheel-driven EVs. They compared with alternatives that do not use DYC and showed the effectiveness of DYC ın the power consumption [13]. Koboyashi *et.* al have shown the effectiveness of the DYC method for energy loss during steady-state steering by formulating the relationship between power loss and cornering resistance, together with motor and inverter losses [14][15].

Some the studies looked at the energy efficiency from a lateral stability perspective. Zhang *et.* al developed an optimal torque distribution (OTD) strategy for four in-wheel driven drivetrain configuration. Different weighting coefficients are used for objective function of vehicle stability and low energy consumption. To solve the objective function of the low energy consumption, the sequential quadratic programming (SQP) technic was applied. Because SQ needs a complex solving process, this method is not suitable for real-time application, but it can obtain better vehicle stability and fuel economy [16]. Sun *et.* al have studied a switching principle between DYC for energy economy and lateral stability of four-wheel driven EV. In this study, they made offline optimization for torque distribution using EM efficiency. The simulation results show that the proposed combined controller provide safe and more efficient driving than only DYC for stability controller [17].

On the contrary, there have not been many paper for both torque vectoring and energy consumption optimization in the tracked electric vehicle application. In one of the few relevant studies done by Huang *et.* al., they added an extra motor called a power coupling system to enhance high-speed steering capability. The control has been performed through an optimization-based torque distribution strategy. The simulation result clarified that the developed system and control method enhanced steering response for high-speed driving [18].

This paper presents the potential benefit analysis of torque control for dual-motor fully electric tracked vehicles by considering drivetrain losses. In this framework, the paper starts by introducing the prototype vehicle architecture, which was developed to investigate the electrification benefit of tracked vehicles. The rest of the paper is as follows. The third section is devoted to modelling the electrical machine, power electronic converter, and transmission system. In section four, the power consumption analysis is carried out firstly, based on the models developed in section two to characterise the losses, and second based on the lateral dynamics. Finally, the paper ends with conclusions in the last section.

2. ELECTRIC TRACKED VEHICLE

The electric track vehicle investigated in the study is an autonomous fully electric rubber-tracked vehicle. The vehicle itself and the schematic of the vehicle prototype is shown in Fig.1. The battery left and right electrical machines (EMs), power electronic converters (PEC), reduction gear, and sprocket constitute the main components of the powertrain with the related Electronic Control Units (ECU), which are not shown in the figure due to simplicity. Each EM driver transfers electric power between the electric machine and battery pack. Each motors supply power to each sprocket through the two speed-reduction gearboxes with a fixed gear ratio to allow the operator to make the most of the EM's power available while moving slowly through challenging terrain, respectively.

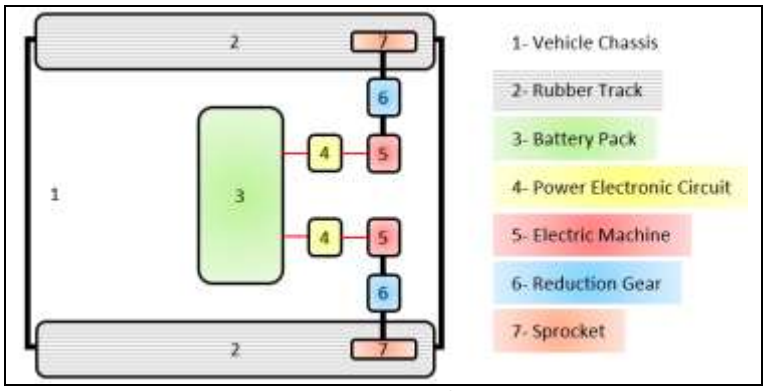

Figure 1. The powertrain schematic of electric tracked vehicle

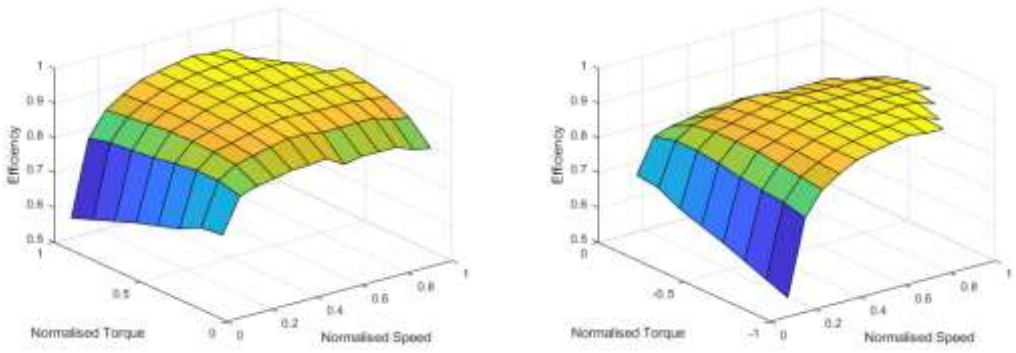
The coordinated control of the longitudinal and lateral motion is achieved by torque control through the traction motors on both sides of the vehicle. It is important to note that based on the specifications, the vehicle and powertrain are configured so that continuously variable steering and speed control are feasible at the same time.

3. DRIVETRAIN MODEL

There are three dominant factors when power consumptions of electric drivetrain are modelled. These are power losses of the EM, PEC and mechanical transmissions. There are some several nonlinear effects at the source of the losses which come from environmental conditions, disturbances and nonlinear characteristic of the equipment. There can be seen in the literature some modelling approach to investigate the power consumption. In this study, these losses are calculated by efficiency maps and formulation approaches for known characteristics of the equipment.

3.1. Electric Machine

The on-board EMs are modelled using their torque versus speed characteristics and efficiency maps. The torque maps of both rear right and rear left EMs are given both for traction and braking in Fig. 2. Since both EMs are identical the maps are presented only for one of the motor. Normalised torque and rotational speeds of both EMs were defined as inputs whereas efficiency is defined as output.



a. **b.**

Figure 2. Electric machine efficiency maps a. traction mode b. regeneration mode

3.2. Power Electronics

The power consumption of the PEC consists of the conduction and switching losses. Conduction losses is caused by the internal resistance of the switching device whereas switching losses are due to the on-off characteristics of the current and voltage during switching. Hence, they are proportional to current, voltage, on-off times and switching frequency. The efficiency maps of PECs both for the rear right and rear left EMs are shown in Fig. 3.

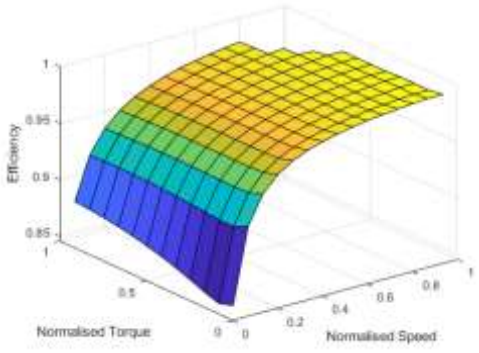


Figure 3. Power electronic converter efficiency maps of both EMs.

3.3. Transmission

There are two gears between rubber track and electric motor for each side of the vehicle. These gears are reduction gear and sprocket. When the reduction gear reduces the rotational speed range of the motor output shaft, it increase the torque range for sprocket. Main concern of the reduction gear is matching speed-torque needs for motor and track of the vehicle. Purpose of the sprocket is transmitting the power of the motor to the vehicle track and it is also called as traction gear. Basically, output speed and torque of the motor divided and multiplied through reduction gear ratio respectively. And after that output torque and speed of the reduction gear transmitted to the rubber track via sprocket.

$$\hat{Q}_m = \begin{cases} \eta_g \dfrac{Q_{track}}{i_g \aleph_Q} & P_t < 0 \\ \dfrac{Q_{track}}{\eta_g i_g \aleph_Q} & P_t > 0 \end{cases} \quad (3)$$

$$\hat{w}_m = \frac{w_{track} i_g}{\aleph_w} \quad (4)$$

Where i_g and η_g are total gear ratio and efficiency; Q_{track} is the torque in the rubber track, $\hat{Q}_m$ is the normalized torque on each motor, $\hat{w}_m$ is the normalized angular speed of the wheel; $\aleph_Q$ and $\aleph_w$ are normalisation factors expressed as maximum value of torque and speed respectively. These parameters are obtained by multiplication of two gear parameters for efficiency and gear ratio terms separately.

$$i_g = i_{rg} i_{tg} \quad (5)$$

$$\eta_g = \eta_{rg} \eta_{tg} \quad (6)$$

Where i_{rg} and η_{rg} are gear ratio and efficiency of the reduction gear; i_{tg} and η_{tg} are gear ratio and efficiency of the traction gear.

4. POWER CONSUMPTION ANALYSIS

4.1. Drivetrain Power Consumption Characterisation

It is known that the efficiency of the electric machines and inverters changes with working current and voltage speed generally. Moreover, direct relationships can be established between current-voltage and torque-speed. Furthermore, the power consumption can be modelled as a nonlinear function the speed and torque. In this study, these nonlinear maps are used to calculation of the power consumptions for the motor and inverter. In addition, the power consumption of the transmission is calculated from theoretical efficiency of the gears. The drivetrain power consumption characteristic is shown in Figure 4. The characteristic is shown for four different speed starting from 0.96 km/h up to 10.2 km/h.

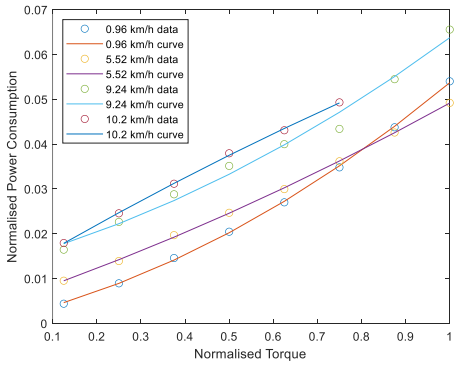

Figure 4. Power consumption curve fitting as a function of required torque for different motor speeds.

This characteristic behaviour of the power consumption can be represented by a second-degree polynomial which is given as:

$$\hat{P}_c(\hat{Q}_m, \hat{w}_m) = a_2 \hat{Q}_m{}^2 + a_1 \hat{Q}_m + a_0 \tag{7}$$

$$\hat{P}_c = \frac{P_c}{\aleph_P} \tag{8}$$

where a_0, a_1 and a_2 are polynomial coefficients, $\hat{Q}_m$ is the normalised torque vector containing the motor coefficients vary with motor speed; $\hat{P}_c$ is the normalize power consumption of the motor and $\aleph_P$ is a normalisation factor expressed as maximum power of the motor. The data is fitted separately for the positive and negative torques for total amount of motor and inverter. The total motor power loss can be expressed as sum of the power losses in traction and regeneration, where both these power losses are given by:

$$\hat{P}_{c,m}^{Q+} = \sum_{k=1}^{2} \hat{Q}_{m,k} \hat{w}_{m,k} \left(\frac{1}{\eta_k^{Q+}} - 1 \right) \tag{8}$$

$$\hat{P}_{c,m}^{Q-} = \sum_{k=1}^{2} \hat{Q}_{m,k} \hat{w}_{m,k} \left(1 - \eta_k^{Q-} \right) \tag{9}$$

where η^{Q+}, η^{Q-} are the efficiency in traction and regeneration of the motors respectively. The subscript 'k' indicates the left and right electric machine. The curve fitting success of the determined polynomials for traction and regeneration can be seen in Figure 5.

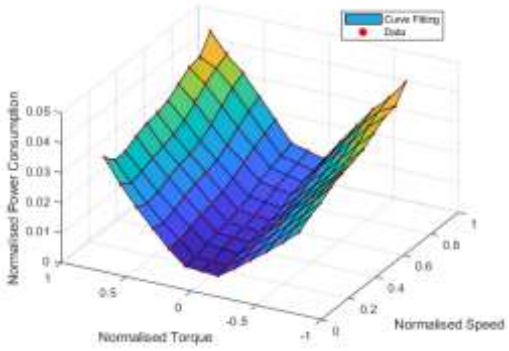

Figure 5. Power consumption curve fitting as a function of normalised torque and speed.

4.2. Vehicle Lateral Dynamics Effect

In an EV with at least two EMs on the same axle, it is possible to generate either a destabilising yaw torque to reduce understeer, or a stabilising yaw torque to increase understeer. The direct yaw torque is provoked by the uneven torque distribution between the two sides of the EV. The torque demands on each side are calculated in Equation 10 from Q_T, total axle torque, and Q_Y, required yaw torque.

$$Q_{mR} = 0.5Q_T - Q_Y\frac{r_g}{L_t} \quad (10)$$

$$Q_{mL} = 0.5Q_T + Q_Y\frac{r_g}{L_t} \quad (11)$$

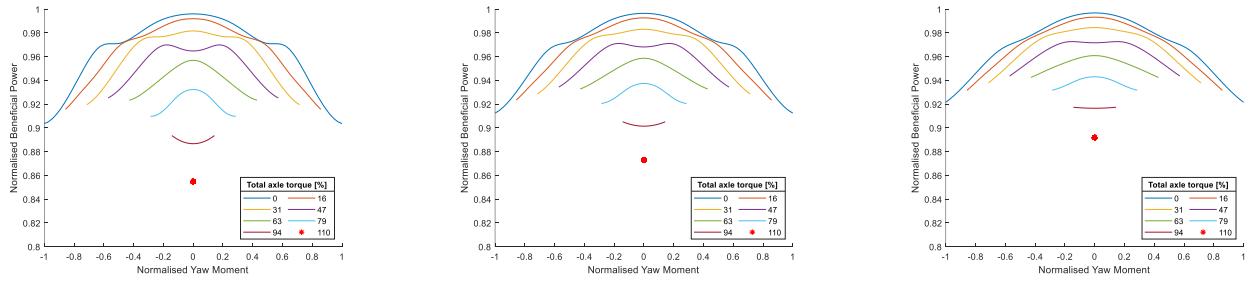
In this equation, r_g and L_t are represent the traction gear radius and track width respectively. In Figure 6 there are some examples of motor power loss with respect to the direct yaw torque. The direct yaw torque for these cases is calculated as follows:

$$Q_{mL} = Q_T,\ Q_{mR} = 0 \Rightarrow Q_Y = 0.5Q_{mL}\frac{L_t}{r_g} \quad (12)$$

$$Q_{mL} = 0,\ Q_{mR} = Q_T \Rightarrow Q_Y = -0.5Q_{mR}\frac{L_t}{r_g} \quad (13)$$

$$\hat{Q}_Y = \frac{Q_Y}{\aleph_{QY}} \quad (14)$$

where $\hat{Q}_Y$ is normalized yaw torque and $\aleph_{QY}$ is the normalisation factor expressed as the maximum value of the Q_Y.



a. **b.** **c.**

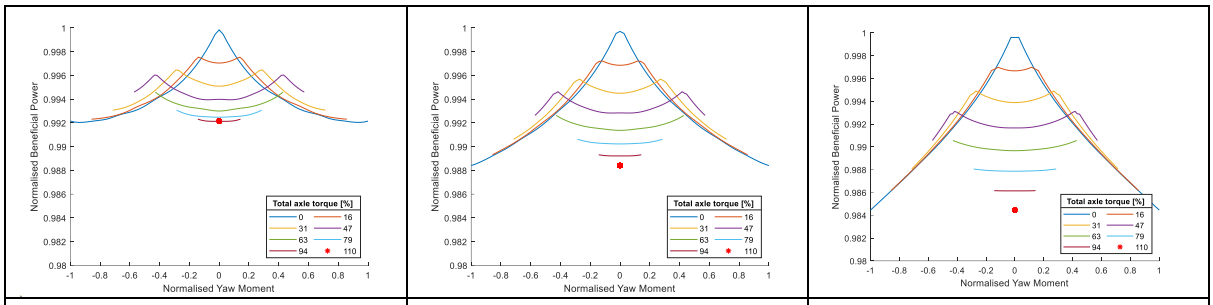
Figure 6. Beneficial power of electric machine as a function of normalised yaw torque with respect to normalised total axle torque and normalised vehicle speed of **a.** 0.1, **b.** 0.5 **c.** 1

As it can be seen from the Figure 6, electric machine power consumption has a wavy characteristic for most of the total axle torque and vehicle speed conditions. Especially for the 86% of total axle torque, power consumption can be minimized at the two different local minimum for nonzero yaw torque value. In contrast, generally, minimum power consumption can be obtained at the zero yaw torque value.
The normalized power losses of the inverter in the propulsion and the regeneration mode are calculated as follows:

$$\hat{P}_{c,i}^{Q+} = \frac{P_{me}}{\aleph_P}\left(\frac{1}{\eta_i} - 1\right) \quad (14)$$

$$\hat{P}_{c,i}^{Q-} = \frac{P_{me}}{\aleph_P}(1 - \eta_i) \quad (15)$$

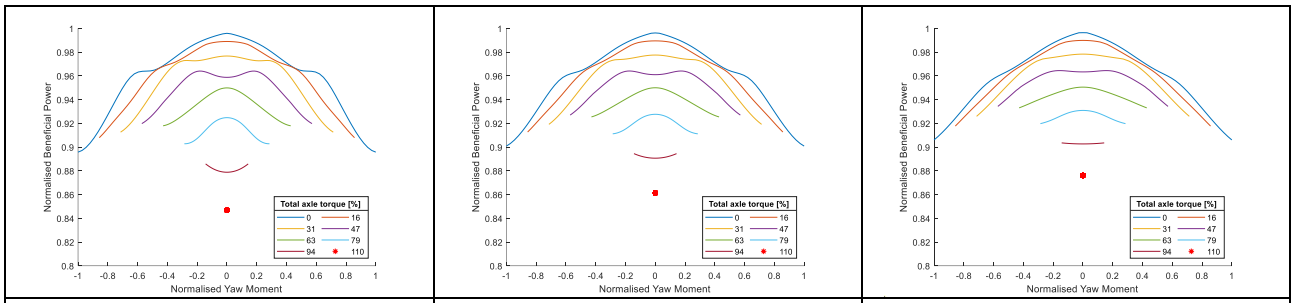
Where P_{me} is the input electrical power to the electric motor and η_i is the efficiency of the inverter. From Figure 7, as it can be seen that the minimum power consumption is obtained with nonzero yaw torques beyond zero total axle torque. Minimum consumption can be achieved at one of the local minimum of the curves.



a. **b.** **c.**

Figure 7. Beneficial power of PEC as a function of normalised yaw torque with respect to normalised total axle torque per cent and normalised vehicle speed of **a.** 0.1, **b.** 0.5 **c.** 1

The power consumption of the powertrain is including transmission, motor and inverter power consumptions. From Figure 8 it can be seen that optimal solution is achieved at the zero yaw torque situation generally. In addition, at the 86% of total axle torque, there are two local optimum.



a. **b.** **c.**

Figure 8. Beneficial power of drivetrain as a function of normalised yaw torque with respect to normalised total axle torque per cent and normalised vehicle speed of **a.** 0.1, **b.** 0.5 **c.** 1

Relationship between torque demand and direct yaw torque is shown in Figure 9. It indicates the maximum yaw torque usability with the actual vehicle configuration.

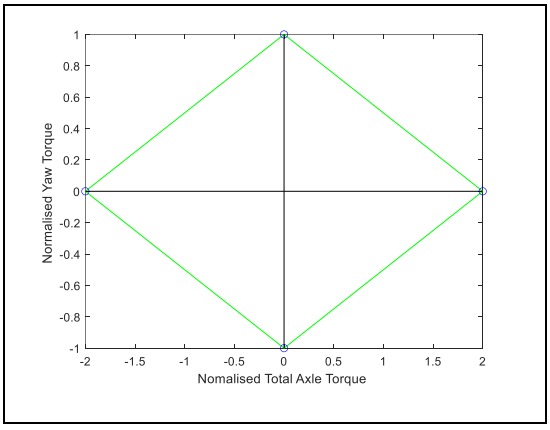


Figure 9. Normalised yaw torque vs total axle torque.

More specifically, from Figure 9 it is possible to see the behaviour of the yaw torque with respect to the total axle torque. When the total axle torque is either the maximum or the minimum value the only yaw torque possible is zero, whilst when the total axle torque is equal to zero, the yaw torque can be either the maximum or the minimum value.

5. CONCLUSION

This paper presents the potential benefit analysis of torque vectoring for dual-motor fully electric tracked vehicles by considering electric machine (EM), power electronic circuit (PEC) and transmission losses. In order to get as close as possible to the results in practice, nonlinear characteristics for the power consumption of the EM, PEC and transmission are modelled. The analysis investigates the power consumption the system for whole working range that vehicle can work. Based on the analysis carried out, the power consumption of the drivetrain with respect to the driver torque request can be represented as a second-order polynomial function that is monotonically increasing. In addition, lateral dynamic analysis have shown that there are one local minimum in the power consumption of the drivetrain at constant total axle torque with respect to yaw moment, while two local optimum exist for certain region. As a result of these analysis, yaw torque has been found to have a large effect on power consumption and characteristic differs according to the working area. It is believed that the result of that study will shed light on the use of controller design based on independent torque variation of in-wheel or on-board configuration vehicles.

ABSTRACT

Considering today's environmental problems, carbon emission is of great importance, and weight reduction studies are carried out on materials used in automotive parts in academia and industry. Lighter and more environmentally friendly composite materials such as long natural fiber-reinforced composite materials are developed to decrease CO_2 emissions by decreasing the weight of automotive parts. The aim of this study is to develop 30 wt.% long jute fiber reinforced polypropylene composites instead of 20 wt. % talc-filled polypropylene copolymer (PP) used in the trunk hood interior trim part. Long jute fiber-reinforced composite is produced by using continuous impregnation and granulation line (LFT-G). Mechanical (tensile, flexural, and Charpy impact) tests, Differential Scanning Calorimeter (DSC), and Heat Deflection Temperature (HDT) analysis are performed. Volatile organic content (VOC) and Sound Transition Loss (STL) are determined and compared with 20 wt. % talc-filled PP. The trunk hood interior trim part is manufactured by using an injection molding process. Mold flow analysis of 20 wt. % talc-filled PP and 30wt.% long jute fiber reinforced PP is performed. CAD data and which points were instrumented, and the x, y, and z excitations corresponding to these points were studied. Stress-strain curves of 20 wt.% talc filled PP, and 30 wt.% long jute fiber reinforced PP were studied. Static-dynamic finite element analysis was performed. 70% and 63% increase in tensile and flexural strength were obtained, respectively, while the weight of the 20 wt. % talc filled part, which was 1582 grams, was reduced approximately 12% with the developed 30% jute reinforced composite material. In addition to the fuel savings and the economic gain due to the weight reduction, positive contributions will be made to the ecological balance with the reduction of CO_2 emission to be achieved at the same time.

Keywords: long fiber reinforced polypropylene, LFT-G production line, lightweight, automotive in-trim parts, mold flow analysis

1. INTRODUCTION

Considering today's environmental problems, carbon emission is of great importance. For this reason, weight reduction studies are carried out on materials used in automotive parts in academia and industry in recent years. Among the solutions produced to reduce weight-related carbon emissions and carbon footprint, the reduction of part weight and the design and development of more environmentally friendly materials come to mind. In the automotive industry, mineral and glass fiber-filled polypropylene-based thermoplastic composite materials are widely used. Solving the problem of weight is possible by producing composite materials by using environmentally friendly fillers or reinforcement materials that are lighter than the currently widely used talc and glass fiber. Natural fibers have some benefits over traditional reinforcing materials in terms of cost, density, renewability, abrasiveness, and biodegradability. Natural fibers such as jute, coir, sisal, pineapple, ramie, bamboo, banana, etc., have been very popular in the development of natural fiber-reinforced composite materials in value-added applications [1-3]. Jute is one of the cheapest natural fibers,

and among natural fibers, it has the highest production volume. Due to its easy availability and cost advantage, jute fiber is preferred.

The particle sizes and forms of natural materials affect the mechanical values of the composite material. Natural filling materials in the form of particle generally decreases in mechanical values. It is possible to use fibers in short and long forms. Short fibers could be broken down during processing in the extruder and could not provide the desired mechanical properties. Therefore, it has come to the fore to use natural fibers in long-form. There are many studies about natural fiber reinforced composite production and characterization in literature. In one of the studies in literature, ordinary kenaf and twisted kenaf are used to develop composite and focused on the mechanical properties of hybrid kenaf/glass-reinforced composites for utilization in passenger car bumper beam [4]. Another study was about the fabrication of epoxy reinforced structural composites reinforced by long bamboo fibers which are obtained by using a novel mechanical extraction process [5]. Different types of long natural fibers are used not only in thermoplastic matrices but also in epoxy matrices to increase the mechanical properties; for example, the addition of aligned long harakeke fiber was found to significantly enhance the tensile and flexural properties of epoxy in a study made in literature [6].

In applications where natural fibers can be used in automotive, it is selected from among the parts that are generally used in non-load bearing; parts with low aesthetic requirements can be painted or covered with fabric, and especially when the part weight is higher compared to other plastic parts. The trunk hood interior trim is a part whose weight is open to decrease with material and design changes compared to other interior trim parts, is not exposed to high mechanical load, and can be evaluated in natural fiber applications, generally colored with pigment or covered with fabric.

In this study, twisted long jute fiber reinforced polypropylene-based composites are produced by the continuous impregnation method, and trunk hood interior trim part was manufactured by using injection molding machine. Thermal, mechanical, and physical properties of composites were investigated by various characterization methods and compared with current used 20 wt.% talc-filled polypropylene copolymer. In addition to the reduction in density and improvement in mechanical values with the use of natural long fibers, environmentally friendly composite material was produced with a more environmentally friendly approach.

1. MATERIAL AND METHOD

1.1 Materials

Polypropylene and twisted long jute fiber (Figure 1) are used as a polymer and a natural fiber reinforcement, respectively, in this study. Polypropylene purchased from Borealis AG, has MFI value of 110 to ensure wetting of long fibers. Long jute fiber supplied from Nagase Singapore (PTE) Ltd. It has a thickness of around 1.5 mm. A maleic anhydrite-based coupling agent was also used to increase compatibility between the matrix and the natural fiber.

Figure 1. Twisted long jute fiber

.

1.2 Methods

1.2.1 Production of long fiber reinforced composites

Long jute fiber reinforced polypropylene-based composites are produced by using continuous impregnation and granulation line (LFT-G) which is showed in Figure 2. Composites are dried for around 4 hours to get injection molded test samples before the injection molding process. Characterization samples are obtained by using injection molding.

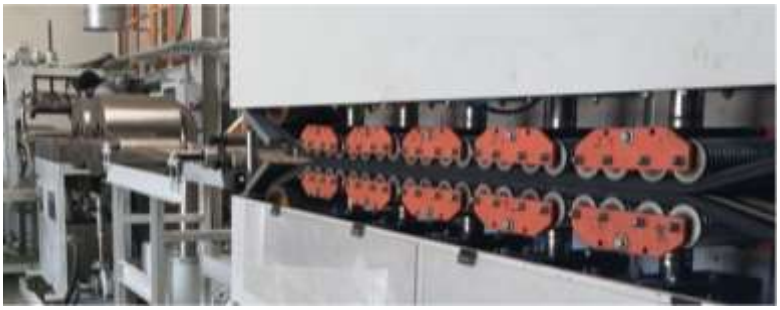

Figure 2. LFT-G line

The length of 30 wt. % long jute fiber reinforced PP granules was produced around 12 mm (Figure 3a-3b).

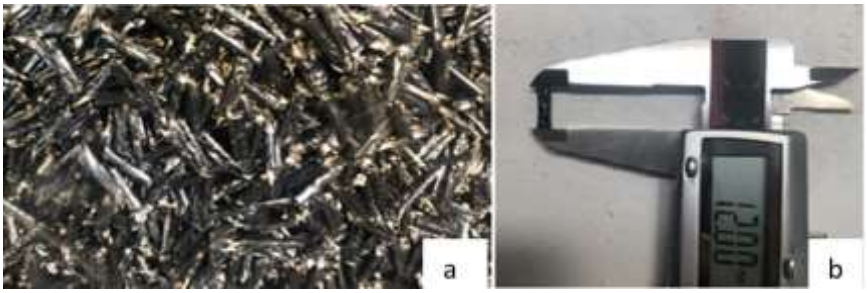

Figure 3. a. 30 wt.% long jute fiber reinforced polypropylene composite granules, b. length of the composite.

1.2.2 Characterization of composite materials

The tensile and flexural properties of the composites were investigated using a Hegewald & Peschke universal testing machine. The tensile tests were performed at a crosshead speed of 50 mm/min according to ISO 527 Standard. Three-point bending tests were conducted to characterize the flexural properties of the PP-based composites by following the ISO 178 Standard. The tests were carried out at a constant crosshead speed of 2mm/min and span length of 32 mm. Tensile and flexural strength and modulus values were obtained by the average of three test results.

Notched and Un-notched Charpy Impact testing was conducted using ISO 179 Standard on Zwick Impact Tester. Tests were operated at room temperature with 5 J Stricker and span length of 70 mm.

The melting point of composites is determined by using DSC according to ISO 11357 Standard. Heat deflection temperature (HDT) is determined according to ISO 75 Standard by using Coesfeld HDT-Vicat Testing Instrument.

VOC test was performed by GC-MS (Gas Chromatography-Mass Spectrometry). Sound Transition Loss (STL) values (dB) of the samples were obtained according to ASTM E2611-09 Standard for measuring the normal sound transmission of acoustic materials based on the transfer matrix method.

1.2.3 Analysis of interior trunk closing part

Mold flow analysis of 20 wt. % talc filled PP and 30 wt. %jute fiber reinforced PP is performed. CAD data and which points were instrumented and the x, y, and z excitations corresponding to these points were studied. Stress-strain curves of 20 wt. % talc filled PP and 30 wt. % jute fiber reinforced PP were studied. Meshed model/CAE analysis and static-dynamic analysis were performed.

2. RESULTS AND DISCUSSION

2.1 Development of composite material

Mechanical and thermal characterization results are given in Table 1. The weight of the trunk hood interior trim part is 1582 grams. The weight of this trim part produced with 30 wt. % long jute reinforced composite material developed in this study is 1400 grams. With the use of 30 wt.% long jute fiber reinforced material, the weight of the part was reduced by approximately 12 %.

Tensile strength and elastic modulus of 20 wt. % talc-filled PP is increased from 23 MPa to 39 MPa by reinforcing PP with 30 wt. % long twisted jute fiber. In the literature, there are studies that ensure an increase in tensile strength and modulus by using natural fibers. For example, twisted kenaf material, which is fabricated by the hot impregnation method, presents a good tensile strength when it is compared with the current used material [4]. According to the data in the literature, compared with the tensile properties of 20 wt. % long glass fiber reinforced PP that is specified for interior applications from Ford Motor Company, many NFRCs with fiber content higher than 30 wt. % have attained higher tensile modulus values [8]. While flexural strength and flexural modulus of 20 wt. % talc-filled PP is 33 MPa and 1590 MPa, respectively. Flexural strength and flexural modulus of 30 wt. % long jute reinforced PP composite found as 51 MPa and 3600 MPa, respectively. It is found in the literature that twisted kenaf fiber could help to increase the flexural modulus and strength of glass fiber reinforced composites [4]. Charpy notched and un-notched impact strength of 30 wt. % long jute reinforced PP composite were found to be 6.5 kJ/m^2 and 20 kJ/m^2, respectively, which are higher than 20 wt. % talc-filled composite. When the literature is investigated, it has been seen that Izod notched impact strength is increased by 60% and above with the addition of 50 wt. % jute fiber, which is produced by a continuous pultrusion technique, in natural long fiber pellets whose length is 6 mm [9].

The melting point of the 30 wt.% long jute fiber reinforced PP composite did not change when comparing with talc-filled PP, but HDT temperature increased from 60 ˚C to 124 ˚C. VOC test results are given in Table 2. When Table 2 is examined, it is seen that the amount of volatile organic compounds decreases when long jute fiber is used in composite instead of 20 wt. % talc-filled PP. It is given in Table 3. It is observed that as the number of natural fiber increases, the sound transmission loss of the material increases at low and high frequencies. Better sound absorption properties were obtained in the study, which uses long wheat straw and polypropylene web for developing lightweight composites [7].

Table 1. Comparison of 20 wt.% talc-filled PP composite with 30 wt.% long jute fiber reinforced PP composite

	20 wt.% talc-filled PP composite	**30 wt. %. long jute fiber reinforced PP composite**
Tensile Strength (MPa)	23	39
Young's Modulus (MPa)	1500	2100
Flexural Strength (MPa)	33	51
Flexural Modulus (MPa)	1590	3600
Charpy Notched Impact Strength, (kJ/m^2)	5.6	6.5
Charpy Un-notched Impact Strength, (kJ/m^2)	16	20
Melting point (ºC)	161	160
Heat Deflection Temperature (ºC)	60	124

Table 2. VOC values of 20 wt. % talc filled PP and 30 wt. % long jute fiber reinforced PP.

Samples	VOC (µg/m^3)
20 wt. % talc filled PPc	2.8
30 wt. % long jute fiber reinforced PPc	2.1

Table 3. Sound transmission loss values of materials

Frekans [Hz]	Sound Transmission Loss [dB]		
	PP	20 wt.% talc filled PP	30wt.% long jute fiber reinforced PP
100	34.37	35.17	47.48
125	48.33	42.49	57.36
160	43.45	45.03	60.79
200	33.95	42.22	56.99

400	30.34	30.28	40.88
500	24.90	24.03	32.44
630	22.00	20.41	27.55
800	19.59	16.97	22.91
1000	21.75	21.24	28.68

2.2 Analysis of trunk interior part

Tool design in combination with runner selection as well as injection molding properties are extremely important to preserve fiber length and orientation. The selected 'trunk hood interior trim part' is a suitable automotive part where mold flow simulation for long fibers has been run. Functional tests and dimensional checks with coordinate measuring machine proved parallel results with simulations. 30 wt. % long jute fiber reinforced polypropylene performed to achieve the potential of 12 % weight reduction in comparison to parts standard material 20 wt. % talc-filled polypropylene composite.

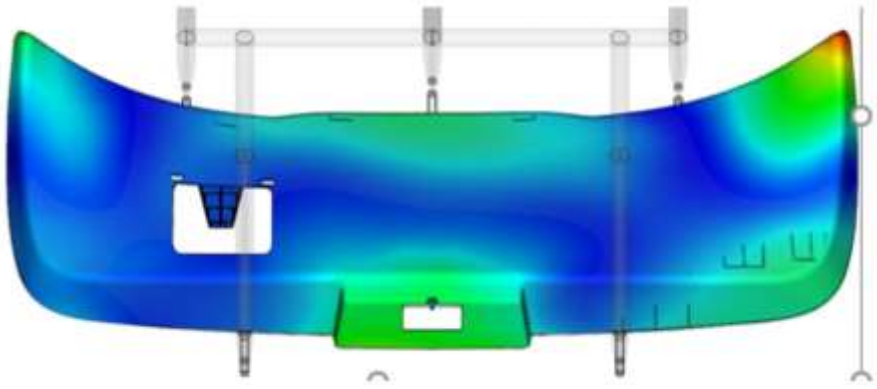

Figure 4. Moldflow analysis cooling diagram.

Figure 5. Injection moulded; a. 30 wt.% long jute reinforced PP-based interior part (above), b. 20 wt.% talc filled PP based interior part (below)

Injection molding trials have given great feedback regarding defining design parameters for long natural fiber reinforced thermoplastic compounds, tool design, and material development towards commercialization and industrialization of this sustainable approach.

The selected automotive case study part is the trunk hood interior trim part, as shown in Figure 6 in red and green.

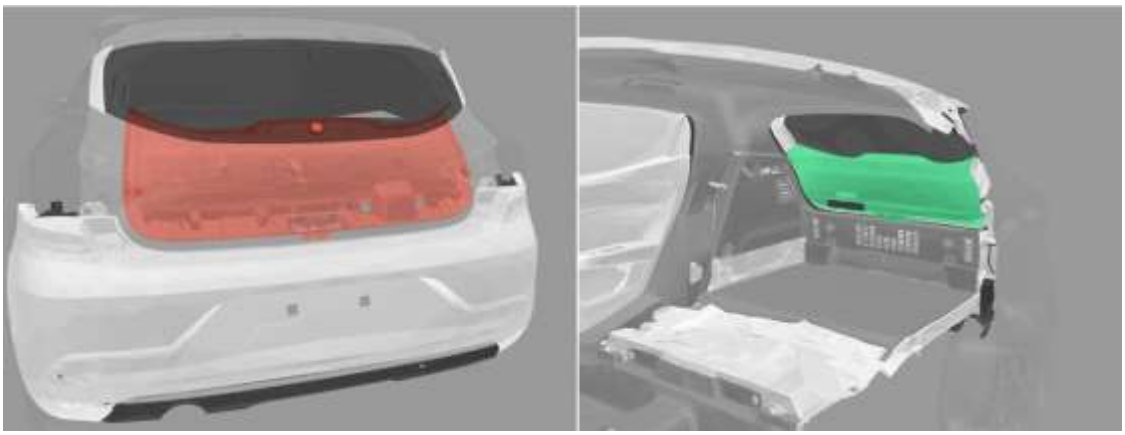

Figure 6. Part in assembled position on the vehicle

Modal Frequency simulations have been performed to investigate the NVH behavior of the parts at actual vehicle positions with representative boundary conditions. Hyperworks Commercial Software packages have been used in simulations. As shown in Figure 7, modal frequency response analysis showed close results indicating material change would not yield any change in free modes of the parts in virtual environment—Figure 8.

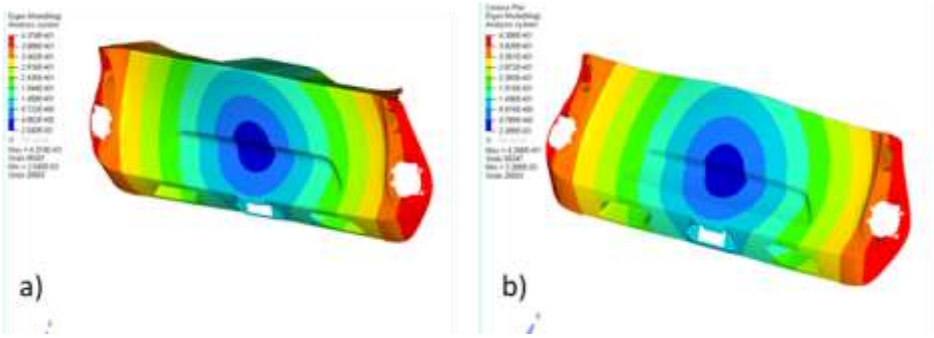

Figure 7. a) Original material in first mode b) PP+Jüte composite in first mode

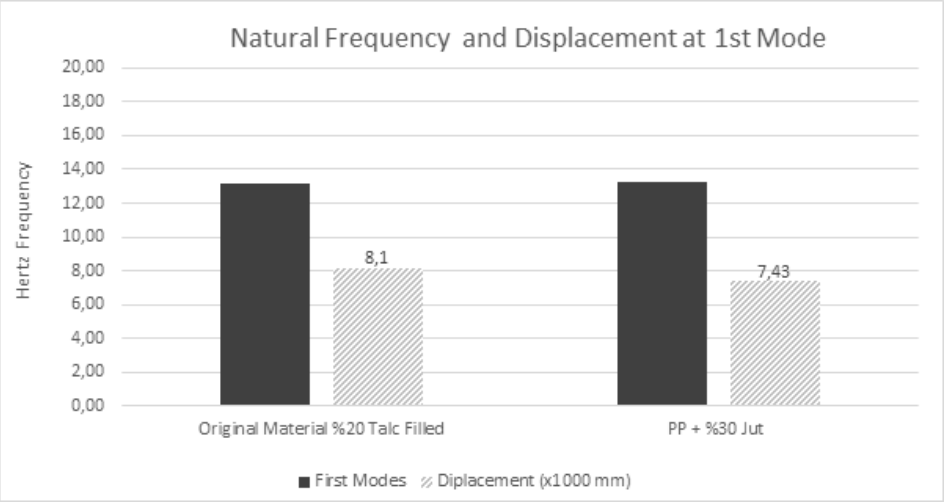

Figure 8. 1st natural modes of the selected materials and relative displacement in 1st mode

Physical tests have also been performed. 15K km aging durability test has been performed with prototype parts. Test results showed conformity to Renault Test specs, and parts have been signed off. Road Load Noise (RLN) measurements have been taken from reference locations of the part under certain testing conditions. As shown in Figure 9, RLNs give similar results in the Cartesian axis for driving conditions at high speed. Both materials have similar behavior from an acoustic perspective. Subjective evaluation of the part performance is rated to conform the Renault's specs.

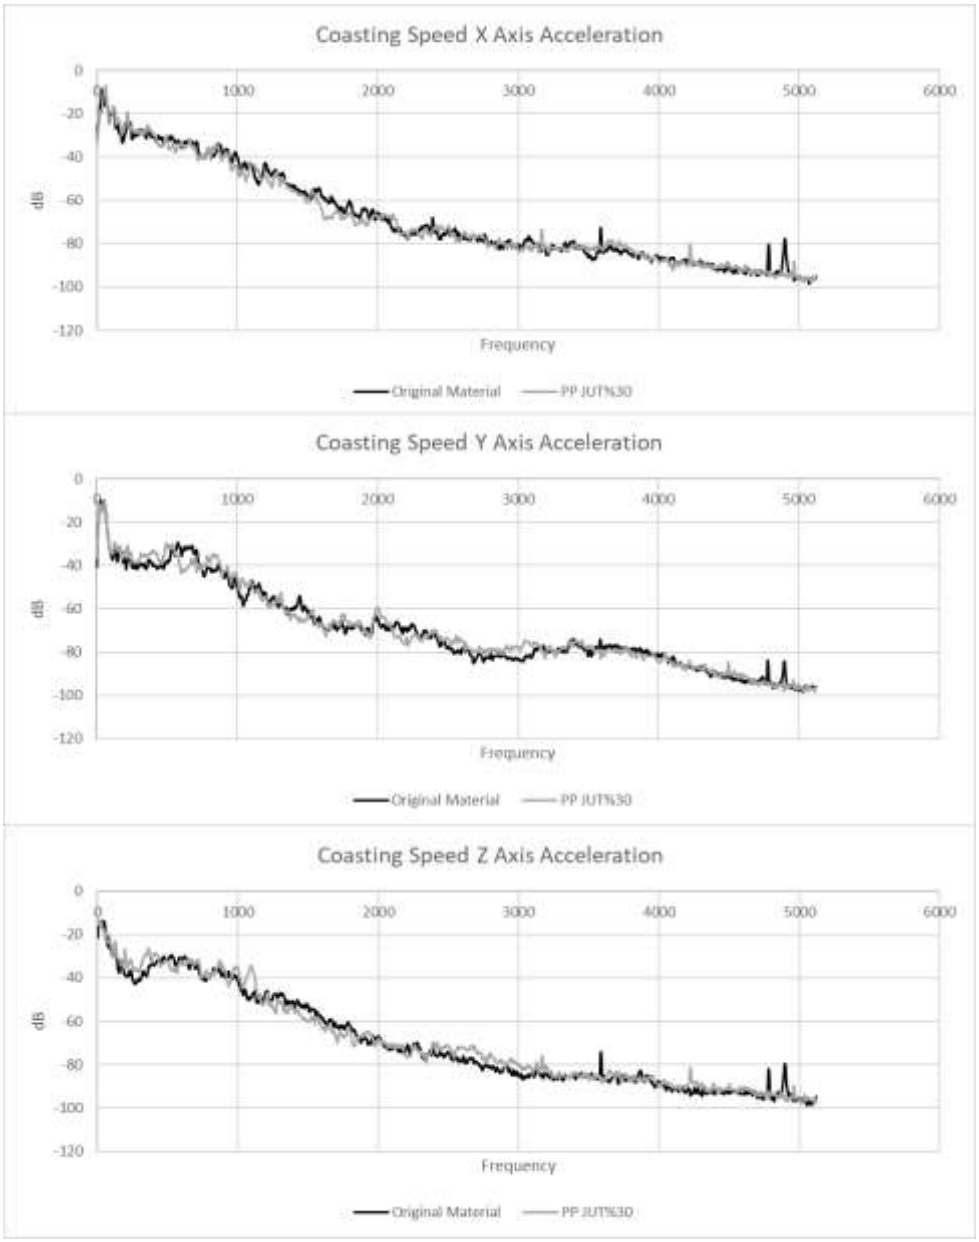

Figure 9. Coasting Speed condition acceleration values

3. CONCLUSION AND RECOMMENDATIONS

With the development of a PP composite material with long natural fiber additives with the impregnation method, the fiber/matrix interface is improved, suitable for injection molding, the weight has been reduced by 12%, a composite that can reduce carbon emission and has better mechanical values has been obtained. The mechanical values of the composites produced by the impregnation method were found to be much higher; thus, the mechanical values could be improved with the use of natural fibers. With the mitigation, besides the fuel-saving and the economic gain it will bring, positive contributions will be made to the ecological balance by reducing the CO_2 emission to be achieved at the same time.

ABSTRACT

Advanced driver-assistance systems (ADAS) are becoming more and more complex day by day. To solve this complexity, existing architectures must be changed or re-designed according to needs. Since re-designing existing architectures is a time-consuming and financially expensive activity, most of the time it is aimed to meet new needs with small additions to existing architectures. ADAS can be classified as safety-critical systems since any malfunction or failure can cause death or severe injury. In safety-critical real time systems, handling precise timing of the periodic tasks is one of the most important challenging part for time-triggered scheduler architectural design procedure. Each design approach has several advantages among others by taking into consideration of reliability and performance. In this paper, it is aimed to offer new design approach for resource limited specific use-case for ensuring critical activation timing of periodic tasks with minimal impact on reliability of timing deviation.

Keywords: Advanced Driver-Assistance Systems, Time Triggered Scheduling, Real Time Operating Systems, Safety Critical architecture, Performance and Reliability Analysis

1. INTRODUCTION

The complexity of autonomous driving platforms has increased day by day, with the development of cutting-edge technology for advanced driving assistance systems such as adaptive cruise control and pedestrian detection which serves the higher level of self-driving cars. To achieve level 4 or 5 autonomous driving standards [1], it is necessary to develop, improve and increase the number of sensor technologies in the vehicle. As there are more inputs introduced, the system load increases and it affects performance. For example, LiDAR sensors are becoming more and more popular as never before which helps identification, modelling and 3D mapping of environment. Until recently, these sensors, which were not preferred due to its high-cost, [2] and complexity it brings together, are becoming one of the most important technologies for autonomous driving day by day. In addition to being usable, it may cause some changes in the designs of autonomous driving platforms to provide robustness, reliability and performance. The work required to process sensor data requires high computing power and consumes system resources, causing a challenge in terms of reliability and performance. In such complex structures, controlling the synchronization and scheduling of the works often becomes very complex task. Architectural decisions to handle complex structure should be taken considering safety requirements. ISO 26262 introduces the international functional safety standarts in automotive applications. Potential hazardous risks can be minimized to acceptable levels by applying these standarts.

To accommodate the requirements of different systems and classes of applications and to offer flexibility and choice for the system integrator, we implement different scheduling methods and paradigms such as data-driven and event-driven in our platform products. Nevertheless, we see that time-triggered scheduling as the solution of choice for the tasks of the highest safety and real-time demands. In our work, it is offered new design approach in addition to existing time triggered scheduler architecture for resource limited fully utilized multi-core SoCs on a real-time operating system. We analysed consequences of new architecture in terms of performance, reliability, and safety to predict potential harm risk of periodic tasks.

2. TIME TRIGGERED ARCHITECTURE

In real time systems, scheduler is responsible for determining which task will be executed on the central processing unit (CPU). Scheduling algorithms can be divided into two main parts by considering architecture: static and dynamic. In

dynamic scheduling, algorithm decides the task scheduling during runtime. In static scheduling approach, task characteristics such as start and finish time, worst case execution, period are already modelled before the runtime. This approach would be beneficial since it provides less runtime overhead on the CPU and deterministic system behavior [3]. Static scheduling is used to achieve predictable timing of tasks and a deterministic system behavior, which is an important concern for safety-critical domains such as automotive and avionics industry. Time triggered architecture is based on the static schedule table [4] which is available before runtime. Activation time, deadline, period, core affinity and worst-case execution time for each task are adjusted during the compilation process. Schedule table consists of several time slices that are defined for executable runnable with parameters explained above. Time slices not only exist for runnable activation, but also for synchronization slot at specific time in hyper period, which is generally used at the beginning of each hyper period. In this specific synchronization slot, lag between expected and actual activation of hyper period beginning is calculated, and according to this calculated difference and synchronized time, activation of all runnable entities in hyper period can be adjusted by considering global time.

During runtime operations, scheduler component uses a static schedule table, executes the tasks, and monitors the safety violation in terms of period and worst-case execution time. This architecture provides less system utilization compared to dynamic scheduling since static scheduling is determined before the runtime, there is no flexibility regarding the execution of tasks. Considering all these data, it still makes this architecture preferable because it is the best solution for determinism. Schedule table creation is complicated process since all the activation times and worst-case execution times should be perfectly estimated with static-analysis tools considering computation chain requirements between tasks and monitoring each task for foreseen parameters. In this work, visualization of the static schedule table (**Figure 1**) is done by taking advantage of the methods mentioned in [5] which is helpful to identify potential worst-case execution time or computation chain violations in early time before deploying actual scheduling table on runtime.

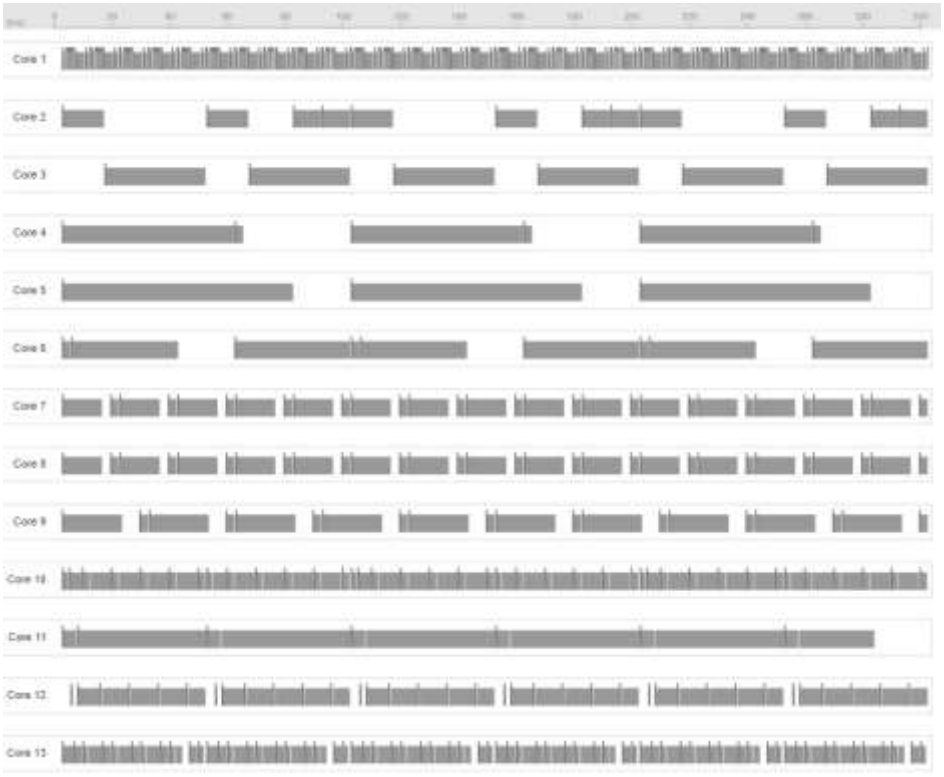

Figure 1. Schedule Visualization

3. TIME SYNCHRONIZATION

In real time systems, task processing should be handled in precise timing to fulfil hard real-time requirements. Most of the time, system architecture consists of multiple system on a chip (SoC) and electronic control unit (ECU) that needs to be synchronized in time manner to ensure each task is scheduled according to predefined schedule tables. Due to nature of microprocessor architecture, synchronization between hosts should be performed continuously with respect to master and slave architecture. Slave host timing should be corrected periodically according to master host timing. Time synchronization protocols are introduced to achieve this goal. In this work, IEEE 802.11AS gPTP standard is used to

provide time synchronization between several components (**Figure 2**). Protocol explains architectural information to achieve accurate time synchronization between nodes connected to the same network. It aims to determine propagation delay and time offset between hosts to correct timing of slave host. After the synchronization between components is established, the global time information in each component is used for synchronization of time-triggered scheduler.

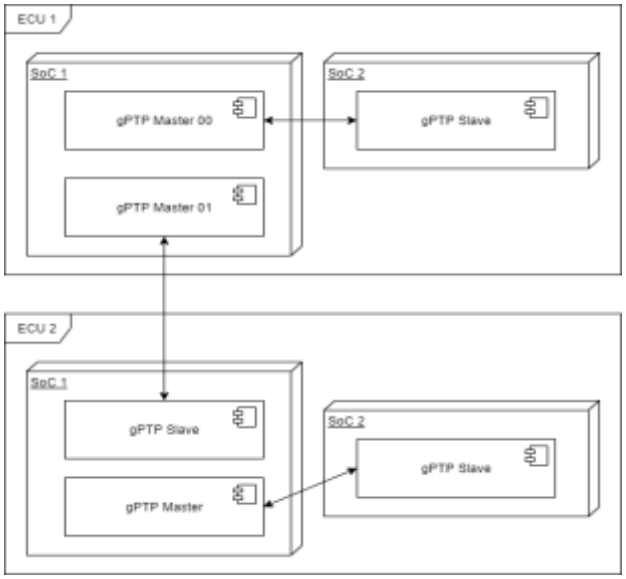

Figure 2. Time Synchronization between Multiple ECUs and SoCs

4. EXISTING ARCHITECTURE AND IMPLEMENTATION

Implementation of existing architecture is based on timer interrupts for controlling the execution of periodic tasks by obeying configured time slice parameters. Time triggered controlling of scheduling is performed on user-space level in addition to kernel space scheduler. In accordance with the multi-core architecture, one scheduler process is deployed on each CPU core, it is responsible to control tasks in the same core that is configured with core affinity parameter for each task. Each scheduler process operates the decision of which task will be executed on the core according to the schedule table which is defined statically. Each scheduler process is responsible for maintaining adjustment of the table that belongs to itself at the beginning of hyper period by considering synchronized time with gPTP protocol.

One process for each core architectural decision would be beneficial to enable POSIX-conformant signal handling since the signals can be only sent to specific process (**Figure 3**). This approach also helps to increase robustness during runtime. Scheduling operation continues even if single scheduler process on specific core terminates because of unexpected reasons. There is only one Local Advanced Programmable Interrupt Controller (LAPIC) timer available per CPU core. Each process uses LAPIC timer interrupt to control timing operations on the core that it belongs. LAPIC timer supports three different modes: Periodic, One-Shot and TSC-Deadline. In this implementation, TSC-Deadline mode is preferred since it uses CPU's time stamp counter instead of using the CPU's external/bus frequency, it gives higher precision compared to One-Shot mode because time stamp counter is controlled by CPU's nominal frequency.

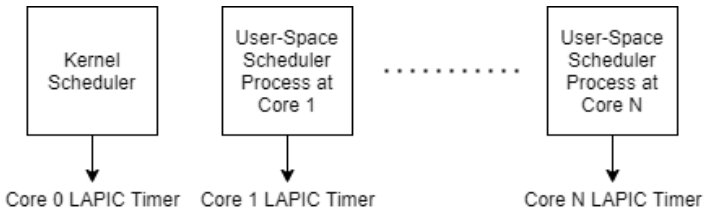

Figure 3. Existing Time Triggered Architecture

User-space scheduler processes should use high precision timer to achieve precise timing of periodic tasks. Only LAPIC timers are available to fulfil desired precise timing for user-space scheduler operation. Also, the kernel of operating system must use LAPIC timer to operate kernel related tasks. Considering all these requirements, LAPIC timer is decided to be used by both kernel and user-space scheduler as clock source. In this situation, it is not possible to run user-space scheduler on core 0 with LAPIC timer because it is already occupied by kernel scheduler as clock source. In

this case, core utilization loss is observed in the use of the system since one of the cores cannot be used for controlling periodic execution of runnable entities.

5. TIMER CONTROLLER ARCHITECTURE

Previous implementation is not eligible to run LAPIC timer under control of user-space scheduler process on core 0 means that operations cannot be performed on this core. To overcome this problem, timer controller feature is introduced. It is based on controlling specific LAPIC timer on desired core for operating more than one scheduler processes on different cores (**Figure 4)**. Timer controller module is designed to handle incoming timer requests from scheduler processes and reply interested core with non-blocking communication when the timer expires for this event.

Design criteria is mainly based on minimum impact on current implementation and provide backward compatibility. During initialization, timer controller core affinity is limited with specific core that is selected for running by thread affinity set function from POSIX thread library. LAPIC timer initialization is performed to operate with TSC-Deadline mode which offers precise timing with the usage of CPU frequency which is 2 GHz. Desired tick value for timer request is written into deadline compare register of LAPIC timer. When the timer expires, LAPIC timer generates a hardware interrupt, and it is attached to event notification mechanism provided by operating system. This event is sent to timer controller internal communication channel to detect timer expiration.

Timer controller initiates communication channels that will be used for communication between controlled scheduler process and timer controller. This channel is used for the synchronization and notification between timer controller and scheduler processes.

Proposed timer controller architecture requires collecting of ticks from controlled cores into timer controller process since it oversees all the timer operations. Ticks are 64-byte values, it needs to be transferred from controlled scheduler process to timer controller as soon as possible. Shared memory is the best solution for this problem, it offers low latency and highest bandwidth IPC available. During the initialization of timer controller process, it initiates the shared memory object, then truncates it with desired size. Processes with access to the shared memory object can read and write with using pointers without any control mechanism that can cause inconsistent results during the operations, it needs to be synchronized. Shared memory with notification event is preferred in proposed architecture to ensure synchronization with the usage of blocking communication feature provided by operating system. To establish synchronization, receiver waits in blocked state until the sender transmits the notification event. In our case, timer controller listens the channel in infinite loop, when the controlled core finishes its write operation into shared memory object, it notifies timer controller process which immediately sets LAPIC timer after reading tick value from shared memory object.

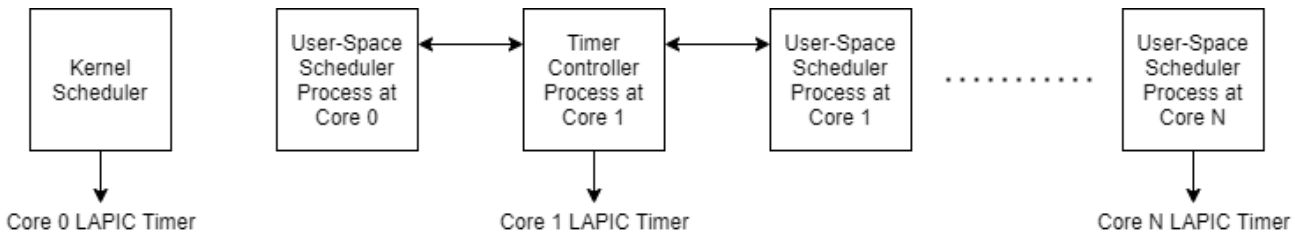

Figure 4. Proposed Timer Controller Architecture

When the LAPIC timer expires, interrupt creates a notification event and timer controller captures the notification, decides which controlled scheduler process should be notified by checking origin of current expired timer request and sends this event to related process with related mechanism provided by operating system.

On the scheduler process side, sync slot is placed at the beginning of each hyper-period in static schedule table for each scheduler process to apply synchronized time into scheduler operation by adjusting the reference start time of hyper-period. In this slot, it is also measured overall lag between theoretical hyper-period beginning and actual beginning time. It is important since first activation of the periodic task in each hyper-period should be scheduled right after the sync slot is completed at the earliest, first runnable activation can be also set to any desired time, but sync slot length decides about boundary of earliest activation of runnable. If worst-case sync slot length should not be selected properly, it may seriously affect the runnable activation time if it is planned to be scheduled right after the sync slot execution finish in schedule table. Sync slot latency and periodicity of runnable entities should be measured properly according to determine potential security impact after the implementation of timer controller architecture to handle limited resources.

6. MEASUREMENT RESULTS AND ENVIRONMENT DETAILS

Intel x86_64 architecture based SoC with 16 CPU cores, 2 GHz CPU frequency and POSIX compliant real-time operating system are selected as development environment. Sync slot latency and periodicity drift of runnable measurements are performed for 17 hours, it was observed that taking the measurements more than this time do not give any further insights. Hyper period is defined as 300 ms on each core. Static schedule table consists of 13 cores only whereas SoC supports 16 cores. First measurement was taken without timer controller, so core 0 is not allocated for any scheduler process. In second experiment, core 13 schedule process and core affinities in static schedule table were shifted to core 0 and timer controller is activated on core 1 to control core 0 and core 1 scheduler processes. It is aimed to observe performance and reliability impact under timer controller usage, so the overall schedule table load is kept as the same, only migration from core 13 to core 0 is performed. All the measurements are performed under full load, runnable entities are stubbed to perform time consuming operation as considering worst-case execution times. Runnable periodicity measurements are based on taking the global time at the beginning of the runnable activation. Runnable periodicity drift calculation is performed by subtracting consecutive activation times.

6.1. Sync Slot Latency Measurements

Table 1. Sync Slot Latency without Timer Controller

Without Timer Controller	Core 1	Core 2	Core 3	Core 4	Core 5	Core 6	Core 7	Core 8	Core 9	Core 10	Core 11	Core 12	Core 13
Maximum (us)	**142**	148	168	169	143	142	146	144	137	137	148	145	**139**
Average (us)	92	96	98	91	88	96	92	99	98	95	99	92	90

Table 2. Sync Slot Latency with Timer Controller

Without Timer Controller	Core 0 (formerly 13)	Core 1	Core 2	Core 3	Core 4	Core 5	Core 6	Core 7	Core 8	Core 9	Core 10	Core 11	Core 12
Maximum (us)	**170**	**228**	141	169	173	144	143	145	145	137	137	149	146
Average (us)	124	172	97	99	90	88	96	93	100	99	96	99	93

6.2. Periodicity Drift Measurements

Table 3. Periodicity Drift without Timer Controller

Runnable	Period Defined in Static Schedule Table (us)	Core	Maximum Difference between Consecutive Activation (us)	Minimum Difference between Consecutive Activation (us)
Runnable_Entity_0	100000	1	100052	99943
Runnable_Entity_1	100000	13	100036	99972

Table 4. Periodicity Drift with Timer Controller

Runnable	Period Defined in Static Schedule Table (us)	Core	Maximum Difference between Consecutive Activation (us)	Minimum Difference between Consecutive Activation (us)
Runnable_Entity_0	100000	1	100179	99824
Runnable_Entity_1	100000	0	100169	99826

		(formerly 13)		

7. CONCLUSION

It is observed that timer controller implementation can increase maximum sync slot latency for significant amount of time on controlled cores, especially in the core that timer controller is operating. Both scheduler and timer controller have the highest priority in the system which causes these two entities to share system resources at the same core. The results of our tests show that timer controller core affinity should be selected properly by considering CPU core that have minimum core utilization in static schedule table. Sync slot latency can be decreased if core affinity selection recommendation is applied. According to test results, sync slot latency increases at core 1 from 142 ns (**Table 1**) to 228 ns (**Table 2**) which can introduce 86 us overhead in each hyper period (300 ms) which causes 0.0286% CPU core utilization loss on each core since sync slot maximum latency should be defined as the same value on each core. Activation time of first periodic runnable in schedule table entity should be selected neatly to prevent activation time drift. Timer controller implementation can significantly affect the periodicity drift of runnable entities on controlled cores. For Runnable_Entity_0 and Runnable_Entity_1, timer controller implementation affects the periodicity drift more than 100 us (**Table 3, 4**) for maximum difference between consecutive activations. System integrator should properly select maximum periodicity drift as requirement before implementing this solution. If runnable entities are required to fit hard real time restrictions, integrator should consider potential side effects like sync slot latency and periodicity drift increase, otherwise timer controller implementation can harm the reliability of the system.

8. CURRENT LIMITATIONS AND FUTURE WORKS

Architecture is based on collecting timer requests from controlled scheduler processes and control them on a single timer controller process. Shared memory is selected as inter-process communication method to get best performance, however it still takes some amount of time. Each controlled process has its own static schedule table for time-triggered events, it would be better to merge all the separate tables into a big table in timer controller itself, inter-process communication overhead can be eliminated in this way. Even if table merge happens, simultaneous timer requests on controlled cores should not be allowed during the static schedule table generation, because non-blocking notification mechanism between timer controller and scheduler process still takes a while and it cannot be eliminated. In our case runnable activation time in schedule tables are already separated, meaning that no simultaneous events exist but minimum gap between consecutive requests should be selected properly to prevent possible time drift for periodic runnable activation because of the delayed notification.

ABSTRACT

Weather seals provide dust, noise, water, and heat isolation of the vehicle. There are two kinds of sealing; dynamic and static seals which are EPDM or Thermoplastic elastomer (TPE) based. Dynamic profiles are used on the moving mechanism of the vehicle and EPDM rubber is the main raw material, with its elastic and sealing performance. TPE materials are generally preferred for static seals which are inner or outer-waist belts. These two materials have been used as a hybrid in corner moldings of glass run channel which can be classified as a semi-dynamic seal and they are bonded with injection molding process. To obtain efficient bonding performance, there are two critical parameters to analyze: material compatibility & process conditions.

The study aims to investigate the injection process parameters that affect the bonding of TPE materials to EPDM in order to eliminate split and delamination in the bonding area. For this purpose, injection speed, holding pressure, gate-joint distance, mold temperature, injection temperature, holding time parameters were investigated. The effect of these factors on the bonding performance was determined by using a fractional factorial experimental design on Minitab statistical program. In conclusion, it is found that the holding time does not have a significant effect on bonding, nevertheless, injection temperature, mold temperature, and injection speed have positive effects and holding pressure has negative effects. Gate to joint distance results were not reliable in this study. In addition, the best and worst injection process parameters were obtained.

Keywords: injection molding, weather-strip seal, hybrid application, bonding performance, design of experiment

1. INTRODUCTION

Automotive weather-strip seals are mainly produced by using EPDM (ethylene propylene diene monomer) with its excellent elasticity & sealing performance and ozone resistance. However, with increasing concern about the environment, thermoplastic elastomers have gained importance over thermoset rubbers, and the usage of thermoplastic elastomers (TPE) in sealing strips is increasing day by day thanks to its properties such as easy processability, low cost, and recyclability. Nevertheless, it is not possible to complete conversion to EPDM materials due to its compression set performance, which is critical for sealing performance, is still better than the TPE materials. [5] That's why thermoplastic elastomers are mostly used in static seals which are inner & outer-waist belts and end welding operations as well as the hybrid applications such as corner molding area of glass run channels shown in Figure 1.

Figure 1. Corner molding - example of EPDM TPE hybrid application in sealing system

The efficient bonding performance of two different materials used in hybrid applications is essential for product quality. This is an actual and important topic in the sector with sustainability demands. In order to ensure successful

manufacturing and eliminate the split and delamination problems in the future, a corresponding working group is also founded by WDK (German Rubber Manufacturers Association) that consists of members from the process chain. [2]
Material combination, design and extrusion process of the EPDM compound affecting the bonding quality are considered as constant and out of scope of this study. Only the injection molding process parameters are evaluated by using WDK 2701 mold created for EPDM-TPE bonding performance tests, shown in Figure 2.

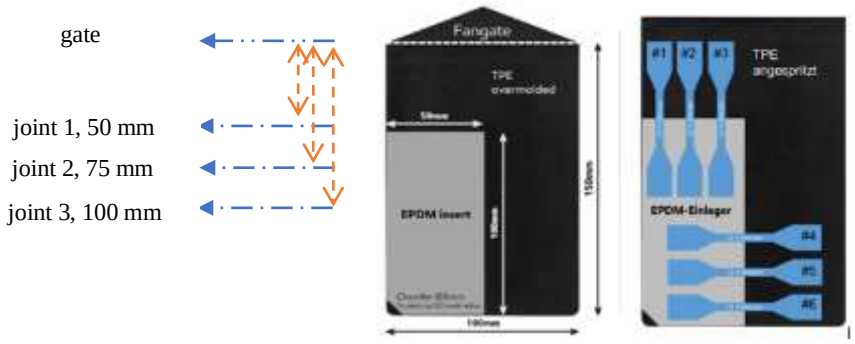

Figure 2. WDK 2701 Mold Design [1]

The physical bonding is obtained during the injection molding process with the penetration of the melted TPE into the microstructure of the cold EPDM surface and co-crystallization at the interface shown in Figure 3. [2] To achieve high bonding performance, it is important to adjust the optimum injection process parameters affect the bonding. Before the application, the EPDM substrate surface quality should be checked in order to ensure that there is no contamination at the interface coming from the cutting operation or compound ingredients. [2] Therefore, the EPDM compound is required to be fresh-cut and cleaned with IPA.

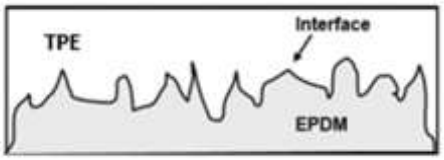

Figure 3. EPDM – TPE interface

In DoE method, screening to identify important factors on the response, various factors that affect the bonding performance are investigated with a statistical approach and the effects of main and interactions are determined. Then, process variables are first screened to determine the best and the worst settings. For this purpose, the following inputs on the bonding performance were studied by using the fractional factorial experimental design on Minitab 17;

A. injection speed – cm3/sec
B. holding pressure – bar
C. gate-joint distance* – mm
D. mold temperature – °C
E. injection temperature – °C
F. holding time – s

*(EPDM sample is cut to adjust the distance, shown in Figure 2)

Cooling time is kept at constant and is adjusted as 40 sec. Tensile strength and elongation at break were selected as response variables. Tensile strength was evaluated in the first order which is directly linked with the bonding performance. Injection pressure and injection time were also recorded as covariates during the experiments.
65 ShrA EPDM compound and 65 ShrA styrene based TPE materials were selected for the study.

TPE-s materials, the styrenic block copolymers are seldom used as pure. Like conventional thermosetting (vulcanizable) elastomers, they can be formulated to meet required processing behavior, and mechanical and physical properties. They can be blended and with other polymers, including conventional elastomers, and compounded with fillers, plasticizers (e.g., oils), processing aids, resins, colorants, and other compounding ingredients and modified according to customer expectations. [1]

In the literature, numerous researches are carried out to identify and understand critical factors and optimum process parameters. Pareek and Bhamniya determined the effect of temperature, pressure, and cooling time on tensile strength of polycarbonate plastic material. It is found that the best combination of process parameters in terms of the tensile strength is 260 °C melting temperature which has the most significant effect (%65.55), 150 bar injection temperature and followed by 7.5 seconds cooling time. [6]
Hexpol TPE company suggests the optimum process parameters for TPE-s materials injection molding as 190 °C-245°C, 260°C for large parts injection temperature, 35-150 MPa injection pressure, high injection speed, 25-75 rpm injection speed, and short holding time and pressure. [3]

2. EXPERIMENTAL PROCEDURE

Process trials are performed in LWB Steinl Injection Molding Machinery, which has 38 tonnes clamping force, given in Figure 3.

Figure 4. A: Injection Molding Machine B: WDK 2701 Mold- Right & Left with same design

The experimental steps carried out in this study are listed as follows;

- Design of Experiments (DoE) plan is created with selected parameters.
- Injection molding process parameters are set according to design of experiment runs.
- Test sample plates in Figure 4 are prepared in which the TPE is injected onto EPDM insert in WDK 2701 mold in Figure 3B and 2 samples are taken from the left & right side of the mold in each run.
- Mechanical tests such as tensile strength and elongation at break are performed on these plates and evaluated.
- EPDM inserts are fresh cut and their surfaces are cleaned with IPA before each run.

Figure 5. Images of EPDM-TPE plates (5 of 35 samples)

Fractional factorial DoE plan is created using Minitab statistical program with the determined low and high values for each factor given in Table 1. Centre points are added to the design by the program and study is performed with 5 factors, 35 runs, 1 blocks and 3 center points.

Table 1. DoE plan - Factors and levels

Factor	Name	Low level	Mean level	High level
A	injection speed – cm3/sec	25	62,5	100
B	holding pressure – bar	100	200	300
C	gate-joint distance – mm	50	75	100
D	mold temperature – °C	40	50	60
E	injection temperature – °C	200	230	260
F	holding time – s	2	3,5	5

Higher bonding energy is related to higher tensile strength. [4] Therefore the process parameters given maximum tensile strength values are defined as the best parameters and the minimum values are taken as worst parameters. The elongation at break results are also evaluated which reduce the risk of breakage when handling the weather-seal after molding. [4] The outputs of the study are considered as the first screened analysis for the further process parameter evaluation and optimization.

3. MEASUREMENTS AND EQUIPMENT USED

Mechanical tests are performed for EPDM and TPE bonding performance evaluation. Tensile strength and elongation at break results are measured with Zwick/Roell Dynamometer referring to ISO 37-Type S2 in flow direction 200 mm/min test speed. Results are analyzed with using Minitab 17.

4. RESULTS AND DISCUSSION

Tensile strength and elongation at break tests are performed and evaluated. Three samples in flow direction are obtained from each set parameters and analyzed with Minitab.

The findings are listed as follows;

- There is not significant difference between the right and left mold results according to T-tests (P-Value is calculated as 0,219, higher than 0.05). Therefore, factors effect analysis is done on the right mold tensile strength results which R2 is 87,60%, in a confident level.

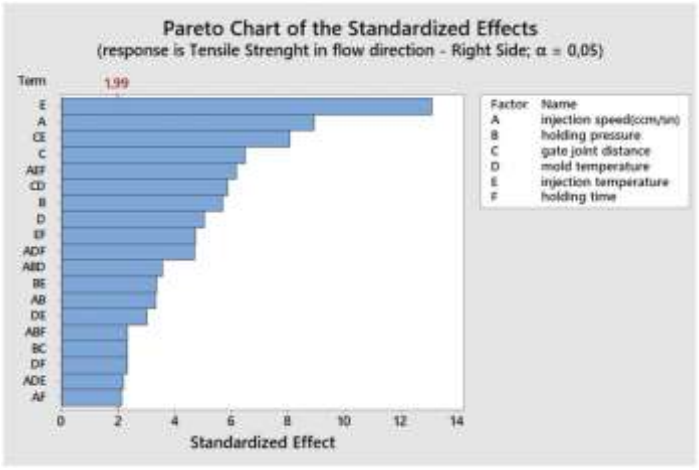

Figure 6. Pareto Chart of Flow Direction Tensile Strength - Right Mold

As it is seen in the Figure 6, injection temperature and injection speed have the highest impact on bonding performance. Except for holding time, each parameter affects the bonding quality by itself. There are also double and triple interactions between the parameters that affect the bonding quality. Please check Figure 6 to see all interactions.

As a result of DoE study, it was obtained that the injection speed, injection temperature, and mold temperature have positive effects on bonding quality (single effect coefficients; 0,7829, 1,1455 and 0,4400 respectively) whereas the distance between the EPDM (joint) – gate, and holding pressure have negative effects (-0,5684, -0,4969). Holding time has no significant effect on bonding performance (-0,0498) Contour plot in Figure 7 also shows that the bonding performance increases with increased injection speed and injection temperature.

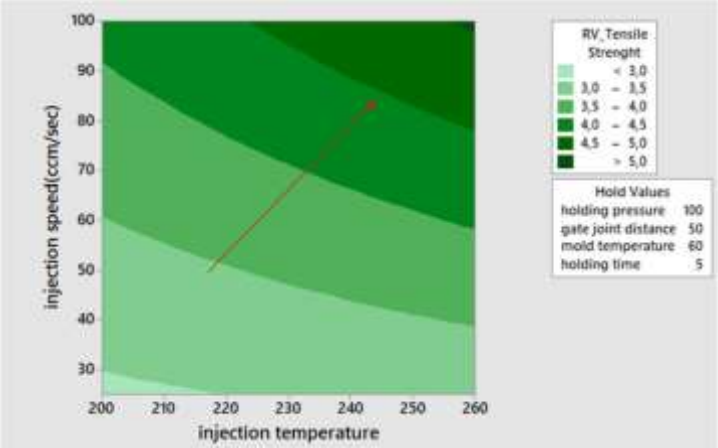

Figure 7. Contour plot of injection speed vs injection temperature

As a result of DoE study, it was obtained process conditions for the best and the worst bonding performances, determined by using DOE response optimizer tool, shown in Figure 8 and Figure 9.

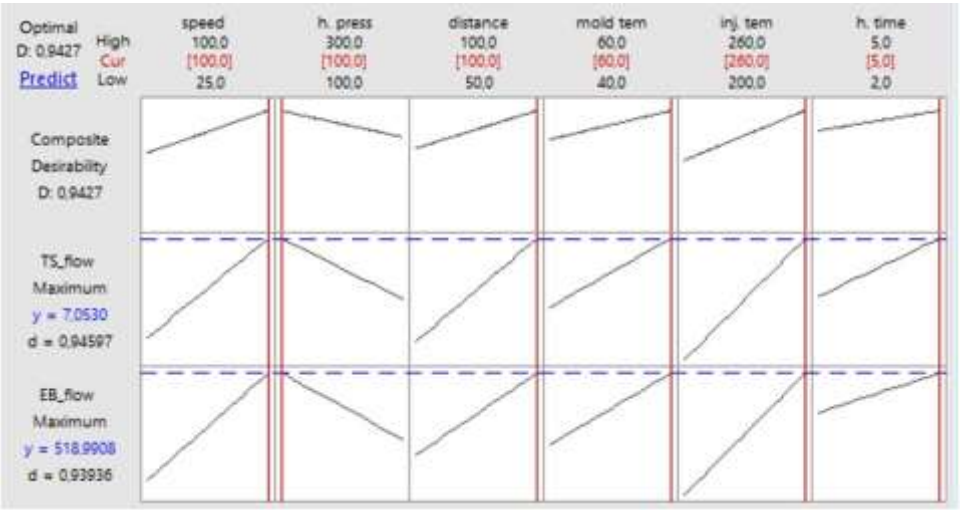

Figure 8. Best process conditions

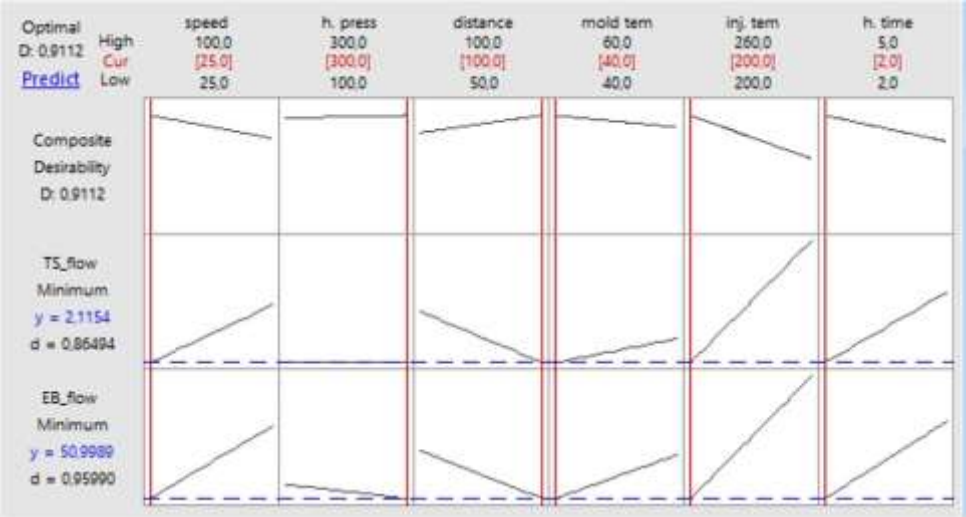

Figure 9. Worst process conditions

5. CONCLUSIONS AND RECOMMENDATIONS

In this study, the effects of injection molding process conditions on the bonding performance by using design of experiment method were investigated. As a result of DoE studies, best process values for bonding application was obtained as follows;

A. Injection speed : 100 cm^3/sec
B. holding pressure : 100 bar
C. gate-joint distance : not reliable result obtained*
D. mold temperature. : 60 °C
E. injection temperature : 260 °C
F. holding time : 5 sec. - no significant effect

* it is obtained that the minimum distance provides the better bonding performance. However, it is not seen in the optimization part of the DOE study.

Above the optimum conditions are determined shows that, the bonding performance is enhanced dramatically with the process parameters. When the thermoplastic elastomer is injected with high temperature, high speed, and low holding pressure to the system, bonding performance is achieved in a high level. High holding pressure causes the material orientation in the mold and deteriorates the bonding quality.

As a further study, gate-joint distance will be kept as constant to be sure the findings and decrease the variations. A new DOE plan will be created by adding cooling time instead of holding time and optimum process parameters will be obtained for different kind of TPE materials.

ABSTRACT

Lightweight designs are frequently used in the automotive industry, depending on environmental impacts. Design and NVH engineers constantly search for new, as traditionally produced insulators reach their natural limits on efficiency increase. To closely follow the developments in insulation materials and to contribute, design changes and measurements are made accordingly. With insulators reinforced with new designs, it is possible to intervene locally against vibroacoustic sources. There are some limitations in these studies, as seen in the literature. The suitability of the insulator to be produced with serial production is one of the critical points. In addition, the resonance frequency that will occur depending on the shape, fixation points, and weight of the insulator formed determines the frequency band in which the insulator will be efficient. If an increase in the efficiency of the isolator is expected in specific frequency ranges, generalizing this study will give a positive result. This study is research on the acoustic effects of metamaterial applications in the automotive industry. NVH engineers decide on material selection by comparing the efficiency of prototype parts created using impedance tubes or reverberation cabin at the material level using the materials in the current state. In this study, the comparison of square pyramid-shaped insulation components with improved sound absorption area compared to traditional solutions in vehicles has been provided. The efficiency of the new generation insulators is presented by measuring the sound absorption coefficient and sound transmission loss values in the measurements made in the reverberation cabin. It is found that better sound absorption coefficients are obtained in the high-frequency range beyond 1250 Hz. Besides, up to 7 dB improvement has been obtained in the sound transmission loss in the range of 2000 - 6300 Hz.

Keywords: Metamaterial; Reverberation Cabin, Anechoic Chamber, Sound Absorption Coefficient, Sound Transmission Loss

1. INTRODUCTION

NVH and design engineers in the automotive industry constantly progress their development activities to provide acoustic comfort on the vehicle. When an acoustic package is to be developed with conventional solutions (Lucas et al, 2021), methods such as increasing the thickness or weight of the insulation material are generally used (Doğru & Pulat, 2020). Performance increase of conventional insulators realized in different configurations such as elastic layer and air gap layer has been examined in the literature (Meriç et al, 2016). However, the improvements made in this way do not comply with the lightweight design logic. For this reason, lightweight designs are directed to increase acoustic efficiency by reducing the weight of the insulators (Kyoung et al, 2019). If newly developed applications are examined, it is known that metamaterials with increased acoustic efficiency with resonance are effective (Claeys et al, 2013). Especially in electric vehicle applications, directly increasing the weight of the material will create a big difference in terms of cost since acoustic effects occur in a different frequency range compared to internal combustion vehicles (Goetchius, 2013). For this reason, an innovative isolator design different from conventional development methods should be investigated. Metamaterial applications are being developed to replace conventional insulation materials (Krushynska et al, 2014). Since these materials show the local effect, they also show the same effect of sound transmission loss in NVH performance efficiency used (Ma & Sheng, 2016). In a study performed with the impedance tube, local improvements in sound transmission loss have been determined using elastic metamaterial as a single layer (Liu et al, 2000). In the automotive industry, acoustic research studies have been performed on the use of metamaterials in the floor carpet section of vehicles (Wu et al, 2019), on ceiling coverings (Zhang et al, 2019), on the dash panel (Chang et al, 2018). Important computational processes are carried out in the development of these parts on the vehicle (Erol et al, 2016). In these studies, it has been observed that metamaterials work similar to the mass-spring system, reducing vibrations and local improvements in sound transmission loss (Sangiuliano et al, 2019).

In this study, a material has been designed to create resonance effects. The efficiency of this structure was tested in associated chambers, composed of two reverberation chambers with a common wall on which the sample part is placed together with the dash panel. Within the scope of the study, sound absorption coefficient and sound transmission loss values were obtained. Approaches such as weight gain or material addition were followed in updating the insulation package with conventional methods. Different conventional material compositions were created to simulate this. In addition to the newly developed design, measurements of conventional materials were also carried out in parallel. Thus, a preliminary study on the necessity of material applications is provided. When metamaterials are applied to the vehicle, a critical prototyping stage should be carried out. This study aims to determine the efficient structure using flat samples before proceeding with the measurements on the vehicle. It will be informative for use on the vehicle dash panel.

2. REVERBERATION CABIN RESULTS

2.1. Sound Absorption Coefficient and Sound Transmission Loss

The reverberation cabin is a device frequently used in the automotive industry to measure the efficiency of sound reducing materials (Duval et al, 2010). An artificial diffuse-field sound is created in the reverberation cabin for sound absorption coefficient measurement. Measurements are made consecutively for the case with and without samples in the cabin. Then, the time required for the attenuation of this sound is calculated by the Sabine Eq. (1) and converted into an absorption coefficient (URL1: 2021). The configuration setup for the measurement of the sound absorption coefficient is shown in Fig. 1a.

$$T_{60} = 0{,}049\ \frac{\cdot}{\cdot\cdot} \tag{1}$$

Where, T_{60} is the time in seconds required for 60 dB damping of a sound generated from the sound source, V is the volume of the room where it is measured, S is the area of the boundary surfaces, and $\bar{\alpha}$ is the average sound absorption coefficient.

Sound transmission loss is expressed by Eq. (2). While measurements are carried out with reverberation-source rooms, the equation takes the form of Eq. (3) because the incoming sound power is measured by a microphone moving over the average sound level of the source room. The transmitted power of the anechoic receiving room is calculated with Eq. (4) to emerge from the surfaces (Piollet et al, 2016). The configuration setup of the sound absorption coefficient is shown in Fig. 1b.

$$TL = 10\ log_{10}\left(\frac{\cdot\cdot 1}{\cdot\cdot\cdot}\right) \tag{2}$$

$$W_i = S_s I_i = S_s\left(\frac{\cdot\cdot\ \cdot}{\cdot}\right) \tag{3}$$

$$W_t = S_m \overline{I_n} \tag{4}$$

Where W_t is the transmitted sound power, W_i is the incident sound power, S_s is the surface area of the sample, I_i is the sound intensity of the source cabin, $\langle \overline{p^2} \rangle$ is the pressure in the reverberation cabin, ρ_0 is the air density and c the speed of sound in the air, S_m is the measurement surface area and $\overline{I_n}$ is the measured normal intensity (Piollet et al, 2016).

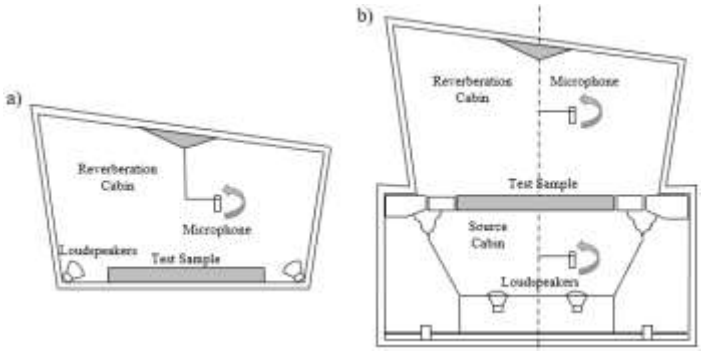

Figure 1. Reverberation cabin configuration a) sound absorption coefficient b) sound transmission loss (Aydın, 2008)

2.2. Materials Used in Study

In this study, a square pyramid-shaped test sample was produced to provide input parameters for a new isolator design. The dimensions of the sample produced according to the reverberation cabin sample sizes are 1x1.2m. On the back of the new design, a polyester fibrous fabric layer is used. In turn, reference configurations frequently used in the automotive industry were preferred in layers and turned into samples. These configurations were added to the study, and the efficiency of the solution to be evaluated in the newly proposed metamaterial class was evaluated compared to other solutions.

. **Table 1.** Sample table

Sample No	Layer Configuration
S 1	Proposed Square Pyramid Solution + Polyester Fabric
S 2	Polyurethane 50 kg/m^3
S 3	Polyurethane 50 kg/m^3 + EPDM 3000 g/m^2
S 4	Polyurethane 50 kg/m^3 + EPDM 5000 g/m^2
S 5	Polyurethane 50 kg/m^3 + Foil 30 g/m^2 + Felt 1500 g/m^2
S 6	Polyurethane 50 kg/m^3 + Thin Fabric 100 g/m^2 + Felt 1500 g/m^2

In the proposed solution, a polyurethane injection mold was created to form a square pyramid. The first layer was obtained by forming a 50 kg/m^3 polyurethane material in this mold. Then, a single-layer polyester fiber-based fabric was added to this layer with double-sided tape application.

Figure 2. Proposed square pyramid type metamaterial solution

2.3. Results

The sound absorption coefficient measurements made in the reverberation cabin are shown in Fig. 3. If the measurement results are examined in detail, it is seen that the proposed square pyramid solution has a superior performance in terms of sound absorption coefficient at frequencies of 1250 Hz and above. S3 and S4 solutions made of polyurethane and EPDM layers have higher sound absorption coefficients between 630 and 1250 Hz. Felt solutions, S5 and S6, presented effective results in the low-frequency range up to 630 Hz. Application of a single layer of polyurethane, S2, has the worst results in the mid-high frequency range starting from 630 Hz

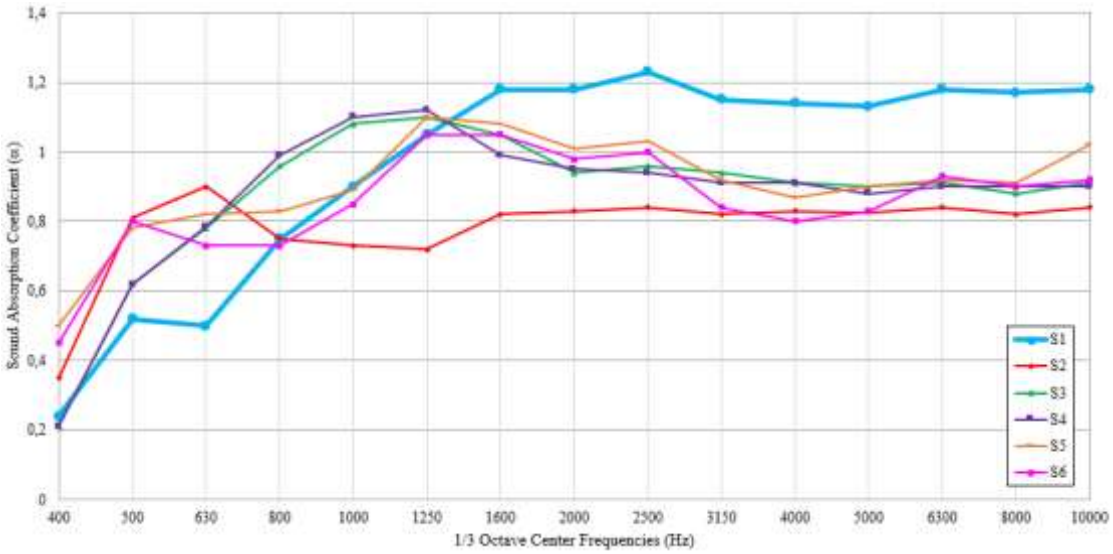

Figure 3. Sound absorption coefficient results with reverberation cabin

The reason for getting negative results on a single polyurethane layer is the lack of the mass layer in the solution. Instead, a mass-spring mechanism should be created to provide better insulation. In the proposed square pyramid shaped S1 solution, the pyramids have a mass effect due to their shape and provide a high sound absorption coefficient.

Fig. 4 shows the sound transmission loss values of the solutions measured within the associated chambers. Since the S1 solution does not show a mass-spring effect in a single layer, it has been the solution with the lowest sound transmission loss. S3 and S4 curves present high sound transmission loss with the help of the mass effect of a heavy layer in EPDM. However, if the figure is examined in detail, the metamaterial solution proposed in this study has the highest sound transmission loss in the 2000-6300 Hz range. In this way, this solution can be preferred when it is necessary to provide a solution within this frequency band.

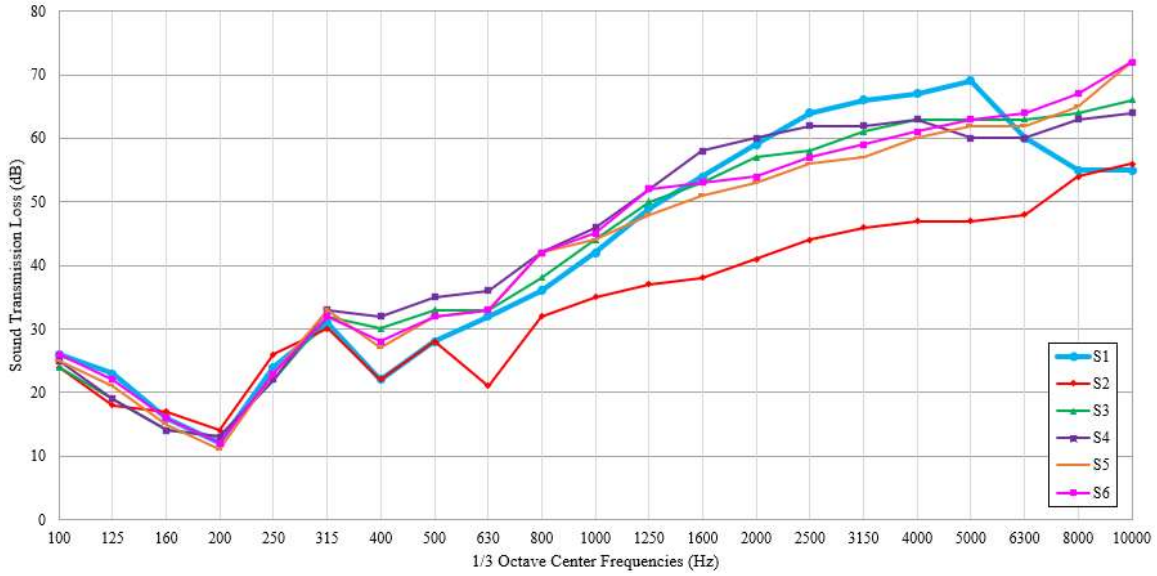

Figure 4. Sound transmission loss results with reverberation cabin

It has been observed that the square pyramid solution providing the mass-spring system provides local improvement. Due to the resonance effect, a high level of sound transmission loss has been achieved in a certain frequency range. The isolator material designed in this study provides damping by activating in the indicated frequency band range due to the resonance. For metamaterial application to perform damping in the desired frequency band, it is necessary to tune the resonance frequencies accordingly [8].

2.3. Potential Usage Areas

Potential areas where the developed insulator can be applied to the vehicle are shown in Fig. 5a. The desired frequency range for the application can be determined by the help of acoustic tests for specific issues like engine noise or road noise. An application is proposed as a remedy to engine noise issues by improving isolation performance. The solution is foreseen as a local patch on the firewall panel, leading to no increase in the total weight of the related parts. Patch of insulation material may provide a local improvement in the frequency band. However, the transfer path of the higher noise should be determined, and acoustic analysis should be performed with prototype applications.

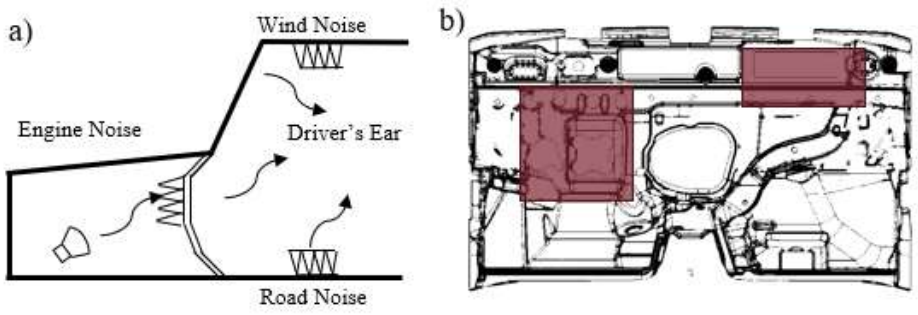

Figure 5. Potential areas b) on vehicle b) on firewall steel

In this section, the acoustic advantages of the proposed application are mentioned. The solution should still be investigated technically for packaging requirements and mass production. In addition, attention should be paid to the cost analysis of the solution since it differs much from conventional designs. A detailed study should be carried out for situations that require application on the vehicle due to these aspects open to development.

3. CONCLUSIONS

This study includes research for the use of a new metamaterial. Metamaterials, as can be seen from the literature, are developing fields of work in the automotive industry. In this study, an application example was carried out with a square-type pyramid.

The solution was tested within the reverberation chamber for sound absorption coefficients and associated chambers for sound transmission loss characteristics. It is observed that better sound absorption coefficients are obtained in the high-frequency range beyond 1250 Hz. Besides, up to 7 dB improvement has been obtained in the sound transmission loss in the range of 2000 - 6300 Hz.

There are disturbing sound sources in vehicles that can be active in specific frequency ranges. In this way, it has been proven that effective damping can be achieved using metamaterials to dampen a sound source. Instead of changing the weight across the part, a significant change can be achieved with a small patch.
This study provided detailed research prior to application on the vehicle. Detailed design for proper metamaterial application is to be made by the NVH findings on the vehicle in development. In such an application, the resonance frequencies of the design to be produced should be determined. However, design space requirements, mass production process, investments, and total cost of the application need to be considered.

ACKNOWLEDGEMENTS

We would like to thank DTA engineering for sound transmission loss measurements. We also would like to thank A-PLAS company for the procurement of metamaterial component samples.

KANO MODEL IN THE R&D DEPARTMENT OF THE AUTOMOTIVE SECTOR

Elif Burcu Çetin, Özgür Mesut

Tofaş Türk Otomobil Fabrikası A.Ş., R&D, Bursa, Türkiye
Elif.burcuyalcinkaya@tofas.com.tr, Ozgur.mesut@tofas.com.tr

ABSTRACT

Nowadays, customer expectations have started to shape the automotive sector. To respond to rapidly changing customer expectations in this sector; is a must for being competitive in the sector.

These expectations should be spread not only to salespeople but also to all employees who affect vehicle design. Considering this situation, we tried to understand customer expectations by using the KANO method with our R&D colleagues. With this method, we can understand which features are exciting or unnecessary in the vehicle that the customer will buy.

In this study, it is aimed to develop the optimum solution alternatives for the customer by using "customer-oriented design" approach. Teams were formed for the areas to be focused on, and interviews were made with real customers. In these studies, interviewed with 200 people and 13 different areas and customer expectations were evaluated.

As a result of this study, based on the pain points of the customer, feedback was collected on which features should be added or which unwanted features should be removed to a vehicle to be designed or development

Keywords: Kano Method, R&D, Customer Expectations, Automotive, Customer-oriented design

1. INTRODUCTION

It is estimated there are about 1.4 billion drivers in the world, but the number may be higher and closer to 2 billion. And also the Turkish Statistical Institute announced the "Motor Vehicles Statistics" for December 2019. Accordingly, as of the end of last year, the total number of vehicles in Turkey registered to traffic reached 23 million [1]. In a world where there are so many vehicles and drivers, customer expectations also different and in this situation, car manufacturers ought to respond to these expectations to become competitive.

In the automotive industry, many departments have been established to understand customer expectations and to respond to these requests. The main task of these departments is to understand and analyze customer expectations. They use different methods to understand and analyze these expectations. After understanding these expectations, studies are carried out to determine the features that should be in the vehicle by meeting with the relevant departments. But these expectations are changing very rapidly and all requirement and exiting features shows difference according to different for people using different models of vehicles. Since these expectations take a long time to be transferred to the designer team, customer expectations are faced with the past and not the actual situation.

As TOFAŞ R&D, we realized the project of Kano Model in the R&D Department of the Automotive Sector to quickly interpret customer expectations and directly meet the customer and the designer. It is planned to collect customer expectations directly by the designers by conducting face-to-face interviews with the vehicle owners in the model determined with this study. With the Kano model studies, we wanted to shape our designs by trying to learn the effect that features on the vehicle will have on the customer.

The Kano model is briefly explained as;

Noriaki Kano, a Japanese researcher and consultant published a paper in 1984 with a set of ideas and techniques that help us determine our customers satisfaction with product features. These ideas are commonly called the Kano Model and are based upon the following premises:[2]

Customer's Satisfaction with our product's features depends on the level of Functionality that is provided (how much or how well they're implemented);

You can determine how customers feel about a feature through a questionnaire

Features can be classified into five categories; These categories are determined according to the questionnaire answers. (Figure: 1)

The Kano model of customer satisfaction is a useful tool to classify and prioritize customer needs based on how they affect customer satisfaction (Kano et al., 1984). It captures the nonlinear relationship between product performance and customer satisfaction. In practice, four types of product attributes are identified: (1) must-be attributes are expected by the customers and they lead to extreme customer dissatisfaction if they are absent or poorly satisfied, (2) one-dimensional attributes are those for which better fulfillment leads to linear increment of customer satisfaction, (3) attractive attributes are usually unexpected by the customers and can result in great satisfaction if they are available, and (4) indifferent attributes are those that the customer is not interested in the level of their performance (5) The reverse features are the situation where the customer does not want these features but in the product given by the company. [3,4]

Functional		Dysfunctional		Category
I expect it	+	I dislike it	→	Must-be
I like it	+	I dislike it	→	One-dimensional
I like it	+	I am neutral	→	Attractive
I am neutral	+	I am neutral	→	Indifferent
I dislike it	+	I expect it	→	Reverse

Figure 1: Kano Evaluation

2. MAIN SECTIONS

The Study's aim is to understand the needs of the customers and to determine effects on the customer and decide which functions ought to be added/developed/optimized. By these studies, for the first time, R&D designers have met with customers to get their expectations on the final product. Normally, this expectation is gotten by The Customer Experience and Product Planning Department and they are shared with the R&D Designer. First-time Designers faced and saw customer's problems and pain points in the first place by interviewing with the real customers.

Customer feedbacks has taken 13 different areas by designer, these are; parcel shelf, central console, front door panel, PLS door panel, roof shelf, button group, color & material, PLS door handle, trunk area, dashboard, tailgate, air vent & buttons.

Before starting customer interviews, benchmark studies have been done to understand competitor vehicle situations. Working principles, positive/negative aspects, and whether competing products can provide customer needs were questioned. At this stage, existing competing products were examined both as physics and previous studies were examined. it was seen that there were no components that fully meet the customer needs. The information obtained as a result benchmarking study has guided designers in the customer interview period.

Figure 2: Benchmark Results

According to customer expectation and benchmark study results, the questions were prepared for each determined, area and then vehicle services were visited for real vehicle drivers. Prepared questions asked them to get their expectations on these components. After the customer interviews, the main problems were determined for each component. For example, the main problems of roof shelf are;

- Falling the objects during acceleration
- Sliding the objects during driving
- Missing sunglasses box
- No easy access to roof shelf
- Noise problem on storage objects
- Color tones
- Less volume
- Visibility problem of the object

After determining customer main problems, designers have made Kano analysis by using customer insights and pain points.

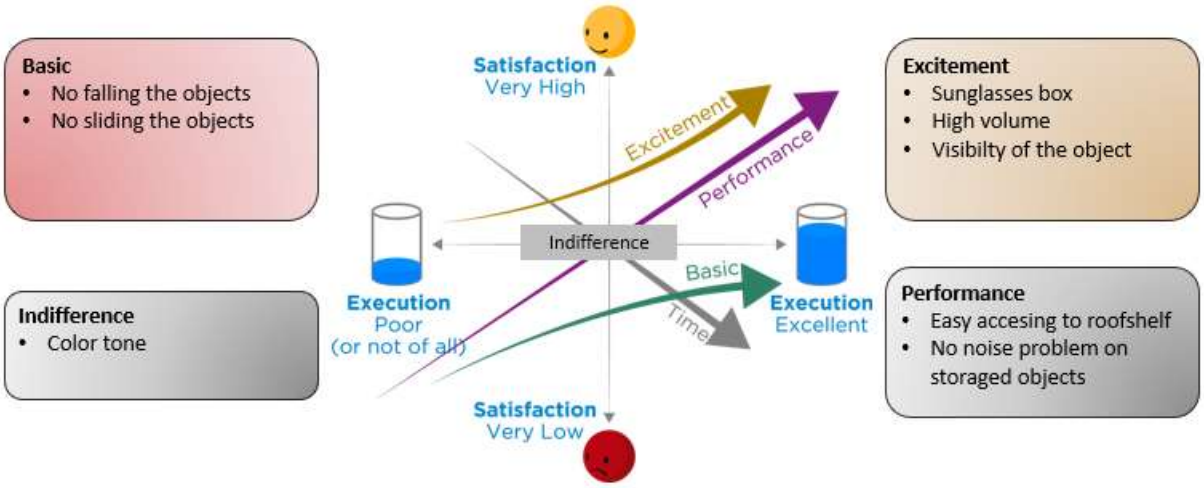

Figure 3: Kano results

The aim is to develop the optimum design which matches with customer needs especially the subjects above. While designers were developing the optimum design, they considered manufacturability and quality parameters, because of that, they did not answer all customer expectations. for this reason, they created different alternatives and showed their mock-ups to customers.

The aim was to find out how much of the customer's expectations were met, and if there were any points to be improved, it was determined. As a result of all this studies, one design was determined as optimum design at all points.

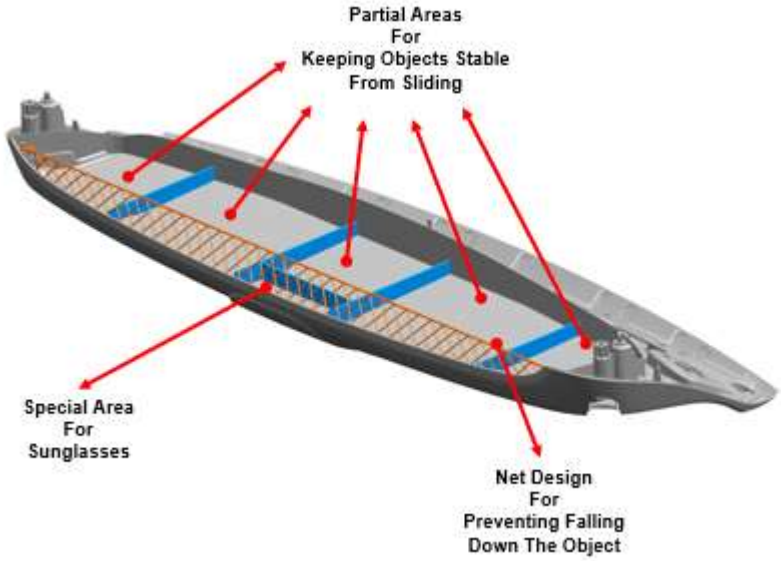

Figure 4: Final roof shelf design

The defined design was not met all customer expectations that defined customer-oriented design studies. However, the most optimum design was in terms of cost, producibility, and quality parameters. And more user friendly than serial production roof shelf.

3. CONCLUSION

In this study, the problems of commercial vehicle users regarding 13 different components in the vehicle were determined by the Kano Method and new customer-friendly designs were introduced. Mock-ups of new designs have been prepared and tested by users.

The optimum designs revealed at the end of the study do not meet all the expectations of the customer. Because of optimum designs; it was created by considering the whole of cost, producibility, and quality parameters. However, all new designs are more user-friendly than designs that find on serial production vehicles. With these new designs, customer satisfaction will increase.

OTOMOTİV INFOTAINMENT TESTLERİNDE GÖRÜNTÜ İŞLEME TEKNİKLERİNİN KULLANIMI

Muhammed Doruk Çapraz, Seyhan Mutlu, Ayberk Tekin, Anıl Onur Canbaz
[1]TOFAŞ Türk Otomobil Fabrikası A.Ş., Ar-Ge, Bursa, Türkiye

Özet

2000'li yılların ilk çeyreğini geçerken otomotivde bilgi-eğlence sistemleri yerini pekiştirdi. Gösterge panelleri dijitalleşirken, klima ayarları, geri görüş sistemleri, telefon bilgileri ve dikiz aynaları da bu ekranlarda kendilerine yer buluyor. Kullanıcının birebir temas halinde olduğu bu sistemlerin üzerinde görsel hataların olması durumunda ise müşteri memnuniyeti oldukça etkilenmektedir. Bu tip hataların müşteriye ulaşmadan çözülmesi adına test sistemleri de yıllar içinde gelişmiştir. Bu sistemlerin başlıcaları olan HIL (Hardware In the Loop) ve SIL (Software In the Loop) sistemlerini kullanarak bilgisayarla görme teknolojisi ile yeni test metotları kendine yer bulmaktadır. Bu çalışmada otomotivde, bilgi eğlence sistemlerinde, görüntü işleme teknolojisi ile gerçekleştirilen testler ve bu alanda geliştirilen test senaryolarından bahsedilecektir.

Anahtar Kelimeler: Otomotiv, Bilgi-Eğlence Sistemleri, Test, HIL (Hardware In the Loop), Görüntü İşleme

USAGE OF IMAGE PROCESSING TECHNOLOGY IN VALIDATION OF VEHICLE INFOTAINMENT SYSTEMS

Abstract

Over the first quarter of 21st century, the content and the popularity of Infotainment Systems in vehicles has increased a lot. While the instrument panels are digitalized, new features such as HVAC controls, rear view cameras and cell phone menus have found a place on these screens. These systems, which are in front of the customer and used in every driving experience, will highly affect the customer satisfaction in case of an error. In parallel to E&E content increase in the automotive industry, new validation methods have been developed too in order to detect and solve such misbehaviors before they reach the final customer. By using HIL & SIL Systems, image processing technology create quick and robust ways to check the digital panels in terms of validation. In this study, infotainment tests and scenarios developed with image processing technology in automotive industry will be mentioned.

Keywords: Automotive, Infotainment, Validation, HIL (Hardware in Loop), Image Processing

1. Giriş

Gelişen teknoloji ve değişen müşteri beklentileri doğrultusunda araçlar ve araçlarda kullanılan parçalar sürekli olarak kendilerini yenilemektedir. Geçmişte otomobiller yalnızca bir noktadan başka bir noktaya ulaşım aracı olarak görülürken günümüzde güvenlik, konfor ve performans beklentileri ağır basmaktadır. Otomobillerle yapılan yolculukları daha keyifli hale getirmek için de Bilgi Eğlence (Infotainment) sistemleri araçlarda yaygın olarak kullanılmaya başlanmıştır. Araçlarda kullanılan Bilgi Eğlence Sistemlerinin içeriği giderek artarken, bu sistemlerin müşteri memnuniyetine doğrudan etki ettiği gözlenmektedir. Araç seçiminde de kullanıcılar tarafından bu sistemler değerlendirme kriterleri arasında yer almaktadır.

Ürün geliştirme süreçlerinde, üretilecek ürünler için çeşitli regülasyon ve tasarım gerekliliklerinin sağlanması beklenir. Otomotiv sektöründe tasarlanan ve üretilen bu ürünler standartları yüksek ve ülkelerce kabul gören birçok norm onayından geçer. Bu onayların sağlanması için üretilecek araç ve ekipmanlar Elektrik ve Mekanik anlamda üreticiler ve yan sanayi kuruluşları tarafından çeşitli testlere tabi tutulmaktadır.

Endüstri 4.0 ile Bilgi Eğlence sistemlerinin testlerinde de otomatize edilmiş testler tercih edilmektedir. Görüntü işleme teknolojisi ile Döngüdeki Donanım - HIL (Hardware In the Loop) test sistemlerinin beraber kullanıldığı yeni test metotları ile kullanıcıya hatasız komponentler ulaştırmak üzere çalışmalar sürdürülmektedir (Çapraz, 2019). Bu

çalışmada da örnek olarak "KM hesaplama stratejisi" ve "Yakıt Dolum Stratejisi" test metotları incelenmiş, geleneksel metotlar ile kıyaslama yapılmış ve bilgisayarla görme ile yapılan testlerin avantaj ve dezavantajları sunulmuştur.

2. Otomotiv Testleri

Otomotiv sektöründe gerek kullanıcı güvenliği gerekse müşteri memnuniyeti için araçta bulunan tüm parçalar yüksek güvenlik standartları altında testlerden geçmektedir. ISO 16750 normu ile otomotivde bir standart sağlanmış ve üreticiler bu normun gerekliliklerine sadık kalarak tasarımlarına yön vermeye başlamışlardır. ISO 16750 normu alt başlıklar altında,

- ISO 16750-1: Genel kurallar ve terminoloji
- ISO 16750-2: Elektriksel testler
- ISO 16750-3: Mekanik testler
- ISO 16750-4: Klimatik testler
- ISO 16750-5: Kimyasal testler

olarak sınıflandırılmıştır (URL 1). Üreticiler ise bu normlardan faydalanarak kendi test normlarını geliştirirken bazı üreticiler ise doğrudan ISO normlarını kullanmaktadır. Bu çalışmada Elektriksel Testler başlığı altında incelenen testlerden Infotainment Testleri ve bu testlerin görüntü işleme teknikleri ile otomatikleştirilmesi incelenmiştir.

2.1 Otomotiv Infotainment Sistemleri

Infotainment sistemleri görsel ve işitsel anlamda müşterinin sürüşünü kolaylaştırma ve daha eğlenceli bir hale getirmek için araçlarda yer almaktadır (Macario, 2009). Otomotiv Gösterge Panelleri, Radyolar, Sanal Gösterge Paneli (Head Up Display) bu sistemlerden bazılarıdır. Geçmişte gösterge panelleri mekanik, radyolar ise analog iken; günümüzde gösterge panelleri dijitalleşiyor ve radyolar da dijital yayın çağına ayak uyduruyor (Kumar, 2012). Geniş ekranları sayesinde kullanıcının araç ile ilgili çok fazla bilgiye ulaşabildiği, ayarları değiştirip kişiselleştirebildiği, telefon ekranını yansıtarak dinlemek istediği müziği rahatça seçebildiği İnsan Makine Arayüzü olarak sürüş deneyiminde çok önemli bir rol oynuyorlar.

Geçmiş yıllarda navigasyon gibi özellikler araç üreticileri tarafından müşterilere sunulmazken, günümüzde bu özellikler standart olarak birçok araçta mevcuttur. Navigasyon ünitesi araçlara entegre olurken ilk zamanlarda yalnızca radyo ekranlarında kendine yer bulurken günümüzde sürücünün gözünü yoldan ayırmamasını sağlamak ve sürüş güvenliğini artırmak adına gösterge panellerine de bu bilgiler taşınmaktadır (Han, 2016). Hatta son geliştirilen araçlarda 3 boyutlu yeni çözümler de sunulmaktadır (Nurminen, 2006). Navigasyon gibi son teknolojinin yanı sıra gösterge panellerinin otomobillere ilk entegre edilme amacı olan hız gösterimi, devir gösterimi, motor suyu sıcaklığı gösterimi, yakıt durumu gösterimi gibi birçok özellik günümüzde halen müşteriye iletilmektedir. Bunların yanı sıra gösterge panelleri araçların kullanıcı ile görsel olarak iletişim odağı olması sebebiyle araç ile ilgili kullanıcıya görsel ve işitsel uyarılar verme görevlerini de sürdürmektedir.

İlk yıllarda oldukça az sayıda olan bu sistemlerin fonksiyonlarına günden güne yeni özellikler gelmektedir. 5G teknolojisinin gelişimiyle beraber V2X (Vehicle to X) olarak isimlendirilen ve aşağıdaki gibi dallara ayrılan bir haberleşme sistemi bütününe geçilecektir (Kawser, 2019).

- V2V – Vehicle to Vehicle (Araçtan-Araca)
- V2I – Vehicle to Infrastucture (Araçtan-Altyapıya)
- V2P – Vehicle to Pedestrian (Araçtan-Yolcuya)
- V2N – Vehicle to Network (Araçtan-Ağa)

Tüm bu sistemler araç içindeki komponent çeşitliliğini artıracak ve fonksiyonlar daha karmaşık bir hale gelecektir. İlerleyen dönemlerde tüm bu sistemlerin ülkelerin regülasyon zorunluluğu haline geleceği, kullanıcının can ve mal güvenliğinin emanet edileceği göz önünde bulundurulursa bu sistemler üzerindeki komponentlerin daha önce belirtilen regülasyon ve tasarım kriterlerine göre detaylıca testlerden geçirilmesi her zamankinden daha fazla önem kazanacaktır.

2.2 Otomotiv Infotainment Testleri

Araçlarda bulunan tüm komponentler yukarıda bahsedildiği gibi ISO normları ışığında testlere tabi tutulmaktadır. Elektriksel testlerde de bu normlar altında farklı standartları vardır. Bu test alanları,

- Telematik Testleri
- Network Testleri
- Diagnostik Testler

- Fonksiyonel Testler
- EMU (Elektro Manyetik Uyumluluk) – EMC (Electro Magnetic Compatibility)

ana başlıkları altında toplanabilir. Telematik testleri için ISO 22902-1:2006 Kara Araçları – Otomotiv Multimedya Ara yüzü (Road Vehicle – Automotive Multimedia Interface) (URL 2) normu referans alınarak testler gerçekleştirilmektedir.

Araç üzerindeki sistemlerin test gereksinimleri belirlenirken etkileşimde olduğu çevre birimler ve dış etmenler göz önünde bulundurulmaktadır. Komponentin çevresinde bulunan üniteler ile haberleşme ihtiyacı var ise Network, kendi iç hata yönetimi var ise diyagnostik testi, manyetik alandan etkilenmeye müsait ise EMU testi (Tamilarasu, 2014), komponent özelinde ve sistem özelinde performans testi ve kendisine has fonksiyonlar ve algoritmalar barındırıyor ise fonksiyonel anlamda testlere tabi tutulması gerekmektedir. Ayrıca sürücüye görsel geri bildirimler veren bir komponent ise üzerinde barındırdığı göstergeler ve indikatörlerin kontrollerden geçirilmesi gerekmektedir.

Infotainment sistemleri araç üzerinde bulunan birçok ünite ile haberleşmesinin yanı sıra müşterinin de odak noktasında bulunan komponentlerdir. Diğer ünitelerden gelen verileri işleyerek görsel çıktılar vermektedir. Bu çıktıların doğruluğu için fonksiyonel doğrulamanın yapılması ve indikasyonların da ayrıca doğrulanması gerekmektedir.

Fonksiyonel doğrulama işlemleri için komponentin içinde koşan yazılım test edilmektedir. Her fonksiyon için yazılım içinde birtakım algoritmalar barındırmaktadır. Bu algoritmalara örnek vermek gerekirse, Yol Bilgisayarı Hesaplama Algoritması aşağıdaki matematiksel bağıntıya uygun olarak çalışmaktadır.

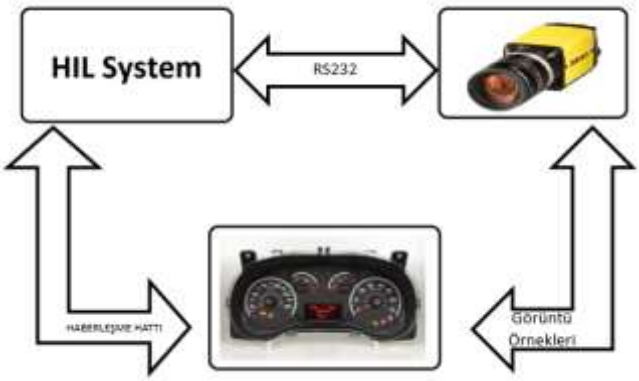
$$X = V \times t \tag{1}$$

Bu denklemde “X” alınan yol, “V” hız ve “t” ise geçen zamandır. Tüm bu bilgiler gösterge paneline haberleşme mesajları aracılığıyla iletilmekte ve bu bilgiler ile gösterge paneli ilgili hesaplamayı yapmaktadır. Bu hesaplamalar sonucunda ortaya çıkan değer kullanıcıya gösterge panelinin “TRIP” ekranında gösterilmektedir.

Değerin doğruluğunu denemek için test normu ışığında binlerce km değer ölçümü yapılması gerekmektedir. Bu doğrulamalar esnasında sisteme farklı girdiler ile bozucu girişler de uygulanarak yazılım zorlanmalıdır. Bu işlem için çalışacak bir test görevlisi saatlerce ekranı takip etmekte ve fiziksel olarak çaba harcamak durumundadır. Erken geliştirme faaliyetlerinde de bu denemeleri yapma imkânı bulamamaktadır. Bundan dolayı yazılım ve algoritma doğrulama aşamalarında SIL (Software in the Loop) sistemleri ile bu algoritmalar otomatik olarak test edilebilir ve ürün aşamasına gelmeden olası hatalar erken teşhis edilebilir (Castro, Santos, 2016). Aynı zamanda donanım aşamasına geçildiği zaman da doğrulma faaliyetlerinin yapılması gerekmektedir. Tıpkı SIL sistemlerinde olduğu gibi donanımsal olarak da sistemler otomatik olarak test edilebilmektedir. Bu testlerde HIL (Hardware in the Loop) sistemlerinden faydalanılmaktadır.

Şekil 1. Örnek bir HIL Sistemi

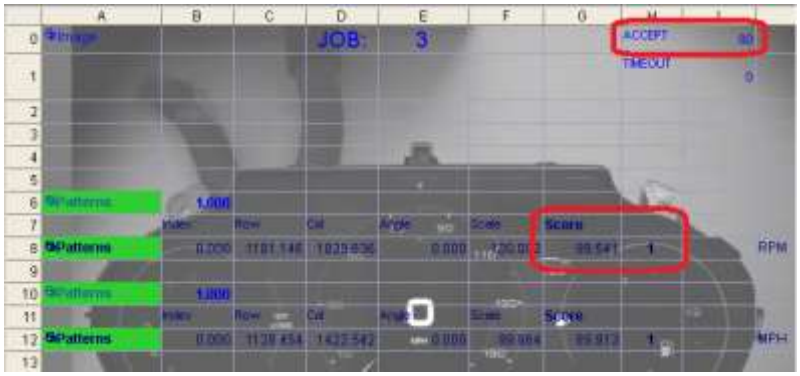
HIL sistemlerine araç üstünde bulunan tüm komponentler gerektiği durumlarda sanal olarak, gerektiği durumlarda ise gerçek olarak eklenerek tüm sistem etkileri statik ve dinamik olarak test edilebilmektedir. HIL sistemi ile sistem üzerinde haberleşme hattı yoluyla veya Analog-Dijital Girişler uygulanarak komponent davranışları gözlenebilmektedir. “TRIP” örneğinden yola çıkarak inceleme yapacak olursak, Araç hız bilgisi ve süre haberleşme yolları aracılığı ile gösterge paneline gelmektedir. Bu veriler işlenerek ekrana yansımakta ve diğer üniteler ile de haberleşme hattı üzerinden işlenen veri paylaşılmaktadır (Sharmila, Venkadesan, 2015).



Şekil 2. Infotainment HIL Sistem Topolojisi

Haberleşme hattından gelen mesajlar doğrulandıktan sonra ekranda da doğrulamanın yapılması gerekmektedir. Bu işlem için HIL sistemleri ile çalışan görüntü işleme sistemleri devreye girmektedir. Test adımlarında belirlenen hız ve belirli zaman aralıkları ile öngörülen değerler sisteme öğretilerek kontroller gerçekleştirilir. Manuel olarak yapılan bir teste kıyasla, otomatik yapılan bir test 3 kat daha hızlı olarak sonuçlanmaktadır.

Görüntü işleme tekniklerinden "metin algılama" tekniğinden faydalanılmaktadır. Bu tekniği uygulamadan önce tüm karakter ve görseller net ve çeşitli görseller ile sisteme öğretilmektedir. Önceden öğretilen karakterler puanlandırılarak tespiti yapılacak metin veya görsel algılandığı anda kıyaslama süreci başlamaktadır.

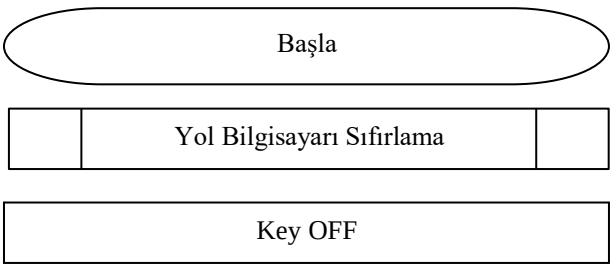


Şekil 3. Metin algılama Skorlama

Yukarıdaki örnek görüldüğü üzere kabul edilebilir puan %80 olarak belirlenmiştir. Kamera ile elde edilen görüntü ile eğitilen görüntüler beklenen sonuçlar açısından kıyaslandığı zaman bu değer 80 üzerinde ise kabul edilir ve test olumlu olarak sonuçlanır. 80 altında bir değer alması halinde ise gerek şart sağlanmadığı için test hatalı olarak sonuçlandırılmaktadır.

3. Otomatize Infotainment Testlerinin Gerçeklenmesi

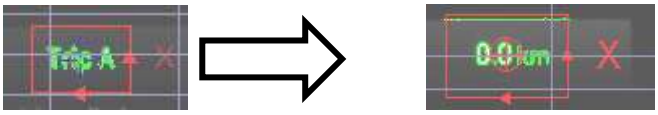
Önceki bölümde belirtildiği üzere sistemlerin testleri için manuel ve otomatik olmak üzere 2 metot vardır. Testlerin otomatize edilmesi için ön hazırlık süreci gerekmektedir. Test koşullarının oluşturulması ve bilgisayarla görme işlemleri için ilgili adımların tanıtımı bu hazırlık aşamalarının parçasıdır. Toplam kat edilen yol (TRIP) hesaplaması için aşağıdaki akışta bir test kurgulanır.



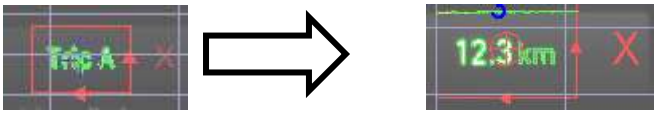
Key ON
Gösterge ekranı kontrolü
Motor On konuma alınır
Gösterge ekranı kontrolü
Yakıt tüketimi= Min değer set edilir
Gösterge ekranı kontrolü
Yolculuk 100km/h olarak set edilir.
Gösterge ekranı kontrolü
Hesaplama için Min süre beklenir.
Gösterge panelinin tanımlı menzil değeri kontrolü yapılır.
SON

Tablo 1. TRIP Test Akış Diyagramı

Yukarıda belirtilen diyagrama göre test, ilgili test stüdyosunda yazıldıktan sonra bilgisayarla görme işlemleri için gerekli öğretmeler yapılmaktadır. Bu test için TRIP ekranında meydana gelecek 'karakter' değişimleri ve bu karakterlerin konumu kontrol edileceği için metin tanıtımı yapılarak ilerlenir (Reddy, 2016).



Şekil 4. TRIP Karakter Tanıtımı



Şekil 5. TRIP Test Sonu Ölçüm

Test esnasında hata ile karşılaşılması durumunda hata anı kayıt altına alınarak test raporu otomatik olarak oluşturulmaktadır.

Gösterge paneli üzerinde bir diğer fonksiyon olan anlık yakıt tüketimi algoritmasının da doğrulanması için test koşulu oluşturularak sistemde haberleşme mesajları takip edilmektedir. Yakıt miktarı ölçümü basit şamandıra sistemi ile

yapılmaktadır. Şamandıranın yüksekliği değiştikçe direnç değerinde meydana gelen değişim takip edilerek sistemlere yakıt durum bilgisi verilmektedir. Gösterge paneli ölçümden sorumlu değil, bu değerin görselleştirilmesinden sorumlu komponenttir. Ölçümü yapan komponent haberleşme yolları aracılığı ile bu bilgiyi gösterge paneline taşımaktadır. Sistem doğrulama testlerinde ilgili yakıt değeri gösterge paneline girdi olarak gönderilmektedir. Buna göre ekrandaki değişim son değer ile kıyaslanarak göstergede yakıt seviyesini gösterecek, kritik eşik değerine ulaştığı anda ise "Düşük Yakıt Seviyesi" ikonunu yakarak kullanıcıyı uyaracaktır. Bu ikonun yanma ve sönme süreleri ise testler sırasında ayrıca ölçülmelidir.

Yakıt seviye göstergesi bar tipi ise kenar tanıma işlemi ile, hareketli çubuk ise konum bazlı nesne tanıma işlemi ile seviye tespiti yapılabilmektedir. Yakıt kritik eşik ölçümü sonucunu da ekranda görmek için ilgili ikon kenar tanıtma ile öğretilerek tepkileri ölçülmektedir.

Şekil 6. Düşük Seviye Yakıt Tespiti

Algoritmaya göre anahtar-açık konumunda iken yakıt deposu ölçüm değeri haberleşme yolu aracılığı ile gösterge paneline iletilmektedir. Bu değer, eşik değerin altında ise ilgili ikon yakılır (Şekil 4). Yanma süresi sistem tarafından ölçülerek, test gereklilikleri ile uygunluğu kontrol edilmektedir. Yanma süresi limitler arasında ise sonuç pozitif olarak raporlanmaktadır. Değil ise hatalı durumun ölçümleri test raporuna aktarılarak negatif sonuç vermektedir.

4. Sonuçlar

Bu çalışmada otomotiv sektöründe Infotainment komponentlerinin doğrulanmasında HIL sistemleri ve Görüntü İşleme tekniklerinin kullanımı incelenmiş, avantaj ve dezavantajları aşağıda açıklanmıştır.

Sayısı artan Infotainment komponentlerinin karmaşıklığı günden güne artmaktadır. Bu artış daha fazla test senaryosu oluşturmayı gerektirmektedir. HIL sistemleri ve görüntü işleme tekniklerinin birlikte kullanımı ile bu komponentler çok daha hızlı test edilebilmekte ve insana bağımlılık azaldığı için hata oranı azalmaktadır. Bu da daha güvenilir test sonuçları elde edilmesini sağlamaktadır. (Kluge, 2013). Görüntü işleme teknikleri ile insan gözü ve yardımcı enstrümanlar ile yapılamayacak ölçümler yüksek hassasiyetle yapılarak kusursuz testler gerçekleştirilmektedir. Bununla beraber sistematik raporlama özellikleri sayesinde geçmişe dönük bir arşiv oluşturma imkânı vermektedir. Bu sistemlerin dezavantajlarını inceleyecek olursak, dijital ekranların daha da yaygınlaşması ile ekran içerikleri de her güncellemede değişebilir bir hale gelmiştir. Bu değişimlerin testleri için tüm görüntü işleme senaryolarının tekrar tanıtılması gerekliliği ortaya çıkacaktır (Benchamardimath, 2014). Ancak zaman ve maliyet tasarrufu, test doğruluğu, raporlama kolaylığı gibi avantajların burada öngörülen dezavantajlardan çok daha ağır bastığını görüyoruz. Bu durum, gelecekte test alanında bu sistemlerin çok daha geniş yer bulacağını göstermektedir.

5. Teşekkür

Bu çalışma TOFAŞ Ar-Ge EE Sistemler Müdürlüğü bünyesinde yürütülmüştür.

ÖZET

Bu çalışmada, bir otomobil yan sinyal lambasının LED sürücüsü için tasarlanan elektronik karttan iletilen emisyon (CE) seviyesini tahmin etmek amacıyla CISPR 25 test kurulumunun zaman bölgesinde SPICE benzetiminin gerçekleştirilmesi hedeflenmiştir. Bu kapsamda, öncelikle, otomotiv sektöründe EMC testlerinden iletilen emisyon testi incelenmiştir. Daha sonra, elektronik karta ait test düzeneğinin, sadece devre elemanlarının yer aldığı ve ek olarak PCB yollarının yer aldığı iki farklı SPICE modeli oluşturulmuştur. Her iki modelin zaman bölgesinde benzetimleri gerçekleştirilmiştir. En yüksek iletilen emisyon (CE) değeri 150 kHz – 30 MHz frekans aralığında sadece devre elemanlarının yer aldığı modelde 250 kHz'de, 14,48 dBnV olarak bulunurken, PCB yollarının dahil edildiği modelde 173,16 kHz'de 35,75 dBnV olarak elde edilmiştir. 30 MHz – 108 MHz frekans aralığında her iki model için CE değerleri, sırasıyla, 32,50 MHz'de -47,30 dBnV ve 70,91 MHz'de 15,31 dBnV olarak bulunmuştur. Bunlara ilaveten, bu elektronik kartın iletim yollu emisyon testi yarı yankısız odada gerçekleştirilmiştir. Ölçüm sonuçlarına göre en yüksek CE değerleri, 150 kHz ile 30 MHz frekans aralığında 213,13 kHz'de 32,24 dBµV olarak elde edilmişken, 30 MHz ile 108 MHz frekans aralığında 53,39 MHz'de 27,60 dBµV olarak bulunmuştur.

Anahtar kelimeler: LED sürücü kartı, elektromanyetik uyumluluk, iletilen emisyon testi, SPICE model, benzetim

MODELING AND SIMULATION OF THE CONDUCTED EMISSION TEST FOR THE LED DRIVER BOARD OF THE CAR SIDE MARKER LAMP

ABSTRACT

In this study, it has been aimed to perform the SPICE simulation in time domain of the CISPR 25 test setup for estimating the level of conducted emission (CE) from the electronic board designed for the LED driver of the side marker lamp of a car. In this sense, firstly, the conducted emission (CE) test, which is one of the EMC tests in automotive industry, has been examined. Afterward, two different SPICE models related to the test configurations of electronic board involving both the circuit elements solely and the one with PCB traces, have been constructed. Simulations of both models have been performed in the time domain. The highest CE values for the model including circuit elements have been obtained as 14.48 dBnV at 250 kHz and for the model including PCB traces have been acquired as 35.75 dBnV at 173.16 kHz in the frequency range of 150 kHz – 30 MHz, respectively. For the frequency range of 30 MHz – 108 MHz, for both models CE values have been found as -47.30 dBnV at 32.50 MHz and 15.31 dBnV at 70.91 MHz, respectively. In addition to these, the conduction path emission test for this electronic board has been carried out in a semi-anechoic chamber. According to the measurement results, whilst the highest CE values have been obtained as 32.24 dBµV at 213.13 kHz in the frequency range of 150 kHz - 30 MHz, they have been found as 27.60 dBµV at 53.39 MHz in the frequency range of 30 MHz - 108 MHz.respectively.

Keywords: LED driver board, electromagnetic compatibility, conducted emission test, SPICE model, simulation

1. GİRİŞ

Son yıllarda otomotiv sektöründe elektronik sistemlerin karmaşıklığı ve işlevselliği artmaktadır. Bu artışın tüketicilerin talebine yanıt olarak gelecekte de devam etmesi beklenmektedir. Modern otomobillerdeki yeni sistemler veya mevcut olanların yenilenmesi ile araç içerisindeki ortamda elektromanyetik bozucu sinyal seviyesinin artışına bağlı olarak

elektromanyetik uyumlulukla ilgili karmaşık mühendislik sorunları ortaya çıkmaktadır [1]. Elektromanyetik uyumluluk (EMC), elektromanyetik ortam içeresinde bir cihaz veya sistemin hatasız çalışması ve aynı zamanda bu cihaz veya sistemin çevredeki cihazların çalışmasında hata oluşturacak bir girişime neden olmaması olarak tanımlanmaktadır [2].

Otomotiv aydınlatma sistemlerinde kullanılan elektronik elemanlardan birisi olan ışık yayan diyotlardaki (LED) son gelişmeler, farklı uygulamalar için yeni ufuklar açmıştır. LED'lerin yüksek verimliliğe ve dayanıklılığa sahip, küçük boyutlarda ve farklı özelliklerde üretilebiliyor olması geleneksel aydınlatma teknolojilerine göre önemli avantajlar sunmaktadır. Özellikle elektrikli araçların günümüzde yaygınlaşmasından dolayı, aydınlatma ürünlerinde halojen ampul yerine LED kullanımı elektrikli araç menzillerini arttırmaktadır. Ancak otomotivde LED'lerin sürülmesi için kullanılan elektronik devrelerin önemli özelliklere sahip olması gerekmektedir. Tasarımcılar tarafından ele alınması gereken temel gereksinimlerden biri sürücü devrelerinin standartlarca belirtilen EMC testlerinden başarıyla geçmesidir. Yasal regülasyonları sağlayan LED seçimi ve LED'in çalışması için optimum düzeydeki gerekli akımın belirlenmesi, elektronik sistemde yer alan kapasite ve bobin gibi pasif elemanlar, diyot gibi aktif elemanlar, baskılı devre kartında (PCB) yer alan yollar, kuplaj mekanizmaları ve sürücü modülündeki kablo ve konektörler bu gereksinimlerin karşılanması için kritik hale gelmektedir [3].

EMC testleri yüksek maliyetli ve zaman alan süreçlerdir. Maliyeti düşürmek ve zaman kazanmak için testten önce ya da testte başarısız olan PCB'lerdeki kusurları belirlemek amacıyla tasarım mühendisleri benzetimlere başvurur [4]. Elektronik sistemlerin EMC seviyelerini tahmin etmek için benzetimler giderek daha çok kullanılan bir yöntem haline gelmektedir. Bu eğilim, sayısal çözüm yöntemlerinin ve modelleme metodolojisi yaklaşımlarının geliştirilmesiyle desteklenmektedir [5].

PCB'ler elektronik sistemlerin temel birimini oluşturur. Devredeki herhangi bir elemanın veya yolların yapısının değiştirilmesi sistem düzeyinde elektromanyetik girişim (EMI) seviyelerinin değişmesine yol açabilir. Sisteme ait benzetim modeline sahip olmak, bu değişikliklerin elektromanyetik uyumluluğa etkisini tahmin etmek için zaman ve maliyet açısından verimli bir çözüm yöntemidir. Model, kartı oluşturan tüm bileşenlerin ve ara bağlantıların yer alacağı şekilde oluşturulmalı ve yakın çevre ile etkileşimini içermelidir.

Elektronik devreler, SPICE (Simulation Package with Integrated Circuit Emphasis) gibi paket programlar kullanılarak tasarlanmaktadır. Devrenin, gerilim ve akım değerlerini hesaplanması, zaman ve frekans bölgesindeki cevaplarının incelenmesi için benzetimleri yapılır. Aynı şekilde gürültü gerilim ve akımlarının benzetimlerinin yapılması EMC testleri öncesi uygulanabilir bir yöntemdir. Benzetim ile analiz yöntemi için üretici firmalar aktif elemanların elektriksel davranışlarını karakterize eden SPICE modellerini paylaşmaktadırlar. PCB üzerindeki yollar için iletim hat modelleri kullanılırken, pasif elemanlar, via, kablo ve konektörler için ise elektriksel eşdeğer devrelere başvurulur.

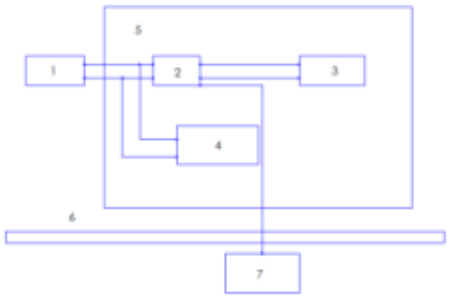
Bu çalışmada, bir otomobil yan sinyal lambasının LED sürücüsü için tasarlanan elektronik karttan iletilen emisyon seviyesini tahmin etmek amacıyla CISPR 25 test kurulumunun zaman bölgesinde SPICE benzetimi gerçekleştirilmiştir. Bu kapsamda, öncelikle, otomotiv sektöründe EMC testlerinden iletilen emisyon testi incelenmiştir. Daha sonra, elektronik karta ait test düzeneğinin, sadece devre elemanlarının yer aldığı ve ek olarak PCB yollarının yer aldığı iki farklı SPICE modeli oluşturulmuştur. Her iki modelin zaman bölgesinde benzetimleri gerçekleştirilmiştir. Bunlara ilaveten yan sinyal lambasının LED sürücü elektronik kartına ait iletim yollu emisyon testi yarı yankısız odada gerçekleştirilmiştir. Benzetim sonuçları ile EMC test sonuçları karşılaştırılarak oluşturulan modellerde yer alan devre elemanları ve PCB yollarının etkisi incelenmiştir.

2. İLETİLEN EMİSYON (CE) TESTİ

Otomotivde uygulanan elektromanyetik uyumluluk testleri PCB ve araç düzeyinde olmak üzere ikiye ayrılmaktadır. PCB düzeyinde olan testlerde, tasarımı yapılan elektronik sistemin tek başına çevreye yaydığı elektromanyetik gürültü seviyesi ve çevrede bulunan diğer elektronik sistemlerin yaydığı gürültüden etkilenme seviyesi tespit edilir. Elde edilen ölçüm sonuçlarının uluslararası standartlar ve üretici firmaların kendi belirledikleri değerlerin altında kalması esastır. Ölçüm sonuçlarında tek bir frekansta dahi belirlenen seviyenin üzerinde bir değer gözlemlenirse test başarısız sayılır. Elektronik sistem üzerinde emisyonu azaltıcı ve bağışıklığı arttırıcı değişiklikler gerçekleştirilerek sistem tekrar teste tabi tutulur. Araç düzeyinde olan testte ise tüm fonksiyonları çalışır vaziyette olan araca, ilgili standartların limitleri çerçevesinde bağışıklık ve emisyon testleri uygulanmaktadır. Tüm testler yarı yankısız ya da üretici firmanın standartları gereği tam yankısız odalarda gerçekleştirilmektedir [6-8].

Çalışmada bir yan sinyal lambasının LED sürücü kartına ait iletilen emisyon testi incelendiğinden bu bölümde iletilen emisyon testi ve test düzeneği açıklanmıştır.

İletilen emisyon testi, test altındaki elektronik sistemin çalışması sırasında bağlı olduğu şebeke veya telekomünikasyon ağı gibi noktalara iletim yoluyla aktardığı elektromanyetik gürültüyü tespit etmek amacıyla yapılmaktadır [9]. Test, Şekil 1'de verilen düzenek kullanılarak gerçekleştirilmektedir.



Şekil 1. İletilen emisyon test düzeneği

Ölçüm frekans aralığı 150 kHz-108 MHz olup, testlerde 150 kHz-30 MHz ve 30 MHz-108 MHz aralığında her bir ürüne ait bütün kablolar üzerinden iletilen elektromanyetik seviyelere bakılmaktadır. Ölçüm sonuçlarında standartlarda belirtilen sınır değerlere 6 dB ve daha yakın olan frekanslar tespit edilmektedir.

Şekil 1'deki deney düzeneğinde bulunan bileşenler 1; güç kaynağı, 2; hat stabilizasyon ağı (LISN), 3; test altındaki cihaz (DUT), 4; yük simülatörü, 5; toprak düzlemi, 6; ekranlı muhafaza, 7; ölçüm ekipmanları şeklindedir. DUT'un üzerinde bulunduğu toprak düzleminin kenarlara olan uzaklığı minimum 100 mm'dir. LISN ile DUT arasındaki mesafe ise 200 mm olmalıdır. Bununla birlikte DUT ile toprak düzlemi arasında, bağıl dielektrik sabiti $\varepsilon_r \leq 1.4$ olan 50 mm kalınlığa sahip bir düzlem vardır [10].

3. YAN SİNYAL LAMBASININ LED SÜRÜCÜ KARTINA AİT İLETİLEN EMİSYON TESTİ BENZETİMİ VE EMC TESTİ

Bu bölümde ilk olarak incelenen yan sinyal lambasının LED sürücü kartına ait iletilen emisyon test düzeneğinin, sürücüye ait elektronik kartta yer alan aktif ve pasif devre elemanlarının ve PCB yollarının SPICE modellerinin oluşturulma yöntemleri açıklanacaktır. Sonrasında bu modeller kullanılarak test düzeneğinin SPICE devre modelleri oluşturulacak ve benzetimler yapılacaktır. Daha sonra bu elektronik karta ait CISPR 25 standartında tanımlanan iletilen emisyon test düzeneği ve ölçüm sonuçları incelenecektir. Son olarak ise benzetim sonuçları ile EMC test sonuçları karşılaştırılıp yorumlanacaktır.

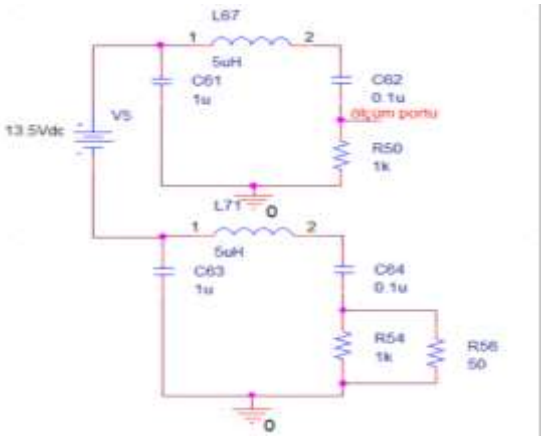
3.1. İletilen Emisyon Testi Benzetimi

Yapılan benzetim çalışmasında testte yer alan farklı türden bileşenlerin iletilen emisyon seviyesine etkisini incelemek amacıyla oluşturulan SPICE modeller en basitten daha karmaşığa gidecek konfigürasyonlarda oluşturulmuştur. SPICE modeller, benzetim yapan programlar için o elemanın değişen koşullar altında davranışını matematiksel olarak tahmin etmek amacıyla kullanılan bir devre bileşeninin metin açıklamasıdır. SPICE modelleri, direnç gibi pasif bir devre elemanının en basit tek satırlık açıklamalarından yüzlerce satır uzunluğunda olabilen son derece karmaşık alt devrelere kadar çeşitlilik gösterir. Bu modeller kullanılarak benzetim uygulamalarında devre elemanları oluşturulup analizler gerçekleştirilmektedir.

İki farklı SPICE model oluşturulmuştur. İlk model sadece devre elemanlarının bulunduğu, PCB yollarının yer almadığı, ikincisi ise devre elemanlarına ek olarak PCB yollarının yer aldığı modeldir. Oluşturulan modeller kullanılarak iletilen emisyon test düzeneğine ait SPICE devre modeli oluşturulmuş ve zaman bölgesinde benzetimi gerçekleştirilmiştir. Elde edilen veriler, daha sonra frekans bölgesine aktarılmıştır. SPICE modeller ve yapılan benzetimler, Cadence firmasına ait OrCAD PSpice programı kullanılarak gerçekleştirilmiştir.

3.1.1. Hat Stabilizasyon Ağı (LISN) SPICE Modelinin Oluşturulması

Otomotiv sektöründeki elektronik ürünler için EMC testlerinin tamamında LISN (Line Impedance Stabilization Network) adı verilen üç kapılı bir düzenleyici devre kullanılır. Kullanılan LISN cihazı CISPR 25 standartında tanımlanmıştır. Bu tanımlama kullanılarak benzetim programında SPICE model oluşturulmuş ve Şekil 2'de gösterildiği gibi batarya ile bağlantısı sağlanmıştır. Elektronik devrenin giriş gerilimi, araç merkez motor kontrol ünitesinden (ECU) gelmektedir ve değeri 12 V'dur. Ancak, EMC testlerinde toleranslar da dikkate alındığından giriş gerilimi 13,5 V olarak ayarlanmıştır.



Şekil 2. Benzetim ortamında oluşturulan LISN SPICE modelleri

İletilen emisyon ölçümleri hem bataryanın pozitif hattı hem de negatif hattı için gerçekleştirilir. Bu nedenle ölçümlerde iki LISN cihazı kullanılır. Belirli bir hatta ölçüm yapıldığında, o hat ile ilişkili LISN'in ölçüm portlarından analiz yapılır ve diğer LISN'nin ölçüm portu 50 Ω yükle sonlandırılır.

3.1.2. Devre Elemanlarının SPICE Modellerinin Oluşturulması

Aktif devre elemanlarının modellerinin oluşturulmasında üretici firmalardan temin edilen SPICE model dosyaları kullanılmıştır. İncelenen yan sinyal lambasının LED sürücü elektronik kartında aktif devre elemanı olarak diyot, TVS diyot ve LED bulunmaktadır. Diyot olarak Taiwan Semiconductor firmasına ait 1A 600V S1J modeli kullanılmıştır [11]. TVS diyot olarak ST Microelectronics firmasına ait 24V 600W SM6T24CA modeli kullanılmıştır [12]. LED olarak ise Nichia Corporation firmasına ait NFSA172CT modeli kullanılmıştır. Kullanılan LED'in ileri yön gerilimi 3V ve ileri yön akımı 150 mA'dir. Ayrıca LED'in merkez dalga boyu 600 nm ve spektral genişliği 100 nm olup yasal regülasyonlara uymaktadır. LED'in lümen çıkışı ise 50 lm olup yine regülasyonların gerekliliklerini sağlamaktadır [13]. Benzetimde kullanılan aktif devre elemanlarına ait modeller Şekil 3'te gösterilmiştir.

(a) (b) (c)

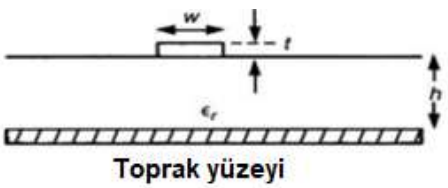
Şekil 3. Aktif devre elemanlarının SPICE modelleri (a) S1J diyot (b) SM6T24CA TVS diyot (c) NFSA172CT LED

Pasif devre elemanlarının eşdeğer elektriksel modellerinde, iletkenin kendi özelliklerinden kaynaklı olarak omik, endüktif ve kapasitif etkiler de yer almaktadır. DC çalışmada bu etkiler ihmal edilirken frekans yükseldikçe devre elemanlarının eşdeğer empedansları değiştiğinden bahsedilen etkilerin dikkate alınması gerekmektedir. Bu çalışmada kullanılan devrenin giriş gerilimi DC olduğundan pasif devre elemanlarındaki etkiler dikkate alınmayıp benzetim programı kütüphanesinde yer alan devre elemanları kullanılmıştır.

3.1.3. PCB Yollarının SPICE Modellerinin Oluşturulması

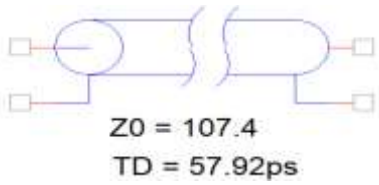
PCB' de yer alan yolların SPICE modelleri iletim hattı modelleri ve iletken eşdeğer devre modelleri kullanılarak oluşturulmuştur. Modellerde yer alan parametreler yolların özelliklerine göre değişiklik göstermektedir. Yan sinyal lambasının LED sürücü kartının PCB'sinde yer alan yollar sahip oldukları özelliklere göre mikroşerit hat ve PCB bakır iletken hat modeli ile modellenmiştir.

Mikroşerit hat Şekil 4'te gösterildiği gibi substrat olarak bilinen bir dielektrik katman kullanılarak toprak düzleminden ayrılmış bir iletken şeritten oluşmaktadır [14].



Şekil 4. Mikroşerit hat yapısı

Burada w yol genişliğini, t yol kalınlığını ve h toprak düzlemi ile iletken yol arasındaki mesafeyi temsil etmektedir. Benzetim programında mikroşerit hattın SPICE modeli için Şekil 5'te verilen TLINE isimli kayıpsız iletim hat modelini temsil eden devre elemanı kullanılmıştır [15]. Burada kayıpsız iletim hattı modeli kullanılmasının sebebi hattın direnç ve kondüktans değerlerinin ihmal edilebilecek seviyede küçük ve DC giriş gerilimi sebebiyle deri kalınlığının oldukça büyük olmasıdır.



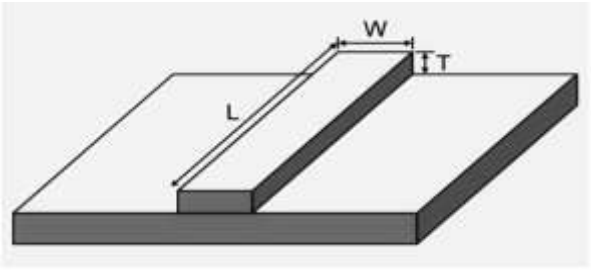
Şekil 5. Mikroşerit hat için kullanılan kayıpsız iletim hattı SPICE modeli

Şekil 5'te verilen TLINE devre elemanı, Z_0 karakteristik empedans ve T_D yayılım gecikmesi olmak üzere iki parametreye sahiptir. Mikroşerit hatlar için karakteristik empedans eşitlik (1), yayılım gecikmesi ise eşitlik (2) kullanılarak hesaplanmaktadır [14].

$$Z_0 = \frac{87}{\sqrt{\varepsilon_r + 1{,}41}} \ln\left(\frac{5{,}98.h}{0{,}8.w + t}\right) [\Omega] \quad (1)$$

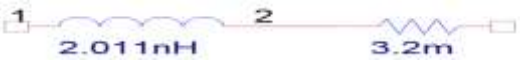
$$T_D = 3{,}333\sqrt{0{,}475.\varepsilon_r + 0{,}67}\ [ns/m] \quad (2)$$

İncelenen PCB'de yer alan bazı yollar mikroşerit iletim hattı modeline uymadığından Şekil 6'da gösterilen PCB bakır iletken hat modeli ile modellenmiştir [16].



Şekil 6. PCB bakır iletken hat yapısı

Burada W yol genişliği, T yol kalınlığını ve L'de yol uzunluğunu ifade etmektedir. Bakır yolların iletken özelliklerinden dolayı sahip olduğu direnç ve endüktans değerleri (3) ve (4) eşitlikleri kullanılarak hesaplanmış ve Şekil 7'de gösterildiği gibi birbirlerine seri bağlanarak modellenmiştir.



Şekil 7. PCB bakır yolu SPICE model örneği

Bakır yolun direnç değeri eşitlik (3) ile hesaplanmıştır [16].

$$R = \rho.\frac{L}{T.W}.[1 + \alpha(temp - 25)]\ [\Omega] \quad (3)$$

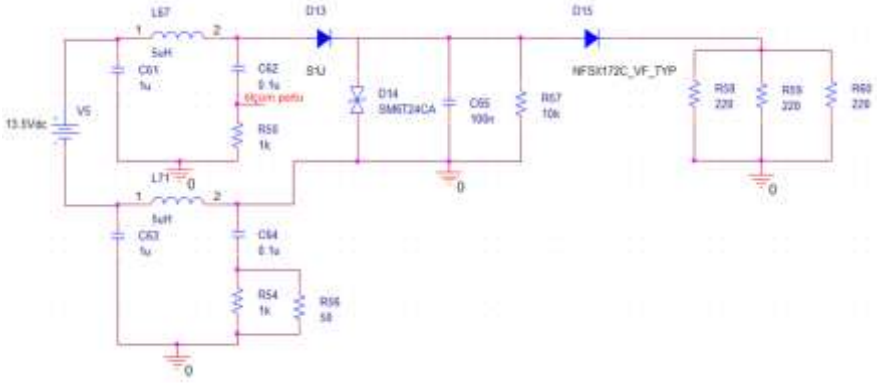
Burada ρ özdirenç, α ise sıcaklık katsayısını ifade etmektedir. Bu çalışmada direnç değerleri 25 °C sıcaklık değeri için hesaplamıştır. Bakır yolun endüktans değeri ise eşitlik (4) hesaplanmıştır [16].

$$L = 0{,}2.len\left(\ln\left(\frac{2.len}{W + T}\right) + \frac{0{,}223(W + T)}{len} + 0{,}5\right)\ [H] \quad (4)$$

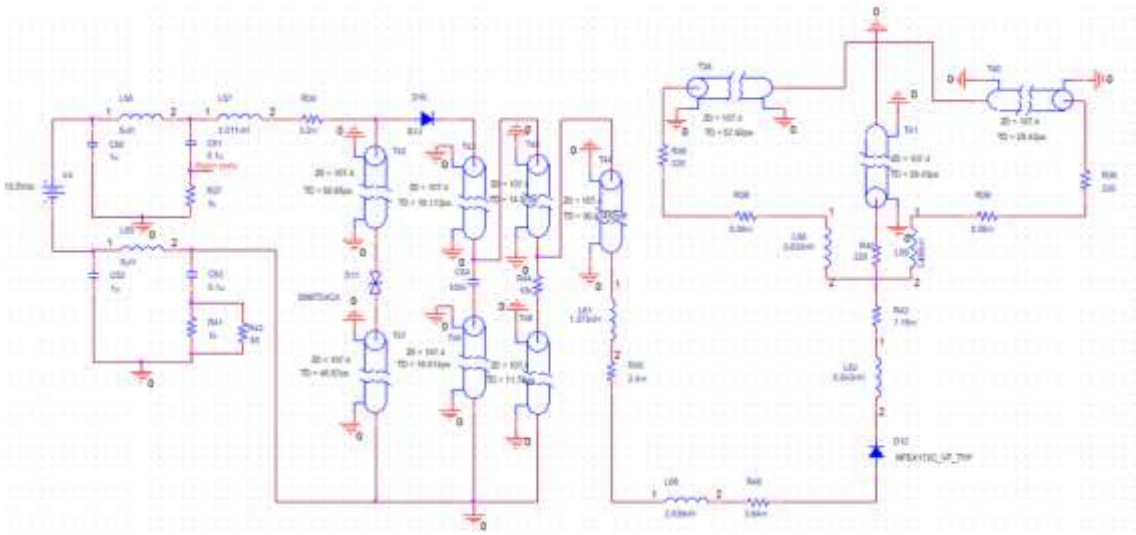
Burada, len yol uzunluğunu ifade etmektedir.

3.1.4. İletilen Emisyon Test Düzeneğine Ait SPICE Modelin Oluşturulması

İletilen emisyon test düzeneği, batarya, LISN cihazı ve PCB SPICE modelleri bağlantısı sağlanarak modellenmiştir. Burada PCB'nin SPICE modelinin oluşturulmasında iki farklı konfigürasyon belirlenmiş ve bunlar önceki bölümlerde anlatılan modeller ve hesaplamalar kullanılarak Şekil 8 ve Şekil 9'da gösterildiği gibi oluşturulmuştur. Şekil 8'de, sadece devre elemanlarının yer aldığı, iletilen emisyon testi SPICE modeli, Şekil 9'da ise devre elemanlarına ek olarak PCB yollarının yer aldığı, iletilen emisyon testi SPICE modeli verilmektedir.



Şekil 8. Sadece devre elemanlarının yer aldığı iletilen emisyon testi SPICE modeli



Şekil 9. Devre elemanlarına ek olarak PCB yollarının yer aldığı iletilen emisyon testi SPICE modeli

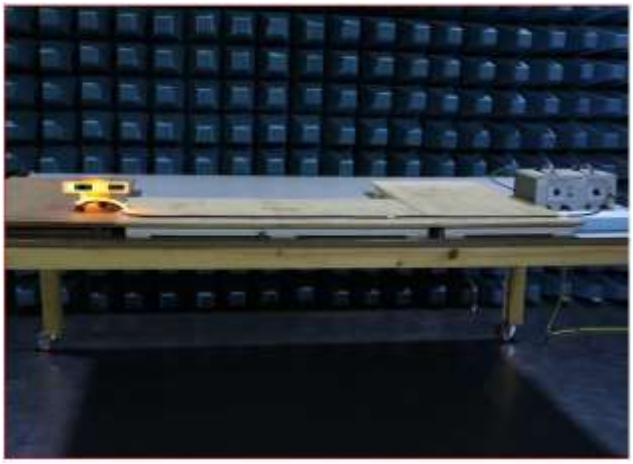
3.1.5. İletilen Emisyon Testi SPICE Benzetim Adımları ve Sonuçları

Kullanılan paket programda hazırlanan modellerin geçici hal (transient) analizi ile zaman bölgesinde benzetimleri gerçekleştirilmiş ve elde edilen veriler hızlı Fourier dönüşümü (FFT) aracılığı ile frekans bölgesine aktarılmıştır. Benzetim süresi 2 µs seçilmiş ve sık örnek alarak doğruluğun artırılması amacıyla adım aralığı 2 ns olarak ayarlanmıştır. Benzetimler, kullanılan paket programın toprak konfigürasyonları ile ilgili kısıtlı imkâna sahip olması nedeniyle negatif güç hattı için gerçekleştirilmeyip sadece pozitif güç hattı için gerçekleştirilmiştir.

Ölçüm sonuçları incelendiğinde en yüksek iletilen emisyon (CE) değeri 150 kHz – 30 MHz frekans aralığında sadece devre elemanlarının yer aldığı modelde 250 kHz'de, 14,48 dBnV olarak bulunurken, PCB yollarının dahil edildiği modelde 173,16 kHz'de 35,75 dBnV olarak elde edilmiştir. 30 MHz – 108 MHz frekans aralığında her iki model için CE değerleri, sırasıyla, 32,50 MHz'de -47,30 dBnV ve 70,91 MHz'de 15,31 dBnV olarak bulunmuştur.

3.2. İletilen Emisyon Test Düzeneği ve EMC Test Sonuçları

İncelenen sistem için iletilen emisyon testi, CISPR 25 standartında belirtilen deney düzeneğinde 150 kHz-30 MHz ve 30 MHz-108 MHz frekans aralıklarında Şekil 10'da gösterilmiş olan yarı yankısız odada gerçekleştirilmiştir. Ölçümler güç hattının pozitif ve negatif uçları için ayrı ayrı yapılmıştır.



Şekil 10. Yarı yankısız odada gerçekleştirilen iletilen emisyon testi

Ölçümlerde daha doğru sonuçlar tepe gibi (QP) detektörlerle alınmakla birlikte süreler uzun olduğundan öncelikle tepe (PK) detektörü ile hızlı tarama uygulanır. Cihazın emisyon limitlerine yaklaştığı ya da geçtiği frekanslarda QP detektörü ile ölçümler tekrarlanır. PK ile yapılan hızlı taramalar en kötü hali yansıtır. Bu nedenle PK detektörü ile yapılan ölçümlerde sonuçlar limitlerin 6-10 dB altında kaldığı takdirde QP detektörü ile ölçüm yapmadan cihazın testleri geçtiği kabul edilir [7]. CISPR 25 standartlarında iletilen emisyon testi için belirtilen sınır değerler Tablo 1'de verilmiştir [8].

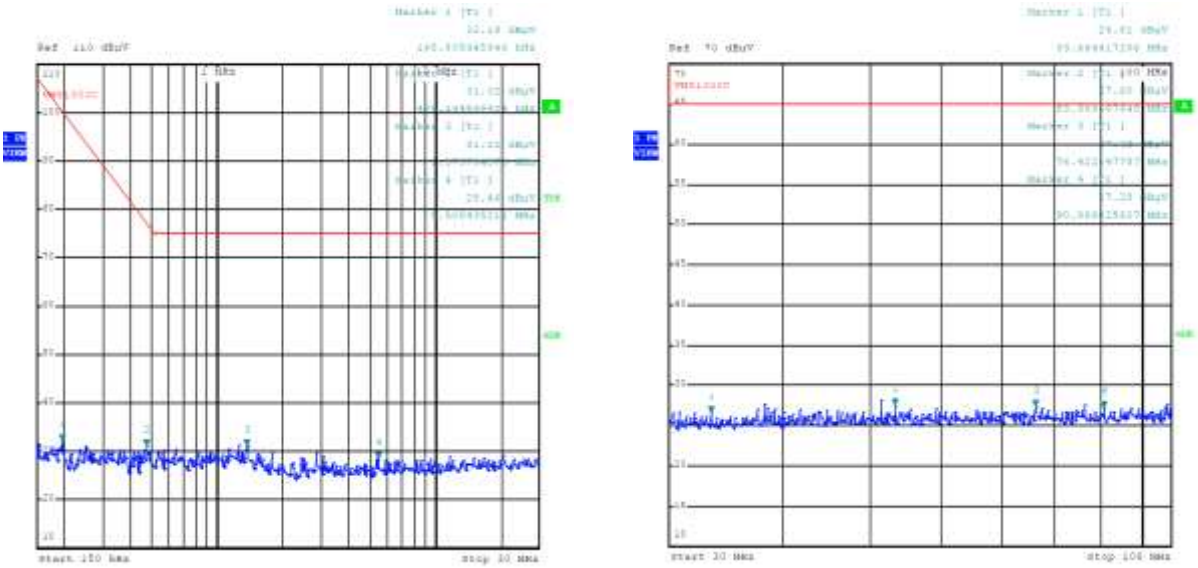
Tablo 1. CISPR 25 standartlarında iletilen emisyon testi sınır değerleri

Frekans (MHz)	**PK Limiti (dBµV)**			**QP Limiti (dBµV)**			**Ortalama Limit (dBµV)**		
	Sınıf			**Sınıf**			**Sınıf**		
	3	**4**	**5**	**3**	**4**	**5**	**3**	**4**	**5**
0,15 – 0,52	107 – 59,51 x log(f/0.15)[a]			-			97 – 59,51 x log(f/0.15)[a]		
0,52 – 30	75			-			65		
30 – 108	65			-			55		

Tablo 1'de a, formüllerde frekansın MHz olarak girilmesi gerektiğini ve log ifadesinin 10 tabanına göre logaritmayı temsil ettiğini belirtmektedir.

Elektronik kartın içerisinde bulunduğu tüm aydınlatma modülüne testler uygulanmaktadır. Ölçüm sonuçlarında emisyon değeri mavi çizgi ile gösterilmekte olup standardın belirttiği limit değer ise kırmızı çizgi ile belirtilmektedir. Sonuçlar Şekil 12'de gösterilmiştir.

150 kHz ile 30 MHz frekans aralığında pozitif güç hattı için gerçekleştirilen ölçüm sonucu Şekil 12 (a)'da gösterilmiştir. Sonuç incelendiğinde referans değer 110 dBµV'dur ve 6 dB sınırı 55 olup bu değere en yakın nokta 213,13 kHz'de 32,24 dBµV 'dir. 30 MHz ile 108 MHz frekans aralığında pozitif güç hattı için gerçekleştirilen ölçüm sonucu şekil 12 (b)'de gösterilmiştir. Sonuç incelendiğinde referans değer 70 dBµV'dur ve 6 dB sınırı 36 olup bu değere en yakın nokta 53.39 MHz'de 27.60 dBµV 'dir. Bu çalışmada sadece pozitif güç hattı için benzetimler gerçekleştirildiğinden negatif güç hattı için yapılan ölçüm sonuçları dikkate alınmamıştır.

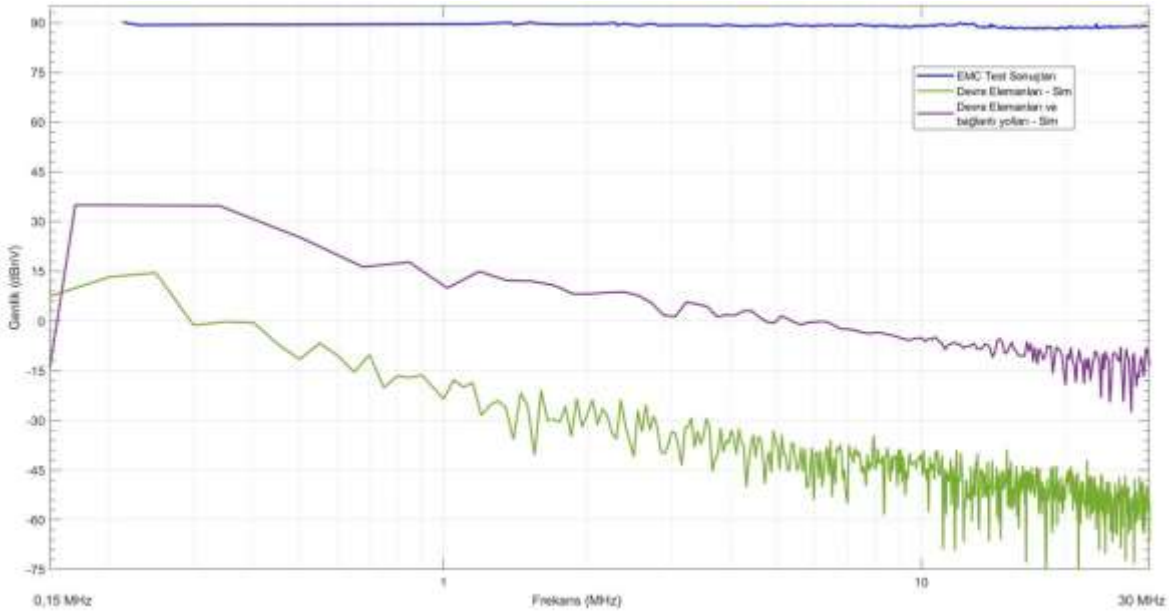


(a) (b)

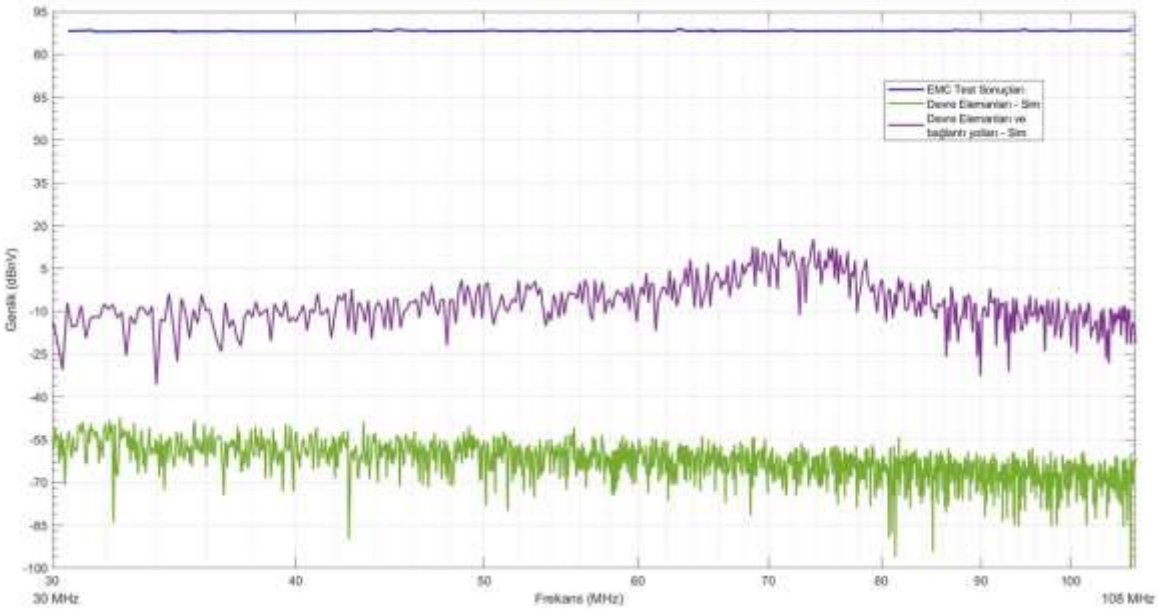
Şekil 12. Pozitif güç hattı için iletilen emisyon testi ölçüm sonuçları. (a) 150 kHz – 30 MHz ölçüm sonucu (b) 30 MHz – 108 MHz ölçüm sonucu

3.3. Benzetim Sonuçları ile EMC Test Sonuçlarının Karşılaştırılması

Şekil 8 ve 9'da verilen modeller için 150 kHz – 30 MHz ve 30 MHz – 108 MHz aralıklarında frekans değerlerine ait pozitif güç hattı için yapılan iletilen emisyon testi benzetim sonuçları ve sisteme ilişkin gerçek test sonuçları, sırasıyla, Şekil 13 ve Şekil 14'te verilmiştir.



Şekil 13. 150 kHZ – 30 MHz frekans aralığında sadece devre elemanlarının yer aldığı ve ek olarak PCB yollarının yer aldığı modellerin iletilen emisyon testi SPICE benzetim sonuçları



Şekil 14. 30 MHZ – 108 MHz frekans aralığında sadece devre elemanlarının yer aldığı ve ek olarak PCB yollarının yer aldığı modellerin iletilen emisyon testi SPICE benzetim sonuçları

Şekil 13 ve Şekil 14'te görüldüğü üzere sadece devre elemanlarının yer aldığı modele PCB yollarının dahil edilmesiyle her iki frekans aralığı için iletilen emisyon seviyeleri yükselmiştir. Ancak benzetim sonuçlarındaki iletilen emisyon seviyelerinin gerçek test sonuçlarına göre düşük kaldığı gözlemlenmiştir. Bu durum PCB'de yer alan elektriksel davranışları lineer olmayan etkilere sahip bileşenler, vialar, konektörler ve kuplaj mekanizmalarının modellere dahil edilmemesinden kaynaklanmıştır.

4. SONUÇLAR VE TARTIŞMA

Bu çalışmada bir otomobil yan sinyal lambasının LED sürücüsü için tasarlanan elektronik karttan iletilen emisyon seviyesini tahmin etmek amacıyla CISPR 25 test kurulumunun zaman bölgesinde SPICE benzetiminin gerçekleştirilmesi hedeflenmiştir. Bu amaçla ilk olarak otomotiv sektöründe uygulanan EMC testlerinden iletilen emisyon testi incelenmiştir. Sonrasında sürücü kartına ait iletilen emisyon test düzeneğinin SPICE modeli oluşturulmuştur. Testte yer alan farklı türden bileşenlerin emisyon seviyesine etkisini incelemek amacıyla sadece devre elemanlarının yer aldığı ve ek olarak PCB yollarının yer aldığı iki farklı SPICE model oluşturulmuştur.

Birinci ve ikinci model için ilk olarak test düzeneğinde yer alan hat stabilizasyon ağı (LISN) cihazının CISPR 25 standartında verilen eşdeğer devre modeli referans alınarak SPICE modeli oluşturulmuştur. Daha sonra elektronik kartta yer alan devre elemanları için SPICE modeller oluşturulmuştur. Aktif devre elemanları için üretici firmalar tarafından paylaşılan SPICE model dosyaları kullanılmıştır. Pasif devre elemanları için ise benzetim programının kütüphanesinden faydalanılmıştır. Sonrasında ikinci model için PCB yollarının SPICE modelleri oluşturulmuştur. Burada yolun özelliklerine göre mikroşerit iletim hat ve PCB bakır iletken hat modelinden faydalanılmıştır. Mikroşerit iletim hat modeli için program kütüphanesinde yer alan kayıpsız iletim hattı modeli kullanılmış ve bu model için parametre olarak karakteristik empedans ve yayılım gecikmesi hesaplanmıştır. PCB bakır iletken hat modelinde ise yolun direnç ve endüktansı hesaplanıp seri bağlanarak modellenmiştir.

Daha sonra planlanan iki konfigürasyon için de SPICE devre modelleri oluşturulmuş ve kullanılan paket programında geçici hal (transient) analizi ile zaman bölgesinde benzetimler gerçekleştirilmiştir. Elde edilen veriler hızlı Fourier dönüşümü (FFT) aracılığı ile frekans bölgesine aktarılmıştır. Benzetimler, kullanılan paket programın toprak konfigürasyonları ile ilgili kısıtlı imkana sahip olması nedeniyle negatif güç hattı için gerçekleştirilmeyip sadece pozitif güç hattı için gerçekleştirilmiştir. Sonuçlar incelendiğinde en yüksek iletilen emisyon (CE) değeri 150 kHz – 30 MHz frekans aralığında sadece devre elemanlarının yer aldığı modelde 250 kHz'de, 14,48 dBnV olarak bulunurken, PCB yollarının dahil edildiği modelde 173,16 kHz'de 35,75 dBnV olarak elde edilmiştir. 30 MHz – 108 MHz frekans aralığında her iki model için iletilen emisyon değerleri, sırasıyla, 32,50 MHz'de -47,30 dBnV ve 70,91 MHz'de 15,31 dBnV olarak bulunmuştur. Sadece devre elemanlarının yer aldığı modele PCB yollarının dahil edilmesiyle iletilen emisyon seviyeleri yükselmiştir.

Son olarak yan sinyal lambasının LED sürücü kartına ait iletim yollu EMC testi yarı yankısız odada gerçekleştirilmiştir. Pozitif güç hattı için gerçekleştirilen ölçüm sonuçlarında en yüksek iletilen emisyon değeri 150 kHz ile 30 MHz frekans aralığında 213,13 kHz'de 32,24 dBµV olarak bulunurken. 30 MHz ile 108 MHz frekans aralığında 53,39 MHz'de 27,60 dBµV olarak bulunmuştur. Benzetim sonuçları ile EMC test sonuçları karşılaştırıldığında benzetim sonuçlarındaki iletilen emisyon seviyelerinin gerçek test sonuçlarına göre düşük kaldığı gözlemlenmiştir. Bu durum PCB'de yer alan elektriksel davranışları lineer olmayan etkilere sahip bileşenler, vialar, konektörler ve kuplaj mekanizmalarının modellere dahil edilmemesinden kaynaklanmıştır.

Gelecekte, bilgisayar ortamında yapılması hedeflenen baskılı devre kartlarının elektromanyetik uyumluluk analizi ve modellenmesi için bu çalışma bir altyapı oluşturmaktadır. Bu bağlamda, oluşturulmuş olan modellere, elektronik kart üzerindeki diğer bileşenler de dâhil edilerek gerçek test düzeneklerine daha yakın kurulumlar gerçekleştirilip bu durumun analiz sonuçlarına etkisinin incelenmesi hedeflenmektedir. Ayrıca, elde edilecek analizlerin doğruluğunu artırmak adına 3D elektromanyetik tam dalga benzetim programları aracılığı ile testlerin tekrarlanması ve sonuçlarla karşılaştırılarak yorumlanması planlanmaktadır.

ÖZET

Farklı kimyasal ve mekanik özellikleri bir arada bulunduran 3. nesil çeliklerin otomotiv endüstrisinde kullanımı hızla artmaktadır. Çinko kaplı bu çeliklerin nokta direnç kaynağı (RSW) sırasında sıvı metal gevrekliği (SMK) meydana gelebilmekte ve kaynak bölgesinde meydana gelen SMK hassasiyeti mikro çatlaklara sebebiyet verebilmektedir. Bu nedenle kaynaklı malzemelerin kaynak bölgesi mukavemet özellikleri kötüleşmektedir.

Bu çalışma kapsamında, nokta direnç kaynak esnasında punta bölgesinde meydana gelen, mekanik özelliklerin azalmasıyla ilişkilendirilen SMK fenomeni ve olası etkilerinin anlaşılması amaçlanmıştır. Bu amaçla, 1200 MPa kopma mukavemetine sahip çelik malzemeler 3 farklı parametrede nokta direnç kaynağı ile birleştirilmiştir. Kaynak bölgesinde meydana gelen mikro çatlak oluşumları, konumları, yoğunlukları ve derinlikleri optik mikroskop yardımıyla incelenmiştir. ITAB'da (Isı tesiri altında kalan bölge) SMK hassasiyetinin yüksek olduğu ve ergime bölgesine oranla SMK çatlaklarının punta çevresinde yoğunlaştığı tespit edilmiştir. Mikro çatlak çevresine EDS analizleri gerçekleştirilmiş olup punta yüzeyinden tane sınırları boyunca ilerleyerek ergime merkezine doğru yönlenen SMK çatlaklarının ara yüzeyinde Zn varlığı tespit edilerek çatlakların SMK çatlağı olduğu kanıtlanmıştır. Son olarak numunelere çekme-makaslama testi uygulanmış ve kopma mukavemeti ile çatlak yoğunluğu arasında bağlantı kurulmaya çalışılmıştır.

Anahtar kelimeler: 3. Nesil Çelikler, Galvaniz kaplama, Nokta direnç kaynağı, Sıvı metal kırılganlığı (SMK).

LIQUID METAL EMBRITTLEMENT IN RESISTANCE SPOT WELDING OF THIRD GENERATION STEELS

ABSTRACT

The use of 3rd generation steels, which have different chemical and mechanical properties, is rapidly increasing in the automotive industry. Liquid metal embrittlement (LME) can occur during resistance spot welding (RSW) of these zinc-coated steels, and the sensitivity of LME in the weld area can cause microcracks. Therefore, the weld zone strength properties of welded materials can deteriorate.

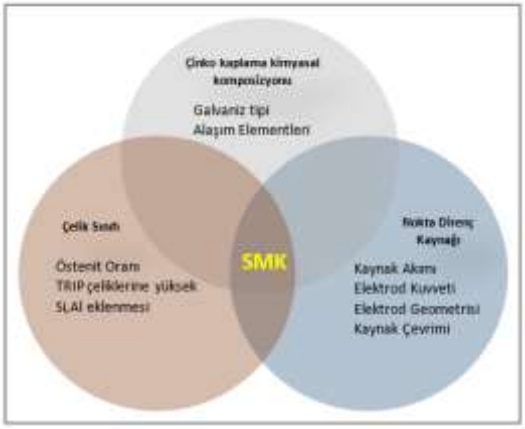
Within the scope of this study, it is aimed to understand the LME phenomenon and its possible effects, which occur in the spot region during resistance spot welding and are associated with the decrease of mechanical properties. For this purpose, steel sheet materials with a tensile strength of 1200 MPa were joined by resistance spot welding in 3 different parameters. Micro crack formations, locations, densities and depths in the weld area were examined with the optical and electron microscope. It has been determined that the sensitivity of LME is high in HAZ (heat affected zone) and LME cracks are concentrated around the spot compared to the melting zone. EDS analyzes were carried out around the microcrack and the presence of Zn was detected at the interface of the LME cracks starting from the spot surface and continuing along the grain boundaries towards the melting center. The detected cracks are proven to be LME cracks. Finally, the tensile-shear test was applied to the welded samples and the relationship between the breaking strength and the crack density was tried to be established.

Keywords: 3rd Generation Steels, Galvanized coating, Resistance spot welding, Liquid metal embrittlement (LME).

1. GİRİŞ

Otomotiv endüstrisinde garanti sürelerinin artması, korozyon koruması gerekliliğini beraberinde getirmiş ve galvanizli çelik uygulaması önemli ölçüde artmıştır. Müşterilere daha güvenilir ürünler sunmak için araç gövdesinin %30 ila 100'ünün galvanizli çelikten imal edilmesi tavsiye edilmektedir (Chung, Wang, Durandet, 2019). Bu nedenle son günlerde, sadece kaplamasız çelikler değil, aynı zamanda galvanizli ve yüksek dayanımlı çelikler de geliştirilmektedir.

Galvanizleme ile korozyon koruması için çeliğe ince bir çinko tabakası uygulanır. Çoğunlukla galvanizleme, sıcak daldırma galvanizleme işlemi ile gerçekleştirilir. Çünkü en basit ve ekonomik olanı sıcak daldırma galvanizlemedir. RSW sırasında, ergimiş Zn, çelik yüzeyinde tane sınırlarına kolaylıkla sızar. Katılaşma ile çatlaklar ve gevrek kırılmalar meydana gelir. SMK'nın sıvı Zn, kaynak parametreleri, SMK'ya duyarlı alaşımlar gibi çeşitli faktörler nedeniyle geliştiği yaygın olarak bilinmektedir. Şekil 1'de, galvanizli çelikleri SMK'ya duyarlı hale getiren birleşik faktörler görülmektedir (Wook-Sang, Ashutosh Jae Pil, 2020). Otomotiv montajında en yaygın birleştirme işlemi halen nokta direnç kaynağıdır. Nokta direnç kaynağı (RSW) sırasında SMK'nın meydana gelmesi son birkaç yılda dikkat çekmiştir ve bu alandaki araştırmalar halen devam etmektedir. SMK mekanizmalarını açıklamak için literatürde çeşitli araştırmalara rastlanmıştır (Glickman, 2011). Shunk et al. çelik (katı)/Zn (sıvı), Al alaşımı (katı)/Zn (sıvı) ve Ti alaşımı (katı)/Cd (sıvı) gibi çeşitli metaller arasında SMK'ya duyarlılığını analiz etmiştir (Ling, Wang, Kong, 2018). Kaynak parametrelerinin SMK şiddeti üzerindeki etkisini belirlemek için bir dizi çalışma yapılmıştır ve sonuçlar daha büyük bir ısı girdisinin daha şiddetli SMK çatlamasına karşılık geldiğini göstermektedir (Kim, Kim, Kim, Chung, Choi, 2014), (Barthelmie, Schram, Wesling, 2016) (Ashiri, Shamanian, Salimijazi, Haque, Bae, Ji, Chin, Park, 2016). SMK'nın oluşması için Ashiri ve arkadaşları üç faktörün mevcut olması gerektiğini bulmuştur: bir sıvı gevrekleştirici katı metal ile doğrudan temas halinde olmalıdır, alt tabaka hassas bir mikro yapıya sahip olmalıdır ve alt tabaka çekme gerilmeleri altında olmalıdır (Ashiri, Shamanian, Salimijazi, Haque, Bae, Ji, Chin, Park, 2016).



Şekil 1. Sıvı metal kırılganlığı (SMK) oluşumu şartları (Wook-Sang, Ashutosh Jae Pil, 2020).

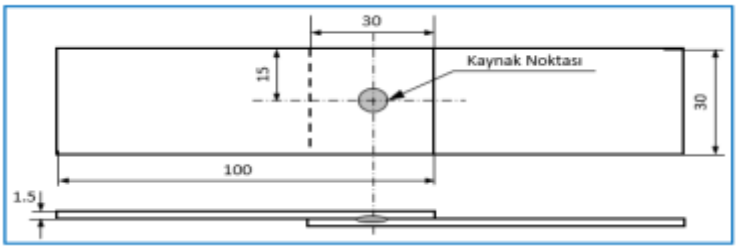
Son yıllarda, sıvı çinko ile temas halinde olan belirli bileşim ve mikro yapılara sahip geliştirilmiş yüksek mukavemetli çeliklerin (AHSS) SMK'ya karşı oldukça duyarlı olduğu belirlenmiştir. Cho ve arkadaşları ile Lee ve arkadaşları sıcak presleme gibi yüksek sıcaklıkta malzeme işleme proseslerinde sıvı çinko ile temas halindeki çeliklerde SMK gözlemlemişlerdir (Cho, Kang, Lee, De Cooman, 2014) (Lee, Fan, Sohn, Lee, De Cooman, 2012). Ark kaynağı ve lazer kaynağı gibi diğer kaynak yöntemlerinde SMK çatlağına rastlanmamıştır (Razmpoosh, Macwan, Biro, Chen, Peng, Goodwin, and Zhou, 2018). Araştırmacılar bu durumu çatlakların oluşması için ek stres gerektiğine yormuşlardır. Tolf ve arkadaşları DP1000 çeliklerinde direnç nokta kaynaklı bağlantılarında görülen yüzey çatlaklarını incelediklerinde sıcak daldırma galvaniz kaplamalı çeliklerin SMK'ya elektrogalvanizli çeliklerden daha duyarlı olduğunu tespit etmişler (Tolf, Hedegard, Melander, 2013). Kim ve arkadaşları ise kaynak parametrelerinin galvanizli TRIP590 dirençli nokta kaynaklarında çatlama oranı üzerinde etkisi olduğunu gözlemlemişlerdir (Kim, Kim, Ji, Chung, and Du, 2014). Lee ve diğerleri çinko kaplı TWIP (Twinning incuded plasticity) çeliklerinde bir direnç nokta kaynağındaki SMK çatlaklarının, östenit tane sınırları boyunca sıvı Zn'nin sızması ile oluştuğunu öne sürmüştür (Lee, Jo, Sohn, Kim, Song, Kim, Kim, Kim, and Lee, 2019). Genelde nokta direnç kaynaklarında SMK mekanizması olarak Zn difüzyon modeli tercih edilir. Kaynağın en başında sıcaklık düşüktür. Ana metal ve kaplama orijinal hallerinde korunur. Punta merkezine elektrot ile baskı kuvveti uygulanır. Kaynak zamanı ilerledikçe sıcaklık yükselir. Ana malzeme ostenite dönüşür ve kaplama yüksek sıcaklıkta ergir. Puntanın merkezindeki kaplama elektrot ile reaksiyona girer ve sıvı faz elektrot kuvveti altında dışarı atılır, bu durum önemli bir Zn kaybıyla sonuçlanır. Mekanik veya termal gerilimlerden kaynaklanan bir çekme geriliminin varlığı nedeniyle, difüzyon hızı çok hızlı olduğu için Zn atomları ostenit tane sınırları boyunca çeliğe yayılır (Kang, Cho, Lee, and De Cooman, 2016). Ve sonuç olarak yayılan Zn tane sınırlarının zayıflamasına neden olur. Tane sınırları çekme gerilmesi altında açılabilir ve çatlaklar oluşabilir. Çatlaklar oluştuktan sonra punta merkezine yakın yüzeyde sıvı Zn yeterli olduğundan kılcal etki ile çatlaklar dolabilmektedir. Bu çalışmada SMK'ya duyarlı çelik bir malzeme üzerine farklı kaynak parametrelerinde nokta direnç kaynağı uygulanmış ve kaynaklı bağlantının kaynak bölgesi bazı tahribatlı ve tahribatsız test yöntemleri ile karakterize edilmeye çalışılmıştır.

2. MALZEME, KAYNAK METODU VE DENEYSEL PROSEDÜR

Bu çalışmada, 1.2 mm kalınlığında akma dayanımı 774 (± 4,7) MPa, çekme dayanımı 1104 (±3,78) MPa ve % uzaması 16,3 (±0,5) olan, galvaniz kaplamalı TBF (Dönüşüm etkili plastisite katkılı beynitik ferritik) çeliği kullanılmıştır. Çelik saclar 30x100 mm boyutlarında lazer kesim makinesinde kesilerek ve etonol ile yüzeyleri temizlenerek kaynağa hazırlanmıştır. Kaynak operasyonu 200 kVA, 50 Hz frekansta alternatif akım ile çalışan bir elektrik direç nokta kaynak makinesinde bakır alaşımlı 6.0 mm çapında elektrodlar ile saclar 30 mm üstüste bindirilerek gerçekleştirilmiştir. Numunelere ait kaynak parametreleri Tablo 1'de, çekme-makaslama test numune ölçüleri ise Şekil 2'de verilmiştir. Kaynaklı numunelere manyetik parçacık testi yapılarak SMK nedeniyle oluşan çatlaklar tespit edilmiş, METACUT 302 metalografik numune kesme cihazı ile kaynak bölgeleri, çatlak oluşum yerlerinden kesilmiştir. Kaynaklı numuneler kaynağın kesit bölgesinden ECOPRESS 52, otomatik kalıplama presi ile bakalite alınarak, numune yüzeylerine FORCIPOL 202 zımparalama ve parlatma cihazı ile standart metalografik yöntemle zımparalama ve parlatma işlemleri yapılmıştır. Numune yüzeyleri Nikon Epiphot 200 Inverted model optik mikroskopla incelenerek SMK çatlakları tespit edilmiş olup, çatlak uzunlukları ölçülmüştür. Belirlenen SMK çatlakları CARL ZEISS ULTRA PLUS GEMINI FESEM model taramalı elektron mikroskobu ile detaylı incelenerek çatlaklar üzerinden elementel analiz (EDS) yapılmıştır. Çekme-makaslama testleri 5 mm/dk çekme hızında ve 50kN kapasiteli SHIMADZU cihazında gerçekleştirilerek, farklı kaynak parametreleriyle elde edilen kaynak çiftlerinin mekanik özellikleri karşılaştırılmıştır.

Tablo 1. Kaynak işleminde kullanılan kaynak parametreleri.

Numune No	Kaynak akımı (kA)	Elektrod kuvveti (bar)	Darbe (puls)	Kaynak zamanı (ms)	Dövme zamanı (ms)
N1	8,5	250	2	200	300
N2	9,2	300	1	300	300
N3	8	300	3	500	300



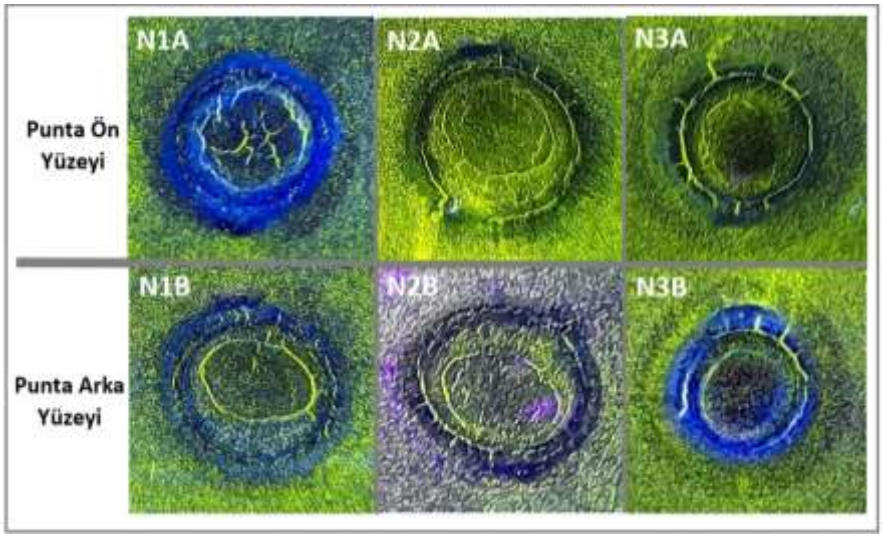
Şekil 2. Çekme-makaslama test numunesi ölçüleri.

3. SONUÇLAR VE TARTIŞMA

SMK hassasiyetine sahip çelik bir malzeme üzerine üç farklı kaynak parametresi ile nokta direnç kaynağı ile birleştirilmiş kaynaklı numunelerden elde edilen sonuçlar ve yorumlamaları aşağıda verilmiştir.

3.1. Manyetik Parçacık Testleri

SMK analizlerinde meydana gelen çatlakları tam olarak tespit etmek önemlidir, aksi takdirde elde edilen veriler yanlış ve yanıltıcı olabilir. Kesitlerini alarak numunelerin makro ve mikro inceleme yöntemi, yüzey çatlaklarını tespit etmek için sıklıkla kullanılmaktadır. Kesme hattının çatlaklardan geçip eçmediğinden emin olmak ve dikkat etmek gerekir. Ancak punta yüzeyinde meydana gelen birçok çatlak sığ olduğundan yüzeyde görülemeyebilir. Sıvı penetrasyon testi, X-ışını testi gibi tahribatsız muayene yöntemleri, nokta kaynaklarının yüzeyindeki derin çatlakları tespit etmek için kullanılabilir. Bu çalışmada, floresan manyetik parçacık testi yöntemi tel kesme ile kesit almadan önce nokta kaynaklarının yüzeyindeki çatlakları tespit etmek için kullanılmıştır. Üç farlı parametre ile elde edilen numunelere ilk önce manyetik parçacık testi yapılmış punta yüzetindeki SMK çatlak yoğunluğu ve yerleri tespit edilmiştir. Şekil 3'te manyetik parçacık test sonuç görselleri görülmektedir. Şekil değerlendirildiğinde tüm numunelerde gerek kaynak metalinde gerekse ITAB'da çatlakların olduğu ve çatlak miktarlarının kaynak esnasındaki parametre değişiminden etkilendiği bir gerçektir.



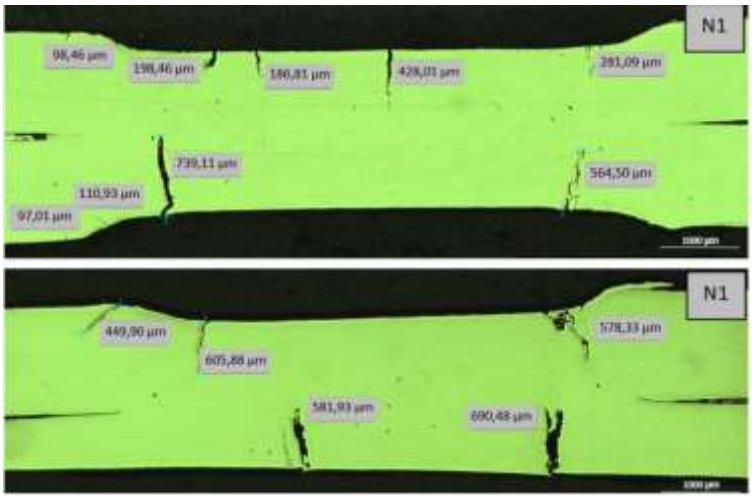
Şekil 3. Manyetik parçacık test sonucu örnekleri.

Manyetik parçacık testi sonuç görsellerinden yararlanılarak kaynaklı numunerin kesitleri çatlakların yoğun olduğu doğrultuda Şekil 4'de görüldüğü gibi arayüzey makro yapı analizleri için alınmıştır. N3 numaralı numune iki parçaya bölünerek kesitleri incelenirken N2 üç parçaya bölünerek kesitlerin arayüzeyleri incelenmiştir.

Şekil 4. Manyetik parçacık testi için numune hazırlana görseli.

3.2. SMK makro yapısı ve EDS analizleri

Farklı nokta direnç kaynak parametreleri kullanılarak birleştirilen kaynaklı numunelerden elde edilen makro görüntüler Şekil 5-7 aralığında verilmiştir.

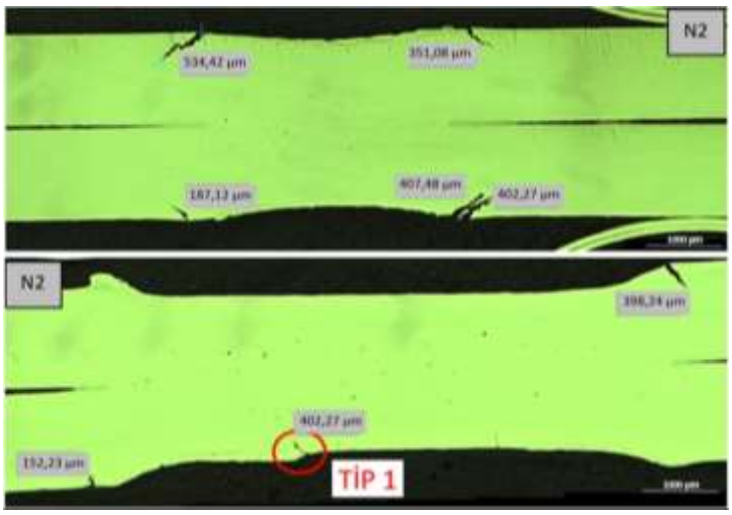


Şekil 5. N1 kodlu numunelerden alınan mikro çatlak görüntüleri ve çatlak uzunlukları.

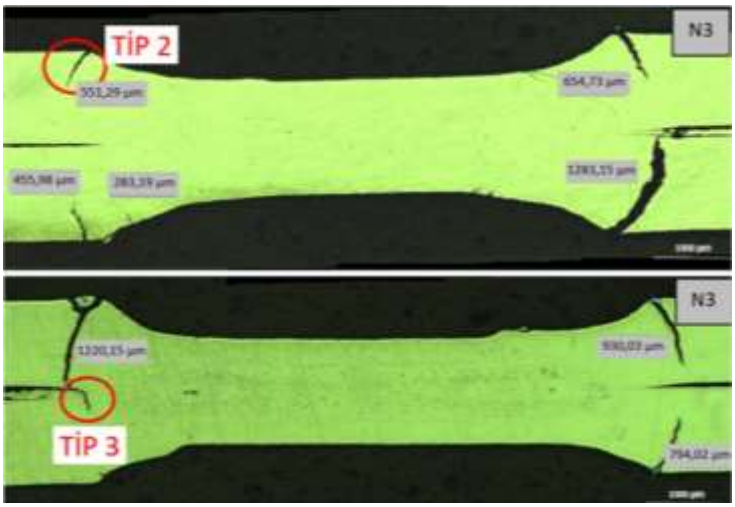
Şekil 5, 6 ve 7'de kesit alınan punta kaynaklı numunelerin optik mikroskop ve elektron mikroskobu arayüzey incelemeleri gerçekleştirilmiş olup tespit edilen çatlaklar ölçülerek toplam derinlikleri hesaplanmıştır. N1'e ait toplam çatlak derinliği 5611,04 µm, N2'ye ait toplam çatlak derinliği 2835,767 µm ve N3'e ait toplam çatlak derinliği 6172,54 µm olarak tespit edilmiştir. Nokta direnç punta kaynağında ısı girdisi aşağıda 1 nolu denklemde görülen eşitlik ile hesaplanmaktadır. Q ısı girdisi, I kaynak akımı, R elektrik direnci, t kaynak zamanı ve K ise ısı kayıpları olarak tanımlanır.

$$Q = I^2 RtK \quad (1)$$

Numuneler, N1'e ait baskı kuvveti dışında aynı koşullarda kaynak operasyonuna tutulmuştur. Bu nedenle, 1 nolu denkleme göre R ve K sabit olarak kabul edilmiş N2 ve N3 kodlu numunelerin ısı girdilerini hesaplanmış, N2'ye ait ısı girdisi değeri 25,392 olarak tespit edilirken N3'e ait değer 96.000 olarak tespit edilmiştir.

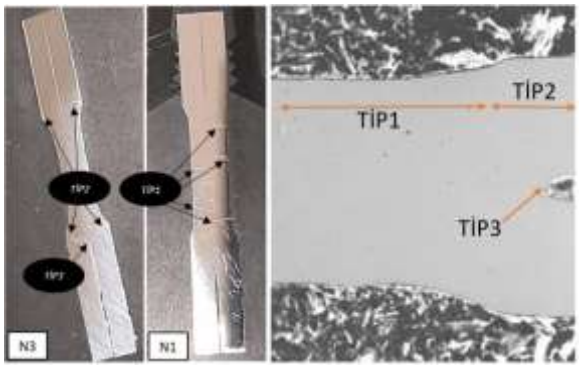


Şekil 6. N2 kodlu umunelerden alınan mikro çatlak görüntüleri ve çatlak uzunlukları.



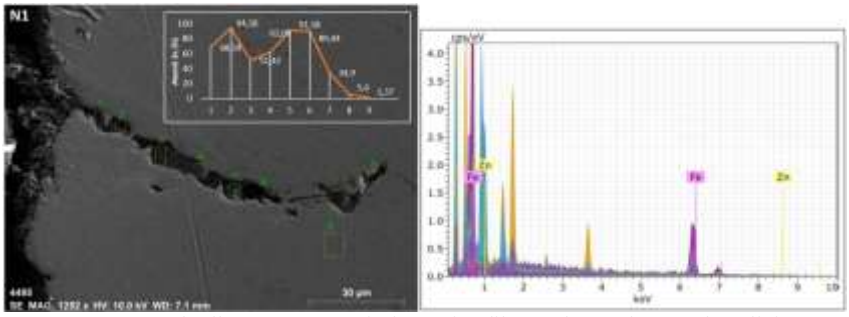
Şekil 7. N3 kodlu numunelerden alınan mikro çatlak görüntüleri ve çatlak uzunlukları.

Bu çalışmada kaynak numunelerinde bulunan çatlaklar literatür verileri ışığında üçe ayrılmıştır (Şekil 8). Bu çatlaklar; -kaynak esnasında elektrodun baskısı altında oluşan çatlaklar (Şekil 6) (TİP 1), -elektrod girintisinin altında ve ITAB'da bulunan çatlaklar (Şekil 7) (TİP 2) ve -birleştirilen malzemelerin arayüzelerinde bulunan çatlaklar (Şekil 7) (TİP 3) olarak belirlenmiştir. Tumulurdu LME hassasiyeti olan çelikler üzerine yaptığı çalışmasında SMK çatlaklarını 3 sınıfta toplamıştır. Tip 1 çatlaklar, elektrot girintisi altında bulunanlardır, Tip 2, ısıdan etkilenen bölgede (ITAB) elektrot girintisinin dışında meydana gelenlerdir ve Tip 3, iki sacın arayüzeyinde bulunanlardır (Tumulurdu, 2019).

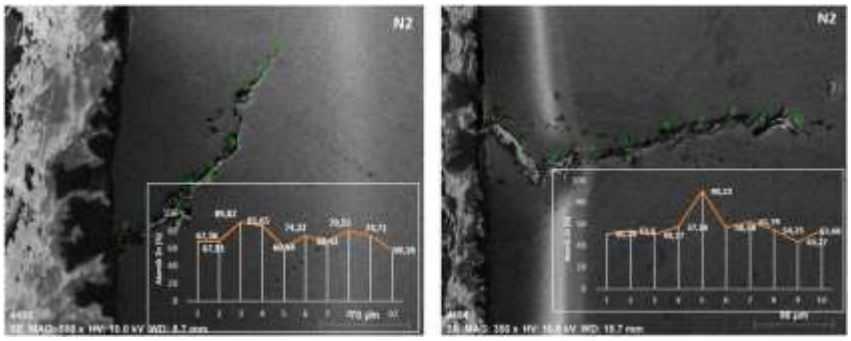


Şekil 8. Meydana gelen SMK çatlaklarının sınıflandırılması.

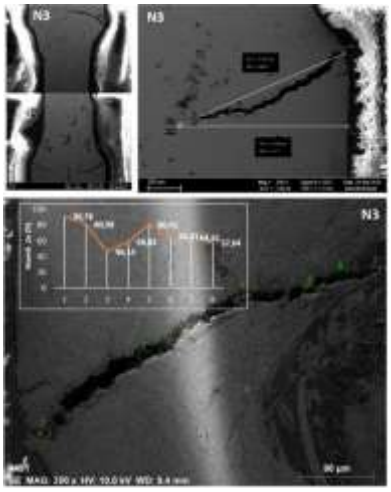
Nokta direnç kaynak yöntemi ile farklı kaynak parametrelerinde birleştirilen kaynaklı numunelerde bulunan çatlak bölgeleri EDS çalışmaları ile analiz edilmeye çalışılmış ve elde edilen sonuçlar Şekil 9-11 arasında numune kod sıralamasına göre verilmiştir. Tespit edilen söz konusu çatlaklar, taramalı elektron mikroskobu (SEM; Scanning Electron Microscope) ile tespit edilip çatlak yüzeyinden kaynak çekirdeğine doğru EDS (EDS; Energy Dispersive X-ray Spectroscopy) dedektörü ile bölgesel elemental analizler yapılmıştır. Şekil 5, 6 ve 7'ye ait çatlaklara elemental analiz yapılarak SMK çatlakları olduğu varsayılan çatlakların başlangıcından bitişine kadar rastgale aralıklarla yapılan bölgesel elemental analizler gerçekleştirilmiştir. Gerçekleştirilen analizlerde çatlak içlerinde Zn aranmış ve yüzeyden derinlere indikçe Zn oranlarındaki değişim gözlemlenmiştir. Kırık içi yapılan atomik boyuttaki elemantal analiz sonuçları incelenen mevcut çatlakların SMK çatlağı olduğunun göstergesi olarak kabul edilse de bu çalışma EDS çalışma prensibinden kaynaklı olabilecek hataların bilincinde gerçekleştirilmiştir. Çünkü yer yer boş (içinde malzeme olmayan) kırık içlerinden alınan elemental analiz değerleri yanıltıcı olabilir. Ayrıca çatlak içerisinde mevcut olan çinko seviyesi, tarama yapılan malzeme seviyesinden düşük olduğu için elde edilen sonuçların net doğruluğunu söylemek gerçekçi olmayabilir. Bu nedenle SEM görüntüleri üzerinde çizilen Zn grafiğinin dalgalı bir seyir göstermesi bu bilgileri doğrular niteliktedir.



Şekil 9. N1 kodlu numune üzerinde tespit edilen çatlağın elemental analizi.



Şekil 10. N2 kodlu numuneye ait çatlakların elemental analizi.



Şekil 11. N3 kodlu numuneye ait SMK çatlak görüntüleri ve çatlakların elemental analizi.

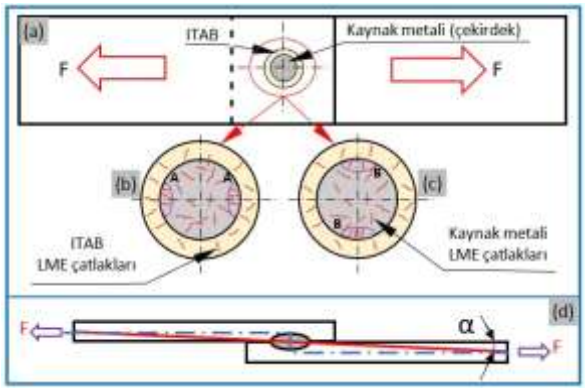
Şekil 9-11 arası verilen EDS analiz sonuçlarına göre, analiz yapılan tüm çatlaklarda çinkonun bulunduğu ancak miktarının net olarak ölçülemediği söylenebilir. Ling ve arkadaşları galvanizli Q&P980 çeliğinin direnç nokta kaynağı sırasında SMK çatlamasına karşı duyarlılığı araştırırken çatlaklara enine EDS çizgi tarama analizi yapmışlar ve haritalama sonuçlarına göre Zn içeriğinin tüm çatlaklarda farklı olduğunu tespit etmişlerdir (Ling, Chen, Kong,Wang, Pan, Lei. 2019). Murugan ve arkadaşları çatlaklar boyunca elektron probu mikro analizi (EPMA) yapmışlar ve aldıkları sonuçlara göre tüm çatlakların çinko veya çinko ve bakır karışımı içerdiğini kanıtlamışlardır. Yüzeye yakın tüm çatlakların başında yaklaşık %80 civarında çinko olduğu gözlemişler ve çatlak derinleştikçe çinkonun giderek azaldığını ve %5- seviyelerine kadar düşebildiğini tespit etmişlerdir. Puntanın merkezine doğru meydana gelen çatlaklarda çinko içeriği %80 civarında iken diğer lokasyonlardaki çatlakların %30-40 civarında çinko içerdiğini rapor etmişlerdir (Murungan, Vijayan, Park. 2020).

3.3. Çekme Makaslama Testleri ve Kopma Modları

Yapılan çekme-makaslama testleri sonucunda her bir kaynak parametresinde birleştirilen 3 kaynaklı numunenin kaynak bölgesinden (kaynak metali ve ITAB) ölçülen çekme-makaslama dayanımlarının birbirlerinden uzak olduğu Şekil 12'de görülmektedir. Burada en büyük fark N1 nolu numunede ölçülürken onu sırasıyla N3 ve N2 numuneleri takip etmektedir. Bu sonuçlar Şekil 1'de verilen manyetik parçacık test görüntüleri ile birlikte değerlendirildiğinde uyum içerisinde oldukları söylenebilir. Öncelikle kaynak metalinde bulunun çatlak miktarının artmasının, çekme-makaslama dayanımını düşürdüğü bir gerçektir. Kaynak metalinde bulunan çatlak miktarının artması da çekme testi esnasında çentik oluşturma ihtimalinden dolayı artmakta dolayısıyla da mukavemet değerleri azalmaktadır. Şekil 12'de verilen çekme-makaslama değerlerinin parametre değişimlerine bağlı olarak birbirlerinden farklılık göstermesi Şekil 13 a'da verilen şematik gösterim ile açıklanabilir. Burada çekme-makaslama testi esnasında ilk yüke maruz kalan kısmın A ile gösterilen bölge (Şekil 13 b) olduğu düşünüldüğünde bu kısmın çentik etkisi oluşturarak kopmanın düşük yüklerde gerçekleşmesine sebebiyet verecektir. Aksi durumda yükün ilk maruz kalacağı bölgede çatlak olmayışı veya çatlak yönünün kopma eksenine göre çentik etkisi oluşturacak biçimde konumlanmaması mukavemetin yüksek değerlerde ölçülmesi ile sonuçlanacaktır (Şekil 13 c). Ayrıca kaynaklı bölge çekme testi esnasında hem çekme kuvvetine hem de kesme kuvvetine maruz kalmaktadır. Bu durum Şekil 13 d'de şematik olarak gösterilmiştir. Çekme-makaslama testi esnasında kaynak metali sadece nötr eksende (mavi çizgi) çekmeye maruz kalmayıp aynı zamanda α açısında çapraz çekmeye (kırmızı çizgi) zorlanmaktadır. Bu nedenle kaynak metalinde bulunan SMK çatlakları ilk olarak kesmeye maruz kalan bölgeye denk geldiğinde bağlantı dayanımının düşük olacağı bir gerçektir. Sonuç itibarı ile kaynak esnasında kaynak metalinde oluşan çatlakların miktarı, konumu, büyüklüğü (derinliği) ve çekme yönüne göre açıları son derece önemli oldukları bir gerçektir. Bu nedenle aynı parametrede birleştirilen ve çekme-makaslama testine tabi tutulan üç numunenin her birinden ölçülen değerler arasındaki farkın belirgin olmasının beklenen bir sonuç olduğu söylenebilir.

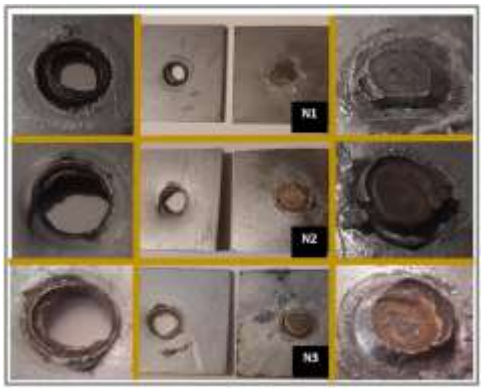
	N1	N2	N3
1. ölçüm	9,2	19,14	14,04
2. ölçüm	20,88	24,38	18,96
3. ölçüm	16,35	25,18	11,94
Ortalama	15,47	22,9	14,98

Şekil 12. Kaynaklı numunelerin çekme-makaslama sonuçları.

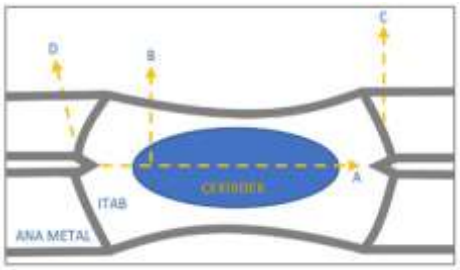


Şekil 13. Kaynak bölgesi çatlak oluşumu (şematik).

Şekil 14'de kaynaklı numunelerin kesme-makaslama test sonrasında kopma yüzeyleri verilmiştir. Kaynaklı numunelerdeki kopma tipi düğmelenme tipi kopma olduğu görülmüştür. Nokta direnç kaynaklı numunelerin kopma türlerinin arayüzey ayrılması "Mod A" olarak adlandırılırken, kısmi arayüzey ayrılması "Mod B" ve düğmelenme "Mod C ve Mod D" olarak üç farklı şekilde meydana gelmekte ve adlandırılmakta olup Şekil 15'de şematik olarak gösterilmiştir (Xinmin, Xiaoyun, Yansong, Guanlong, 2007). Arayüzey ayrılması tipi kopmayı gösteren Mod A'da kopmanın punta arayüzeyini tam merkezden ikiye bölen, orta bölgesindeki çizgi doğrultusunda merkeze doğru ilerleyerek meydana gelen kopma tipidir. Arayüzey ayrılması kaynak parametrelerinin yetersiz olduğunu, düşük ısı girdisine bağlı olarak meydana gelen yetersiz kaynak bölgesini gösteren kopma tipidir. Mod A ayrılma ile sonuçlanan birleştirmelerin çekme-makaslama taşıma yükü değeri düşüktür. (Chao, 2003)



Şekil 14. Çekme makaslama testleri sonrasında meydana gelen hata modları.



Şekil 15. Çekme-makaslama ve çapraz-çekme test numunelerinde karşılaşılan kopma türleri.

Mod B'de kopmanın kaynak çekirdeği arayüzeyinde başladığı ve kaynak çekirdeği orta bölgesindeki çizgiye dik doğrultuda devam ederek kısmi arayüzey ayrılması tipi sergilediği görülmektedir. Düğmelenme tipi kopmalar ise genellikle ITAB'ın dış kısmında meydana gelmektedir. Ana malzeme/ITAB ara yüzeyinden Mod C şeklinde veya sadece ana malzemeden Mod D şeklinde meydana gelebilir. Nokta direnç kaynaklı birleştirmelerin çekme-makaslama testi sonrasında kopma türlerinin düğmelenme tipi olması istenir. Düğmelenme tipi kopma, kaynak parametrelerin uygun olduğunu gösteren kopma türüdür (Pouranvari, Ranjbarnoodeh 2012). Şekil 14'de verilen kopma modları incelendiğinde her üç numunenin de düğmelenme modunda koptuğu ancak düğme büyüklüklerinin farklı olduğu görülmektedir. Bu sonuç çekme-makaslama değerleri ile birlikte yorumlandığında düğme çapından ziyade çatlağın konum ve büyüklüğünün çekme-makaslama dayanımı üzerinde daha etkili olduğu söylenebilir.

4. SONUÇLAR

SMK, katı metalin uygun sıcaklık ve stres koşulları altında sıvı metal ortamında gevrekleşmesi olarak bilinmektedir. Bu çalışmada Zn kaplı 3. Nesil çeliklerin RSW sırasında LME oluşumu gözden geçirilmiştir.

- Punta kaynaklarının yüzeyine açılan SMK kaynaklı çatlaklar NDT ve optik/elektron mikroskobu görüntüleme yöntemleri ile görüntülenmiştir.
- Çatlak içi ve dışı yapılan atomik boyuttaki elemantal analiz sonuçları çatlakların SMK çatlağı olduğunu göstermiştir. Çatlak içi elemental analiz sonuçları çatlak boyunca çinko oranın %40 ila %90 aralığında değiştiğini göstermiştir.
- Çatlak bölgesine bağlı olarak üç farklı çatlak tipi tanımlanmıştır.
- Kaynaklanabilirlik çalışmaları, kaynak sırasında ısı girdisinin artmasıyla çatlamanın şiddetinin arttığını göstermektedir.
- SMK çatlak miktarı, konumu ve büyüklüğü ile çekme mukavemeti kaybı arasında bir ilişki olduğu görülmüştür. Çatlak konumu ile mukavemet kaybındaki değişimin çatlağı çevreleyen stres alanları ile açıklanabildiği söylenebilir.
- SMK çatlaklarının şiddeti tanımlanırken çatlak konumunun mutlaka dikkate alınması gerektiği sonucuna varılmıştır.
- Çalışma kapsamında her 3 numunede meydana gelen kopma türü düğmelenme modunda olup, elektrod girintisi çevresinde ana metalde meydana gelen SMK çatlakları ayrılmaya sebebiyet vermiştir.
- Aynı parametrede birleştirilen ve çekme-makaslama testine tabi tutulan üç numunenin her birinden ölçülen değerler arasındaki fark oldukça belirgindir. Bu belirgin farkın sebebi kaynak esnasında kaynak metalinde oluşan çatlakların miktarı, konumu ve çekme yönüne göre açıların farklı olmasıdır.

INVESTIGATION OF THE EFFECTS OF HELIX ANGLE AND INLET VELOCITY ON COLLECTION EFFICIENCY IN AN AXIAL CYCLONE SEPARATOR

Emre Oruç, İrfan Karagöz[1]

Bursa Uludag University, Department of Mechanical Engineering, Bursa, Turkey
[1] Correponding Author: İrfan Karagöz, karagoz@uludag.edu.tr

ABSTRACT

Cyclone filters, which have many application areas, are also used in air intake systems of heavy vehicles and construction machines. Cyclone models with three different helix angles in the same body structure were numerically examined. The analysis were performed at three different inlet velocity applying the RSM (Reynold Stress Model) turbulence model. In addition, by applying DPM (Discrete phase model) method and injection of particle sizes from 0,1μm to 10μm into the cyclone separator in two phases, the collection yields and total collection efficiency results were obtained. Accordingly, it was concluded that the collection efficiency increases exponentially with increasing inlet velocity and decreases with increasing helix angle.
Keywords: Axial cyclone separator, helix angle, inlet velocity, pressure drop,

1. INTRODUCTION

Cyclone separators are effective elements in comparison to other systems used for particle removal in industrial field and they are much simpler and more efficient. They are frequently being preferred methods in many areas of industry, especially in mining, chemistry, textile, medical industry, vacuum cleaner industry, test separation and heavy vehicles and where dust removal processes are present. In general, two different cyclone designs exist. These are axial and revers-flow (tangential) cyclones. Each design differs according to the place and application conditions. Therefore, choosing the optimum cyclone model is indispensable. In order to pre-select the optimum model, many different experimental and theoretical studies have been performed by researchers. Although cyclone separators do not look like complex systems, they are many distinct parameters affecting their performance. Many researchers have investigated how these parameters affect the performance of cyclone separators and found many different experimental and numerical studies. As a result of the experimental and numerical studies, they determined how different performance parameters such as collecting efficiency, pressure losses, classification efficiency of cyclone separators affects the cyclone separators. Gong et al. (2012) studied on an axial flow cyclone separator. They investigated the effects of the helical structure on the axial cyclone separator of the cyclone separator. In their numerical analysis, they made different inspections with the RNG k-ε turbulence model and RSM turbulence models and emphasized that the RSM model gives more accurate results in comparison to the k-ε turbulence model. They also stated that the change of the helix angle has a significant effect on the collecting efficiency and pressure drop of the cyclone separator. They stated that the decrease of the helix angle of the cyclone separator result in increase of the collection efficiency and pressure drops. Especially the turbulence model chosen in numerical studies is of great importance in terms of the accuracy of the study. Gimbun et al. (2005) numerically analyzed the impacts of temperature and inlet velocities of Stairmand and Bohnet type cyclones on cyclone pressure drop using CFD method. During their analysis, they used different turbulence models and investigated the superiority of these models over each other. They compared the results of numerical analysis with other experimental studies in the literature. As a result of these comparisons, they stated that while the RSTM turbulence model was verified with only 3% deviation supported by the experimental data, this error margin was between 14-18% in the RNG k-epsilon model. Wu et al. (2016) conducted analyzes with different vortex finder designs for an axial cyclone model. In their studies, they investigated the effects of the conical design in the immersion pipe and the spaces on the vortex finders on energy efficiency. They used the RSM model as a turbulence model. Based on the entropy values, they determined the energy consumption values. They examined the cyclone model in four different regions and determined its effects on total energy consumption. They achieved the maximum separation effect while reducing the energy consumption amount by an average of 35% with their own design. Eddy forces generated in the cyclone separator are one of the most important parameters affecting performance in axial cyclone separators. Teke (2010), in his Numeric study, examined the effect of this expansion on pressure losses by enlarging the inlet cross section area of a cyclone separator. When he compared his results with each other, he observed that pressure losses increased by increasing the entrance area provided that the outlet pipe diameter remained constant. Another point is that inlet velocities had an effect on pressure losses. He stated that the pressure loss increases as the inlet velocity increases in his

studies with 5 different cyclone separator models, namely fixed entrance area and fixed exit area, at velocities of 5.1, 10, 15, 20 and 25 m/s. In addition, he emphasized that the change did not affect the pressure losses much in his analyzes by changing the aspect ratios in the inlet region by keeping the entrance area of the cyclone separator inlet section constant, but he emphasized that the differentiation became more visible as the ratio increased, and stated that this was due to the effect of the change in tangential velocities. In this case, it has been shown that increasing the flow rate for cyclone separators in general increases the performance of the cyclone. In addition, pressure losses are an important factor for cyclone separators, because in places where there are no natural forces, it determines the amount of energy that the fans will spend. (Luan et al. 2014), in their study, the performance effect of resistances on axial cyclone separators and Wu et al. (2016) examined the performance effects of different constructions of the outlet pipe in axial cyclone separators. In this study, the performance parameters of an axial cyclone separator were numerically analyzed. Cyclone models with three different helix angles were analyzed at different inlet velocities. The effect of these analyzes on individual collection efficiency in particle sizes from 0,1µm to 10µm was investigated. In addition, analyzes were performed using the RSM turbulence model. Particles were injected using the DPM feature. Accordingly, it was determined that the input velocity and helix angle are one of the most important parameters of the collection efficiency.

2. Numerical Simulation

One of the most important functions affecting the cyclone working efficiency in axial cyclone separators is the vortex forming constructions. In this study, the effects of vortex formers on three different helix angles were investigated under different inlet velocity effects. Each model is designed with the help of CAD (Computer Aided Design) program. Cyclone length and body diameters are the same in all three designs, and the variable parameter was only the helix angles. The size of the cyclone body is also equivalent to the inlet area size and is designed in 18mm diameter. The cyclone length (excluding the outlet pipe, the part from the inlet to the particle collection area) is designed as 80 mm. The helical area starts 3 mm after the entrance and the helix start and end length is designed as 27mm. In this study, 3 different helix angles were determined for 3 different cyclone models. A spiral winding with a diameter of 18 mm around a 27 mm long shaft is designed in 1, 2 and 3 turns. From here, the helix angle of the 1st, 2nd, and 3rd models are 56.3°, 36.8° and 26.5°, respectively.

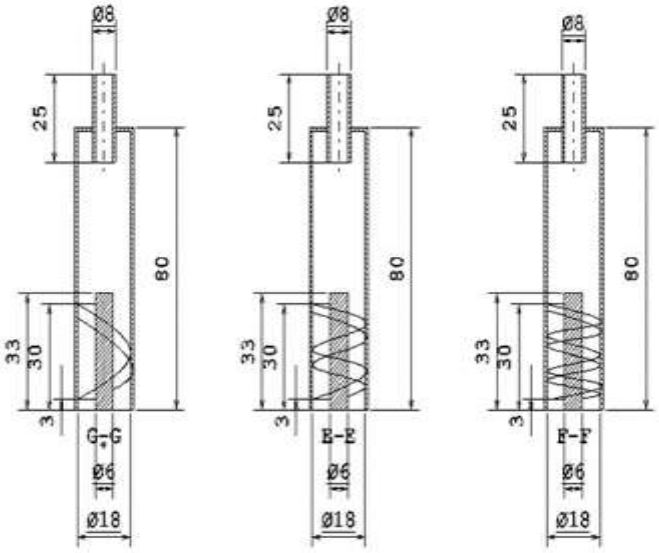

Fig.1. Cyclone Separators Modeled According to Different Helix Angles Drawing Image

2.1. Mesh Generation

In this study, an axial flat bottom cyclone separator was numerically analyzed at different inlet velocities and different helix angles. Mesh grids were created with the help of Ansys (19.1) Workbench software. Tetrahedral grids have been preferred due to some complex regions in the geometry. The grid properties are given in Table 1. and model mesh construction is given in figure 2.

Table 1. The grid properties of Cyclone Separator Models

Mesh Properties	**Model 1**	**Model 2**	**Model 3**
Element Type	Tetrahedron	Tetrahedron	Tetrahedron
Number of Element	615368	630465	646576
Number of Nodes	119683	123135	126795
Max. Skeewnes	0,83	0,82	0,81
Min. Orthogonal	0,17	0,18	0,19
Max. Element Size	1 mm	1 mm	1 mm
Average Element Size	0,5 mm	0,5 mm	0,5 mm

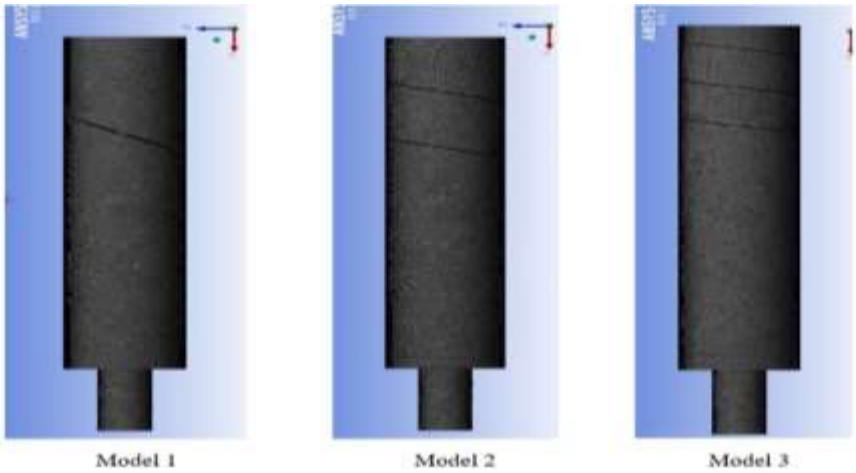

Fig.2. Mesh Structure for Each Model

Analyzes were double checked by increasing the grid number for each model. Illustrating the independence of the study from the grid elements was aimed here. In the analysis made in the grid elements 790453, 932218 and 1050882 for model 1, in the numbers of 811767, 958528 and 1078386 for model 2, and in the grid elements 831527, 982919 and 1107427 for model 3, the analyzes made in the grid elements given in table 1. were compared and the cyclone separator physical properties changes were found to be within acceptable values. This situation showed that the mesh independence of the study is valid in the values of the number of grids created.

The various terms in these equations are $D_{T,ij}$,C_{ij}, φ_{ij}, ε_{ij} and should be modeled to close these equations. However, C_{ij}, $D_{L,ij}$ and P_{ij} do not require any modeling. These sections describe the assumptions modeling required for equation set closing.

In each model, RSM as turbulence model and SIMPLEC as solution algorithm (semi-implicit method pressure-linked equations consistent), QUICK for momentum, PRESTO for pressure! (Pressure Staggering Option) were selected. In addition, second order values were selected for Turbulence kinetic energy and turbulence dissipation rate, and first order values for Reynold Stress.

2.2. Numerical Methods

Equations available in Fluent software were applied in this study. The models created were made ready for mathematical solution method after the mesh structuring was completed. First, after the equations solved in a single phase continuous regime converged with the RSM turbulence model, particles of certain sizes were injected into the system and two-phase flow was started. During this process, the DPM method was used. Particles from 0.1 micron to 10 micron were analyzed separately for each inlet velocity and model.

2.2.1. Single Phase Flow Model

The flow field created as the first model was realized by using the Reynolds stress turbulence model. RSM model are extremely useful equations especially for cyclone separators. RSM can be considered as the most complex turbulence

model provided by ANSYS FLUENT. RSM has the potential to give accurate predictions for complex flows as the mechanism explains the effect of curvature of rotation, eddy and strain rate changes in a better and much more convergent way than other equation models.

2.2.2 Boundary Conditions

Three different boundary conditions are defined for the axial cyclone separator as inlet, outlet and Wall. The defined boundary conditions are entered into the system as common for each model.
Inlet: For the axial cyclone separator, 3 different inlet velocities were used in 3 different models (5, 10, 15 m / s). Air was injected into the system with the cyclone separator inlet cross section perpendicular to the normal. Fluid parameters for axial entrance; fluid density is defined as ρ = 1,22 kg / m3, fluid viscosity μ = 1,79e-05. In addition, the turbulence density is 5%, the turbulent viscosity ratio is 10 and the roughness value is 0.5.
Outlet: Cyclone separator outlet pipe has been analyzed as open to atmospheric environment. The fluid outlet zone is pressure centered.
Wall: No-slip boundary condition called no-slip has been applied for the wall zone.
Reflect: The reflect boundary condition is used for wall regions. In this way, the particles entering into the cylinder followed a path without getting lost in the system until the outlet or collection area.
Trap: This boundary condition is defined for the region where the particles will be held. With this definition, the particles reaching the trap surface are assumed to be kept in that area and cannot continue to move in the cylinder.
Escape: With this boundary condition, the particles entering the cyclone separation continue to the fluid outlet without being held by the cyclone separator and are deemed to have left the cyclone separator after reaching this area.
For DPM, Max. Number of step = 50000, Step length factor = 5 and Total flow rate = 1e-20 kg /s.

3. RESULT

3.1. Flow Parameters in Single Phase Flow

3.1.1 Pressure Drop

In the study, physical conditions were determined before the particles were injected into the system. The pressure contours created for each model and inlet velocity are shown in the figure 3.

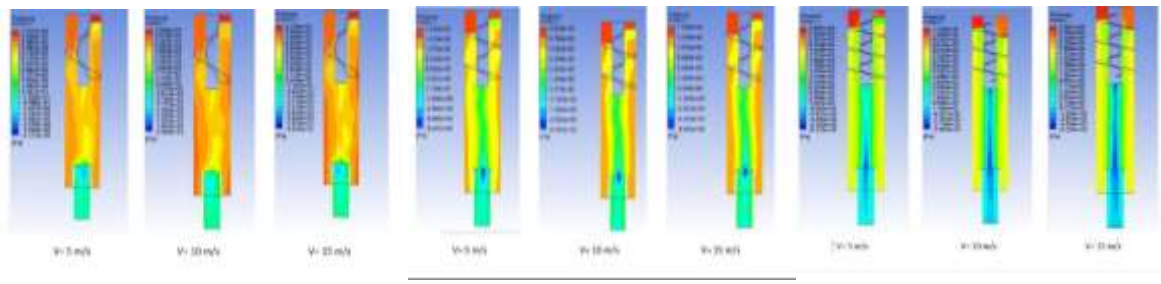

Fig. 3. Contours of Static Pressure (pa) for Each Model and Each Inlet Velocity

As seen in the figure 3. the regions where the pressure differences are high are generally higher in the area around the body cylinder than in the center. This is due to the vortex effects that occur within the body cylinder. The fluid in the center moves faster than the wall. In this case, the pressure increases from the center to the wall. Negative pressure zones are also observed in some regions in the center. This situation is expected in vortex flows.

In general, when comparisons are made for three different models, the regions of pressure change that occur are the same, but their values differ. Pressure zones, which vary in experimental and numerical studies by Gong (2012), show similarities.

When the pressure values are compared for all three models in Figure 3. one of the main reasons affecting the pressure changes is undoubtedly the differences in the inlet velocity. It has been observed that as the velocity of the fluid entering into the cyclone separator increases, the pressure differences in the cyclone separator also increase. Another main reason that increases the pressure difference is the difference in the helix angle. Pressure differences decrease with increasing helix angle. The reason for this is that the vortex effects occurring in the cyclone separator decrease with the increase of the helix angle and as a result, the fluid in the cyclone separator becomes stagnant.

3.1.2. Velocity Distributions

Cyclone separator analyzes are extremely complicated and difficult to solve systems. It is very difficult to make experimental calculations especially in the regions inside the cyclone separator. For this reason, CFD-based solutions are extremely important in this kind of analysis. In the study, velocity profiles were created within the cyclone separator for each model and inlet velocity. A virtual plane passing through the center of the cyclone separator was taken as reference. The velocity profiles are shown in contours in Figure 4.

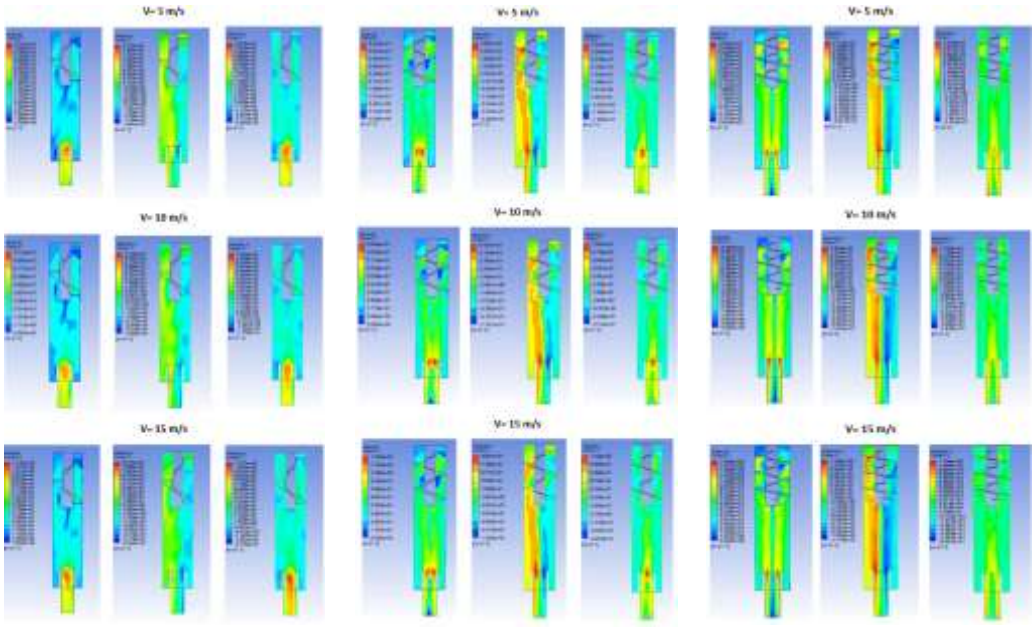

Fig. 4. Velocity Distributions Contours Display for Each Model

As seen in Figure 4., as the fluid velocity entering into the cyclone separator increases, the velocity values inside the cyclone increase locally. In addition, it was determined that the helix angle increased the effect of velocity components in the cyclone separator. The separation force in cyclone separators arises from the centrifugal force provided by the cyclone to the air entering at a certain velocity due to its construction. Owing to the spiral shaped construction used, eddy and centrifugal forces occur. The greater the velocity of the dusty air entering the cyclone, the greater this centrifugal force. The centrifugal force of this force of the dusty air that makes the vortex movement gives them an inertia depending on the size of the particles it contains. This inertia take away them to the cyclone inner wall.

3.2. Separation Efficiency

In the study, the results of the analyzes performed in the solid-gas phase for each cyclone separator model were shared. The efficiency calculation for the cyclone separator was calculated as in Equation 1.

$$\text{cyclone collection efficiency} = \frac{\text{the number of particles helded in the dust collector}}{\text{total number of particles injected into the system}} \quad (1)$$

Particle sizes given in the charts are in micron size and dust collection efficiencies from 0.1 µm to 10 µm were calculated. Analyzes for each cyclone separator model were performed at 5, 10, 15 m/s inlet velocities. During the analysis a total of 1858 particles for each particle size were injected into the system. The amount of dust collected in the collecting area determined at the lower point of the cyclone body was compared with the total amount of dust.

3.2.1. Fluid Velocity-Collection Efficiency Relationship into the Cyclone Separator

In this study, calcium sulphate particles at three different inlet velocities were used for three different cyclone separator models and their separation efficiency was further investigated. These particles were injected into the cyclone separator in 20 different sizes from 0.1 micrometer to 10 micrometer in total. 1858 particles were injected for each particle size of

a specific 20 particle size. As part of the particle size analysis, 180 different analyzes were performed according to the model, inlet velocity and particle size variables in total, and the results were shared in graphics in Figures. 5, 6 and 7.

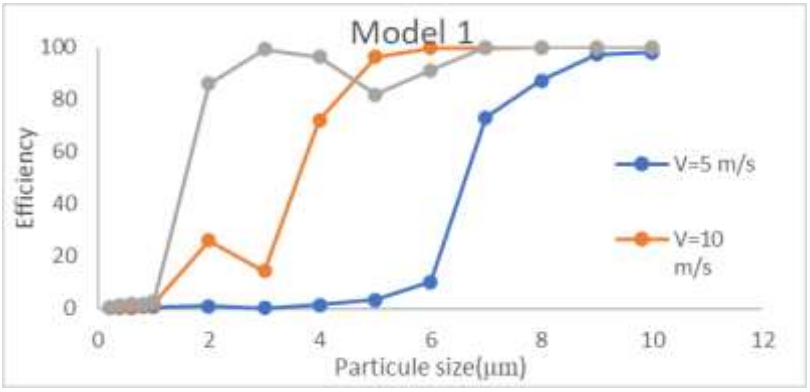

Fig 5. Collection efficiency for each inlet velocity for Model 1

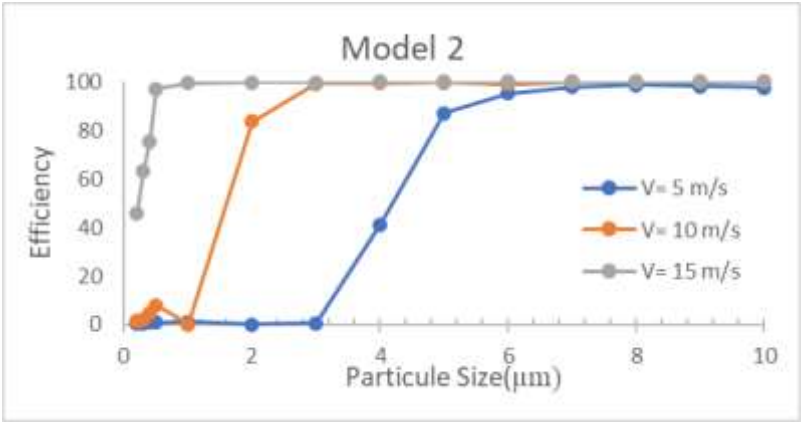

Fig 6. Collection efficiency for each inlet velocity for Model 2

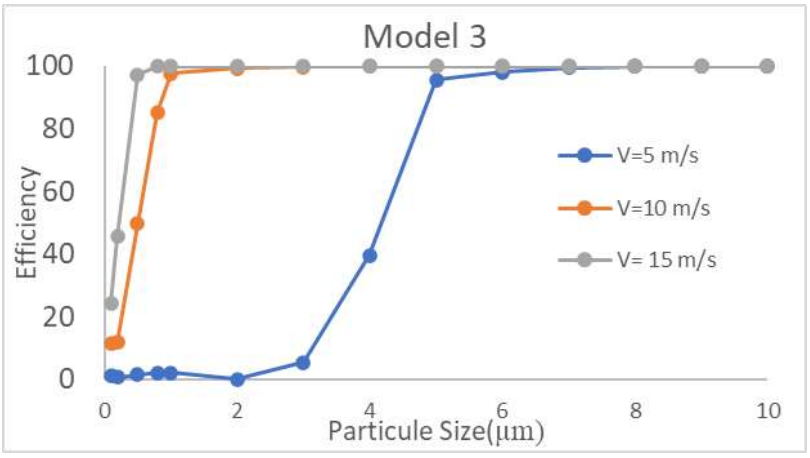

Fig 7. Collection efficiency for each inlet velocity for Model 3

As illustrated in Figures 5, 6 and 7, there is a direct proportion between the velocity of the fluid entering the cyclone separator and the collection efficiency. However, this relationship also increases the pressure losses that occur in the cyclone separator.

Karagöz et al. (2013), on the other hand, inspected the effect of the inlet velocity on the cyclone collection efficiency with the changes it made on the flow rate by keeping the other parameters for the cyclone separator constant. The obtained result clarified that the collection efficiency increased as the velocity increased, as it was also addressed and obtained in the present study. Again, Kaya and Karagöz (2009) observed that lower collection efficiencies at low cyclone separator inlet velocity would be obtained.

3.2.2. The Effect of Helix Angle on The Collection Efficiency

In this study, 3 different helix angles were determined for 3 different cyclone models. A spiral winding with a diameter of 18 mm around a 27 mm long shaft is designed to be 1, 2 and 3 turns. From here, the helix angle of the 1st, 2nd, and 3rd model is 56.3°, 36.8° and 26.5°, respectively. Analyzes were made for each model at 3 different inlet velocities

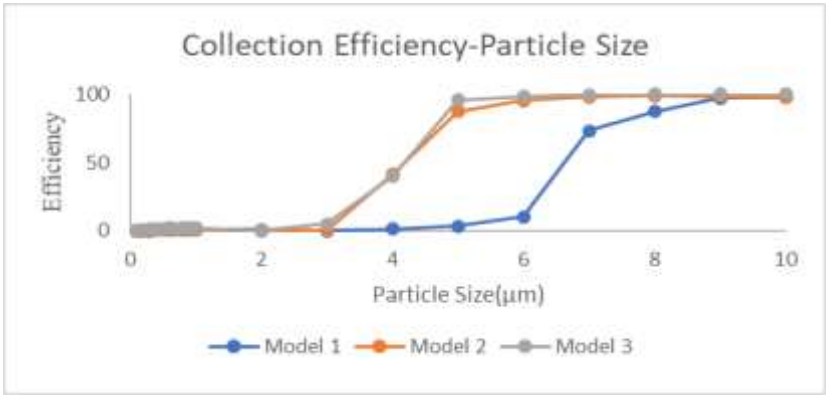

Fig 8. Collection Efficiency of Helix Angle For Each Model at 5 m/s inlet velocity

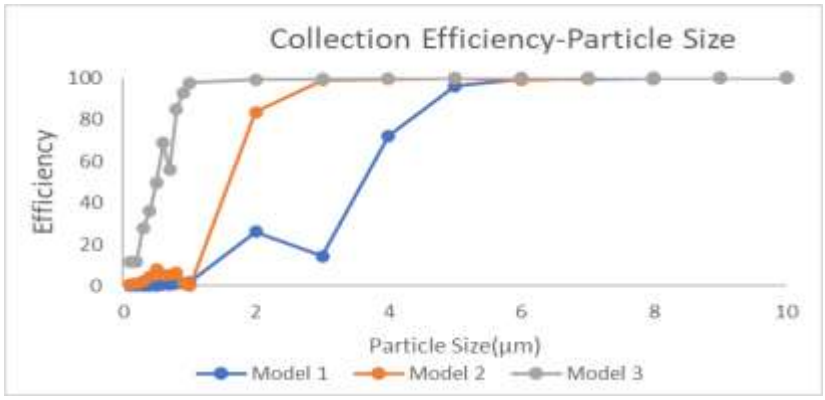

Fig 9. Collection Efficiency of Helix Angle For Each Model at 10 m/s inlet velocity

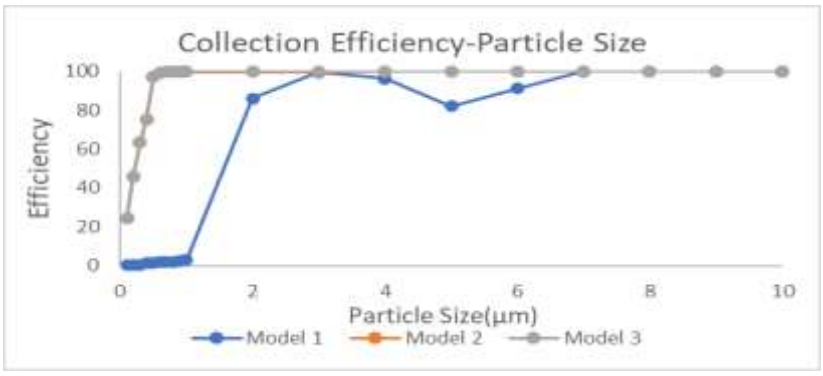

Fig 10. Collection Efficiency of Helix Angle For Each Model at 15 m/s inlet velocity

As illustrated in the figures 8, 9 and 10 the collection efficiency increases as the helix angle decreases. This is due to the decrease of the helix angle and increase of the number of spiral steps on the same length shaft. In this way, more effective swirl zones in the cyclone separator and more effective centrifugal forces towards the wall are formed. In this way, the collection efficiency increases.

In his experimental and numerical study, Gong (2012) made analyzes with the differences he created in helix angles. One of his results is that the collection efficiency increases with the decrease of the helix angle. He also backed his work numerically and experimentally.

4. CONCLUSION

In the study, cyclone models, which appear in the literature as axial cyclone separators, where the fluid enters and leaves the system on the same axis, were examined. Analyzes are created in computer-based software that relies on CFD science and is commercially available nowadays. In this study, Solidworks 2018 CAD software was used to create geometry, Workbench in ANSYS 19.1 to create a digital network, and Fluent software in ANSYS 19.1 to create analyzes. Both single-phase and multi-phase analyzes were carried out in the study. In the single-phase analysis, first of all, the physical conditions of the cyclone separator, ie pressure loss and velocity profiles, were determined. In the two-phase analyzes, particles were injected into the specified conditions. The behavior of these particles in the cyclone separator and the collection performance of the cyclone separator are calculated.

The velocity of the fluid entering the cyclone separator was examined for each model at 5, 10 and 15 m/s velocities. For all three models, it has been observed that as the velocity of the fluid entering the cyclone separator increases, the collection efficiency increases. In their studies, Zhu and Lee (1999) investigated the effects of the velocity of the fluid entering the cyclone separator on the cyclone separator collection performance and found that the collection performance increased with the increase of the fluid inlet velocity. This situation overlaps with our work.

Considering the effect of the helix angle on the cyclone separator, it was observed that the cyclone collection performance increased with the decrease of the helix angle. In other words, as the number of turns of the spiral structure used as a vortex generator at the inlet of the cyclone separator increases, the helix angle decreases and this in final increases the collection efficiency.

Another analysis on cyclone separator models is related to pressure drops. In three different cyclone separator models, as a result of the analysis performed at three different inlet velocities, it was observed that the pressure drops increased with the decrease of the helix angle. By keeping the models constant, it was observed that pressure drops increased again with the increase of inlet velocities. This is due to the increase of centrifugal forces in both components of the cyclone separator.

ÖZET

Son yıllarda yüksek enerji yoğunlukları ve uzun çevrim ömrü sayesinde lityum iyon bataryalar yoğun olarak araştırılmaktadırlar. Lityum iyon bataryalar, tüketici elektroniğinden savunma elektroniğine kadar geniş bir kullanım alanına sahiptir. Lityum iyon bataryaların kullanımının tehlikeli olması nedeniyle gerçekleşen hata ve arızalar geçmişten günümüze kadar can kayıplarına ve ekonomik zararlara sebep olmuştur. Bu sebeple kaza riskini azaltmak, fonksiyonlarının devamını sağlamak ve güvenirliği artırmak için makine ve araçlarda uzun yıllardır bakım yapılmaktadır. Bataryaların bakım planları, tahmin ve sağlık yönetimi yardımı ile sistemin duruma dayalı bakım planının bir parçası olarak güvenli bir şekilde kullanılmaktadırlar. Bataryanın tahmin ve sağlık yönetimi değerlendirmesinin temeli, bataryanın sağlık durumu ve kalan faydalı ömür tahminine dayanmaktadır. Bu çalışmada, bir lityum iyon bataryanın sağlık durumu ve kalan faydalı ömür bilgilerini tahmin etmek için Uzun-Kısa-Süreli Bellek Ağı yöntemi kullanılmıştır. Uzun-Kısa-Süreli Bellek Ağı yöntemi, NASA Ames Prognostics Center of Excellence veritabanında halka açık olan bir batarya veri kümesine uygulanmıştır. Deneysel sonuçlar, lityum iyon batarya uygulaması için Uzun-Kısa-Süreli Bellek Ağı algoritması kullanılarak bataryanın sağlık durumu ve kalan faydalı ömür tahmini sağlayabildiğini göstermektedir.

Anahtar Kelimeler: Lityum-iyon batarya, Tahmin ve Sağlık Yönetimi, Derin öğrenme, Uzun-Kısa-Süreli Bellek Ağı.

REMAINING USEFUL LIFE PREDICTION OF LITHIUM-ION BATTERY WITH A DEEP LEARNING-BASED MODEL

ABSTRACT

In recent years, lithium-ion batteries have been investigated intensively owing to their high energy densities and long cycle life. Lithium-ion batteries have a wide range of usage from consumer electronics to defense electronics. Due to the faults and failures caused by the unconscious use of lithium-ion batteries which accidents have caused loss of life and economic damage in many areas until today. For this reason, maintenance has been carried out on machines and vehicles for many years to reduce the risk of accidents, ensure the continuity of their functions and increase reliability. Batteries are used safely as part of the system's condition-based maintenance plan, with the help of maintenance plans, forecasting, and health management. The basis of the battery's prognostics and health management assessment is based on the battery's state of health and remaining useful life estimation. In this study, a Long-Short-Term Memory method is used for estimating the state of health and remaining useful life information of a lithium-ion battery. The Long-Short-Term Memory method is applied on a battery dataset, which is publicly available on the NASA Ames Prognostics Center of Excellence database. Experimental results demonstrate that the state of health and remaining useful life estimation can be provided by using the Long-Short-Term Memory algorithm for lithium-ion battery application.

Keywords:, Lithium-ion Battery, Prognostic and Health Management, Deep learning, Long-Short-Time Memory.

1. GİRİŞ

Lityum-iyon bataryalar, günümüzde ticarileştirilen ikincil bataryalar arasında en iyi derece enerji yoğunluklu bataryalardır. Diğer ikincil bataryalara kıyasla nispeten hafif olmaları ve yüksek enerji yoğunlukları nedeniyle taşınabilir ürünlerden büyük enerji depolama sistemlerine kadar teknolojinin çeşitli alanlarında yaygın olarak kullanılmaktadırlar. Özellikle elektrikli araçların yaygınlaşmasıyla birlikte batarya depolama kapasitesi ve kararlılık sorunlarını çözmek için lityum-kükürt, lityum-hava, sodyum-magnezyum ve katı hal bataryaları gibi yeni nesil bataryalar geliştirilmektedir ve aracın kilometre performansına katkısını arttırmaktadır. Lityum-iyon bataryalarda performans, maliyet, enerji yoğunluğu, güç yoğunluğu, güvenlik gibi parametrelerinin kıyaslanmasına dair detaylı bilgi için Hannan ve arkadaşlarının (2018) çalışmasına bakılabilir. Ancak bu yeni nesil bataryaların ticarileştirilmeden önce çözülmesi gereken pek çok sorunu mevcuttur. Bu nedenle, ileriye doğru hareket ederken, lityum iyon batarya pazarının genişlemeye devam etmesi beklenmektedir. Özellikle cep telefonu ve kişisel mobilite (elektrikli bisiklet, elektrikli mobilet vb.) pazarının büyümesiyle birlikte, verimli enerji kullanımı ve lityum iyon bataryaların kararlılık sorunu giderek daha önemli hale gelmiştir. Azaltılmış kullanım ömrü, tekrarlanan şarj-deşarj, aşırı şarj, aşırı deşarj ve aşırı akım gibi sorunlara neden olabilmektedir. Ayrıca, elektrikli bisikletlerin ev içinde şarj edilmesiyle birlikte ev sahipleri tarafından genellikle kullanım ömrü dikkate alınmadan şarj edilmektedir ve bu durumda oluşan aşırı ısınma ve ateşleme nedeniyle yangın kazalarına yol açmaktadır (Kim ve Moon, 2021).

Lityum-iyon bataryalar, nominal kapasiteleri başlangıç kapasitelerinin %80'inin altına düştüğünde ömrünü tamamlamış oldukları kabul edilmektedir (Cordoba-Arenas ve ark., 2015; Majeau-Bettez ve ark., 2011). Bu bataryaların ömrünün tahmin edilmesi, verimli kaynak kullanımı, istikrarlı yönetim ve enerji depolama cihazlarının istikrarlı kullanımı için çok önemlidir. Yaşam ömrünün tahmini üzerine çok fazla araştırma yapılmasına rağmen, temsili olanlar Sim ve arkadaşları (2013) tarafından yapılmış bir çalışmada iyi bir şekilde özetlenmiştir. NASA tarafından, bataryanın iç empedansı ölçülerek bir ömür çalışması önerilmiştir, ancak bu, pahalı ekipman ve karmaşık deneyler kullandığı için pratik uygulamalar için uygun değildir (Gao ve ark., 2017; Kim ve Moon, 2021).

Teknolojik olarak Tahmin Sağlık Yönetimi (PHM, Prognostics of Health Management), bir sistemin mevcut sağlık durumunu (SoH, State of Health) ve kalan faydalı ömrünü (RUL, Remaining Useful Life) tahmin etmeyi amaçlamaktadır (Qui ve ark., 2003; Wang ve ark., 2018; Jafed ve ark., 2017). Spesifik olarak RUL tahmini, sistem güvenliğini ve güvenilirliğini analiz etmek, garanti etmek ve geliştirmek için PHM'nin temel teknolojisidir. Genel olarak, tahmin değerlendirme için iki ana yaklaşım vardır; veriye dayalı ve fizik tabanlı modeller. Lityum-iyon bataryalarının RUL tahmininde veriye dayalı modeller literatürde çok ilgi görmektedir (Wang ve ark., 2018; Long ve ark., 2013; Liu ve ark., 2010; Chaoui ve ark., 2017, Xia ve ark., 2018; Liu ve ark., 2015; Zhou ve ark., 2016; Ng ve ark., 2014; Cheng ve ark., 2015; Yang ve ark., 2018; Khumprom ve Yodo, 2018). LSTM, veriye dayalı modeller arasında öne çıkan algoritmalardan birisidir.

LSTM tabanlı tahmin ve sağlık durumu yönetimi çalışmalarının son birkaç yılda gerçekleştirilen uygulamaları Tablo 1'de yer almaktadır (Kara, 2021).

Tablo 1. Son birkaç yılda gerçekleştirilen çalışmalarda lityum-iyon bataryaların LSTM modellerinin bir özeti

Referans	Yıl	Yöntem	Açıklama
Zhang ve ark.	2018	LSTM + RNN	RUL tahmini
Wang ve ark.	2018	DLSTM	Artımlı öğrenme ve L2 düzenlemesi ile RUL tahmini
Ellefsen ve ark.	2019	RBM + LSTM + GA	Yarı denetimli öğrenme kullanarak RUL tahmini
Hu ve Yu	2019	LSTM + DBN	RUL tahmini
Qu ve ark.	2019	LSTM + PSO	SOH ve RUL tahmini
Yong-sheng ve ark.	2020	CEEMDAN-LSTM	Yeni bir yaklaşım ile RUL tahmini
Wen ve ark.	2021	LSTM - tabanlı	Optimize edici (RS ve TPE) ile RUL tahmini
Yayan ve ark.	2021	LSTM - tabanlı	Yeni bir yaklaşım ile SOH tahmini
Kara	2021	CNN+LSTM+PSO	Hibrit bir yaklaşım ile SOH ve RUL tahmini

RS: Rastgele Arama (Random Search), TPE: Ağaç Parzen Tahmincisi (Tree Parzen Estimator)
RBM: Sınırlandırılmış Boltzman Makineleri (Restricted Boltzman Machines), GA: Genetik Algoritmalar (Genetics Algorithms)
RNN: Tekrarlayan Sinir Ağı (Recurrent Neural Network), PSO: Parçacık Sürü Optimizasyonu (Particle Swarm Optimization)
DBN: Derin İnanç Ağı (Deep Belief Network), CEEMDAN: Uyarlamalı Gürültü ile Tam Grup Ampirik Modu Ayrışma (Complete Ensemble Empirical Mode Decomposition with Adaptive Noise)

Bu çalışmada, lityum iyon bataryaların SoH ve RUL'sini tahmin etmek için Uzun Kısa Süreli Bellek Ağı (LSTM) kullanılarak veriye dayalı bir modelin ön çalışması sunulmuştur. Bu çalışmanın etkinliği, NASA Ames Prognostics Excellence Center'dan (PCoE) alınan lityum iyon batarya veri setinde test edilmiştir (Saha ve Goebel, 2007). Bölüm 2'de, PHM uygulamasına genel bakışı ve bu çalışmada kullanılan lityum-iyon bataryanın özellikleri sunulmuştur, Bölüm 3'te, LSTM analizi ve modellemesi incelenmiştir, Bölüm 4'te, deneysel sonuçlar yer alırken, Bölüm 5'te, sonuç ve gelecekteki olası çalışmalar yer almaktadır.

2. TAHMİNLER VE SAĞLIK YÖNETİMİ

PHM, sistemin duruma dayalı bakım (CBM, Condition-Based Maintenance) planının bir parçası olarak dahil edilmesi gerekmektedir. CBM planı önleyici bir strateji olarak kabul edildiğinden bakım görevlerinin yalnızca ihtiyaç duyulduğunda gerçekleştirileceği anlamına gelmektedir. Bu ihtiyaç, belirli bir sistemin bileşenlerinin sağlık durumu veya bir bütün olarak sistemin sağlık durumu sürekli olarak değerlendirilerek belirlenebilmektedir (Camci, ve Chinnam, 2010). CBM, teşhis ve tahmin olmak üzere iki ana görevi içermektedir. Teşhis, SoH olarak tanımlanan sistemin mevcut sağlık durumunun ve arızaların tanımlanması sürecidir, tahmin ise arızaya kadar geçen süreyi kestirim sürecidir. Bir arıza gözlemlenmeden önce kalan süre, bir sistemin kalan faydalı ömrü (RUL) olarak tanımlanır (Jennions, 2011). Sistemler arızalanana kadar çalıştığında ciddi olumsuz sonuçlardan kaçınmak için bakımlar sistem hâlâ çalışır durumdayken yapılması gerekmektedir. Bu tür bakımlar erken planlar ve hazırlıklar ile çözüme ulaşılmaktadır (Eker ve ark., 2012). Bu nedenle, özellikle kritik sistemler için CBM, sistemin işleyişinin bir parçası olarak uygun şekilde dahil edilmesi gerekmektedir. Sistemin tahmini, CBM'de çok önemli bir faktördür. Tahmin süreçleri ayrıca iki aşama içermektedir. Tahminlerin ilk aşaması, mevcut sağlık durumunu veya sağlık durumunu (SoH) değerlendirmeyi amaçlamaktadır. Literatürde bu aşamayı tanımlamak için genellikle kullanılan terimler, aynı zamanda tanılama kapsamında da değerlendirilebilecek olan, önem derecesi tespiti ve bozulma tespitidir. Bu aşamada örüntü tanıma gibi görevleri gerçekleştirmek için sınıflandırma veya kümeleme teknikleri kullanılabilmektedir. İkinci aşamada amaç, bozulma eğilimi tahmin edilerek ve kalan faydalı ömrü (RUL) belirlenerek arıza süresini tahmin edilmesidir. Trend projeksiyonu, izleme teknikleri veya zaman serisi analizi bu aşamaya dahildir. Tahmin analiziyle ilgili akademik makalelerin çoğu sadece ilk aşamayı ele almaktadır (Qui ve ark., 2003; Khumprom ve Yodo, 2018; Javed ve ark., 2017). Bu çalışma, batarya sistemindeki tahminler ile hem birinci hem de ikinci fazlarına odaklanılan hem SoH hem de RUL'u oluşturmayı ve analiz etmeyi amaçlamaktadır.

Genel olarak, tahmin değerlendirme için mevcut iki ana yaklaşım vardır; veriye dayalı model ve fizik tabanlı modeller. Veriye dayalı yöntemler, arızaya kadar çalıştırılan sistemlerden yeterli veri veya örnekler gerektirirken, fizik tabanlı yöntemler sistemin arızalarını arıza ilerleme fiziği yoluyla değerlendirir. Hem veriye dayalı hem de fizik tabanlı modelin ayrıca farklı gereksinimleri ve kullanım durumları vardır. Bu çalışmada, lityum-iyon batarya tahminlerinin veriye dayalı modeli ele alınmıştır.

2.1. Lityum-İyon Batarya Tahminleri

Bu çalışmanın tahmin analizinde kullanılan lityum iyon batarya verileri, NASA Ames Prognostics Excellence Center (PCoE) veri deposundan alınmıştır (Saha ve Goebel, 2007). Bu veri seti, 18650 boyutlu şarj edilebilir lityum iyon bataryaların test sonuçlarını içermektedir. Deneysel veriler, şarj, deşarj ve empedans olmak üzere üç farklı lityum iyon batarya çalışma test koşulundan elde edilmiştir. Bütün deneyler oda sıcaklığında gerçekleştirilmiştir. Şarj durumunda, gerilim 4,2 V'ye ulaşana kadar 1,5A sabit akımda gerçekleştirilmiştir ve ardından şarj akımı 20 μA'ya düşene kadar sabit bir gerilimde şarj etmeye devam edilmiştir. Deşarj durumunda, gerilim 2,7 V, 2,5 V ve 2,2 V'a düşene kadar 2 A sabit akımda da gerçekleştirilmiştir. Aynı testler 5, 6 ve 7 numaralı bataryalar için de yapılmıştır. NASA Ames, empedansı ölçmek için elektrokimyasal empedans spektroskopisi (EIS, Electrochemical Impedance Spectroscopy) yöntemi (0,1 Hz'den 5 kHz'e kadar frekans taraması) kullanılarak yapılmıştır. Birden çok döngüde tekrar tekrar şarj ve deşarj testleri yaparak, bataryaların yaşlanma özelliklerini hızlandırmaktadır. Bataryalar, nominal kapasiteden %30 azalma olarak tanımlanan ömür sonu kriterlerine ulaştığında testler sonlandırılmıştır (Khumprom ve Yodo, 2018).

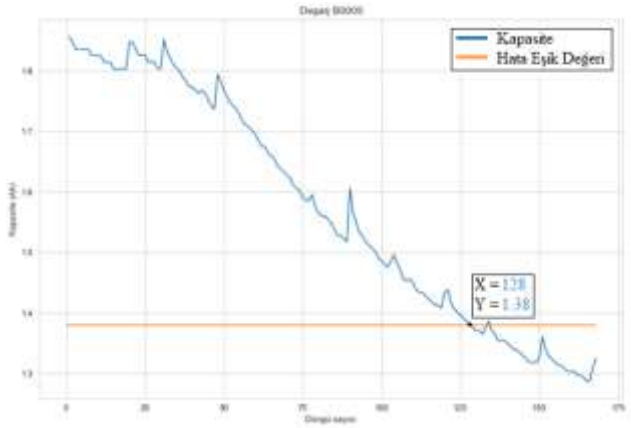
Batarya durum tahminini değerlendirmek için bataryanın SoH'si tanımlanmalıdır. Bu nedenle, SoH, RUL ile birlikte kullanılan veriye dayalı modelin ana tahmin özniteliği olacağından, SoH'nin net tanımı önemlidir. Bataryanın durum tahmin analizi için batarya veri setindeki bazı parametreler ile Şarj Durumu (SoC, State of Charge) ve SoH tanımı gereklidir. Lityum-iyon bataryanın bir döngüdeki şarj ve deşarj sürecine dair detaylı bilgi Wei ve arkadaşlarının (2018) gerçekleştirdiği çalışmada yer almaktadır. Bataryanın şarj durumu, batarya sisteminin güvenilirliğini göstermektedir. Literatürdeki SoC tanımı, mevcut şarj miktarı ile maksimum şarj miktarı arasındaki orandır (Yang ve ark., 2007; Bai ve ark., 2014). Bazı durumlarda, mevcut şarj miktarı, batarya üreticileri tarafından sağlanan nominal kapasite ile de değiştirilebilir. SoC matematiksel olarak Eş. (1)'de ifade edilmiştir.

$$SoC = \frac{Q_{mevcut}}{C_N} = \frac{Q_{mevcut}}{C_{max,p}} \quad (1)$$

Burada Q_{mevcut}, mevcut durumdaki şarj miktarını ve C_N ise batarya üreticisi tarafından belirlenen kapasite oranıdır. SoC'yi ölçmenin farklı yollarının yanı sıra SoH, batarya sağlığı yönetimi için bir başka önemli parametredir. SoH, batarya sisteminin sağlık durumunun doğrudan göstergesidir. SoH genel olarak Eş. (2)'de tanımlanmıştır.

$$SoH = \frac{C_{max,p}}{C_N} \quad (2)$$

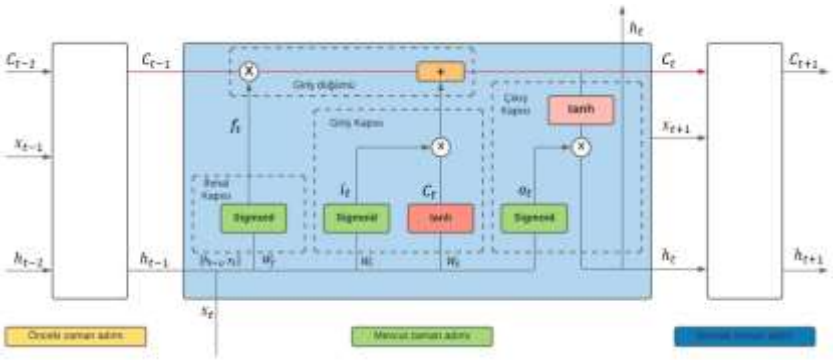
Burada $C_{max,p}$, mevcut zaman durumunda çalışan bataryadan ölçülen maksimum pratik kapasiteyi temsil etmektedir. Bu parametre bataryanın yaşlanmaya maruz kalmasının etkisiyle zamanla yok olabilmektedir. Bir batarya tahmin sağlık yönetimindeki en önemli görevlerden biri, $C_{max,p}$,'yi doğru bir şekilde tahmin etmektir, çünkü sırasıyla SoC ve SoH tahminleri için hem Eş. (1) hem de Eş. (2)'de $C_{max,p}$ gereklidir. Test edilen batarya veri seti, bataryanın tüm yaşlanma bilgilerini içermektedir ve bataryanın SoH değeri, döngü 0'dan döngü 168'e kadar hesaplanmıştır. Kapasitesi başlangıç değerinin %70'ine (1,38 Ah) düştüğünde batarya ömrünün sonlandığı kabul edilmektedir. Şekil 1'de 5 nolu bataryanın SoH eğrisinde döngü sayısı arttıkça SoH'sinin katlanarak azaldığı görülmektedir.



Şekil 1. Tüm Li-ion batarya ömrü boyunca kapasite değişim eğrisi

3. LSTM-TABANLI RUL TAHMİNİ

Gers ve arkadaşlarının (1999) önerdiği LSTM modeli, bu bölümde lityum-iyon batarya RUL tahmini için açıklanmıştır. Temel LSTM mimarisi Şekil 2'de gösterildiği gibi, x_t mevcut zaman adımındaki girdiyi, h_{t-1} önceki zaman adımındaki çıktıyı ve h_t geçerli zaman adımındaki çıktıyı temsil etmektedir. C_{t-1} önceki zaman adımındaki ve C_t mevcut zaman adımındaki hücre belleğidir. Hücre belleğinde yer alan bilgiler bilgi aktarımı için kullanılmaktadır. Bu bilgiler iletim boyunca değişime uğramamaktadır. LSTM temel olarak bir ihmal kapısı, giriş kapısı, giriş düğümü ve çıkış kapısı içermektedir.



Şekil 2. Temel LSTM iç yapısı (Gers ve ark., 1999)

İhmal kapısı, bilgilerin analiz edilmesi ile hücrede kalmasına karar verebilme yeteneğine sahip olduğundan çok önemlidir. Bu yüzden lityum-iyon batarya RUL tahmini için kullanılan ihmal kapısı, bir sonraki zaman adımının tahmin

sonucunu etkilemeyen önceki bazı gereksiz bilgileri atabilmektedir. Giriş kapısı ve giriş düğümü, depolanan yeni bilgilerin belirlenmesini sağlamaktadır. Çıktı kapısı, bilgi çıktısını sağlamaktadır. Bu nedenle, Şekil 2'ye göre, LSTM'nin temel formülleri aşağıdaki eşitliklerde ifade edilmektedir:

$$f_t = \sigma(W_f * [h_{t-1}, x_t] + b_f) \quad (3)$$

$$i_t = \sigma(W_i * [h_{t-1}, x_t] + b_i) \quad (4)$$

$$\tilde{C}_t = \tanh(W_C * [h_{t-1}, x_t] + b_C) \quad (5)$$

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \quad (6)$$

$$o_t = \sigma(W_o * [h_{t-1}, x_t] + b_o) \quad (7)$$

$$h_t = o_t * \tanh(C_t) \quad (8)$$

burada σ, sigmoid fonksiyonudur; W_f, W_i, W_C ve W_o ağırlık matrisleridir; b_f, b_i , b_C ve b_o bias vektörleridir. Lityum iyon batarya RUL tahmini için LSTM uygulandığında, üç sorun ortaya çıkmaktadır (Khumprom ve Yodo, 2018). İlk olarak, stokastik gradyan inişi (SGD, stochastic gradient descent), mini toplu gradyan inişi ve RMSprop gibi geleneksel gradyan iniş yöntemleri hızlı yakınsamayı garanti edememektedir. İkinci sorun, aşırı uydurma olgusudur. Son sorun ise dinamik tahmindir. LSTM'in hızlı yakınsamaya sahip olabilmesi için uyarlamalı moment tahmini (ADAM, Adaptive Moment Estimation) kullanılmıştır (Wang ve ark., 2018). Kingma ve Ba (2014) tarafından önerilen ADAM yönteminin, öğrenme hızı kaybını, yavaş yakınsamayı ve kayıp fonksiyonundaki önemli değişiklikleri önleyebildiği belirtilmiştir (Khumprom ve Yodo, 2018).

3.1. Değerlendirme Kriteri

Bu çalışmada, tahmin performansını değerlendirmek için ortalama karekök hatası (RMSE, Root Mean Square Error), ortalama mutlak hata (MAE, Mean Absolute Error) ve RUL tahmin hatası (RUL_{hata}) kullanılmıştır:

$$RMSE = \sqrt{\frac{1}{t}\sum_{i=1}^{t}(y_i - f(x_i))^2} \quad (9)$$

$$MAE = \frac{1}{t}\sum_{i=1}^{t}||y_i - f(x_i)|| \quad (10)$$

$$RUL_{hata} = RUL_{tahmin} - RUL_{gerçek} \quad (11)$$

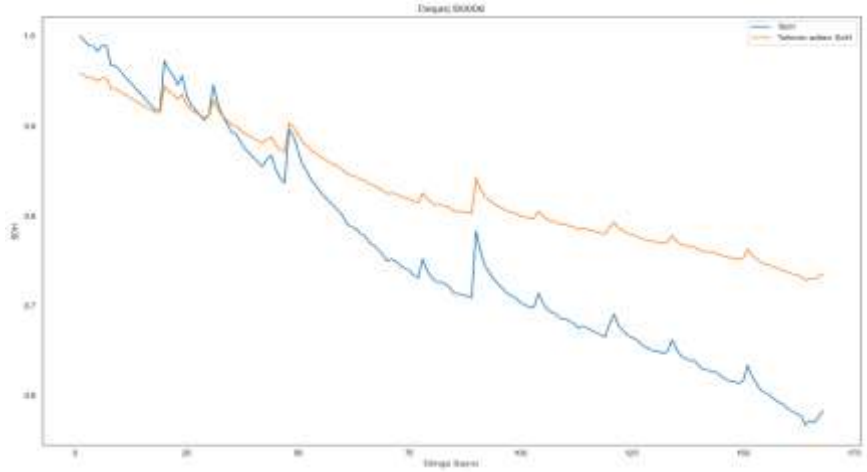
Burada, y_i gerçek değerdir ve $f(x_i)$ tahmin edilen değerdir; RUL_{tahmin}, tahmin edilen RUL'dur ve $RUL_{gerçek}$, gerçek RUL'dur (Wang ve ark., 2018).

4. DOĞRULAMA

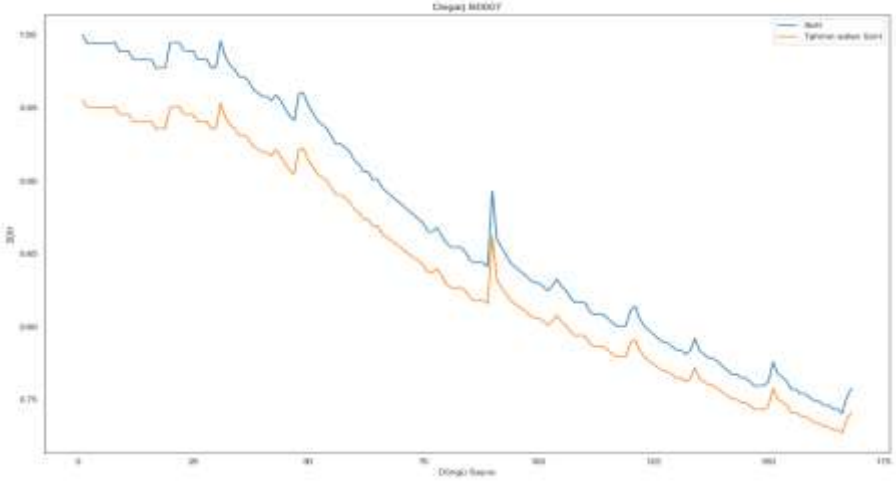
Derin öğrenme tabanlı model (LSTM), 5 nolu batarya üzerine kurulmuştur. Test için 6 ve 7 nolu bataryalar kullanılmıştır. Önce SoH bilgisi tahmin edilmiş ve daha sonra RUL tahmin edilmiştir (Tablo 2). SoH ve RUL tahminlerine ait grafikler Şekil 3'te sunulmuştur.

Tablo 2. Lityum-iyon bataryalarda SoH ve RUL tahmini sonuçları

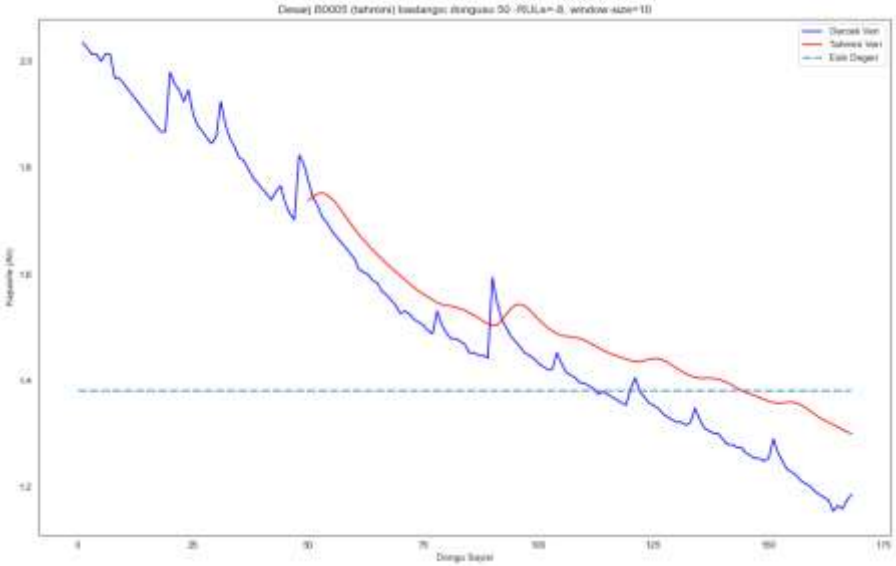
Batarya Numarası	SoH RMSE	RMSE	MAE	RUL_{hata}
#5	0.0895424	0.088	0.63792	32
#6	0.0923652	0.057	0.82514	22
#7	0.0304412	0.038	0.91305	15



Şekil 3a. 6 nolu bataryaya ait SoH tahminlerine ait grafik



Şekil 3b. 7 nolu bataryaya ait SoH tahminlerine ait grafik



Şekil 3c. 5 nolu bataryaya ait SoH ve RUL tahminlerine ait grafikler

5. SONUÇ

Tahmin ve sağlık yönetimi (PHM), lityum iyon bataryanın güvenli bir şekilde çalışmasını sağlayabilmektedir. Bataryanın tahmin ve sağlık yönetimi değerlendirmesinin temeli, bataryanın sağlık durumu ve kalan faydalı ömür tahminine dayanmaktadır. Bu çalışmada, bir lityum iyon bataryanın sağlık durumu ve kalan faydalı ömür bilgilerini tahmin etmek için Uzun-Kısa-Süreli Bellek Ağı yöntemi kullanılmıştır. Uzun-Kısa-Süreli Bellek Ağı yöntemi, NASA Ames Prognostics Center of Excellence veritabanında halka açık olan bir batarya veri kümesine uygulanmıştır. NASA #5, #6 ve #7 batarya veri setlerindeki doğrulama sonuçları, yöntemin uygulanabilirliğini ve etkinliğini göstermektedir. Ancak, çalışma koşulları ve ortam sabit kabul edilmiştir. Farklı işlemlere ve ortamlara dayanan lityum-iyon batarya ve çeşitli batarya verilerine dair RUL bilgisi, gelecekteki araştırmalarda dikkate alınacaktır. Ayrıca, lityum-iyon batarya PHM'si için belirsizliklerin yönetimi de önemlidir. Temel amacı, çeşitli belirsizliklerin etkisini analiz etmek ve tahminler için bir güven katsayısı sağlamaktır. Gelecekte, makine öğrenmesi ve derin öğrenme tabanlı belirsizlik teknolojileri, lityum-iyon batarya belirsizliklerinin yönetimini gerçekleştirmek için dikkate alınacak ve eklenecektir.

ÖZET

Otomotiv endüstrisindeki öncelikli konulardan biri olan araç ağırlık hafifletme çalışmaları, her yeni dönemde daha sıkı bir şekilde takip edilen emisyon hedeflerinin yakalanabilmesi ve araç yakıt ya da enerji tüketim değerlerinin en aza indirilebilmesi için gerekli bir koşul haline gelmiştir. Otomobil üreticileri, daha düşük emisyona sahip motor geliştirme ya da daha uzun menzile ulaşmayı hedefleyen elektrik motoru, batarya ve batarya yönetim sistemleri geliştirme çalışmalarının yanında, araç ağırlık hafifletme çalışmalarını da uygulayarak gerek hedef CO_2 emisyon değerlerine gerekse daha uzun menzil değerlerine ulaşabilmektedir. Araç ağırlık hafifletme çalışmalarında son yıllarda yüksek mukavemetli ve enerji sönümlemesi yüksek olan kompozit malzemelerin kullanımı araç gövdesinde yaygın kullanıma sahip çelik malzemelerin yerini almaktadır.

Günümüz otomotiv sektöründe artan rekabetin bir sonucu olarak; firmalar farklı pazar ve segmentlerdeki modelleri için araç gövdelerindeki yapıları mümkün olduğunca yoğun bir şekilde ortaklaştırarak maliyet yükünün azaltılması ve sonucunda azalan maliyetler ile ürün pazarlama açısından daha rekabetçi bir yapı elde etmeyi amaçlamaktadırlar. Geliştirilen araç mimarileri; üretilen modellerin hedef ihtiyaçlarını karşılayarak, bu modellerin üretildiği mevcut tesislerin üretim alt yapılarını da en az şekilde etkileyerek, ortak parça ve sistem kullanımının artırımıyla daha rekabetçi olmaktadırlar.

Bu çalışmada, üretimi devam eden Sedan model bir aracın alt gövdesi üzerinde, daha önce çelik malzemeden geliştirilen araç arka taban bölgesinin, mevcut araç mimarisinden beklenen yapısal performans hedeflerini koruyarak araç ağırlık performansını iyileştirecek şekilde kompozit bir malzeme ile yer değiştirecek şekilde tekrar tasarlanması süreci, bu sayede araç hafifletme çalışmalarının farklı boyutlarda araç gövdelerine de uygulanabilirliğinin analizi ve tasarım girdileri incelenmiştir.

REDESIGN OF SPARE WHEEL WELL AREA IN AUTOMOBILES USING COMPOSITE MATERIAL WITHIN THE SCOPE OF MODULARITY

ABSTRACT

Vehicle weight reduction, which is one of the priority issues in the automotive industry, has become a necessary condition for achieving emission targets that are more strictly followed in each new period and minimizing vehicle fuel or energy consumption values. Automobile manufacturers can reach both target CO_2 emission values and longer range values by applying vehicle weight reduction studies as well as developing engines with lower emissions or developing electric motors, batteries and battery management systems that aim to reach longer range. In recent years, the use of high-strength and high-energy absorbing composite materials in vehicle weight reduction studies has replaced steel materials that are widely used in vehicle body.

As a result of the increasing competition in today's automotive sector; The companies aim to reduce the cost burden by commoning the structures in the vehicle bodies for their models in different markets and segments as intensely as possible and to achieve a more competitive structure in terms of product marketing with reduced costs. Developed vehicle architectures; They become more competitive by meeting the target needs of the models produced, by minimally affecting the production infrastructure of the existing facilities where these models are produced, and by increasing the use of common parts and systems.

In this study, the process of redesigning the rear floor part of a Sedan passenger car, which was previously developed from steel material which is still in production with a composite material to improve the vehicle weight performance while maintaining the structural performance targets expected from the existing vehicle architecture, thus Analysis of the applicability of vehicle lightening studies to vehicle bodies of different sizes and design inputs were examined.

Keywords: GMT, GMTex, composite material, weight reduction, modularity, modular design

1. Giriş

Modüler bir ürün tasarlamanın en önemli artılarından biri üretim esnekliğine sahip oluşu ve yeniden tasarım şartlarında azaltılmış Ar-Ge giderleri ile fayda sağlamasıdır. Ön ürün tasarımı sırasında, modülerliği bileşenlere ve alt sistemlere akıllıca tasarlamak, başarılı bir ürün hattının geliştirilmesine yönelik önemli bir adımdır [1]. Modülerlik, ürün geliştirmede veya endüstriyel üretim konfigürasyonunda birçok endüstriyel sektör tarafından benimsenen bir stratejidir. [3] İlk olarak, modülerlik faaliyetlerinin çoğu, öncelikle stratejik olarak maliyet düşürme odaklı görünmektedir [6], [7]

Otomotivde araç gövde mimarisi bütünleşik olarak tasarlanır. Esnek olmayan platform tasarımlar üzerinde yapılacak değişiklikler için, yeniden tasarlama ve üretim planlaması açısından tekrar bir çalışma gerekliliği ortaya çıkmaktadır bu sebeple esnek olmayan mimariye sahip platform tasarımlar, alternatif tasarım türevleri türetme konusunda başarılı değildir [2].

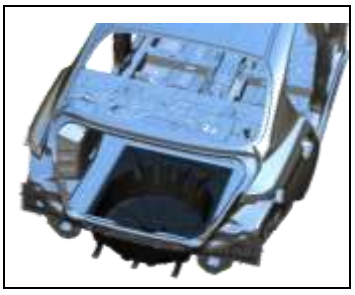
Ayık; çalışmasında [5]. Modular yaklaşımın avantajları ve dezavantajlarından bahsetmiş ve otomotiv sektöründe modülerlik kavramının tasarım üzerinde etkilerinden ve faydalarından bahsetmiştir. Ayrıca otomotiv endüstrisinde modülerlik kavramı ve ortak platform tasarımları geliştiren otomotiv üreticilerinin platform tasarımları hakkında detaylı bilgiler vermiştir.

Bu çalışmada üzerinde çalışılan araç gövdesi üzerinde, aracın ön ve orta bölümü aynı kalacak şekilde sadece arka bölgenin tasarımında yapacağımız ölçüsel değişiklikler ile farklı uzunluklara sahip araç gövdeleri aynı üretim proseslerinden geçerek üretilmektedir.

Aracın boyutlarında değişiklik yapılsa bile motor, şanzıman, aktarma organları, süspansiyon ve benzeri parçaların şasi üzerine monte edildiği noktalarda değişme gerçekleşmemektedir. Ayrıca tasarım esnasında birçok farklı motor tipine göre tasarım yapılabileceğinden dizel, benzin, hibrit araç modelleri arasında geçişte araç gövdesinde minimal değişiklikler ya da herhangi bir değişiklik yapılmaksızın kullanılabilmektedir. [2]. [6]

Otomotiv sektöründe en önemli konulardan biri de araçtan beklenen tüm isterleri yerine getirebilecek hafif araç gövdesi ile yakıt tüketimini azaltarak çevreye duyarlı bir otomobil üretmektir. [4]. Bu sebeple son yıllarda çelik malzeme kullanımı yerini hafif, yüksek mukavemet ve yüksek korozyon direncine sahip kompozit malzemelerin kullanımı almıştır.[8]

Bu çalışmada çelik tasarım ile yapılmış sedan araç alt gövdesine sahip yedek lastik bölgesi yüksek mukavemet ve enerji emilimine sahip GMT/GMTex malzeme (glass mat termoplastik) kullanılarak kompozit olarak yeniden tasarlanmış ve tüm çevre gövde saclarına entegre edilmiştir [9], [8]. Gerçekleştirilen modüler tasarım ile araç performans isterleri sağlanarak araç gövdesi üzerinden 2 kg ağırlık avantajı sağlanmıştır.



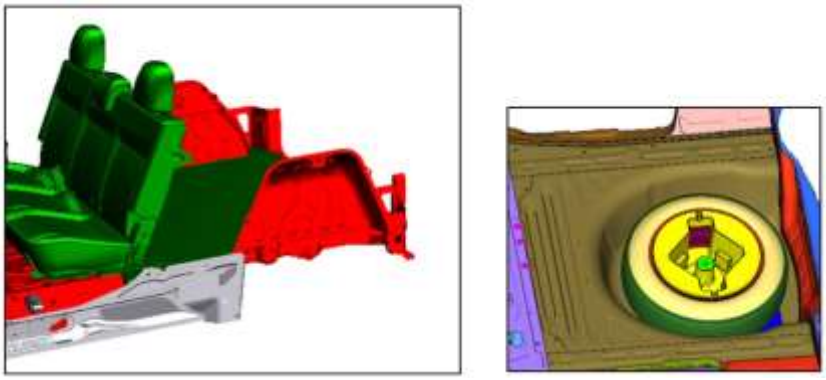
Şekil 1. Kompozit tasarımın araç gövdesine yerleşimi

1.1. Araç Gövde Tasarımının İncelenmesi

Otomobilin tüm bileşenlerinin, üzerinde taşıdığı alt gövdenin arka bölümünü oluşturan ve yedek lastik bölümü olarak bildiğimiz bölge; aracın arka şasi kollarını birleştiren ve arkadan çarpma performansında etkili bir bölgedir. Sekil 2'de görüldüğü gibi, arka bölgenin altında aktarma organları ve tüm motor seçeneklerini kapsayan egzoz sistemi mevcuttur.

Şekil 2. Alt gövdenin arka bölümünün araç altı görünümü

Sekil 3 (a)'da arka bölgenin üst kısmında da arka koltuk bağlantıları, yedek lastik ve tamir kiti mevcut olur. Yedek lastik bölgesinin üzeri halı ile kaplanmaktadır. (b)



(a) (b)

Şekil 3. Alt gövdenin arka bölümünün üstten görünümü

Bölgenin araç performansı incelenmiş, ağırlık azalımı yapılacak bölge sınırları belirlenerek, yeni kompozit parçanın araç gövdesine yerleşimi belirlenmiştir. Buradaki en önemli kriter oluşturulacak modüler yapı ile araç üretim hattında ortaklaştırmayı sağlamaktır.

Şekil 3'te görüldüğü gibi Sedan -HB ve SW model araçlarda ortak platform kullanılmış olup değişen araç uzunlukları sebebiyle sadece arka taban bölgesinde araç gövdesinde spesifik farklılıklar yapılmıştır. Sedan araç üzerinde yeniden tasarladığımız kompozit tasarımı, esnek modüler tasarım avantajını kullanarak diğer platformlara da yaygınlaştırıla bilirliği görülmüştür.

Şekil 3. Sedan-HB ve SW araç alt gövde tasarımları

1.2. Kompozit Parçanın Gövde Üzerinde Tasarımı

Aracın arka taban bölgesinde bulunan yedek lastik sacı sağ ve sol yanda bulunan arka şasi kollarına nokta direnç kaynağı ve gövde macunu ile sabitlenmektedir. Buradaki nokta direnç kaynak pozisyonları ve adetleri ile gövde macunu pozisyonları aracın performansını etkileyen etmenlerden biridir. Şekil 4'te çelik tasarım ile yapılmış arka şasi kolu

parça komplelerini ve kompozit parça tasarımı ile tekrar düzenlenen parça tasarımları gösterilmiştir. Burada mevcut sac kalitesi ve kalınlıkları korunmuştur.

Şekil 4. Arka şasi kollarında yapılan tasarım değişiklikleri

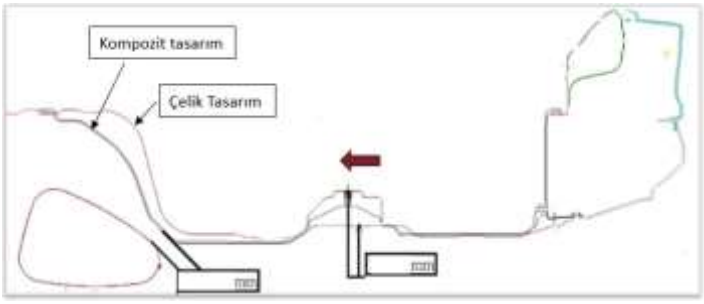
Burada en önemli hususlardan biri aynı parçaların aynı araç gövde üretim hatlarında kullanılabilmeleridir. Gövde üretim referanslarında bir değişiklik olmadan tasarım yeniden oluşturulmuştur.

Şekil 5'te aracın arka bölgesini oluşturan üst gövde üzerindeki arka panel parçanın tasarımı (a) kompozit parçanın araca yerleştirilmesini sağlayacak şekilde tasarım optimize edilmiştir. Böylece araç ağırlığının azaltılması ve istenen ağırlık azalımı hedefine ulaşılmasına katkı sağlamıştır. (b). Güncellenen ilk tasarım üzerine kompozit parçanın araca montajını sağlayacak şekilde yüzey ve formlar yapılmıştır. Sekil 6'da kompozit parçanın araca yerleşim kesitleri gösterilmiştir. Aynı tasarım optimizasyonun diğer platformlara da modüler tasarım avantajı sebebi ile uygulanabilir olduğu belirlenmiştir.

(a) Çelik tasarım (b) Kompozit tasarım

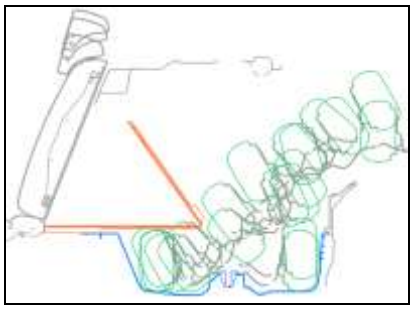
Şekil 5. Arka şasi kollarında yapılan tasarım değişiklikleri

Burada kompozit parçanın araca yerleşimini sağlamak ve yedek lastik bölgesinin hacmini araçta tekrar konumlandırmak gerekliliği sebebiyle; araçtaki yedek lastik yerleşim bölgesi araç önüne doğru kaydırılmıştır. Şekil 6'da Çelik tasarım ve kompozit tasarımın kesit durumu verilmiştir. Belirtilen ok yönünde yedek lastik tekrar konumlandırılmıştır.



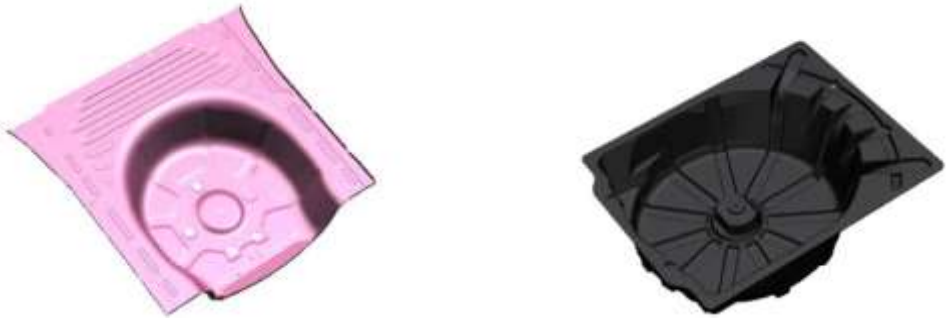
Şekil 6. Kompozit parçanın araçtaki yerleşimi

Tasarım tekrar oluşturulurken araç normlarına uygunluğu tekrar analiz edilmiştir. Burada Şekil 7'ye yedek lastik çıkarma/alma ergonomi sanal doğrulama analizleri yeni tasarıma göre tekrar yapılmıştır.



Şekil 7. Yedek lastiğin araçtan çıkarma/alma sanal doğrulaması

Mevcut tasarımı çelik olan (a) yedek lastik sacı bölgesinde, yeniden tasarlanan kompozit parça tasarımına, parça rijitliği sağlamak amacı ile formlar ve bölgesel federler eklenmiştir. Parçanın ilk öngörü tasarım sonrasında sayısal analiz hesaplarından ve kompozit parça kalıplana bilirlik geri dönüşleri ile tasarım nihai duruma gelmiştir. (Şekil 8) Kompozit parça üzerinde ağrılık optimizasyonu sağlamak amacı ile parça kalınlıkları bölgesel değişkenlik göstermektedir (b).

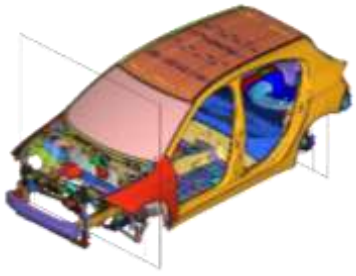


(a) (b)

Şekil 8. Yedek lastik bölgesi sac ve kompozit tasarımı

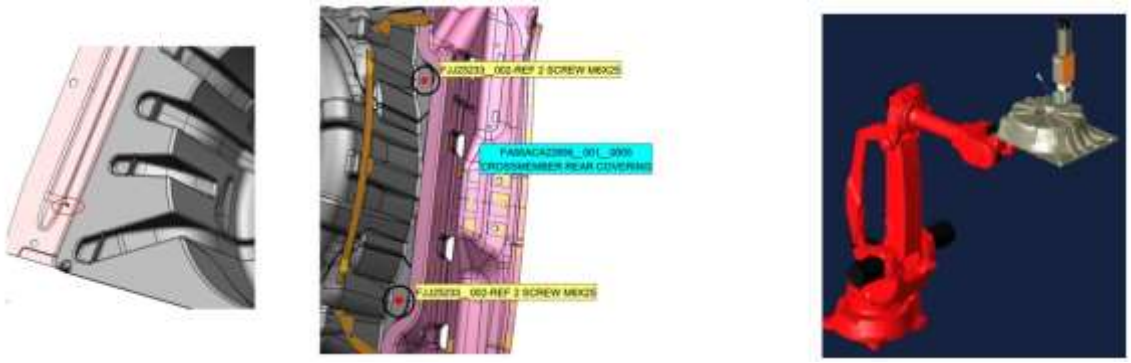
2. Modüler Tasarımın Sayısal Analiz ve Üretim Doğrulamaları

Yapılan sayısal analiz çalışmalarında, araç gövdesi Altair-Hyper mesh yazılımı kullanılmış olup çevrili tüm bileşenleri için arka taban bölgesi sonlu eleman modeli oluşturulmuştur. Arkadan çarpma analizleri, NVH analizleri ve Yapısal analizler tam araç modeli modelinde yapılmış olup mevcut araç performansını koruyarak araç gövdesinde 2 kg ağırlık azalımı yapılmıştır (Şekil 9).



Şekil 9. Sayısal analiz FEM modeli

Kompozit parçanın araç içine montajının yapılabilmesi ve parçanın konumunun tekrarlana bilirliğini sağlamak amacı ile için araç gövdesi ve kompozit parça üzerinde yeni üretim referansları belirlenmiştir. (a) Bu referanslar yardımı ile parçanın araç gövdesine montaj edilebilirlik analizi tamamlanmıştır. (b) (Şekil 10)



(a) (b)

Şekil 10. Kompozit parçanın montaj edilebilirlik doğrulamaları

SONUÇLAR

Otomobil üreticileri, geliştirdikleri otomobil modellerinde gerek yakıt tüketim değerlerinin azaltmak gerekse emisyon hedeflerini yakalamak ya da daha uzun menzile sahip araçlar geliştirmek amacı ile araç hafifletme çalışmalarını mevcut sahip olduğu araç platformları üzerinde de gerçekleştirme ihtiyacı duyabilmektedirler. Bu çalışmada modüler tasarım esnekliği ile ilk araç geliştirme maliyetleri açısından bir yük getirse de ve üretim maliyetleri açısından fayda sağlayacağı görülmüştür.

Bu çalışmada, çelik malzemeden geliştirilen otomobil arka taban bölgesi, karbondioksit emisyonlarını azaltmak amacı ile mevcut araç performans isterlerini koruyarak GMT-GMTex kompozit malzemeden yapılmış ve 2 kg ağırlık avantajı sağlanmıştır. Böylece ilk çelik tasarımda yapılan modüler tasarım esnekliğini kullanarak araç hafifletme çalışmalarının farklı uzunluktaki araç gövdelerine de uygulanabilirliği belirlenmiştir.

TEŞEKKÜR

Bu çalışma Farplas ortaklığı ile TEYDEB 3160497 Projesi kapsamındaki maddi destek ile tamamlanmış olup yazarlar Tübitak'a teşekkürü bir borç bilirler.

ÖZET

Otomotiv sektörü ürün geliştirme süreçlerinde, her ürüne sınırsız özellik eklenerek ürün pazara sunulabilir. Fakat ürün üzerindeki özelliklerin müşteri üzerinde oluşturduğu katma değerin tanımlanması çok önemlidir. Bunun için de müşterinin sesini dilemek ve taleplerini anlayıp tasarıma girdi teşkil etmesi için, ürün geliştirme öncesinde detaylı araştırma yapılması gerekir. Tüm bunlar göz önünde bulundurulduğunda, otomotiv sektöründe rekabetçi olunabilmesi için, müşterilerin ihtiyaçları belirlenmeli ve belirlenen bu ihtiyaçlar minimum seviye de maliyet ile tasarıma yön vermelidir. Bu makale de analiz yöntemi olarak QFD analiz modeli kullanılmıştır. Böylece müşteri ihtiyaçlarına göre optimum ürün tasarımını başarıyla gerçekleştirebilme amaçlanmıştır. Hafif ticari araçlar üzerinde yapılan bu araştırma, ön kapı ve sürgülü kapı kolu tasarımının hem sürücü hem de kullanıcılar üzerindeki memnuniyet veya memnuniyetsizlik üzerindeki etkilerini göstermektedir. Kapı kolu tasarımı için güvenlik gerekliliklerine ek olarak; ergonomi, kapı açma eforları, açma kursları, ses seviyesi ve fonksiyonellik açısından incelemeler sentezlenmiştir. Çalışmanın sonucunda hafif ticari araçlarda ön ve arka (sürgülü) kapı tasarımının yatay olması, açılma yönünün farklılık içermesi, açılma efor ve kapı kolu ölçülerinin, müşterinin araç satın alma konusunda ne derecede önemli olduğu sonucuna varılmıştır. Bu makale de detaylı olarak ön ve sürgülü kapı kolunda belirlenen özellikler müşterilere görseller ile gösterilmiş ve müşteri üzerindeki değer tanımlamaları nicel veriler ile gösterilmektedir.

DOOR HANDLE DESIGN IN COMMERCIAL VEHICLES WITH QFD METHOD INVESTIGATION OF IMPACTS ON THE CUSTOMER

ABSTRACT

In the product development processes of the automotive industry, unlimited features can be added to each product and the product can be brought to the market. However, it is very important to define the added value created by the features on the product on the customer. For this, detailed research should be done before product development in order to ask for the voice of the customer, to understand their demands and to constitute an input to the design. Considering all these, in order to be competitive in the automotive industry, the needs of the customers should be determined and these determined should guide the design with minimum cost. In this article, the QFD analysis model was used as the analysis method. Thus, it is aimed to successfully realize the optimum product design according to customer needs. This research on light commercial vehicles shows the effects of front door and sliding door handle design on satisfaction or dissatisfaction on both driver and users. In addition to the safety requirements for door handle design; reviews in terms of ergonomics, door opening efforts, opening courses, sound level and functionality were synthesized. As a result of the study, it was concluded that the front and rear (sliding) door design of light commercial vehicles is horizontal, the opening direction is different, the opening effort and door handle dimensions are important for the customer in purchasing a vehicle. In this article, the features determined in the front and sliding door handle are shown to the customers with visuals and the value definitions on the customer are shown with quantitative data.

Keywords: QFD, kano, commercial vehicles, door handle, customer experience.

1. GİRİŞ

Günümüzde değişen rekabet şartları firmaların kalite konusundaki yaklaşımlarını değiştirmiştir. Müşteri isteklerinin tam olarak tatmin edilmediği sürece ürün veya hizmetlerin satılabilmesi ve dolayısıyla sürekli kâr etmesi mümkün olamaz. Ürün tasarımında veya geliştirmede; pazarlama, mühendislik, imalat ve kalite fonksiyonlarının ihtiyaç ve beklentilerini müşterinin sesi ile ilişkilendirmek gerekir.

Müşteri memnuniyeti ve bağlılığının sağlanmasında müşteri gereksinimlerinin karşılanması ve bu gereksinimlerin memnuniyet düzeyini nasıl etkilediği önemli bir husustur. İşte bu noktada, QFD; yalın üretim prensipleri doğrultusunda kuruluşun fonksiyonlarını, kaynaklarını ve yetkinliklerini dikkate alarak müşteri beklentilerine odaklanır ve maliyetleri azaltır. QFD'nin en temel planlama aracı Kalite Evi (House of Quality) matrisidir. QFD (Kalite Fonksiyon Yayılımı, KFY); müşteri beklentileri tarafından yönlendirilen ve müşteri odaklı ürün tasarlama ve geliştirme metodudur. Başka bir deyişle QFD, organizasyonların ürün veya süreçlerinin müşterilerinin hem mevcut ve hem de gelecekte ortaya çıkabilecek beklenti ve ihtiyaçlarını karşılayabilmesi için müşteri sesinin teknik özelliklere dönüştürülmesini sağlayan bir metot olarak tanımlanabilir. Bu metot, ürün geliştirilirken bazı teknik veya fonksiyonel gereksinimlerin oluşmasına sebep olur. Gereksinimler ürünün neyi yapması veya neye sahip olması gerektiğini ifade eder, tasarım ise ürünün bu "ne'leri" nasıl yerine getireceğini ifade eder. Bütün bu gereksinimlerin tümü QFD dilinde "müşterinin sesi (voice of the customer)" denir. [1].

Bu çalışmanın amacı, hafif ticari araçlarda ön ve sürgülü kapı kolu tasarımı ile ilgili müşteri ihtiyaçlarını kano modeli ile değerlendirip, rakip araçların kıyaslamaları ve teknik gereksinimlerin tasarıma yansıtılmasıdır. Kapı kolu tasarımı için incelenen özellikler QFD metodu ile sentezlenerek müşteri üzerinde değer oluşturan özellikler belirlenmiştir.

2. KALİTE FONKSİYON YAYILIMI (QFD MODELİ)

KFY ilk kez 1960'ların sonlarına doğru 1970'lerin başlarında profesör Yoji Akao tarafından Japonya'da ortaya atılmıştır [2]. Otomotiv sanayindeki ilk uygulaması Japonya'da, Toyota'da 1973'te arabalardaki kalite problemlerini çözmede yapılmıştır. Uygulama 1979'da Toyota'nın tedarikçilerine de yayılmıştır. 1970'li yıllardan itibaren üzerinde durulan QFD yöntemi (Quality Function Deployment – Kalite Fonksiyonu Yayılımı), müşteri beklentilerinin daha tasarım aşamasından ürün ve hizmetlere yansıtmakla kalmıyor, ürün sunma süresini de kısaltıyor [4]. QFD uygulamasının kalbini ise "Kalite evi" denilen uygulama tekniği oluşturuyor. QFD süreci dört aşamalı bir süreç olarak tanımlanmıştır. Bu aşamalar, QFD sürecinin daha iyi anlaşılmasını sağlar. [3]

QFD sürecinin aşamaları:

Aşama 0: Planlama
Aşama 1: "Müşteri Sesi"nin Toplanması
Aşama 2: Kalite Evinin Oluşturulması
Aşama 3: Sonuçların Analizi ve Yorumlanması

2.1. Aşama 0:

QFD'yi hayata geçirmeden önce yapılacak işletmelere ait bir plan yapılmalıdır. QFD planlama aşaması, proje amaç ve kapsamının belirlenmesi, müşterilerin belirlenmesi, zaman ölçeğinin belirlenmesi, uygulanacak olan ürün ya da hizmete karar verilmesi, QFD takımının kurulması, QFD sürecinin tasarlanması ve gerekli ekipmanlarla tesisin hazırlanması konularını içerir.

2.2. Aşama 1: "Müşteri Sesi"nin Toplanması

Ürünün ilk piyasaya sunulmasında önemli olan, rakip ürüne göre avantaj sağlayabilmektir. Bu ancak müşteri beklentilerinin doğru anlaşılması ile gerçekleşebilir. Müşterilerin sürekli olarak değişen beklentilerinin karşılanması ve buna uygun olarak yeni tasarımların gerçekleştirilmesi gerekmektedir. Sürekli başarılı olabilmek için kuruluşlar, müşterinin istekleri, gereksinimleri ve memnuniyet seviyeleri hakkında bilgilerini kesintisiz şekilde izleyebilecek ve güncelleştirebilecekleri proseslere sahip olmalıdır. Müşteri düşüncelerinin gerektiği şekilde anlaşılamaması, yeni ya da yenilenmiş ürünlerin daha en başta rakip ürünlere göre önemli bir dezavantaja sahip olması anlamına gelir.
QFD, kuruluşlara müşteri isteklerinin güncel dönüşümünü sağlayan bir tasarım yaklaşımıdır ve müşteri sesi başlangıç aşamasını oluşturur.

2.3. Aşama 2: Kalite Evinin Oluşturulması

QFD'de kalite evinin kurulması prosesin temelini oluşturur. Müşteri ihtiyaçlarının tanımlanması ve önceliklendirilmesini ve bu ihtiyaçların teknik özelliklerle ilişkilendirmesini, bunların rakip ürünleriyle karşılaştırılmasını ve böylelikle önemli teknik özelliklerin ve iyileştirmeye ihtiyaç duyulan alanların belirlenmesini sağlar. Kalite evinin temelinde de müşterilerin beğeni ve seçimlerini yansıtarak tasarlanması gerekliliği yatar.
Bu nedenle tasarım mühendisleri ve üretim elemanları ürünün daha fikir aşamasından itibaren çok yakın olarak birlikte çalışmak zorundadırlar.

2.4. Aşama 3: Sonuçların Analizi ve Yorumlanması

Yapılan ön aşamalar ve kalite evinin oluşumu ile çıkan tablo QFD ekibi tarafından analiz edilip yorumlanır.
Elde edilen analiz sonucunda;
• Müşteri istekleri tespit edilmiş,
• Teknik karakteristikler belirlenmiş,
• Müşteri istekleri ile teknik karakteristikler arasındaki ilişkiler belirlenmiş,
• Teknik korelasyonlar belirlenmiş,
• Rakipler arasındaki durum ortaya çıkmış,
Böylece amaca hizmet eden nihai tasarım ve üretim süreci planmış bir sonuç hedeflenmektedir.

3. KALİTE EVİ ŞEMASI

Kalite evi fonksiyonlar arası planlama ve iletişimi sağlayan bir tür kavramsal haritadır. Değişik problemleri ve sorumlulukları olan insanlar evin çatısı altındaki bilgi motiflerinden tasarım önceliklerini kolayca belirleyebilirler.
Kalite Evi'nin kurulmasında izlenmesi gereken adımlar aşağıda sıralanmıştır [3]:

1) Müşteri ihtiyaçlarının ve önceliklerinin belirlenmesi
2) Rakip araçların kıyaslanması ve müşteri önceliklerinin belirlenmesi
3) Müşteri ihtiyaçlarına karşılık gelen teknik karakteristiklerin belirlenmesi
4) İlişki matrisinin oluşturulması
5) Teknik korelasyonların belirlenmesi
6) Teknik değerlendirmenin yapılması ve hedeflerin belirlenmesi

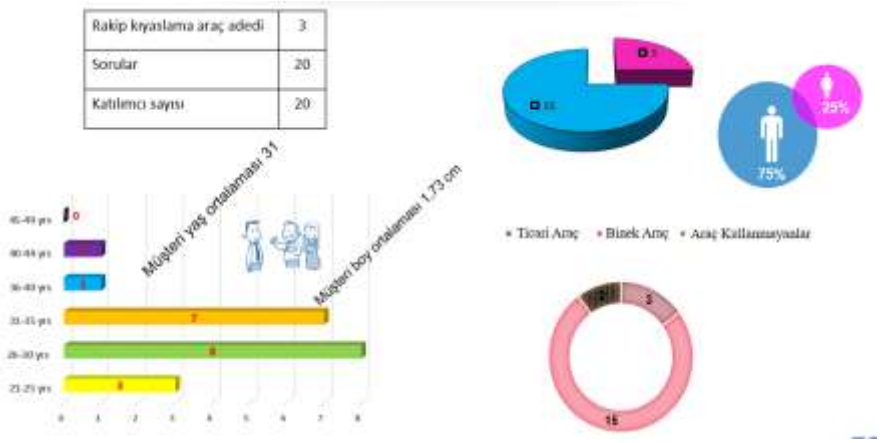
Şekil 1: Kalite Evinin Temel Gösterimi

3.1. Müşteri ihtiyaçlarının ve önceliklerinin belirlenmesi

Müşteri beklentileri, müşterinin ürün ya da ürün özelliklerine ilişkin istekleridir ve bu isteklerin tüketicilerin kendi kelimeleri ile ifade edilmesi önemlidir. Çünkü daha sonra yapılacak tüm çalışmalar bu aşamada belirlenmiş unsurlar tarafından yönlendirilecektir. Müşteri ihtiyaçlarının belirlenmesindeki kaynaklar şunlardır;

- İlgili kişilerin görüşlerinin alınması
- Müşterilerle yapılan bire bir görüşmeler
- Müşterilerden gelen şikayetler
- Pazar araştırmaları
- Müşteri tatmin araştırmaları

Müşteri ihtiyaçları belirlenirken, maliyet ve fiyatlar bu aşamada göz önünde bulundurulmamalıdır. Müşterinin dili ile konuşmalı, ihtiyaçların tüm QFD takımınca doğru bir şekilde anlaşılmasına özen gösterilmelidir.



Şekil 2: Müşteri Profil Analizi

Tablo 1. Araştırma Soruları

S.n.	Soru
1	Ön kapı kolu pozisyonunun yatay ya da dikey olması sizin için önemli midir?
2	Sürgülü (arka kapı) kapı kolu pozisyonunun yatay ya da dikey olması sizin için önemli midir?
3	Ön Kapı kolu tutamacın bırakıldığı andaki ses olup olmaması sizin için önemli midir?
4	Sürgülü (arka kapı) kapı kolu tutamacın bırakıldığı andaki ses olup olmaması sizin için önemli midir?
5	Ön kapı kolu açma eforu (kilidin kilit karşılığından ayrılması) sizin için önemli midir?
6	Sürgülü (arka kapı) kapı kolu açma eforu (kilidin kilit karşılığından ayrılması) sizin için önemli midir?
7	Ön Kapı kolu yerden yüksekliği sizin için önemli midir?
8	Arka Kapı kolu yerden yüksekliği sizin için önemli midir?
9	Kapı kolu stili (estetik olarak) sizin için önemli midir?
10	Passive – entry (anahtarsız çalışma) özelliği (sürücü tarafı) sizin için önemli midir?
11	Passive - entry (anahtarsız çalışma) özelliği (sürücü tarafı + yolcu) sizin için önemli midir?
12	Kapı kolu üzerindeki buton ile açma ve kilitleme özelliğinin olması sizin için önemli midir?
13	Kapı kolunun el teması ile açılıp anahtar ile kitlenmesi özelliğinin olması için için önemli midir?
14	Ön Kapı kolu aydınlatmasının olması (tutamacın olduğu yerde) sizin için önemli midir?
15	Sürgülü (arka kapı) kapı kolu aydınlatmasının olması (tutamacın olduğu yerde) sizin için önemli midir?
16	Kapı kolunun tutamaç bölgesinin (elin girdiği yerin) ergonomisi sizin için önemli midir?
17	Kapı kolunun tek parça olması sizin için önemli midir?
18	Kapı kolunun çift parça olması sizin için önemli midir?
19	Kapı kolundaki anahtar girişinin gizli olması sizin için önemli midir?
20	Kapı kolunun iç tarafında mandallı olması (tutamacın arkasında) sizin için önemli midir?

Şekil 3: Kapı kolu özellikleri

3.2. Rakip araçların kıyaslanması ve müşteri önceliklerinin belirlenmesi

Planlama matrisi, analizi yapılan ürünün müşterinin gözüyle rakip firmalarla karşılaştırılması sağlar. Bu şekilde firma, kendi ürününün piyasadaki yerini daha iyi görebilme şansını yakalar. Müşteri isteklerinin karşılanması halinde bunun ürünün satılabilirliğini nasıl etkilediği ve ürün üzerinde ne kadarlık bir geliştirmeye ihtiyaç olduğu tespit edilmelidir. Müşteriye ürün ile ilgili sorular sorarak, rakip firmaların ürünleri ile karşılaştırma yapmaları istenir. Böylece rakiplerin kuvvetli ve zayıf oldukları yönleri tespit edilmeye çalışılır. Müşteri araştırmayı yapan firmayı ve rakipleri kendi gözünde bir sıralamaya sokar. Daha sonra bu sıralama notlamaya dönüştürülerek kalite evine aktarılır.

3.3. Müşteri ihtiyaçlarına karşılık gelen teknik karakteristiklerin belirlenmesi

QFD'nin bu sürecinde, müşterilerin düşüncelerinin teknik ihtiyaçlara dönüştürülmesidir. Teknik ihtiyaçlar belirlenirken dikkat edilmesi gereken husus, belirlenen müşteri isteklerine doğrudan çözümler bulmak olmamalıdır. Amaç her bir düşünceyi bir veya daha fazla teknik ihtiyaca dönüştürmektir. Teknik ihtiyaçlar ölçülebilir nitelikte olmalı ve müşterinin sesi ile doğrudan ilişkili olmalıdır. Teknik ihtiyaçlara bir takım mühendislik hesaplar, deneysel çalışmalar veya bilgisayarlı simülasyon programları vasıtasıyla çözüm bulunur. Ayrıca bu teknik ihtiyaçlar belirlenirken araştırmayı yapan üretici firmalar kendi teknik imkanlarını göz önünde bulundurmalıdır.

3.4. İlişki matrisinin oluşturulması

Bu aşamaya kadar müşteri ihtiyaçları ve teknik gereksinimler elde edilmiştir. Bu aşamada ise her bir müşteri ihtiyacı ile teknik gereksinimi arasındaki ilişki derecesi belirlenir. Burada amaç her bir teknik karakteristiğin belirli müşteri isteğini karşılamada ne kadar etkili olduğunu ortaya koymaktır.

3.5. Teknik korelasyonların belirlenmesi

Teknik gereksinimler birbirleri ile ilişkilidir. Bunlardan birinin geliştirilmesi amacıyla yapılan bir çalışma, ilgili gereksinime yardımcı olabilir ve bunun sonucunda olumlu veya yararlı bir etki ortaya çıkar. Diğer taraftan, bir gereksinimi geliştirmek için yapılan çalışma ilgili gereksinimi olumsuz etkileyebilir. Kalite evinde yer alan ve teknik gereksinimler arasındaki korelasyonları ifade eden yapıya "çatı matrisi" ya da "korelasyon matrisi" adı verilir [5].

3.6. Teknik değerlendirmenin yapılması ve hedeflerin belirlenmesi

Anlatılan tüm aşamaların gerçekleştirilmesi sonucunda kalite evi ortaya çıkar. QFD ekibi test ve kontroller için gerekli düzenlemeleri yapar. Yapılan kıyaslama sonucunda teknik gereksinimlere ilişkin performans hedeflerinin belirlenmesi aşamasına gelinir. Kıyaslama ile hem iyileştirilmesi gereken yönler ortaya çıkarılır, hem de rakiplere göre üstün veya zayıf taraflar tespit edilir. Gerçekleştirilecek olan aşamalara QFD takımı uygulama zamanı ve maliyeti göz önüne alarak karar verir.

Elde edilen analiz sonucunda;

• Müşteri istekleri tespit edilmiş,
• Teknik karakteristikler belirlenmiş,
• Müşteri istekleri ile teknik karakteristikler arasındaki ilişkiler belirlenmiş,
• Teknik korelasyonlar belirlenmiş,
• Rakipler arasındaki durum ortaya çıkmış,
• Müşteriye ve amaca hizmet eden nihai tasarım ve üretim süreci planmış bir sonuç hedeflenmektedir.

4. SONUÇLAR

Bu çalışmada, 4 farklı hafif ticari araç üzerinde toplam 20 katılımcı ile ön ve sürgülü kapı kolu tasarımı ile ilgili sorular yönetilmiş ve kano metodu aracılığıyla analiz edilmiştir. QFD metodundaki diğer parametreler içinde müşteri sesi dinlenmiş ve gereksinimlerin karşılanmasının veya karşılanmamasının katılımcıların memnuniyeti üzerinde ne derece etkili olduğu ve bu girdilerin tasarım gereksinimleri ile birleştirip müşteri üzerindeki etkisi belirlenmeye çalışılmıştır.

Araştırmaya katılan kullanıcılar, hafif ticari araçlarda kapı kolunun yatay olarak tasarlanması müşterilerin ilgisinin çektiği sonuca varılmıştır. Kullanıcılar, ergonomi açısından kapı kolu mesafesinin yerden yüksekliği 100cm ve kapı kolu uzunluğu olarak da 200mm olması beklenen temel bir özellik olarak belirlenmiştir. Kapı açma efor özelliği için; ön kapı da 60N, sürgülü kapı da ise 65N değerleri katılımcılar tarafından memnuniyet şeklinde değerlendirilmiş ve kesinlikle tasarıma girdi teşkil etmesi tespit edilmiştir. Belirlenen bu değerler tasarım gereksinimlerini de karşılayacak şekilde her projede farklılık gösterebilir. Diğer bir özellik olan anahtarsız giriş özelliğinde ise, müşteri tarafından butonlu mekanik kilitleme ve el teması ile açma özelliği araçlardaki rekabetçiliği artıracağı sonucu çıkmıştır. Bu özelliğin sadece ön kapılarda olmasının yeterli olduğu fakat sürgülü kapılarda da bulunması heyecan verici bir durum olduğu belirlenmiştir. Kapı kollarındaki aydınlatma ve kapı kolunu tek ya da çift parça olma özelliği müşteri ilgilisini çekmemektedir.

Şekil 4. Kapı Kolu Özellikleri

Yine kalite evinin çıktısı olarak, estetik açıdan kapı kolunun gövde renginde olması katılımcıların ilgisini çekmekte ve albenisinin yüksek olduğu sonucu çıkmaktadır. Ön ve arka (sürgülü kapı) kapı kolu açılma yönü olarak Şekil 4'te gösterildiği üzere ön ve arka kapı açılma yönünün farklı olması kullanıcı açısından büyük önem taşıdığı belirlenmiştir.

ABSTRACT

Aydınlatma günümüzde temel bir ihtiyaç olarak görülmekte ve bu konudaki araştırmalara her geçen gün bir yenisi eklenmektedir. Otomotiv sektöründe de aydınlatma büyük önem taşıyor. Sürekli gelişen aydınlatma sektörüne ayak uydurabilmek için otomotiv aydınlatma sektöründe çok önemli gelişmeler yaşanıyor. Günümüz otomotiv firmalarına bakıldığında marka algısının en önemli faktörlerinden biri dış aydınlatmadır. Otomotiv sektöründe en önemli görsel efektler arasında özellikle far ve arka sinyal lambaları konusunda aydınlatma efektleri ve stil çalışmaları yapılmaktadır. Araç aydınlatmasında kullanılan LED (Light Emitting Diode)'lerin hem tarz hem de enerji verimliliği açısından ve ışık tüplerinin bir arada kullanılması avantajlarının yanında dezavantajı ise otomotiv aydınlatmasında istenilen homojenliği olumsuz etkileyen ışık parlama noktalarıdır. Bu çalışmanda homojen olmayan farklı ışık yoğunluğu noktalarına sahip bir ışık kılavuzu üzerinde çalışmalar yapılmıştır. Gerekli simülasyon çalışmaları yapıldıktan sonra deneysel çalışmalar da yapılarak fiziksel doğrulamalar yapılmıştır. Bu çalışma sonucunda geliştirilecek yöntemler ile LED teknolojisinin kullanıldığı otomotiv aydınlatmasında bu rahatsız edici ışık parlama noktaları nedeniyle yapılamayan tasarımlar iyileştirilecek ve aydınlatma ürünlerinin stilleri özgür hale gelecektir.

Anahtar Kelimeler: Işık Kılavuzu, Işık Parlama Noktası, Işık yoğunluğu, Pozisyon Lambası, Otomotiv

IMPROVING HOT SPOTS IN LIGHT GUIDE USED IN AUTOMOTIVE LIGHTING WITH VARIOUS GEOMETRIC DESIGNS

ABSTRACT

Lighting is considered a basic need today and a new one is added to the researches on this subject every day. Lighting is also of great importance in the automotive sector. To keep up with the constantly developing lighting industry, very important developments are being made in the automotive lighting industry. Looking at today's automotive companies, one of the most important parts of branded styles is outdoor lighting. Lighting effects and style work are done especially in the headlamp and rear signaling lamps among the most important visual effects in the automotive industry. In addition to the advantages of the LEDs used in vehicle lighting, both in style and energy efficiency and the light tubes used together with them, the disadvantage such as the hotspot that negatively affects the desired homogenization in automotive lighting. Aims to homogenize the image of the light. To prove the feasibility of this study, studies were carried out on a light guide with different non-homogeneous light intensity points. After the necessary simulation studies were carried out, experimental studies were also carried out and physical verifications were carried out. With the methods to be developed as a result of this study, designs that cannot be made due to this disturbing light intensity in automotive lighting where LED technology is used will be improved and lighting product styles will be liberated.

Keywords: Light guide, Hot spot, Light intensity, Rear lamp, Automotive

1. INTRODUCTION

Aydınlatma teknolojilerinin gelişmesi ile otomotiv aydınlatmasında da farklı aydınlatma seçenekleri mevcut hale gelmiştir. Gelişmeye devam eden bu teknolojide otomotivde kullanılacak seçeneklerin belirlenmesinde enerji tasarrufu ve stilistik detaylar çok önemli bir etkendir. Aynı zamanda homologatif gereksinimleri de göz önünde

bulundurulduğunda, stilistik etkilerin yanı sıra, özellikle pozisyon lambaları sinyal lambaları gibi, renkli bir ışık sinyalinin başlangıcına verilen görsel tepki sürelerinin sürücülerin gözlerinden alınan eşik ışık miktarı enerjisi de önemli bir rol oynamaktadır (Bullough, 2005). Araç aydınlatmalarında kullanılan standart halojen lambalara kıyasla LED gerek enerji tasarrufu yönünden gerek ışık şiddeti, aydınlatma mesafesi ve kısa tepki süresi yönünden gerekse kullanım ömrü açısından çok daha avantajlı bir seçenektir. Flamanlı lamba kullanılan sistemlerde ışık yayılımı ayarlanamaz ve yoğun olarak gerçekleşirken LED kullanılan sistemlerde, ışık yönü ve şiddeti ayarlanabilir ve çıkan ışık belli bir ışıma açısı ile çıkacağından istenilen doğrultuya odaklanabilir. Ayrıca LED üretilirken kullanılan farklı malzemeler ile farklı enerji seviyelerinde fotonlar üretileceğinden ışığın dalga boyu ayarlanabilir olmaktadır (Liu ve Luo, 2011). LED seçeneğinin kullanılması stilistik detaylar da katmak için bir seçenek olarak beraberinde ışık kılavuzu kullanımını da getirmiştir. Gelenekselleşmiş otomotiv LED aydınlatmalarında yeterli ışığın sağlanması için kullanılan LED dizileri dağınık lense sahip olduklarından parlama ve homojenite sorunlarına neden olmaktadır. Işık kılavuzu teknolojisi ile LED dizilerine kıyasla gereken ışığın sağlanmasında kullanılan LED sayısının az olması homojen ışık dağılımında etkili olarak yumuşak ve estetik aydınlatma sağlamaktadır (Yu, Chen, 2013). Işığın ışık kılavuzu içerisinde homojen olarak dağılması aydınlatma ihtiyacından ziyade stil detayları için önemlidir. Işık tüplerinin arka yüzeyi üzerinde yer alan prizmalar, tüp içerisinde yansımalar yapan ışığın bir kısmını dışarı yönlendirir. Prizmanın yönlendirdiği ışık miktarları birbirine yaklaşık olarak eşit olduğunda homojen bir görüntü yakalanmış olmaktadır. Bu çalışma, ışık tüplerinde giriş, çıkış, bükülme noktaları gibi bölgelerdeki ışık yoğunluklarının iyileştirilerek, ışığın görüntüsünün homojenleştirilmesini amaçlamaktadır. Bu çalışmanın olabilirliğini ispatlamak amacıyla, farklı homojen olmayan ışık yoğunluğu noktalarına sahip bir ışık tüpü üzerinde çalışmalar yapılması hedeflenmektedir. Gerekli simülasyon çalışmaları yapıldıktan sonra deneysel çalışmalar da yapılabilecektir. Bu çalışmanın sonucunda geliştirilecek yöntemler ile LED teknolojisinin kullanıldığı otomotiv aydınlatmalarında, bu ışık yoğunluğu sorunundan kaynaklı yapılamayan tasarımların önü açılmış olacak ve aydınlatma ürünleri stilleri özgürleşecektir.

2. OTOMOTİVDE DIŞ AYDINLATMA TEKNOLOJİLERİ

2.1. Light Emission Diode (LED)

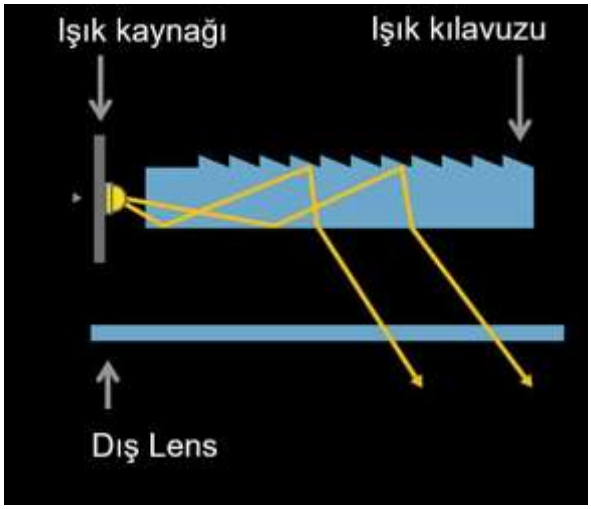
LED'ler birkaç yıl öncesine kadar otomotiv aydınlatma sektöründe sadece üst modellerde kullanılırken, günümüzde daha düşük fiyatlı araç modellerinde de etkin olarak kullanılmaktadır. Önceki aydınlatma teknolojilerinde kullanılan halojen lambalara kıyasla çok daha düşük enerji tüketimi, daha yüksek ışık akısı sağlaması, çok daha kısa tepki süresi, daha uzun kullanım ömrü gibi etkenler LED'lerin aydınlatma sektöründe geniş yer kaplamasını sağlamıştır. Otomotiv aydınlatmasında, özellikle fren lambalarındaki kullanımı kıyaslandığında düşük tepki süresi sayesinde arkadan takip eden sürücünün daha sağlıklı uyarılmasını ve tepki vermesini sağladığından kazaları da önleyerek güvenliği arttırmaktadır (Nair, 2021). Bir diğer kıyaslama da ışık akısı ve aydınlatma mesafesidir. LED'lerin aydınlattığı mesafe, halojen lambalara göre çok daha fazla olduğundan özellikle gece görüşlerinde çok daha konforlu olanaklar sağlamaktadır.

Işık yayan diyot (Light Emitting Diode) olarak bilinen LED'ler, temeli diyot olan, elektrik enerjisini ışığa dönüştüren elektronik devre elemanıdır. Galyum-Arsenik (GaAs), Galyum Arsenik-Fosfat (GaAsP) ya da Galyum Fosfat 'tan (GaP) yapılmış P-N eklem yapıları olan LED'lerdeki eklem noktaları ileri akım yapıldığında, elektronlar n bölgesinden p bölgesine geçerler. Elektron – boşluk (hole) birleşimi gerçekleşerek kızılötesinde veya görünür bölgede fotonlar üretilir ve elektriksel ışıma gerçekleşir (Electro luminescence). LED noktasal bir ışık kaynağıdır, kılıf içine yerleştirilen yansıtıcı bir eleman ile ışığın belli bir doğrultuya yönlendirilebilmesi mümkündür (Erol, 2010). Yüksek güçlü LED'ler enerjilerinin %20- %30'unu ışık enerjisine dönüştürürken, geriye kalan %70-%80 ini de ısı enerjisi olarak yaymaktadırlar. LED'lerdeki bu yüksek bağlantı sıcaklıkları kullanım ömrü, renk kararlılığı ve ışık yoğunluğunu olumsuz etkileyebilmektedir (Huang ve Chen, 2019).

2.2. Işık Kılavuzları

Noktasal bir ışık kaynağı olan LED'lerin sağladığı ışığın yönlendirilmesi ve homojenize edilmesi gerekmektedir. Bu nedenle ihtiyaç duyulan optik tasarım elemanlarından biri de ışık kılavuzlarıdır. Bu kılavuzlar, ışık ışınlarının uzun mesafeler arası taşınmasını sağlayan, katı, plastik bir lenstir ve yapıldığı malzemenin karakteristiğine göre bir kırılma indisine sahiptir. Işık kılavuzlarında genellikle kenar aydınlatma uygulamaları kullanılarak LED ışığının yönlendirilmesi sağlanmaktadır. Bu amaçla kullanılan plakalar, ışık kılavuzu plakası olarak adlandırılmaktadır. Endüstriyel alanda LGP (light guide plate) olarak anılan bu plakalar, %94'e kadar geçirgenlik sunan PMMA (polimetil metakrilat) diğer adıyla akrilik cam veya pleksiglas olarak adlandırılan malzemelerden yapılmaktadır. Şeffaf ve yüksek geçirgenliğe sahip olan bu malzeme sayesinde yüksek ışık parlaklıkları elde edilebilmektedir. Işık kaynağından yayılıp kılavuz içine giren farklı açılardaki ışık ışınlarını yakalayabilme özelliğine nümerik açıklık denir. Nümerik açıklık büyüdükçe daha fazla ışık kılavuz içerisinde yol almaktadır. Işık kılavuzunun üzerine, içeride kılavuzlanan ışığın dışarı yönlendirilmesini sağlayan optik bir eleman tasarlanmalıdır (Şekil 1). Bu optik eleman nokta matrisi, çoklu oluklardan oluşan matris vb. olabilir. Otomotiv aydınlatmalarında en çok kullanılan ve bu çalışmada da ele alınan bir diğer optik

yöntem de dağıtıcı prizmalardır. Işık kılavuzunun üzerine eklenen bu optik desenli prizmalar geometride yapılan ani bir değişiklik olduğundan, pertürbasyon etkisi yaratarak ışığın dağılım karakteristiğine etki eder.



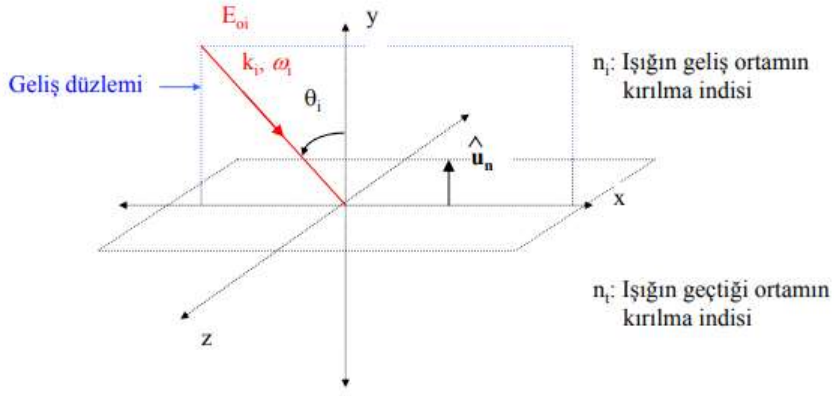
Şekil 1. Işık kılavuzu üzerindeki optik elemanlar

2.3. Homojenlik (Homojenite)

Fiziksel bir tanım olan homojenlik, bir sistemin tüm noktalarının düzenli bir yapıda ve aynı özelliklere sahip olması durumudur (Rennie, 2003). Bu tanıma bağlı olarak ışığın homojenliği de belirli bir alanın her bir noktasından saçılan ışık ışınlarının eşit şiddette olması anlamına gelmektedir. Bu çalışmada homojenite kavramı, ışık kılavuzunda yayılan ışık şiddetlerinin her bölgede yaklaşık olarak aynı olması ile tanımlanmaktadır.

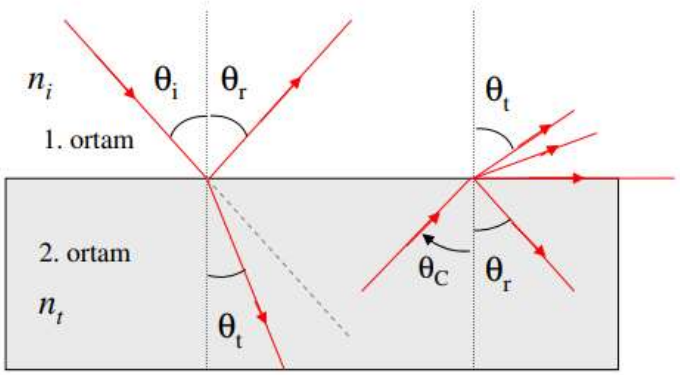
2.3.1. Hot Spot

Işık kılavuzları, yapıldıkları malzemenin karakteristiğine göre bir kırılma indisine sahiptir. Işığın iki farklı ortamdan geçişi Şekil 2'de gösterilen açısal ve düzlemsel tanımlarla yapılmaktadır. Kılavuzda ilerleyen ışığın kayıpsız bir şekilde ilerlemesi, kılavuzun indisi ve dışındaki ortamın indisi ile ilişkilidir. Bu ilişki Snell Yasası ile açıklanabilir (Şekil 3). Kılavuz, yapıldığı malzemeye göre bir kırılma indisine sahiptir. Otomotiv aydınlatmasında kullanılan ışık kılavuzunun dışında hava bulunmaktadır. Işık kılavuzlarında ilerleyen ışık, kılavuzun hava ile birleştiği 2.ortama çarparak yansıma ve kırınım yapar.



Şekil 2. Işığın düzlemler arasındaki tanımı

K_i; Gelen dalganın vektörü
ω_i ; elektromanyetik dalganın açısal frekansı
E_{oi}; Gelen dalganın genliği
U_n; düzlem normal vektörü



Şekil 3. Işığın iki farklı ortamdaki davranışı

Işık kılavuzlarının üzerindeki prizmanın dışarı yönlendirdiği ışık miktarları yaklaşık olarak eşit olduğunda homojenlik sağlanmış sayılmaktadır. Otomotiv aydınlatmalarında kullanılan ışık kılavuzları geleneksel dikdörtgen ışık kılavuzlarından farklı olarak çok daha karmaşık bir yapı sergiler. Işık kılavuzu eğimli yapıda olabilir. Işık kılavuzunun eğimlendiği radyal bölgelerde, kılavuzun giriş ve çıkış yüzeylerinde kılavuzlanan ışığın geliş açısı yüzeye göre farklılık göstereceğinden istenmeyen parlamalar görülebilmektedir. Bu istenmeyen parlama durumu "hot spot", parlamanın olduğu bölgeler de "hot spot noktası" olarak tanımlanır.

Bu çalışmada, kılavuzlanan ışığın kılavuzdan ayrılması sonucunda ortaya çıkan geri yansımalardan dolayı oluşan ışık parlamasının (hot spotun), geometrik optik ile parlama miktarlarındaki değişim incelenmiş ve en optimum yapıya ulaşılmıştır.

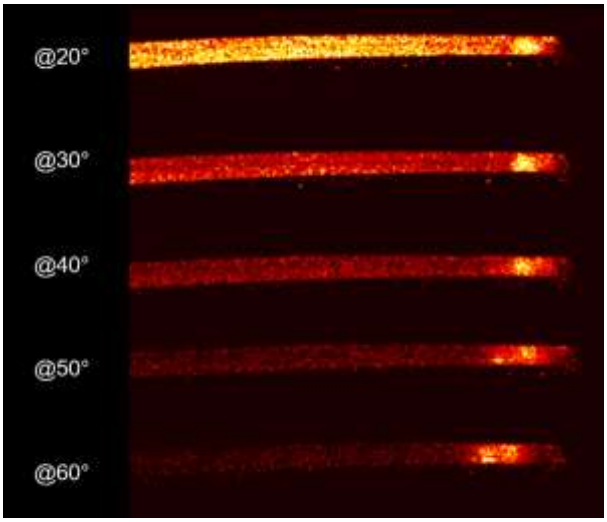
3. DENEYSEL ÇALIŞMALAR

Yapılan çalışmada, PMMA malzemeli ışık kılavuzunun, ışık kaynağından en uzak bölgede; ışığın kılavuzu terk ettiği sırada meydana gelen geri yansımalardan dolayı oluşan hot spotun iyileştirilmesi amaçlanmıştır. Bu çalışmada düz bir bitiş kesim hattına sahip olan ışık kılavuzunda meydana hot spotu iyileştirmek amacıyla 3 farklı çeşit bitiş geometrisi oluşturulmuştur. Ve her bir tasarım optik analiz programı ile analiz edilerek sonuçlar karşılaştırılmıştır.

3.1. Dış Bükey Sonlanma Geometrisine Sahip Işık Kılavuzu

Şekil 4'de gösterildiği gibi ışık kılavuzunun sonlandığı yapı dış bükey bir geometri olarak tasarlanmıştır. Sonrasında optik tasarım programı ile insan gözünün, gerçek üründe göreceği ışık şiddetleri hesaplanarak simüle edilmiştir. Şekil 5'de farklı açılardan elde edilen simülasyon görüntüleri mevcuttur.

Şekil 4. Dış bükey sonlanmaya sahip ışık kılavuzu.

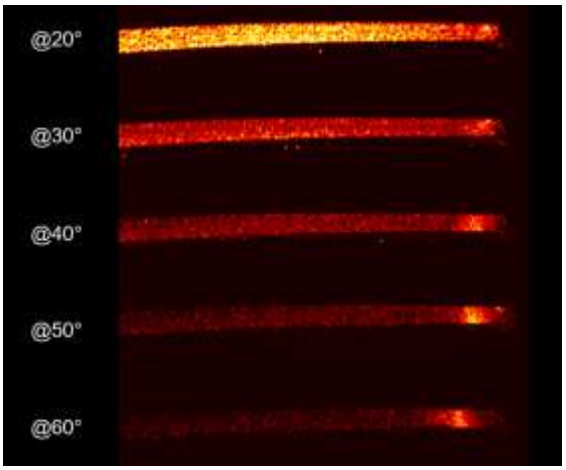


Şekil 5. Farklı görüş açılarından elde edilen simülasyon sonuçları.

3.2. İç Bükey Sonlanma Geometrisine Sahip Işık Kılavuzu

Şekil 6'da gösterildiği gibi ışık kılavuzunun sonlandığı yapı iç bükey bir geometri olarak tasarlanmıştır. Sonrasında optik tasarım programı ile insan gözünün, gerçek üründe göreceği ışık şiddetleri hesaplanarak simüle edilmiştir. Şekil7'de farklı açılardan elde edilen simülasyon görüntüleri mevcuttur.

Şekil 6. İç bükey sonlanmaya sahip ışık kılavuzu.

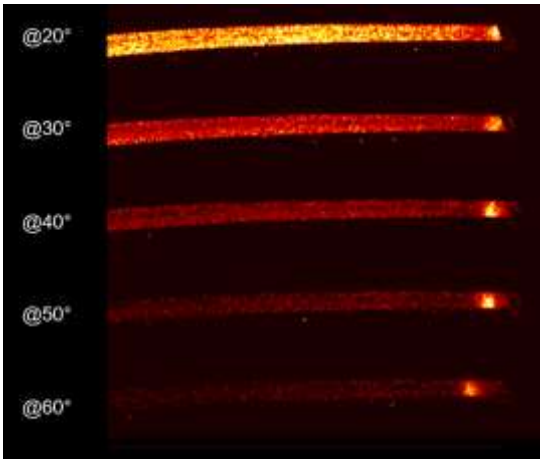


Şekil 7. Farklı görüş açılarından elde edilen simülasyon sonuçları.

3.3. Konik (Taper) Sonlanma Geometrisine Sahip Işık Kılavuzu

Şekil 8'de gösterildiği gibi ışık kılavuzunun sonlandığı yapı konik şeklinde bir geometri olarak tasarlanmıştır. Sonrasında optik tasarım programı ile insan gözünün, gerçek üründe göreceği ışık şiddetleri hesaplanarak simüle edilmiştir. Şekil 9'da farklı açılardan elde edilen simülasyon görüntüleri mevcuttur.

Şekil 8. Konik bükey sonlanmaya sahip ışık kılavuzu.



Şekil 9. Farklı görüş açılarından elde edilen simülasyon sonuçları.

4. SONUÇLAR VE TARTIŞMA

Üç farklı geometrik optik yapı ile, ışık kılavuzunun sonunda oluşan hot spotu minimize etme çalışmaları yapılarak simüle edilmiş ve sonrasında 1cm^2'lik son bölümlerin cd/m^2 ölçümleri alınarak sayısal kıyaslama yapılmıştır (Tablo 1).

Tablo 12: Farklı geometrik sonlanmalara sahip ışık kılavuzlarının son 1cm2 'lik alanlarının aydınlanma değerleri

Görüş Açısı	Dış Bükey Sonlanma	İç Bükey Sonlanma	Konik Sonlanma
20º	390 cd/m^2	230 cd/m^2	280 cd/m^2
30º	370 cd/m^2	220 cd/m^2	285 cd/m^2
40º	355 cd/m^2	200 cd/m^2	270 cd/m^2
50º	345 cd/m^2	205 cd/m^2	270 cd/m^2
60º	348 cd/m^2	200 cd/m^2	240 cd/m^2

Elde edilen sonuçlar göstermektedir ki, iç bükey bir sonlanmaya sahip ışık kılavuzları hot spotun oluşmasını, diğer geometrik yapılara göre minimum düzeye indirgemektedir. Ölçümler özellikle farklı görüş açıları ile yapılmıştır. Çünkü araç üzerindeki dış aydınlatma lambalarını müşteri gözü ile değerlendirdiğimizde, sadece karşıdan değil, aracın çevresinde dolaşarak; farklı görüş açılarında da en iyi aydınlanma homojenitesine sahip olmasını isteriz.

Yapılan bu çalışmada üretim teknolojileri de göz önünde bulundurulduğunda, iç bükey bir sonlandırma geometrisine sahip ışık kılavuzları tasarlamak her ne kadar zor olsa da henüz araç ön geliştirme safhalarında bu geribildirim stil ve araç mimarisi sorumlularına verilerek gerekli alanın oluşturulması sağlanmalıdır.

Elde edilen bu sonuçlarla birlikte benzer yaklaşım sadece ışığın kılavuzdan ayrıldığı yerlere değil; hot spot görülen farklı bölgelere de uygulanabilir. Böylelikle homojen bir dağılıma sahip yapılar elde edilebilir.

TEŞEKKÜRLER

Bu çalışmayı destekleyen TOFAŞ Türk Otomotiv Fabrikasına ve Optik Simülasyonlar konusunda destek veren MAKO'ya teşekkür ederiz.

ASKERİ PALETLİ ARAÇLARIN SÜSPANSİYON SİSTEMİ TASARIMI VE ANALİZİ

Murat MERCAN [1], Fevzi BEDİR [1]

[1] Gebze Teknik Üniversitesi, Makine Mühendisliği Bölümü, Kocaeli, Türkiye
Sorumlu Yazar: Murat MERCAN, e-mail: mmercan@gtu.edu.tr

ÖZET

Zor arazi şartlarında yüksek hareket kabiliyeti istenen askeri paletli araçlar, zeminden kaynaklı titreşim ve kuvvetlerin etkisi sebebiyle tekerlekli araçlara göre daha gelişmiş ve karmaşık süspansiyon sistemlerine sahiptirler. Bu kuvvet ve titreşimler araç gövde yapısına ve diğer ekipmanlara zarar verdiği gibi personelin sağlığı ve sürüş konforunu da etkilemektedir. Bu çalışmada, RecurDyn program kullanılarak bir askeri paletli aracın (M113 Personel Taşıyıcı Araç) süspansiyon sisteminin analizi ve iyileştirme önerileri üzerine çalışmalar yapılmıştır.

Anahtar kelimeler: Askeri Paletli Araçlar, Süspansiyon Sistemi, Soğurulan Güç, Dikey İvme, Yol Titreşimleri, M113.

THE DESIGN AND ANALYSIS OF MILITARY TRACKED VEHICLES' SUSPENSION SYSTEM

ABSTRACT

High mobility is required from military tracked vehicles in difficult terrain condition. For this reason, military tracked vehicles have more advanced and complex suspension systems than wheeled vehicles. Forces and vibrations from terrain not only damage the hull structure and other equipment, but also affect the safety and driving comfort of the crew. In this study, some studies were carried out on the analysis of the suspension system of a military tracked vehicle (M113 Armored Personnel Carrier) and improvement suggestions by using the RecurDyn program.

Keywords: Military Tracked Vehicles, Suspension Systems, Absorbed Power, Vertical Acceleration, Road Vibration, M113.

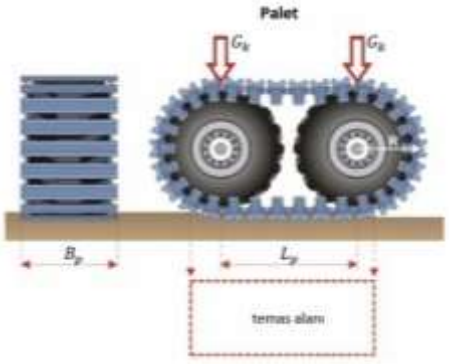
1. GİRİŞ

Zor arazi şartlarında yüksek hareket kabiliyetine sahip olan askeri paletli araçlarda süspansiyon sisteminin tasarımı, bu tip araçların performansını arttırmak açısından önemli bir konu olarak ortaya çıkmaktadır. Literatürde askeri paletli araçların süspansiyon konusuyla ilgili pek fazla ayrıntılı çalışma bulunmamaktadır. Paletli araçların süspansiyon sistemleri, özellikle aracın manevra kabiliyeti ve personelin sürüş konfor kriterleri birlikte göz önüne alınarak tasarlanır. Zor arazi koşullarında yüksek manevra kabiliyetine sahip bir araç süspansiyon sistemi tasarlanabilir, fakat bu arazi koşulları sebebiyle araçta oluşacak yüksek genlik ve frekans içeriğine sahip uyarılar (titreşim ve şok kuvvetleri) yeterli miktarda soğurulamaz ise sürücünün bu aracı kullanamamasına sebep olacaktır. Sürücü bu arazi koşulunda daha düşük hızlarda veya daha az manevra kabiliyetinde aracı kullanabilecektir. Tam tersi olarak düşünüldüğünde ise sürücü çok konforlu bir şekilde araç kullanabilmesi için çok yumuşak süspansiyon sistemleri tasarlanabilir, fakat bu durumda zor arazi şartlarında araç yüksek hızlara çıkamayacak veya yüksek manevra kabiliyetine sahip olamayacaktır.

2. PALETLİ ARAÇ SÜSPANSİYON SİSTEMLERİNİN TASARIM PARAMETRELERİ

Paletli araç süspansiyon sistemi tasarlanırken hem araç manevra kabiliyeti hem de sürüş konforu kriterleri göz önüne alınarak optimum tasarımlar yapılması gerekmektedir. Bu tasarımlar yapılırken özellikle "palet yer basıncı", "süspansiyon doğal frekansı", "teker yükü", "yay kuvveti" ve "sönüm kuvveti" kriterleri hem manevra kabiliyeti hem de sürüş konforu açısından detaylı olarak incelenmelidir.

Palet Yer Basıncı; Paletli araçların zemine yaptığı basınç, aracın tekerler üzerindeki ağırlık dağılımına ve palet konturunun zemine temas alanına bağlıdır. Yüksek palet yer basıncına sahip bir araç özellikle yumuşak zeminlerde zemine saplanarak hareket kabiliyeti azalacaktır. Palet yer basıncı yüksek araçlar karlı, çamurlu ve kumlu zeminlerde daha yüksek hareket kabiliyetine sahiptirler. **Şekil**1'de paletli bir aracın palet ölçüleri ve yük dağılımı temsili olarak gösterilmiştir. Bu bilgiler doğrultusunda **Denklem 1** ve **Denklem 2** aracılığıyla aracın palet yer basıncı hesaplanabilmektedir.



Şekil 1; Paletli bir aracın palet ölçüleri ve yük dağılımı

$$A_p \cong B_p \times \left(1.25 \times r + L_p\right) \quad \{mm^2\} \quad (1)$$

$$NGP_p \cong \frac{2 \times G_k + G_p}{B_t \times \left(1.25 \times r + L_p\right)} \quad \{MPa\} \quad (2)$$

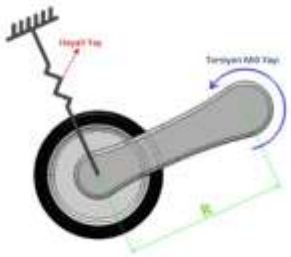
Süspansiyon Doğal Frekansı; Doğal frekans bir sistemin kütlesine ve esnekliğine bağlı olarak hesaplanan ve o sisteme özgü bir parametredir. Araçlarda doğal frekans incelenirken komple yapı temel olarak ikiye ayrılarak incelenmesi gerekmektedir. Bunlar yaylanan kütle ve yaylanmayan kütle olarak tanımlanmaktadır. Yaylanan kütle, süspansiyon kulelerinin üst tarafında kalan gövde komplesi olarak değerlendirilebilir; yaylanmayan kütle ise süspansiyon kulelerinin alt tarafında kalan tekerler ve süspansiyon sistemi kapsayan komple olarak değerlendirilebilir. Yay ve kütleye sahip bir sistemin doğal frekansı **Denklem 5**'e göre hesaplanır.

$$w_n = \sqrt{\frac{k}{m}} \quad \left\{rad/s\right\} \quad (3)$$

$$f_n = \frac{1}{2\pi} w_n \quad \{Hz\} \quad (4)$$

$$f_n = \frac{1}{2\pi}\sqrt{\frac{k}{m}} \quad \{Hz\} \quad (5)$$

Klasik tekerlekli araçlarda kullanılan helisel yaylar sebebiyle süspansiyon kolları doğrusal hareket etme kabiliyetine sahiptirler. Torsiyon mili kullanan bir paletli araçta yay elamanı sistemin dönme merkezinde bulunmaktadır. Bu durumda paletli aracın süspansiyon sisteminin doğal frekansının hesaplanabilmesi için dönme hareketi yapan yay elemanı yerine temsili olarak helisel yay düşünülerek doğal frekans hesabı yapılmalıdır. **Şeki2**'de torsiyon milli paletli bir aracın süspansiyon sisteminin şematik gösterimi yapılmıştır. Torsiyon miller yerine temsili helisel yaylar kullanılacağı için eşlenik yay katsayıları hesaplanmalıdır. **Denklem 6**'dan **Denklem 9**'a kadar bu hesaplama gösterilmiştir. **Denklem 10**'da ise torsiyon milli bir paletli aracın süspansiyon sisteminin doğal frekans hesabı denklemi gösterilmiştir.



Şekil 2; Torsiyon milli paletli bir aracın süspansiyon sisteminin şematik gösterimi

$$KE_{HY} = KE_{TB} \tag{6}$$

$$\frac{1}{2} * k_{HY} * x^2 = \frac{1}{2} * k_{TB} * Q^2 \tag{7}$$

$$x = R * \sin(Q) \qquad \{\sin(Q) \cong Q \ \text{ küçük açılar için}\}$$

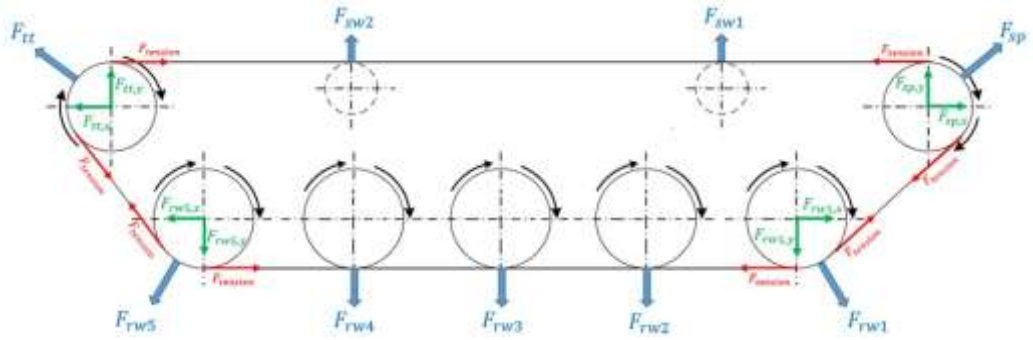
$$x = R * Q$$

$$\frac{1}{2} * k_{HY} * (R * Q)^2 = \frac{1}{2} * k_{TB} * Q^2 \tag{8}$$

$$k_{TB} = k_{HY} * R^2 \tag{9}$$

$$f_n = \frac{1}{2 * \pi} * \sqrt{\left(\frac{k_{TB} * N}{m_s * R^2}\right)} \tag{10}$$

Teker Yükü; **Şeki3**'de paletli bir araçta tekerlere, cer dişlisine, gergi tekerine ve istikamet makaralarına etki eden kuvvetler temsili olarak gösterilmiştir. Palet konturunun üst kısmında olan ve cer dişlisi ile gergi tekeri arasında kalan palet baklalarının ağırlıklarına karşı istikamet makaralarının oluşturduğu tepki kuvvetleri F_{sw1} ve F_{sw2} olarak gösterilmiştir. Palet gergi sisteminin gergi tekerini ötelemesiyle palette oluşan gerginlik $F_{tension}$ olarak, palet tekerinde oluşan tepki kuvveti ise F_{tt} olarak gösterilmiştir. Aynı şekilde palet gerginliği ile cer dişlisine etki eden tepki kuvveti F_{sp} olarak gösterilmektedir. Paletli araçlarda genel olarak 4-7 istasyon bulunmaktadır. Bu sebepten ötürü araç ağırlığını her bir istasyona dengeli şekilde dağıtma imkanı bulunmaktadır. İstasyonlardaki yay kuvvetleri hesaplanarak kurulması durumunda her bir tekere etki eden kuvvet birbirine yakın olacaktır. İstasyonlarda aynı yay katsayılı yay elemanları kullanılması durumunda istasyonların doğal frekansları da birbirine yakın olacaktır. Bu da süspansiyon ekipmanları seçimi ve sistem dinamik analizlerinin yapılmasında kolaylık sağlayacaktır. **Şeki3**'de 2. 3. ve 4. istasyonlarda palet gerginliğinin bir etkisi olmayacaktır. Araç ağırlığı ile bu istasyonlardaki yol tekerlerinde oluşan tepki kuvvetleri F_{rw2} , F_{rw3} ve F_{rw4} olarak gösterilmiştir. 1. ve 5. istasyonlara araç ağırlığı dışında palet gerginliğinin etki edeceğinden dolayı yol tekerlerinin oluşturacağı tepki kuvvetleri farklı doğrultuda olacaktır. Bu kuvvetler F_{rw1} ve F_{rw5} olarak gösterilmiştir. Tüm istasyonlardaki yol tekeri kuvvetlerinin birbirine eşit olması sağlamak için 1. ve 5. istasyon yol tekerlerinde palet gerginliğinden dolayı oluşan dikey kuvvetlerin etkisi göz önüne alınması gerekmektedir. Bu sebepten dolayı araç ağırlığının istasyonlara dağılımı 1.ve 5. istasyondan diğer istasyonlara (2., 3. ve 4. istasyon) palet gerginliğinin etkisi kadar aktarılmalıdır. Tüm bu değerlendirmeler aracın statik veya stabil (araç hızlanma veya yavaşlama hareketi yapmıyor iken) durumu için yapılmıştır. Araç hareket halindeyken cer dişlisinde oluşan moment, palet baklalarının hareketleri, ekipmanların ataleti, sürtünme kuvveti ve yoldan gelen kuvvetlerden, ekipmanlara etki eden kuvvetlerde anlık değişmeler oluşturacaktır.



Şekil 3; Paletli süspansiyon sistemine etki eder teker yükleri

Yay Kuvveti; Yay kuvveti oluşturabilmek için ya metalin esneme özelliğini ya da gazların sıkışabilme özelliğinden faydalanılmaktadır. Amaç metallerin veya gazların kuvvet altında şekil değiştirerek bünyelerinde enerji depolamalarıdır. Kuvvetin etkisi kaldırıldıktan sonra metal veya gazlar başlangıç konumuna dönerler. Askeri paletli araçlarda genel olarak 4 tip yay elemanı kullanılmaktadır. Bunlar;

- Torsiyon Mili (Burulabilen Mil)
- Helisel Yay
- Hidro-pnömatik Süspansiyon Ünitesi (HSU)
- Yol Kolu İçinde Süspansiyon Ünitesi (ISU)

Paletli araç üretin tarihine bakıldığında ilk başlarda torsiyon milli süspansiyon sistemleri kullanırken zaman içerisinde helisel yaylı süspansiyon ve daha sonrasında da hidro-pnömatik süspansiyon sitemleri kullanılmaya başlanmıştır. Fakat savaş koşullarında denenmiş olan paletli araçlarda ağırlıklı olarak torsiyon milli süspansiyon sistemi tercih edilmiştir.

Sönüm Kuvveti; Sönüm elemanları, sürüş esnasında yoldaki engebeler sebebiyle meydana gelecek sarsıntıların şiddetini ve etkisini hafifletmek için kullanılan özel ekipmanlardır. Sönüm elemanlarının genel olarak çalışma prensibi, tekerin yukarı veya aşağı doğru hareketine karşı direnç oluşturmaktır. Teker hareketleri ile sahip olunan kinetik enerji, yay elemanlarında depolanacak potansiyel enerjiye dönüşüm esnasında, sönüm elemanları sistem üzerinden enerji çalarak ısı enerjisine dönüştürürler. Sönüm elemanları sadece araç gövdesine gelen kuvvetleri sönümlemek için kullanılan elemanlar değildir. Aynı zamanda tekerlerin yolu veya paleti iyi kavramalarını sağlarlar ve virajlarda araçların savrulmasını engellerler. Ayrıca tekerlerin yola veya palete iyi basmalarını ve tekerlerin zıplamasını engelleyerek hem çekişi arttırır hem de fren yapıldığını durma mesafesini kısaltırlar. Askeri paletli araçlarda genel olarak kullanılan sönüm elemanları;

- Doğrusal damper (amortisör)
- Hidrolik döner damper
- Sürtünmeli döner damper
- Hidro-pnömatik Süspansiyon Ünitesi (HSU)
- Yol Kolu İçinde Süspansiyon Ünitesi (ISU)

3. APG STABİLİZASYON PARKURU

APG Stabilizasyon parkuru 455m uzunluğundaki beton bir saha üzerine dağıtılan 2 farklı tipte seri engellerden oluşmaktadır [1]. Bu parkur iki farklı sınıftaki araçlarının özelliklerini test etmek için kullanılmaktadır. Tank ve benzeri sınıftaki ağır tonajdaki paletli araçların atış kontrol sistemlerinin stabilizasyonu bu parkurda test edilmektedir. Orta ve hafif tonajdaki paletli ve tekerli araçların süspansiyon sistemi de bu parkurda test edilmektedir. **Şekil4**'de Amerika'nın Aberdeen Test Merkezi'nde bulunan APG Stabilizasyon parkuru gösterilmiştir. Bu parkur özellikle ABD ve NATO tarafından askeri araçları karşılaştırabilmek ve sürüş performanslarını değerlendirebilmek için referans alınan parkurdur.

Şekil 4; Aberdeen Test Merkezi'ndeki APG Stabilizasyon parkuru

4. SÜRÜCÜ TARAFINDAN SOĞURULAN GÜÇ DEĞERİ

Titreşim enerjisinin bir insan tarafından sönümlenebilme hızının bir ölçüsüdür ve engebeli araziden çalışan askeri araçlar için titreşime karşı insan toleransını tanımlamak için kullanılmıştır. Soğurulan güç kavramı, ABD ordusu ve NATO tarafından askeri araçların sürüş kalitesini değerlendirmek için benimsenmiştir. Halihazırda soğurulan gücün üst sınırı, sürücünün konumunda 6 W olarak kabul edilmiştir [2]. Sürüş sınırlayıcı hızı, sürücünün toplam geçen süre boyunca ortalama emdiği gücün 6 W'lık seviyeye ulaştığı hızdır. Soğurulan gücün 6 W değerini geçtiği araç hızı, kritik araç hızı olarak kabul edilmektedir ve bu hızdan yüksek hızlarda gitmek yolcuların sağlığı için sakıncalı olarak değerlendirilmektedir. Soğurulan güç değeri ivme spektral yoğunluk spektrumunun (PSD) uygun transfer fonksiyonu ile çarpılıp integralinin alınmasıyla hesaplanır.

$$P = \sum_{1}^{n} (C_i)(A_i)^2 \qquad \{W\} \qquad (11)$$

Tablo 1; Personel tarafından soğurulan güç formülündeki bileşenler

P	Soğurulan Güç	watts
A_i	i. frekans bandı için RMS ivme değeri	ft/s^2
C_i	i. frekans bandına karşılık gelen ağırlık katsayısı	$\frac{(K_1K_0)*(F_1F_4-F_2F_3)}{(F_3^2+W_i^2F_4^2)}$
W_i	frekans	rad/s
F	katsayı değerleri [2]	-
K	katsayı değerleri [2]	-

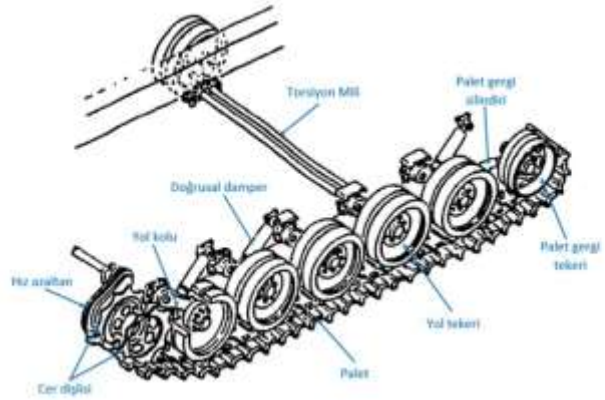
TOP 1-1-014A standardına göre sürücü tarafından soğurulan güç değerinin hesaplanabilmesi için 20 Hz'e kadar olan ivmeler, her bir frekans aralıkları için Butterworth yöntemi ile filtrelenerek grafiklerin RMS (karelerinin ortalamasının karekökü) değerleri bulunmalıdır. Bu RMS değerleri **Tablo1**'deki bilgiler yardımıyla **Denklem 11**'de kullanılır. Çıkan sonuç sürücü tarafından soğurulan güç değeri olarak belirlenir.

5. ÖRNEK BİR PALETLİ ARACIN ÖZELLİKLERİ

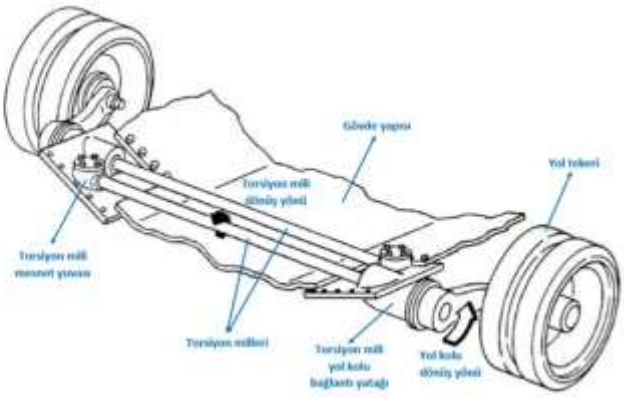
Bu çalışma kapsamında askeri paletli bir aracın süspansiyon sistemi analizi işlenmiştir. Bu analizin yapılabilmesi için dünyada en fazla üretilen ve açık kaynaklarda bilgilerine erişilebilen M113 aracı seçilmiştir [3] [4] [5]. Çeşitli açık kaynaklardan M113 aracının genel ölçüleri ve gövde yapısının mekanik özellikleri ile süspansiyon sisteminde kullanılan ekipmanların mekanik özellik bilgileri toplanmıştır. Bu bilgiler doğrultusunda tüm gövde yapısı, süspansiyon sistemi ve sürücü koltuk sisteminin hareket modeli RecurDyn programında hazırlanmıştır. Mevcut M113 aracının tasarımına göre, belirlenmiş arazi koşullarında sürücünün sürüş konforu göz önüne alınarak aracın sürülebileceği en yüksek hızlar belirlenmiştir. Bu sürüş hızlarının yükseltilmesi veya sürüş konforunun arttırılabilmesi için süspansiyon sisteminde iyileştirme önerilerinde bulunulmuştur. Bu iyileştirme önerileri doğrultusunda yeni modeller hazırlanmış ve koşturulmuştur. Analizler sonucunda mevcut durum ve iyileştirme önerileri sonucu durumların karşılaştırılması yapılmıştır. **Şekil5**'de örnek olarak alınan M113 aracının genel görüntüsü gösterilmiştir.

Şekil 5; M113 aracının genel görüntüsü

Şekil 6'da M113 aracının süspansiyon sisteminde kullanılan ekipmanlar şematik olarak gösterilmiştir. **Şekil 7**'de ise M113 aracının örnek olarak 1 istasyonunda kullanılan ekipmanlar gösterilmiştir. Bu istasyonda doğrusal damperler (amortisörler) gösterilmemiştir. M113 aracında 1.2. ve 5. İstasyonlarda doğrusal damper kullanılmıştır, fakat 3. ve 4. istasyonda doğrusal damper kullanılmamıştır.



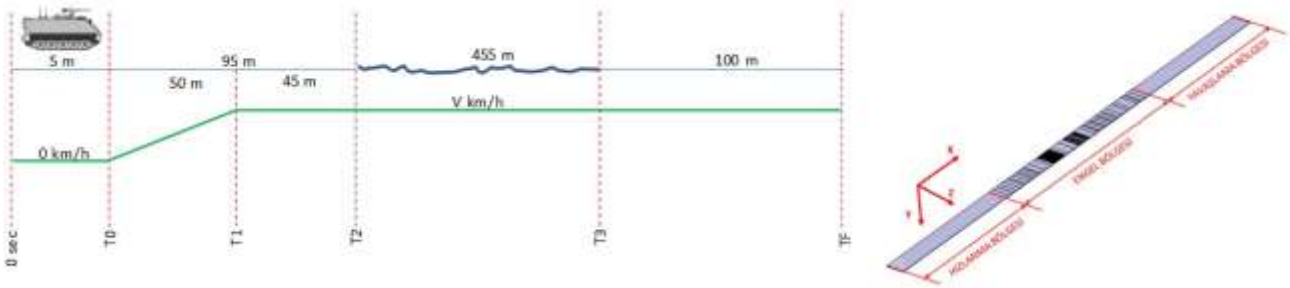
Şekil 6; M113 aracının süspansiyon sistemi ekipmanları



Şekil 7; M113 aracının bir istasyonundaki ekipmanlar

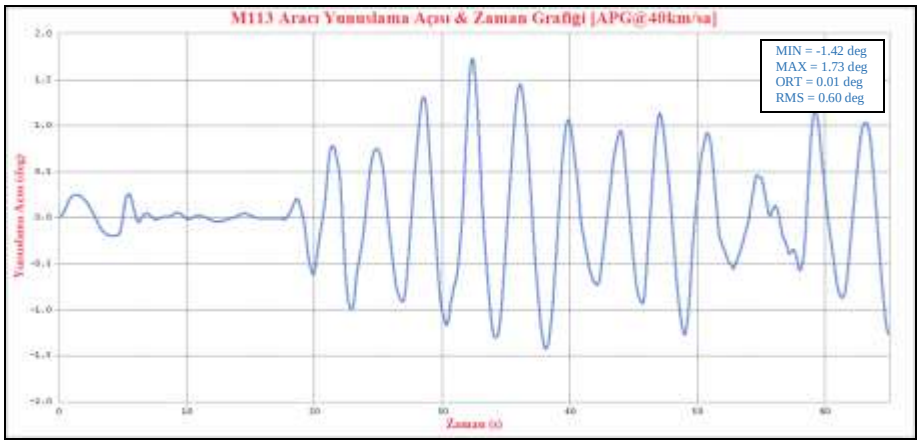
6. ÖRNEK ARACIN APG PARKURUNDA KOŞTURULMASI

Aracın APG parkuruna (stabilizasyon) dengeli ve sabit bir hızda başlayabilmesi için öncesinden şartlandırılmış olması gerekmektedir. APG parkurunun etkileri doğru gözlemlenebilmesi için parkur sonrasında düz bir yolda aracın tekrar dengeye gelmesi gerekmektedir. **Şekil8**'de analizde APG parkurunda süspansiyon performansı ölçülen aracın izlediği yol ve şartlandırılma senaryoları gösterilmiştir. Araç 0 – T0 süresi zarfında hareketsiz bekletilerek tüm süspansiyon ve palet sisteminin dengeye gelmesi beklenmektedir. T0 – T1 süresi zarfında (50m boyunca) araç belirlenen hıza ulaşabilmesi için ivmelendirilmektedir. Araç T1 anında belirlenen hıza ulaşmış olmaktadır. Bu ivmelenme hareketi sebebiyle araçta yunuslama (başvurma) açısal hareketleri olmaktadır. Bu sebeple T1 – T2 zaman zarfından (45m boyunca) yunuslama açısal hareketleri sönümlenebilmesi için araç belirlenen sabit hızla sürüşüne devam etmektedir. T2 anında 455m'lik APG parkuru başlamaktadır. T2 – T3 zaman zarfında araç APG parkurunda koşturulmaktadır. T3 anında APG parkuru sonlanmaktadır. Parkur sonrasında araçta hem yunuslama hem de yalpalama hareketleri oluşacaktır. Bu hareketlerin sönümlenmesi için T3 – TF zaman zarfında (100m boyunca) araç sabit hızla sürüşüne devam etmektedir. TF anında analiz sonlandırılmaktadır.

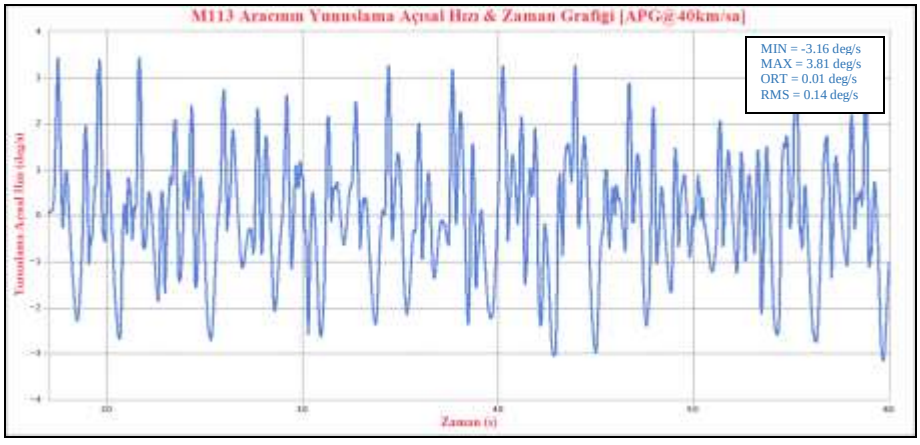


Şekil 8; Analizde koşturulan APG parkuru, öncesi ve sonrası

Sürüş konforu açısından önemli olan yapılan bu açıların türevi olan açısal hızların büyüklüğüdür. Standartta sürücünün sürüş konforunu etkilemeyecek açısal hız üst limit değeri 25 deg/s olarak belirtilmiştir [6]. **Şekil9'de** M113 aracının zamana göre yaptığı yunuslama açı grafiği, **Şekil10**'de M113 aracının yaptığı yunuslama açılarının türevi alınarak zamana göre açısal hız grafiği çizdirilmiştir. APG parkurundan 40 km/sa hızla gidilirken maruz kalınan en üst açısal hız değeri 3.81 deg/s olarak ölçülmüştür. Koltuğunun süspansiyon mekanizması sayesinde sürücünün maruz kaldığı yunuslama açısal hız değeri 1.21 deg/s değerine kadar düşürülmüştür. Bu değerler limitin altında olmasından dolayı aracın yaptığı yunuslama açısal hızı sürüş konforunu etkilememektedir.

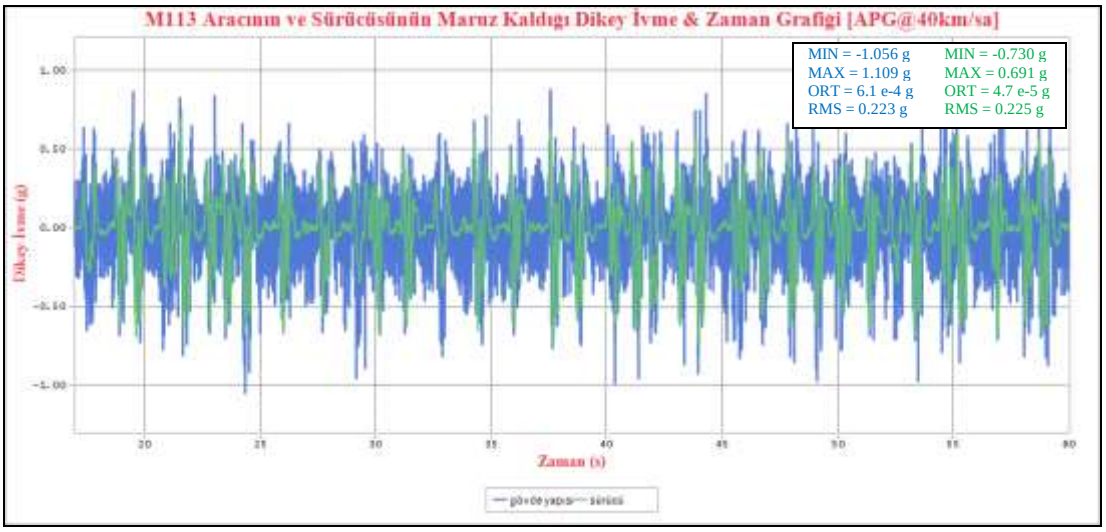


Şekil 9; M113 Aracı Yunuslama Açısı & Zaman Grafiği (APG@40km/sa)



Şekil 10; M113 Aracı Yunuslama Açısal Hız & Zaman Grafiği (APG@40km/sa)

Standartta sürüş konforu ve güvenliği için, sürüş esnasında personelin 2.5 g'nin üstünde dikey kuvvetlere maruz kalmaması istenmektedir [2]. **Şekil11**'deki grafik incelendiğinde sürüş esnasında gövde en fazla 1.109 g değerinde dikey kuvvete maruz kalmıştır. Fakat bu kuvvet koltuk süspansiyonu yardımıyla 0.691 g değerine kadar sönümlenmiştir. Bu sönümleme sayesinde sürücünün maruz kaldığı en yüksek dikey kuvvet, standartta belirtilen 2.5 g dikey kuvveti limitinin altında kalmıştır.



Şekil 11; APG parkurunda 40 km/sa hızla koşturulan M113 aracının ve sürücüsünün maruz kaldığı dikey ivmelerin (g) zamana (s) göre grafiği

Formüller aracılığıyla her bir frekans aralığı için bulunan soğurulan güç değeri toplandığında, sürücünün maruz kaldığı soğurulan güç değeri **4.98 W** olarak bulunmaktadır. Bu değer 6 W'ın altında olmasından dolayı sürücü oluşacak dikey kuvvetler sebebiyle bu parkurda aracı 40 km/sa hız ile sürekli kullanabilecektir.

Tablo 2; APG parkurunda 40 km/sa hızla koşturulan M113 aracının sürücüsünün maruz kaldığı dikey ivmelerin oluşturduğu soğurulan güç değerinin hesap tablosu

M113 aracı APG parkurunda çeşitli hızlarda koşturulmuştur. Bu hızlarda sürücü tarafından soğurulan güç değerleri **Tablo3**'de gösterilmiştir. Değerler incelendiğinde M113 aracının APG parkurundan en yüksek **40km/sa** hız ile geçebileceği anlaşılmaktadır.

Tablo 3: APG parkurunda koşturulan M113 araçlarının değerlerinin karşılaştırılması

APG Geçiş Hızı	Sürücü tarafından soğurulan güç	Gövde yapısında oluşan en yüksek dikey ivme	Gövde yapısının en yüksek yunuslama açısal hızı
30 km/sa	4.75 W	1.99 g	5.03 deg/s
35 km/sa	4.84 W	3.95 g	19.39 deg/s
40 km/sa	4.98 W	1.11 g	3.82 deg/s
45 km/sa	6.33 W	1.45 g	3.77 deg/s
50 km/sa	6.53 W	1.25 g	3.90 deg/s

7. SÜSPANSİYON SİSTEMİ İYİLEŞTİRME ÖNERİLERİ VE ANALİZ SONUÇLARI

Mevcut bilgiler doğrultusunda APG parkurunda koşturulan M113 aracı için, sürücünün en yüksek hızda sürekli sürüş yapabileceği hız seviyesi 40 km/sa'tir. Bu sürüş performans kabiliyetini arttırabilmek için M113 aracının süspansiyon sisteminde bazı değişiklikler değerlendirilmiştir. Bu değişiklikler;

- Süspansiyon sistemine istikamet makaralarının eklenmesi
- 3. ve 4. istasyona da diğerleri ile aynı özelliklerde doğrusal damper takılması
- Süspansiyon doğal frekansının tavsiye edilen aralığa çekilmesi
- Hidro-pnömatik palet gergi sisteminin kullanılması
- Palet ile temas eden metal yüzeylerin kauçuk kaplanması

Tablo4'de mevcut M113 aracının süspansiyon sistemi ile iyileştirme önerilerinin uygulandığı M113 aracının süspansiyon sistemi karşılaştırmalı olarak gösterilmiştir.

M113 aracında cer dişlileri ile gergi tekerleri arasında üst kısımda kalan palet grubu, ağırlıkları sebebiyle yol tekerlerinin üzerine sarkmaktadır. Bu durum palet gerginliğinin her tarafta dengeli bir şekilde dağılmasına engel olmaktadır. Sürüş esnasında palet kılavuz tırnakları yol tekerlerinin arasına giremeyip tekerlere çarpabilmektedir. Ayrıca yüksek hızlara çıkıldığında cer dişlilerinin palet kulaklarını güvenli bir şekilde kavrayamamasından dolayı palet atmaları da gözlemlenebilmektedir. Engellerden geçerken yol tekerlerinin yukarıya doğru hareket etmesinden ötürü ilave palet bollaşması meydana gelmektedir. Bu durumda palet grubu gövde yapısına çarpmaktadır, ya da palet atmaları gözlemlenebilmektedir. Üst palet grubu sarkmaması ve paletlerin yol tekerlerinin arasına girmemesi için istikamet makaraları kullanılmıştır. İstikamet makaraları 1. ile 2. yol tekerinin arasında 1 adet ve 4. ile 5. yol tekerinin arasında 1 adet olmak üzeri her bir tarafta 2 adet olarak konumlandırılmıştır. Konumları, engellerden geçerken yol tekerlerinin yukarıya doğru süpürdüğü alan göz önüne alınarak belirlenmiştir.

Mevcut M113 aracında sadece 1., 2. ve 5. istasyonlarda sönüm elemanı (doğrusal damper) kullanılmıştır. Sürüş esnasında engellerden geçerken yol kollarının en fazla hareket ettiği istasyonlar bu istasyonlardır. Fakat 3. ve 4. istasyonlara da doğrusal damper takılması, diğer istasyonlardaki doğrusal damperlerin etkisi kadar olmasa da yine de yoldan gelen kuvvetlerin sönümlenmesinde yardımcı olacaktır. Ayrıca aracın yunuslama açısı ve yunuslama açısal hızının düşmesine de yardımcı olacaktır.

M113 aracının yay katsayısı, yol kolu boyu, istasyon adedi ve aracın yaylanan kütlesi hesaplamada kullanıldığında sonuç olarak aracın süspansiyon sistemi ortalama doğal frekansı 1.352 Hz olarak çıkmaktadır. Wong'un yaptığı çalışmada paletli bir araç için ideal süspansiyon doğal frekansının $1.1<f_n<1.3$ aralığında olması gerektiğini belirtmiştir [6]. M113 aracının süspansiyon doğal frekansının istenilen aralığa getirilebilmesi için şunlar yapılabilir;

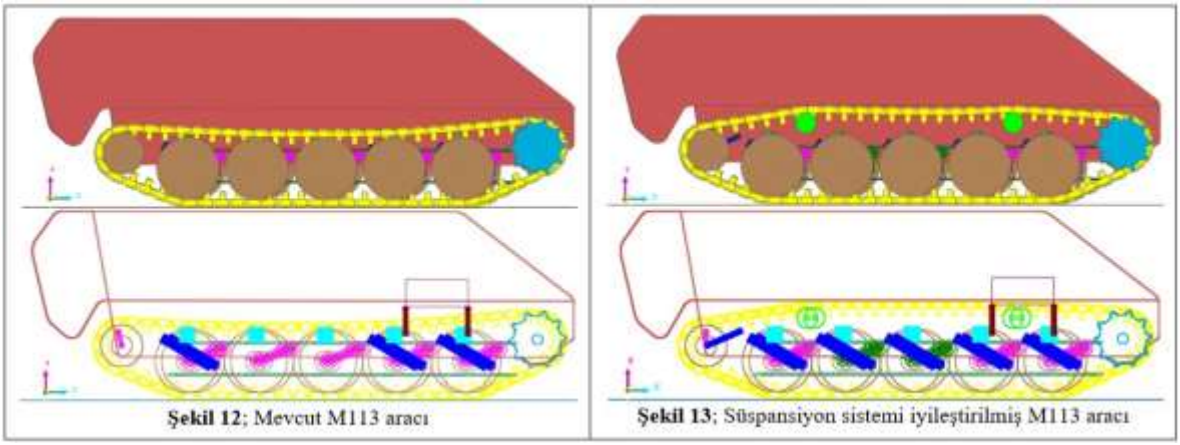
- Yaylanan kütle miktarının arttırılması; Yaylanan kütlenin arttırılması demek, mevcut aracın üzerine ilave yükler konulması demektir. Bu aracın yapısal dayanımını, çekiş gücünü, tırmanma kabiliyetini ve güç grubu performansını düşüren etkenlerdir.
- İstasyon sayısının düşürülmesi; İstasyon sayısının 10'dan 8'e düşürülmesi durumunda süspansiyon doğal frekansı $\sqrt{0.8}$ oranında etkileyecektir. Yani yeni doğal frekans 1.211 Hz olacaktır. Tüm aracın boyu ve araç ağırlığının dengeli bir şekilde tekerlere dağıtılabilmesi için istasyonlar arası mesafe açılmalıdır. Bu durumda araç üzerinde ciddi bir tadilat işi yapılması gerekmektedir.
- Yol kolu boyunun arttırılması; İstenilen doğal frekans aralığına gelebilmek için yol kolu boyunun 5% – 23% oranında arttırılması gerekmektedir. İstenilen süspansiyon doğal frekansının ortalama değer olarak 1.2 alındığında yol kolu boyunun 13%'de artması gerekmektedir. Bu durumda yol koluna bağlı yol tekerlerinin statik – jounce – rebound hareketlerinde tekerlerin birbirine çarpması söz konusu olacaktır. Ayrıca daha önce sistemin izin verdiği yol tekerin dikey yer değiştirme miktarını gerçekleştirebilmek için kullanılabilen burulma açısı değeri düşecektir.
- Yay katsayısı değerinin düşürülmesi; Her bir istasyona kullanılan torsiyon millerinin yay katsayı değeri daha düşük olan versiyonları ile değiştirilebilir. Mevcut arayüzlere uyumlu yeni torsiyon milleri ile istenilen süspansiyon doğal frekansı sağlanabilir. Wong'un yaptığı çalışmada tavsiye ettiği süspansiyon frekansı aralığı değerlendirildiğinde ortalama değer olarak 1.2 Hz alındığında, torsiyon milinin olması gereken yay katsayısı değeri **Denklem 10**'dan yararlanılarak **Denklem 13**'de hesaplanmıştır.

$$k_{TB} = \frac{4 \times f_n^2 \times \pi^2 \times m_{yaylanan} \times R^2}{N} \quad \left\{N.m/_{deg}\right\} \quad (12)$$

$$k_{TB} = \frac{4 \times 1.2^2 \times \pi^2 \times 11439 \times 0.3175^2}{10} = 6555 \quad \left\{N.m/_{deg}\right\} \quad (13)$$

Mevcut M113 araçlarında palet gergi sistemi otomatik değildir. Araç montajı gerçekleştirilirken gergi kolu bir silindir yardımıyla kurulmaktadır. Araç hareket ederken bu silindir kilitli bir yapıda olduğu için yol kolunu ileri veya geriye doğru hareket ettirmemektedir. Palet gergi sistemi, sürüş esnasında araç engellerden geçerken palet konturunun bollaşmasına cevap verememektedir. Palet konturunun bollaşmasını çözümleyebilecek en uygun yöntem, sürüş esnasında palet gergi sisteminin ihtiyaç doğrultusunda hareket ederek bollaşan yapıyı toplamasıdır. Bunun için sabit kurulmuş bir gergi silindiri yerine hidro-pnömatik bir gergi silindirinin kullanılması değerlendirilmiştir. Hidro-pnömatik silindirlerin içerisinde basınçlandırılmış gaz sayesinde her halükarda palet konturuna bir itme hareketi gerçekleştirilecektir. Palet konturunun bollaşması durumunda, silindir boyu dengeye gelecek ihtiyaç miktarı kadar uzayarak paletin gergin kalmasını sağlayacaktır. Palet konturunun normalin dışında ekstradan gerilmesi durumunda ise silindir boyu dengeye gelecek ihtiyaç miktarı kadar kısalarak palet pimleri ve burçlarındaki yüksek gerginliğin azalmasını sağlayacaktır. Bu sayede hem palet baklaların ömürleri uzamış olacaktır, hem de palet konturu hep tutarlı şekilde bütünleşik hareket edecektir.

Tablo 4; Mevcut M113 aracı ve süspansiyon sistemi iyileştirilmiş M113 aracının süspansiyon sistemleri karşılaştırması



Şekil 12; Mevcut M113 aracı

Şekil 13; Süspansiyon sistemi iyileştirilmiş M113 aracı

Süspansiyon sisteminde iyileştirme önerileri uygulanmış M113 aracının APG parkurunda tekrardan farklı hızlarda koşturulmuştur. Her bir hız için sürücü tarafından soğurulan güç değeri, gövde yapısında oluşan en yüksek dikey ivme değeri ve gövde yapısında gerçekleşen en yüksek yunuslama açısal hız hareketi değerleri **Tablo 5**'de verilmiştir.

Tablo 5; APG parkurunda koşturulan süspansiyon sistemi iyileştirilmiş M113 araçlarının değerlerinin karşılaştırılması

APG Geçiş Hızı	Sürücü tarafından soğurulan güç	Gövde yapısında oluşan en yüksek dikey ivme	Gövde yapısının en yüksek yunuslama açısal hızı
30 km/sa	1.04 W	1.46 g	4.18 deg/s
35 km/sa	1.62 W	1.65 g	3.72 deg/s
40 km/sa	2.11 W	2.22 g	3.59 deg/s
45 km/sa	2.47 W	1.97 g	3.13 deg/s
50 km/sa	3.24 W	2.03 g	3.18 deg/s
60 km/sa	5.30 W	2.36 g	3.42 deg/s
65 km/sa	6.19 W	4.83 g	6.81 deg/s

8. SONUÇLAR VE YORUMLAR

Askeri paletli bir aracın süspansiyon sistemi tasarlanırken araç ağırlığı, görev profili, araç hızı, kullanılacağı arazi profiline göre süspansiyon sistemi ekipmanları seçilmeli ve tasarlanmalıdır. Araç ağırlığının etkisi ile palet konturunun oluşturduğu palet yer basıncı; istasyon sayısı; kullanılan yay sertliği, yol kolu boyu ve yaylanan kütlenin ağırlığına bağlı olarak oluşan süspansiyon doğal frekansı; tekerlere düşen araç ağırlığının homojen şekilde dağıtılması; tercih edilecek yay ve sönüm sisteminin özelliklerinin belirlenmesi; kullanılacak olan palet türü (tek pimli, çift pimli, kauçuk …vb.); palet gergi sisteminin etkisi; istikamet makaralarının etkisi; çarpma takozları (bump stop) etkisi; kullanılacak kauçuk ve burç malzemelerinin mekanik özellikleri doğru seçilip hesaplanmalı ve analiz programları ile desteklenmelidir.

Paletli araçlarda, tekerlekli araçlara göre daha çok sayıda istasyon (tekerlekli araçlar için aks) kullanılmaktadır. Bunun sebebi arazideki engellere süspansiyon sistemi daha bütünleşik şekilde cevap verebilmesidir. Arazideki engelleri

yoğunluğu, yüksekliği, genişliği ve sayısı paletli araçta oluşacak kuvvetleri belirlemektedir. Bu engellerin özellikleri (engellerin oluşturduğu frekans ve genlik) ile paletli araçtaki istasyonların arasındaki mesafe, sayısı, yay ve sönüm karakteristiği direk olarak ilgilidir. Hem arazideki engellerin hem de süspansiyon sisteminin bu özellikleri birbirine göreceli olarak sonuç oluşturmaktadır. Örneğin aracın hızının artması ile personele etki eden dikey kuvvet her zaman artmayabilir, bazı düşük hızlarda bu değerler yüksek, başka değerlerde düşük olabilir.

Tablo3'de APG parkurunda mevcut M113 aracı 35 km/sa hız ile giderken gövde üzerinde 3.95 g değerinde dikey ivme oluşmuştur. Bu değer hem daha düşük hızda (30 km/sa) hem de daha yüksek hızlarda (40-45-50 km/sa) sürüş yapılırken gövde üzerinde oluşan dikey ivme değerlerinden daha yüksektir. **Tablo 5**'de süspansiyon sistemi iyileştirilmiş M113 aracının hızlarına göre gövde yapısında oluşan dikey ivmeler karşılaştırıldığında 40 km/sa hızda oluşan dikey ivme diğer hızlardaki değerlere göre daha yüksektir. Süspansiyon sistemi iyileştirildiği için hızlara göre oluşan dikey ivme değerleri arasında değer farkları mevcut M113 aracının değer farklılıklarına göre daha azdır. Yine **Tablo3**'de araç hızlarına göre gövde yapısının yaptığı en yüksek yunuslama açısal hızları karşılaştırıldığında mevcut M113 aracının 35 km/sa hız ile giderken oluşan değer (19.39 deg/s) diğerlerine nazaran çok yüksektir. Araç 35 km/sa hız ile giderken mevcut M113 aracının süspansiyon sisteminin karakteristiği ile APG parkur engellerinin karakteristiği arasında bazı parametreler olumsuz anlamda çakışmaktadır. Süspansiyon sistemi sönümleme hareketi yapamadan başka bir olumsuz parametre değerlerin yükselmesine sebep olmaktadır. Süspansiyon sistemi iyileştirilmiş M113 aracının değerleri incelendiğinde, araç 30 km/sa hız ile giderken gövde yapısının en yüksek yunuslama açısal hızı değeri diğer hızlardaki değerlere göre daha yüksektir. Fakat hızlar arasındaki bu farklılık mevcut M113 aracındaki değer farklılıklarına göre daha az değişkenlik göstermektedir. Gövde yapısı üzerinden ölçülen en yüksek dikey ivme değeri ve yunuslama açısal hızı değeri kısa süreliğine oluşan değerlerdir. Bu değerlerin sürüş güvenliği ve konforu açısında önemli parametreler olmasına rağmen sürüşün sürekliği düşünüldüğü zaman doğru karşılaştırmanın yapılabilmesi için sürücü tarafından soğurulan güç değerinin incelenmesi daha doğru yaklaşım olacaktır. **Tablo3** ve **Tablo 5**'deki hem mevcut M113 aracı hem de süspansiyon sistemi iyileştirilmiş M113 aracının sürücüleri tarafından soğurulan güç değerleri incelendiğinde araç hızı arttıkça değerler artmaktadır.

BÖLÜM 7'de belirtilen süspansiyon sistemi iyileştirme önerileri M113 aracı modeline işlenerek aynı yol koşulları ile RecurDyn programı kullanılarak APG parkurunda koşturulmuştur. Analiz sonuç değerleri (soğurulan güç, dikey yönde ivme, yunuslama açısal hızı) **Tablo3** ve **Tablo 5**'ye girilmiştir. Bu tablolardaki sonuçlar değerlendirildiğinde süspansiyon sistemi için önerilen iyileştirmelerin başarılı olarak sonuç verdiği görülmüştür. İyileştirme sonrası sürücünün maruz kaldığı soğurulan güç değerleri her bir hız için düştüğü tespit edilmiştir. **Tablo 5**'deki bilgiler doğrultusunda, süspansiyon sistemi iyileştirilmiş M113 aracının sürücüsü aracı APG parkurunda en yüksek **60 km/sa** hız ile sürebilmektedir.

ÖZET

Bu çalışmada, askeri kara araçlarının kapı kilitleme mekanizmalarının NATO Stanag-4866 standartlarına uygun olarak gerçekleştirilmiştir. Önceki çalışmamızda geliştirilen kapı kilit mekanizmalarının bu çalışmada askeri zırhlı kara araçlarının kapı kilit açma mekanizmasına yerleştirerek patlama senaryoları ve testleri gerçekleştirilmiştir. Patlama analizleri LS-DYNA programı ile gerçekleştirilmiştir. Patlama senaryoları AEP-62 test ve performanslarına uygun olarak patlama senaryoları uygun olarak hazırlanmıştır. Patlama senaryosu araç altı orta bölge patlama modeli seçilmiştir. Analizlerden elde edilen sonuçlara göre; patlama basınçları 0,85 saniyeden başlamak üzere maksimum değerlere ani bir pik yapmıştır ve 1,2 saniyede 220 GPa değerlerine ulaşmıştır. Araç tabanında 132 mm bir çökme ölçülmüştür. Bu değerin plastik şekil değişim bölgesinde olduğu ve kalıcı hasar meydana geldiği sonucuna varılmıştır.

Anahtar kelimeler: Askeri Kara Araçları, kapı kilit mekanizması, Mayın patlama Senaryosu, NATO Standartı, FEM.

ANALYSIS OF EXPLOSIVE SHOCK WAVE EFFECT ON THE MILITARY VEHICLES WITH A SPECIAL HEIGHT BY USING FINETE ELEMENT METHOD

ABSTRACT

In this study, explosion tests of military land vehicles' door locking mechanisms were carried out in accordance with NATO Stanag-4866 standards. Explosion scenarios and tests were carried out by replacing the door lock mechanisms of military armored land vehicles developed in our previous study. Explosion analyzes were performed with the LS-DYNA program. Explosion scenarios have been prepared in accordance with AEP-62 tests and performances. Under-vehicle middle zone explosion model was chosen for the explosion scenario. According to the results obtained from the analysis; burst pressures made a sudden peak to maximum values starting from 0.85 sec and reached 220 GPa values in 1.2 sec. 132 mm collapse occurred on the vehicle floor. It was concluded that this value was in the plastic deformation region and permanent damage occurred.

Keywords: Military Land Vehicles, Door Lock System, Mine Explosion Scenarios, NATO Standards, FEA.

1. GİRİŞ

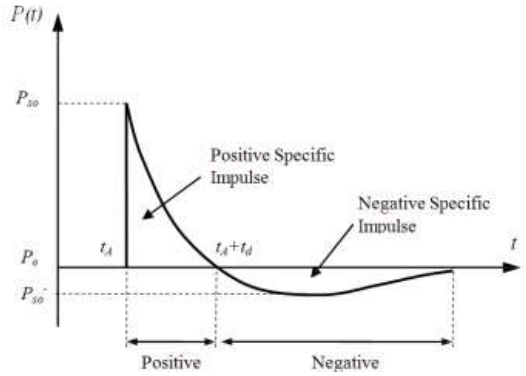
Teknolojik üstünlüğe sahip bir düşmana karşı temel silah olarak patlayıcıların kullanılması 21. yüzyılın başındaki sözde asimetrik savaşın ayırt edici bir özelliğidir. Terör örgütlerinin düzensiz, gerilla türü eylemlere odaklanan, ağırlıklı olarak hareket halindeki araçlar ve ekiplerine yönelik uyguladıkları taktikler, kara mayınları ve el yapımı patlayıcıların oluşturduğu patlayıcı şok dalgasından personelin korunmasını sağlayan araçların devreye girmesini öncelikli hedef haline getirdi. Son yıllarda, NATO ordularının uğradığı kayıpların sürekli artması nedeniyle bu araştırma yoğunlaşmıştır [1]. Patlama sonucunda hızlı bir enerji dalgası açığa çıkmakta ve ortama yayılmaktadır. Patlama türünün gömülü kara mayınları gibi yerleştirilmiş veya bilinen (uzak alan patlamaları) olup olmadığına bakılmaksızın, yapı farklı şekillerde tepki verebilir. Şöyle ki; koruyucu plaka yapı ya patlama dalgasının bir kısmını saptırır ya da plastik deformasyona uğrayarak kısmi veya tamamen parçalanma ve yırtılma deformasyonu meydana gelir. Uniform basınç yüküne maruz kalan plaka elemanlarında bu durum farklı yerel hasar modlarında tepki verebilir. Bu hasar modları başlangıçta Menkes ve Opat [2] tarafından kirişler için sınıflandırılmış, ancak daha sonra Nurrick ve Radford

[3]ve Olson ve arkadaşları [4] tarafından plakalar için geliştirilmiştir. Patlama etkisinin araştırıldığı levhalar üzerinde yapılan geçmiş çalışmaların çoğu, büyük plastik deformasyonlar ve daha sonra yüksek yük kütlelerinde sünek çekme yırtılması gösteren nispeten çelikler üzerinde yoğunlaşmıştır. Ayrıca yakın zamanlarda, ARMOX zırh çelikleri gibi yüksek mukavemetli çeliklere ilgi olmuştur. Langom ve arkadaşları **[**5] yumuşak çelik, ARMOX 370T, alüminyum alaşımı ve fiber takviyeli polimer kompozit plakalar üzerinde lokalize patlatma testlerinin sonuçlarını bildirilmiştir. Özellikle yüksek mukavemetli zırh çeliklerinin deformasyon sırasında depoladığı elastik enerjinin yumuşak çeliğe kıyasla yüksek olduğu gösterilmiştir[6].

Bununla beraber yapılan çalışmalarda kompozit yapı performansı metal yapı performansından daha iyidir. Kompozit yapılar**,** askeri araçlara monte edilerek ilave zırh sağlamak için yüksek mukavemet / ağırlık oranı sağlarlar[7-10]. Abdel Wahab ve arkadaşları[14] hafif yapıların performansına patlama dalgasının etkisini deneysel ve sayısal olarak tartıştı. VSC yapısı, patlama dalgasını aracın gövdesinden uzaklaştırarak aracın dibine iletilen patlama enerjisinin azaltılmasına yardımcı olur. Düz bir yüzey, yüzeyin altında önemli bir basınç konsantrasyonuna neden olur[11,12]. Toprak altına gömülü patlayıcı yüklere maruz kalan V-şekilli gövdelerin hafifletilmesi için çok küçük ölçekli deneyler gerçekleştirdi. 90˚ ve 120˚ eğim açılarına sahip kaynaklı V-şekilli plakalar üzerinde deneysel testler gerçekleştirdi. V şeklindeki plakalar, kara mayını patlama etkilerini simule etmek için gömülü patlayıcılara maruz bırakıldı. Mazek ve arkadaşları[13]araçları mayınlardan korumak için V-şekilli kompozit yapılar için patlatma sahası testleri gerçekleştirdi [14]. Bu çalışmada askeri kara araçlarında geliştirilen kapı-kilit sisteminin mayın patlaması sonucu oluşan şok dalga etkisinin saha testlerinden önce sonlu elemanlar yöntemi ile sanal ortam analizleri gerçekleştirilmiştir.

2. PATLAMA SONUCU OLUŞAN ŞOK DALGA KARAKTERİSTİĞİ

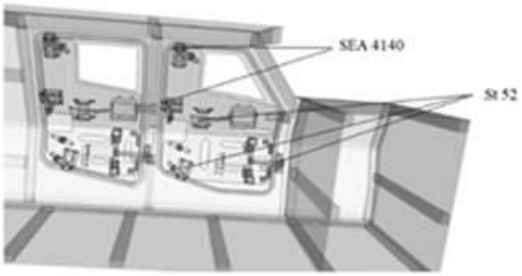
Tipik bir patlama basıncı profili Şekil 1'de gösterilmiştir. Yüksek patlayıcının etkisiyle oluşan patlama etkisi, patlayıcıdan çok yüksek aşırı basınç salınan yüksek hızlı bir şok dalgası şeklindedir. Bu aşırı basınç, basıncın çevredeki havaya genişlemesi nedeniyle mesafe ile çok hızlı bir şekilde azalır**.** Patlamanın ardından tA zamanı içerisinde Pso, basınç değeri aniden pik değerine yükselir, Pso ve bu değer ortam basınç değerinin (Po) üzerindedir. Basınç-zaman profili boyunca iki ana aşama gözlemlenebilir; ortamın üzerindeki kısım t_d süresinin pozitif aşaması olarak adlandırılırken, ortamın altındaki kısım sürenin negatif aşaması olarak adlandırılır. td daha düşük yoğunluklu, daha düşük genlikli ve bekleme mesafesi artış ve ardından pozitif fazın süresindeki artıştan dolayı daha uzun süreli şok etkisi görülür. Patlamanın fiziksel özellikleri, hava patlama dalgası özelliklerini etkiler. Basınç daha sonra t_d zamanında ortam seviyesine düşer. Hatta P_{so} (kısmi bir vakum yaratarak) basıncının altına kadar azalır. P_{so} değeri genellikle tepe yan aşırı basınç, tepe aşırı basınç olarak ifade edilir[15].



Şekil 1. Patlama dalgası basınç-zaman profili

3. SONLU ELEMANLAR MODELLENMESİ

Bu çalışmada kullanılan model mayın patlamasına karşı kara askeri araçlara gelen yüklerin ortaya çıkarılması ve kapı kilit sistemi tasarım parametrelerinin belirlenmesidir. Analizi basitleştirmek için araç 3D CAD modeli ve kapı modeli Şekil 2. de gösterilmiştir.



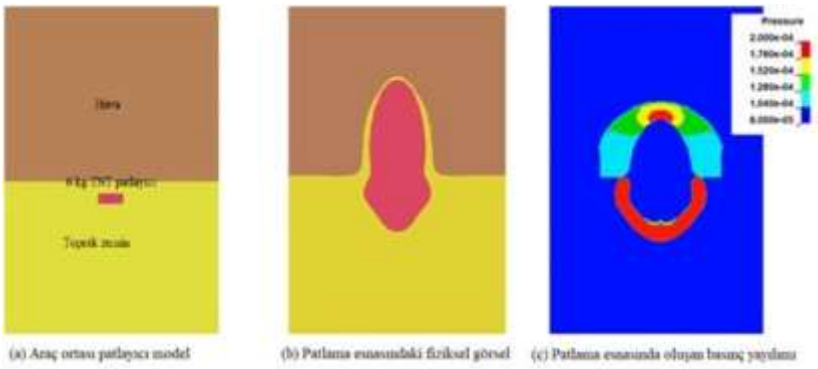
Şekil 2. Araç 3D CAD modeli ve kapı modeli

Sac parçalar ve kapılar 10 mm Armor 500 zırh çeliği olarak alınmıştır. Profiller St52 olarak alınmıştır. LS-DYNA sonlu elemanlar modelinde 425 "Beam Eleman", 244551 Shell element, 45554 Solid element ve 344278 Node içermektedir. Oluşturulan analiz modelinde en kötü durum dikkate alınmıştır ve akslar ve bunların bağlantılı dinamik elemanları modele dahil edilmemiştir. Bunlar yerine noktasal kütle ile dört noktadan bağlantı ifade edilmiştir. Toplam araç ağırlık 11.26 ton alınarak gerçeğe yakın bir model önerilmiştir. Karın altı yüksekliği 400 mm dir.

Model de kaynaklı bölgeler TIED kontak ile ifade edilmiştir. Gerekli cıvata bağlantıları modele dahil edilmiş ve Mxx 12.9 olarak alınmıştır. Özellikle kapı zırhı bağlantı cıvataları, kilit mekanizması ara saç bağlantı cıvataları ve kapı mafsalı cıvata ve 4140 olarak üretilen özel silindirik ince uzun parçalar "BeamEleman" lar ile bu malzeme limitleri baz alınarak modellenmiştir. Bunların haricinde bütün sistem birebirine "Automatic Single Surface" kontak biçimi ile 0.2 sürtünme katsayısı ile kontak tanımı yapılmıştır. Patlama simulasyonunda 6 kg silindirik TNT patlayıcı kullanılmıştır. Patlama senaryosu olarak araç ortası patlama kabul edilmiştir. Bu senaryoda NATO Standartlarına uygun test ve patlama senaryosu oluşturulmuştur[16].

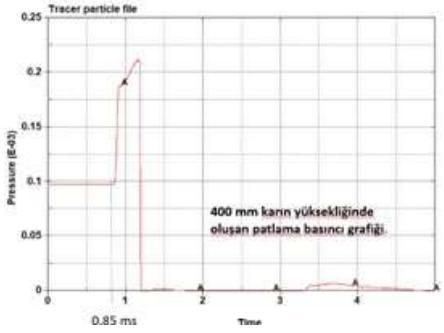
4. SONUÇ VE TARTIŞMALAR

6 kg TNT patlayıcının oluşturduğu araç ortası model ve basınç simülasyonu Şekil 3'de verilmiştir.



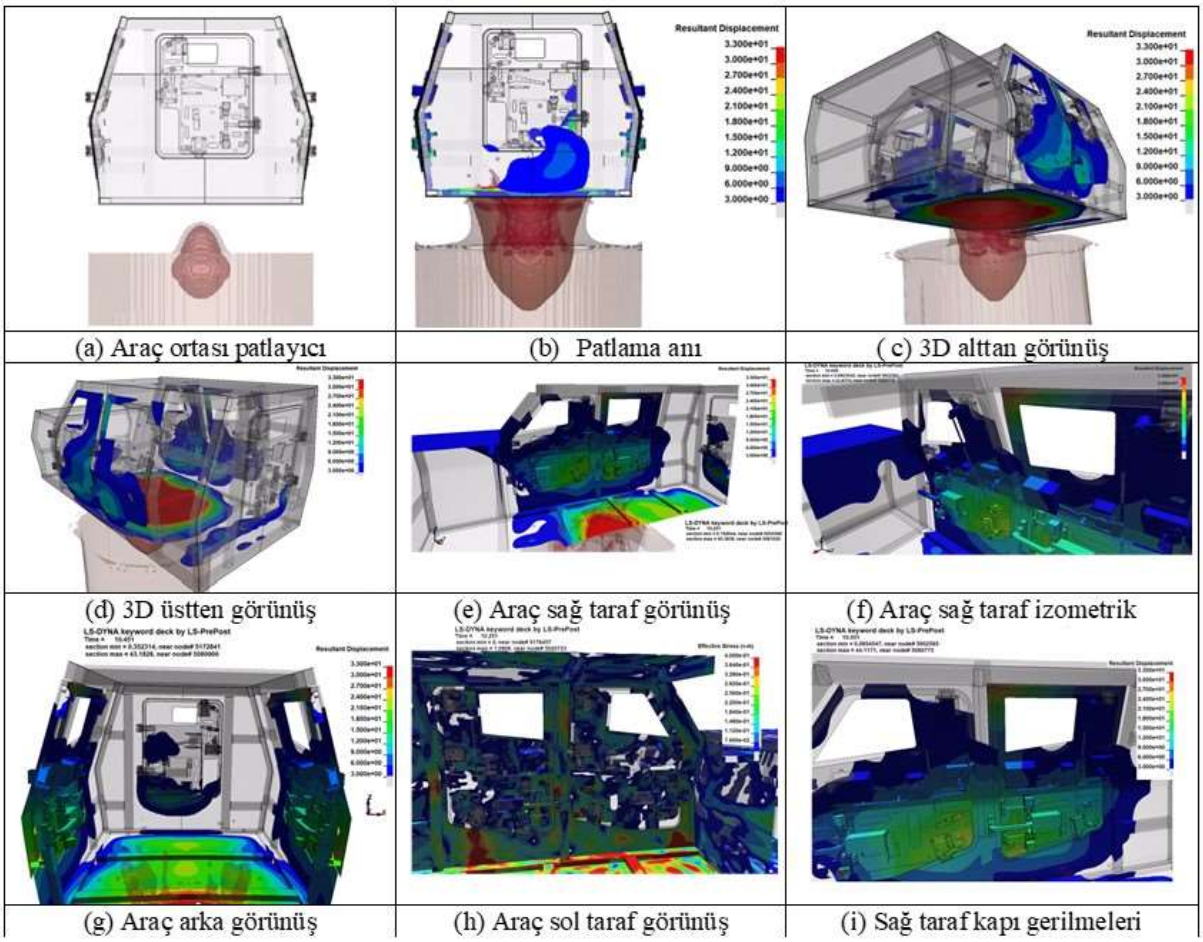
Şekil 3. 6 kg TNT patlayıcının oluşturduğu araç ortası model ve basınç simülasyonu

Simülasyon sonucunda elde edilen basınç yayılımının zamana bağlı olarak değişimi Şekil 4'te gösterilmiştir.



Şekil 4 Patlama sonucu oluşan basınç yayılımının zamana bağlı olarak değişimi

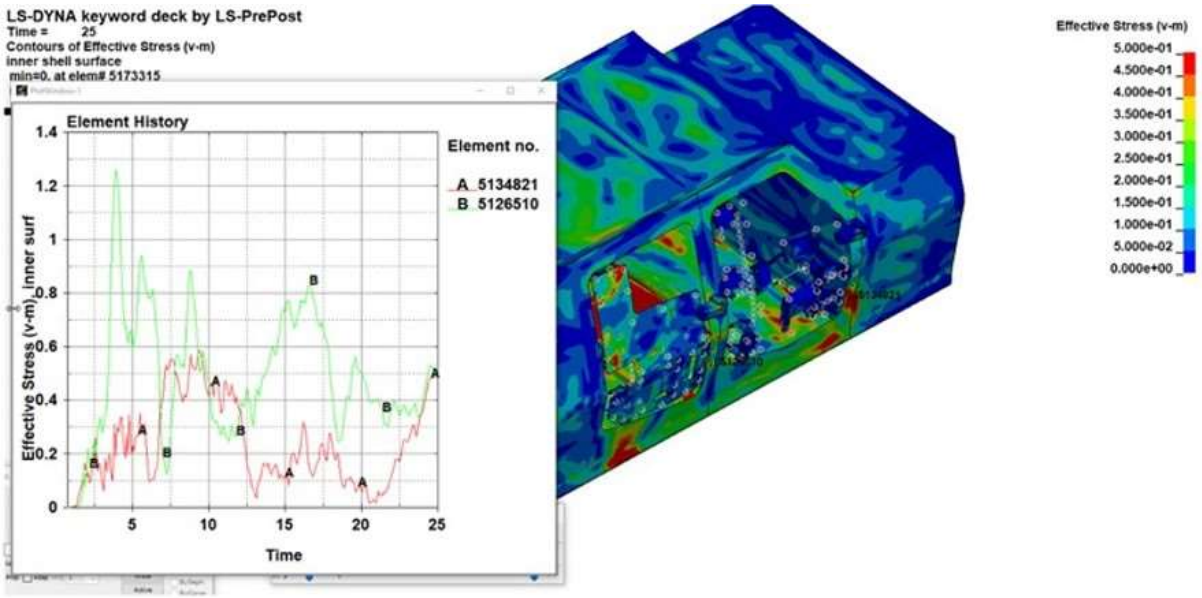
2D model fine mesh metodu ile 0.85 milisaniyede oluşan maksimum basınç değerleri 3D araç patlama modelinde input data olarak alınmıştır. Bu nedenle simulasyon ve analizlerde 3D analizler 0.85 milisaniyeden başlatılmıştır. Araç orta bölgesi patlama simulasyon sonuçları aşağıda Şekil 5' te verilmiştir.



Şekil 5 Araç orta bölgesi patlama simülasyon sonuçları

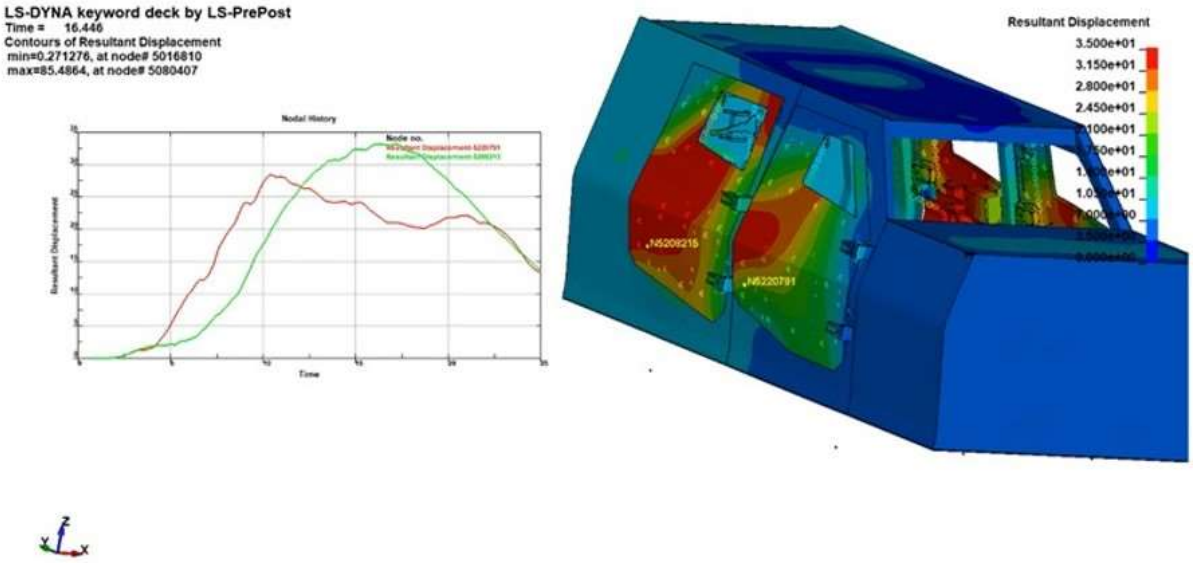
Mayına dayanıklı kilit mekanizması için yapılan farklı patlama analizlerinde de kilit bölgelerinde kullanılan malzeme 4140 ve geometrilerde oluşan gerilmeler STANAG seviye 2 kapsamında oluşan patlamalara dayanıklı olduğu gözlemlenmiştir. Yapılan farklı analizin sonucunda kilit açma/kapama dil mekanizmasında maksimum 400 MPa akma seviyesinin altında gerilmeler görülmektedir. Her bir kapıda toplam üç adet kilit mekanizması ile kapı bağlantılarının patlama sonucu oluşan deformasyonların güvenli aralıklarda olduğu ve kapının açılmasını engellemediği görülmüştür. Kapı dili mesafeleri bu şekilde bir zırhlı araç için yeterli seviyededir. Kapı dilinin e kapının patlama sonucunda geometrisini koruduğu görülmüştür.

Kapılara gelen gerilme ve deplasmanların değişimlerini Şekil 6 ve Şekil 7'da gösterilmiştir.



Şekil 6 Farklı iki element referans alınarak kapılara gelen gerilme değişimleri

Patlama sonucu kapıda oluşan efektif gerilme (GPa) referans alınan iki mesh noktasındaki değerlerdir. Hesaplamalarda Von-Misses akma kriteri kullanılmıştır. Meydana gelen maksimum gerilme yaklaşık 1,3 GPa olarak ortaya çıkmıştır.



Şekil 7 Farklı iki element referans alınarak kapılara gelen deplasmanların değişimleri

Deplasman değerleri ise iki farklı seçilen element numaraları referans alınmıştır. Belirlenen patlama senaryosunda yaklaşık ortaya çıkan hasar deplasmanı 33 mm olarak ölçülmüştür.

5. SONUÇLAR

Bu çalışmada, önceki çalışmamızda geliştirilen askeri kara araçlarının kapı açma kilitlerinin geliştirilmesi sonucu saha simülasyon testleri senaryoları gerçekleştirilmiştir. Patlama analizleri ve simülasyonları LS-DYNA analiz programı ile gerçekleştirilmiştir. Patlama senaryosu Nato standartlarına uygun AEP-62 patlama modellerine uygun olarak hazırlanmıştır. Patlama senaryosu araç orta patlayıcı modeli seçilmiştir. Patlama basınçları 1,2 saniye maksimum değerlere ulaşmıştır. Elde edilen sonuçlarda araç tabanında 132 mm bir çökme oluştuğu ölçülmüştür. Bu değerin şekil değiştirmenin elastik bölgeyi aşarak plastik bölgede hareket ettiği ve sonucunda kalıcı hasar meydana geldiği ifade edilebilir.

ÖZET

Bu çalışmada vakum destekli prototip kalıp kullanılarak yüksek basınçlı döküm yöntemi ile üretilmiş Silafont-36 alüminyum alaşımından üretilmiş numunelerin ısıl işlem sonrası mekanik özelliklerindeki değişim incelenmiştir. Döküm sonrası elde edilen parçalar havada soğutulmuş olup üzerlerinden çıkartılan numunelere farklı ısıl işlem çalışmaları uygulanmıştır. Isıl işlem çalışması öncesinde döküm parçalar X-Ray analizlerine tabi tutularak porozite kontrolleri gerçekleştirilmiştir. Sonrasında döküm sonrası gerçekleştirilen yapay yaşlandırma çalışmaları sonucu TS EN-1706 standardındaki değerler referans alınarak sonuçlar karşılaştırılmıştır. Çalışma sonucunda standarttaki F ve T5 kondisyonuna karşılık gelen akma dayanımı ve yüzde uzama değerleri elde edilirken, çekme dayanım değerine ise yapay yaşlandırma çalışmaları sonucu ulaşılamamıştır. Solüsyona alma çalışmaları sonrası numunelerde mikro porozitelerde şişme ve yüzeyde baloncuklanma problemi gözlemlenmiştir.

Anahtar Kelimeler: Yüksek basınçlı döküm, Silafont 36, Isıl işlem, Mekanik özellikler

INVESTIGATION OF THE HEAT TREATMENT PERFORMANCE OF HIGH PRESSURE CASTED SILAFONT – 36 PARTS

ABSTRACT

In this study, the change in mechanical properties of Silafont-36 aluminum alloy samples produced by high pressure die casting method using vacuum assisted prototype mold after heat treatment were investigated. The parts obtained after casting were cooled in air and different heat treatment studies were applied to the samples removed from them. Before the heat treatment study, the cast parts were conducted to X-Ray analysis and porosity controls were carried out. Afterwards, as a result of artificial aging studies performed after casting, the values in the TS EN-1706 standard were taken as reference and the results were compared. As a result of the study, yield strength and percent elongation values corresponding to the F and T5 condition in the standard were obtained, while the tensile strength value could not be reached as a result of artificial aging studies. After the solution studies, micro porosities and bubbles on the surface were observed in the samples.

Keywords: High pressure die casting, Silafont 36, Heat treatment, Mechanical properties

1. GİRİŞ

Gelişen elektrikli araç endüstrisi ve otomotiv sektöründeki hafifletme hedefleri alüminyum alaşımlarının döküm, ekstrüzyon ve levha ürünleri olarak kullanımını arttırmaktadır. Malzeme ve imalat teknolojilerindeki gelişim ile birlikte deformasyon, ısıl işlem gibi farklı yöntemlerle mukavemeti artırılabilen alüminyum alaşımları, ağırlıklarının düşük olması, yüksek korozyon dayanımı ve yüksek geri dönüştürülebilirliği ile otomotiv endüstrisindeki birçok alanda önemli bir alternatif yaratmıştır [1].

Günümüzde çok yüksek üretim hacimlerine çıkan otomotiv sektöründe döküm parçaların üretiminde yüksek basınçlı döküm yöntemi tercih edilmektedir. Bu yöntem ergimiş alüminyum alaşımının çok yüksek basınç altında kalıba doldurulması esasına dayanmaktadır. Katılaşma tamamlanana kadar da bu yüksek basınç korunur. Bu yöntemin en önemli avantajı karmaşık geometrilere sahip parçaların dahi rahatlıkla üretilebilir olmasıdır. Bunun yanı sıra uygulanan yüksek basınç sayesinde yüksek üretim hızları mümkün olabilmektedir. Bu yöntem ile üretilen parçalarda genellikle

ilave talaşlı imalat işlemi gerektirmez. Ayrıca prosesin özelliği olarak, parçaların yüzeylerinde hızlı soğuma gerçekleştiği için ince taneli bir içyapı oluşarak mekanik özellikler daha iyi olmaktadır [2].

Yüksek basınçlı döküm yönteminde üretilen parçaların kalitesini (yüzey özellikleri, içyapıları ve porozite miktarları) proses parametreleri kadar kullanılan döküm hammaddesi de belirlemektedir. Alaşımı oluşturan elementlerin oranları akışkanlık, dayanım, enerji sönümleme kapasitesi gibi birçok özellik açısından belirleyici olmaktadır. Genellikle ikincil hammaddeden yani alüminyum hurdalarından elde edilen alaşımlardaki element miktarları belirli bir aralıkta tutulamamaktadır. Bu durum döküm ürünlerin porozite oranlarında ve kaynak edilebilirliklerinde önemli problemler ortaya çıkarmaktadır. Örneğin döküm alaşımları içerisinde en yaygın kullanım alanı bulan EN-AC 46000 alaşımdaki yüksek demir (Fe) içeriği dökülebilirlik özelliğini arttırsa da mekanik özelliklerini, ısıl işlem kabiliyetini ve kaynaklanabilirliğini düşürmektedir. Yapısal parçalarda kullanılacak döküm ürünlerinin kaynaklanabilirliği ve ısı işlem kabiliyeti yüksek olması istendiği için de müşteri beklentileri karşılanamamaktadır.
Yapısal parçalarda yüksek basınçlı döküm yönteminde kullanılan en önemli alaşımlardan biri Silafont-36 (AlSi9MgMn) alaşımıdır. Silafont-36 benzeri birincil Al-Si alaşımları sayesinde yüksek uzama değerleri döküm durumunda elde edilebilmektedir. Süspansiyon parçaları, fren parçaları ve motor beşiği gibi otomotiv ürünlerinde Silafont-36 yüksek mekanik özellikleri nedeniyle kullanılmaktadır [3]. Bu alaşım mekanik özellikleri olumsuz etkileyen Fe temelli fazları minimum seviyeye çekmek amacıyla düşük miktarda Fe elementi içermektedir. İğne görünümlü Al5FeSi (β) partikülleri malzemenin mekanik özelliklerine en fazla zararı vermektedir. Mangan elementi Fe elementinin kötü etkisini Al15(Fe,Mn)3Si2 bileşiğini oluşturarak zararlı Al5FeSi fazının oluşma riskini baskılayarak azaltır [4]. Alaşım elementleri içinde magnezyum mekanik özelliklere etkisi açısından öne çıkmakta olup, magnezyum oranı ayarlanarak parça beklentilerine paralel dayanım ve uzama arasındaki ilişki ayarlanabilmektedir [5].

Isıl işlem uygulamaları yüksek basınçlı döküm yöntemi ile üretilen parçaların akma, çekme ve yüzde uzama değerlerini iyileştirmek için uygulanan önemli bir işlemdir. Uygulanan ısıl işlemler en temelde içyapıyı ve buna bağlı olarakta mekanik özelliklerin geliştirilmesini amaçlayan ısıtma ve soğutma işlemlerinden ibarettir. Alüminyum alaşımlarının mukavemetinin arttırılmasında ısıl işlem önemli bir rol oynamaktadır. Bu süreçte sırası ile çözeltiye alma, su verme ve yaşlandırma işlemleri gerçekleştirilir [6]. Bu çalışmada yüksek basınçlı döküm prosesi ile Silafont 36 hammaddeden üretilen parçaların döküm sonrası farklı ısıl işlem koşullarına tabi tutulması ile mekanik özelliklerdeki değişimler incelenmiştir. Döküm sonrasında havada soğutulmuş numunelerin porozite miktarları ve mekanik özellikleri tespit edilmiştir.

2. MATERYAL YÖNTEM

Bu çalışmada vakumlu prototip kalıp ile Silafont 36 alüminyum alaşımı kullanılarak parçalar üretilmiştir. Alüminyum enjeksiyon döküm alaşımı olan Silafont-36, standart enjeksiyon döküm alaşımları ile karşılaştırıldığında, ortalama mukavemet değerlerinde maksimum uzama elde etmek için geliştirilmiş özel bir alaşımdır. Isıl işlem sonucunda %15' in üzerinde uzamaya, ya da 260 MPa civarında akma mukavemetine ulaşılabilir. Bu mekanik özelliklerin yanı sıra enjeksiyon döküm uygulamasında istenilen iyi dökülebilirlik, kalıba yapışmama, talaşlı imalata uygunluk gibi özellikleri sayesinde başta otomotiv sektörü uygulamaları olmak üzere bir çok alanda kullanılmaktadır [3].

Vakumlu prototip kalıp yardımı ile üretilen parçalar üzerinden 5 mm kalınlığında 150 mm x 100 mm boyutlarında 30 adet döküm plaka çıkartılmıştır. Çıkartılan numuneler öncelikli olarak elementel analiz çalışmalarına tabi tutularak standartlara uygunlukları kontrol edilmiştir. Sonrasında 'ASTM E2973-15 Alüminyum ve magnezyum dökümlerin muayenesi için standart dijital referans resimleri' standardı baz alınarak X-Ray ölçümleri ile plakaların porozite kontrolleri gerçekleştirilmiştir.

Son aşamada ise parçalara ısıl işlem uygulanmıştır. Bu kapsamda öncelikle döküm sonrasında havada soğutulmuş numunelere herhangi bir ısıl işlem uygulanmadan (F kondisyonu) mekanik özellikleri tespit edilmiştir. Sonrasında farklı bir numune grubuna 160 °C, 180 °C, 200 °C ve 220 °C sıcaklıklarda yapay yaşlandırma işlemi uygulanmıştır (T5 kondisyonu). Bir diğer numune grubuna ise solüsyona alma ve sonrasında doğal yaşlandırma işlemi (T4 kondisyonu) uygulanmıştır. Etüv fırını olarak Nüve FN 500-P ve kül fırını olarakta Thermnevo piri-100 modeli kullanılmıştır**.** Isıl işlem görmüş plakalar üzerinden alınan numuneler ile Brinnel sertlik ölçümleri gerçekleştirilerek sertlik-zaman grafikleri elde edilmiştir. Ayrıca, ASTM-E8M standardındaki numune boyutları referans alınarak çekme test numuneleri çıkartılmıştır. Isıl işlem sonrası mekanik özellikler çekme test sonuçları kıyaslanarak incelenmiştir.

3. BULGULAR VE SONUÇ

Çalışma kapsamında vakumlu prototip kalıp kullanılarak Silafont 36 alaşımından üretilen parçalara uygulanan Elementel analiz sonuçları Tablo 1'de verilmiştir. Yapılan analiz sonucundan da görülebileceği gibi çalışma

kapsamında prototip olarak üretilen Silafont 36 döküm parça TS EN-1706 standardına elementel içerik olarak uygun gözükmektedir [7].

Tablo 1. Elementel analiz sonuçları ve kıyaslaması

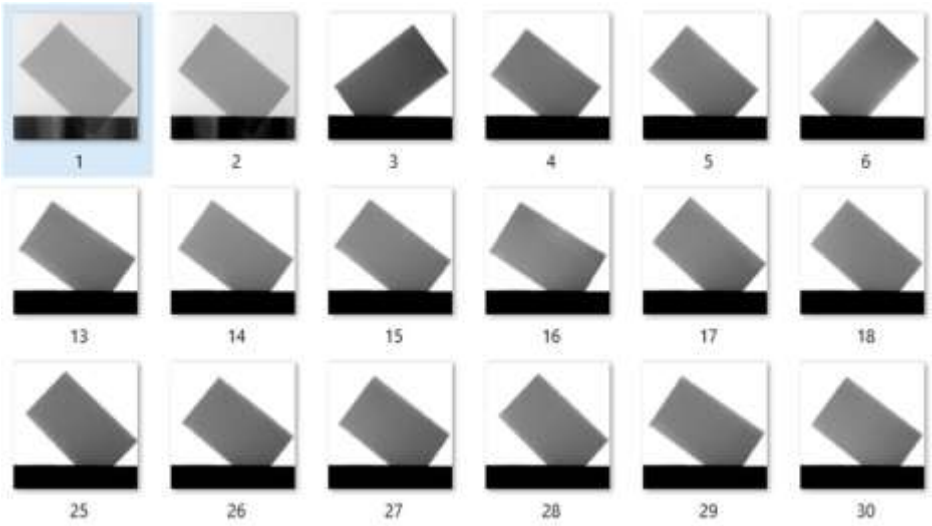
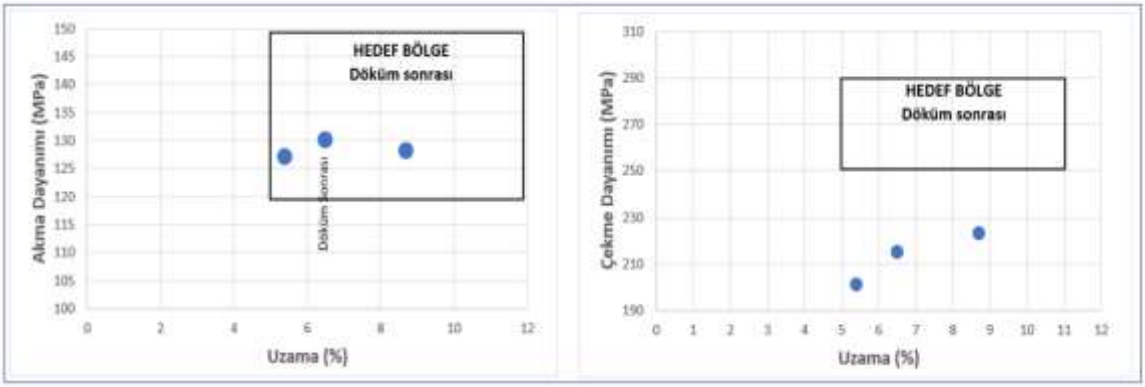
Silafont 36 alaşımı ile yüksek basınçlı döküm yönteminde üretilen numunelerden alınan plakalarda döküm prosesinden kaynaklı porozite miktarlarını tespit etmek için 30 adet levha hazırlanarak X-ray cihazında incelenmiştir. Yapılan ölçümlerde otomotiv sektöründe baz alınan standartlara göre değerlendirme yapılmıştır. Alınan görüntüler Şekil 1'de verilmiştir. 24 parçada porozite görülmediği için Level – 1 olarak tanımlanmıştır. Mekanik testlerde porozite seviyesi en düşük olan bu levhalar kullanılmıştır. X-ray görüntüsü alınan diğer 6 levhada ise düşük oranda poroziteye rastlandığı için Level – 2 olarak sınıflandırılmıştır.



Şekil 1. Parça üzerinden çıkartılmış döküm numunelerinin X-ray görüntüleri

Standartlara uygun olarak hazırlanmış çekme testi numuneleri ile döküm sonrası havada soğutulmuş numunelerin akma dayanımları, çekme dayanımları ve yüzde uzama değerleri karşılaştırılmıştır. Şekil 2'den de görüleceği üzere Döküm sonrası havada soğutulmuş numunelerin akma dayanımı ve uzama değerleri TS EN-1706 beklentilerini karşılamakta olup çekme dayanım değeri ise standarttaki değere ulaşamamıştır.

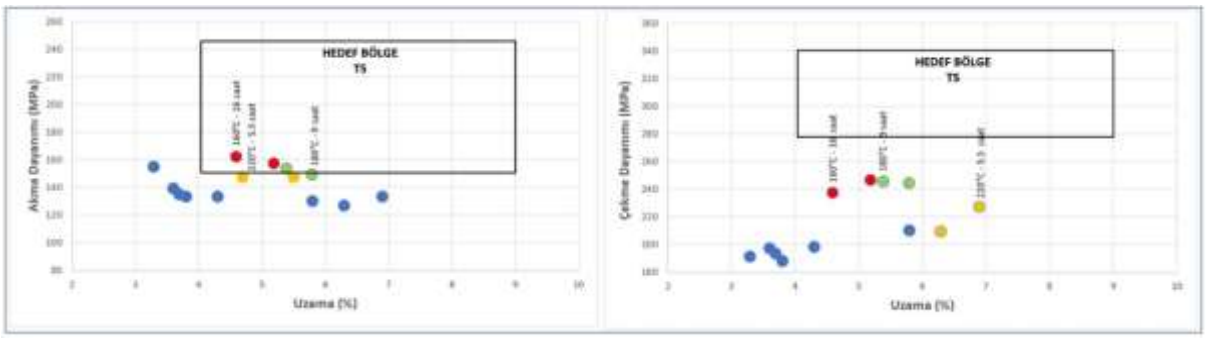


Şekil 2. Döküm sonrası havada soğutulmuş numunelerin mekanik özellikleri

Döküm sonrası havada soğutulmuş numuneler üzerinde farklı sıcaklık (160°C - 180°C - 200°C - 220 °C) ve sürelerde yapay yaşlandırma çalışmaları gerçekleştirilmiş olup sertlik-zaman grafikleri elde edilmiştir. Bu çalışmada pik sertlik değeri 160°C'de 16 saat yapay yaşlandırılmış numunede elde edilmiştir. Bu değerler havada soğutulmuş numunelerde pik değere uzun süreler sonra ulaşılabileceğini göstermektedir.

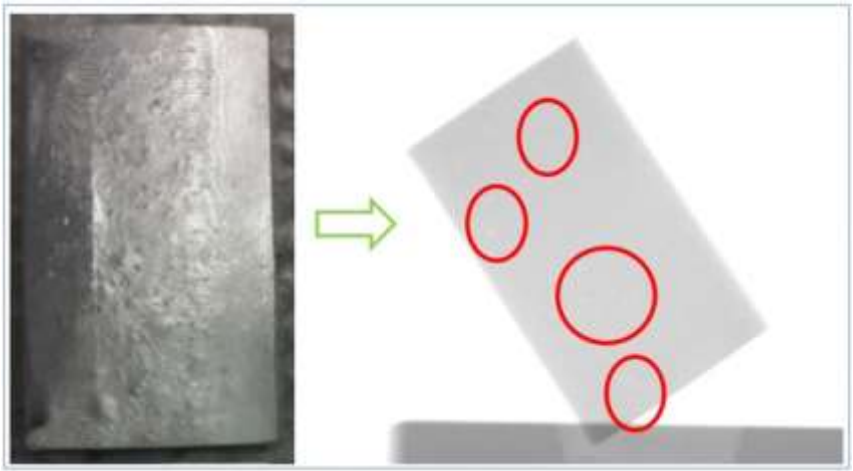
Şekil 3. Döküm sonrası havada soğutulmuş numunelerde yapay yaşlandırmanın etkisi

Sertlik-zaman grafiğine paralel olarak yapay yaşlandırma çalışmaları da gerçekleştirilmiştir. Şekil 4'te döküm sonrası 165°C sıcaklıkta 16 saat ve 180°C sıcaklıkta 9 saat yapay yaşlandırılmış parçaları da içeren ısıl işlem çalışmaları uygulanmış parçalardan alınan numunelerin akma ve uzama değerleri gösterilmiştir. Elde edilen sonuçlar T5 standart isterleri ile kıyaslanmıştır. T5 ısıl işlemi normal şartlarda uygun kalıp kullanıldığı takdirde döküm sonrası suda soğutma ve yapay yaşlandırma işlemi ile elde edilen bir ısıl işlem kondisyonudur. Akma dayanımı ve yüzde uzama değerleri standarttaki isterlerin minimum değerlerine yakındır, fakat çekme dayanım değerleri yapay yaşlandırma sonrası T5 ısıl işlem beklentilerini karşılamamıştır.



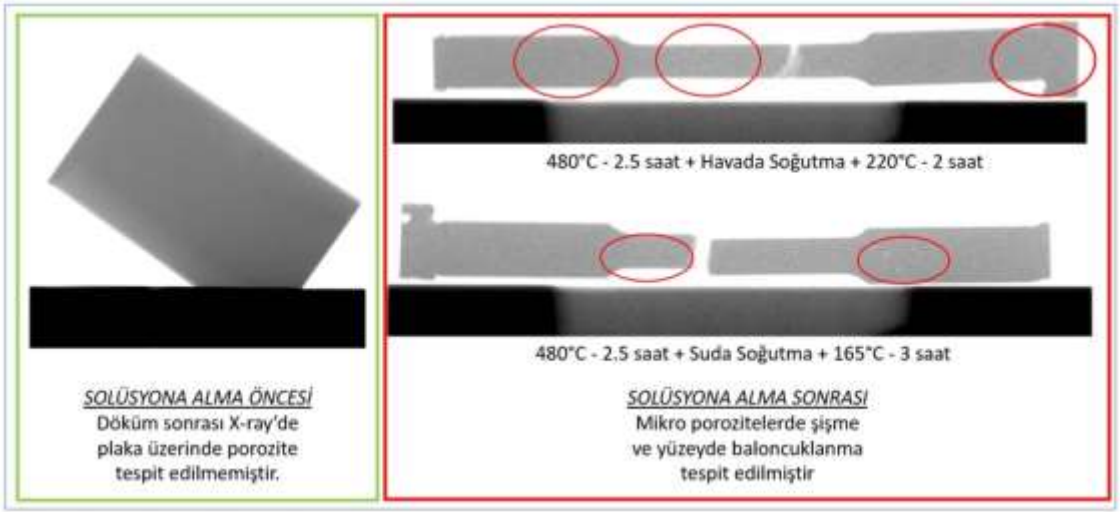
Şekil 4. Döküm sonrası havada soğutulmuş numunelerin yapay yaşlandırma sonrası mekanik özellikleri

Alüminyum alaşımlarında T4 kondisyonu malzemenin en sünek olduğu hali temsil eder ve genellikle şekillendirilecek parçalara uygulanır. Şekil 5'te döküm sonrası T4 ısıl işlemi uygulanmış (Solüsyon alma işlemi + stabil hale gelene kadar doğal yaşlanma) numuneye ait görüntü ve X-ray görüntüsü verilmiştir. Silafont-36 numunesine 480C 'de sıcaklıkta 2.5 saat olarak uygulanan ısıl işlem sonucunda vakum kalıp ile yüksek basınçlı döküm yöntemi ile üretilmiş numunelerde solüsyona alma sonrası çarpılma, yüzeyde baloncuklanma ve mikro porozitelerde şişme gözlemlenmiştir.



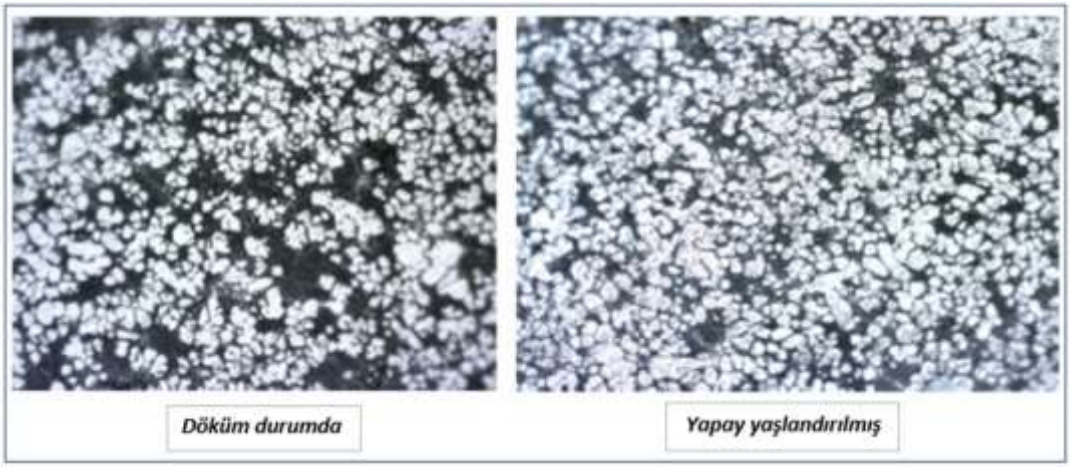
Şekil 5. Solüsyona alma sonrası çarpılma, baloncuklanma ve mikro porozitelerde şişme problemi

Şekil 6'da döküm sonrası yapılan X-ray analizinde Level-1 olarak değerlendirilmiş parçadan elde edilmiş çekme test numunelerinin ısıl işlem sonrası porozite durumu ele alınmıştır. Solüsyona alma sonrası havada ve suda soğutulmuş numunelerin ikisinde de yüzeyde baloncuklanma ve mikro porozitelerde şişme gözlemlenmiştir (Şekil 6). Bu durum mekanik özellikleri özellikle yorulma performansını olumsuz etkilemektedir.



Şekil 6. Solüsyona alma öncesi ve sonrası karşılaştırma

Silafont-36 malzemesinin döküm durumunda ve yapay yaşlandırma sonrası tane yapısı optik mikroskop yardımı ile incelenmiştir (Şekil 7). Beyaz bölge alüminyum zengin α bölgesini ve siyah bölge ise ötektik alüminyum silikon bölgeyi göstermektedir. Silafont-36 malzemesi içindeki Sr elementi sayesinde içyapı modifikasyonunun da gerçekleştiği görülmüştür.



Şekil 7. Silafont-36 tane yapısı

4. DEĞERLENDİRME

Vakumlu prototip kalıpta yüksek basınçlı döküm yöntemi kullanılarak elde edilen parçalarda yüksek oranda poroziteye rastlanmamış ve genel olarak Level-1 olarak sınıflandırılmıştır. Döküm sonrası numunelerde istenilen akma dayanımı ve yüzde uzama değerleri elde edilmiştir. Fakat çekme dayanım değerleri TS EN-1706 ve Silafont-36 firma kataloğu standardının beklentilerinden düşük çıkmıştır. Döküm sonrası gerçekleştirilen yapay yaşlandırma çalışma çıktıları da benzer sonuçları ortaya koymuştur. Solüsyona alma çalışmaları sonrası parçaların yüzeylerinde baloncuklanma ve mikro porozitelerde şişme gözlemlenmiştir.

Silafont-36 firma kataloğunda T5 ısıl işlem uygulamasında suda soğutma ve takibinde oluşacak doğal yaşlanma prosesini önlemek amacıyla 12 saat içinde yapay yaşlandırılması gerektiği dile getirilmektedir. Döküm sonrası havada soğutulmuş Silafont-36 parçalarında özellikle çekme dayanımında standarttaki değerlere kıyasla düşüş gözlenmektedir. İlave olarak ısıl işlem pik sertlik elde etme süreleri de uzamaktadır. Suda soğutmanın çarpılma gibi negatif etkilerini ortadan kaldırmak ve havada soğutmanın sağladığı düşük mekanik özellikleri iyileştirmek amacıyla Mg oranında yükseltme çalışmaları yapılabilir, yapay yaşlandırmanın çok yüksek etkisi olmayacağından dolayı bu tip parçaları F (döküm durumunda) kullanmak daha ekonomik olacaktır.

ÖZET

Yeni nesil AHSS (Advanced High-Strength Steel) 'nin gelişmesiyle, otomotiv endüstrisinde kullanılan kaynak ve üretim süreçlerine yönelik davranışları incelemek de önemli hale gelmiştir. Kaynak, otomotiv endüstrisi tarafından ağırlıklı olarak çelik parçaların montajında kullanılan birincil üretim yöntemidir. Otomotiv endüstrisinde esas olarak çelik parçaların montajı için kullanılan kaynak yöntemi düşük maliyeti, mukavemeti ve mükemmel seri üretim kapasitesi nedeniyle direnç punta kaynağıdır (RSW). Bununla birlikte, RSW, hızlı elektrot kapağı aşınması ve tutarlı kaynak kalitesi gibi alüminyum alaşımı uygulamaları ile ilgili önemli sorunları da beraberinde getirmektedir. Bununla birlikte, yeni nesil AHSS' de uygulanan RSW kaynaklarında bazı problemler gözlemlenmiştir. Bu problem, sıvı metal kırılganlığına (Liquid Metal Embrittlement -LME) bağlanmıştır. Bu çalışmada, otomotiv sektöründe yaygın kullanıma sahip yeni nesil çeliklerde görülen sıvı metal kırılganlığı kavramı üzerine bilgi verilecektir.

Anahtar Kelimeler: Yeni Nesil çelikler, sıvı metal kırılganlığı, nokta direnç punta kaynağı, galvaniz, kaplama

FACTORS CAUSED AND AFFECTING LIQUID METAL EMBRITTLEMENT IN ZINC-GALVANIZED NEW GENERATION STEELS

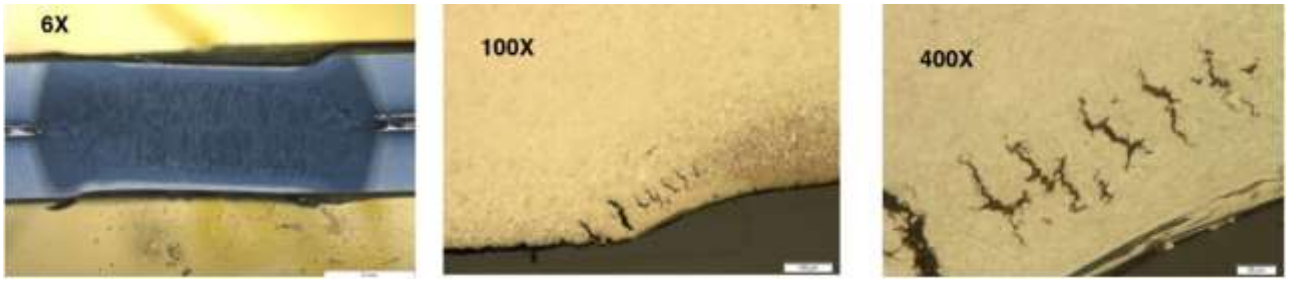
ABSTRACT

With the development of new generation AHSS (Advanced High-Strength Steel), it has also become important to examine the behavior towards welding and production processes used in the automotive industry. Welding is the primary production method used by the automotive industry mainly for the assembly of steel parts. The welding method used mainly for the assembly of steel parts in the automotive industry is resistance spot welding (RSW) due to its low cost, strength and excellent mass production capability. However, RSW also presents significant problems with aluminum alloy applications, such as rapid electrode cap wear and consistent weld quality. However, some problems were observed in the RSW welds implemented in the NEW generation AHSS. This problem has been attributed to liquid metal embrittlement (LME). In this study, information will be given on the concept of liquid metal embrittlement seen in new generation steels, which are widely used in the automotive industry.

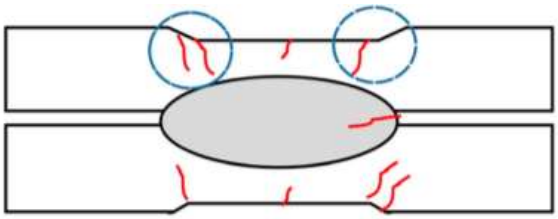
Keywords: New generation steels, liquid metal embrittlement, spot resistance spot welding, galvanization, coating

1. GİRİŞ

LME, yerel bir gerilmeye maruz kalan daha yüksek bir erime noktası üzerinde sıvı bir metal bulunduğunda ortaya çıkar. Kaynak sırasında ergiyen Zn atomlarının çelikteki tane sınırlarına nüfuz etmesi LME olarak adlandırılmaktadır. Galvaniz kaplamalı çeliklerin nokta kaynağı sırasında kaplama, düşük erime noktalı sıvı haline gelir. Elektrot girintisi, yüzey gerilme gerilmesini sağlar. Erimiş çinko çelik alt tabakaya nüfuz edip çatlaklar oluşturduğunda RSW'de sıvı Metal Kırılganlığı (LME) çatlaması meydana gelir. Bu çatlaklar morfolojide taneler arasıdır ve içinde çinko görülür. 3. Nesil çeliklerde bulunan LME süreksizlikleri sığ ve kısadır. Sadece mikroskop altında görülebilir, şekil 1. Sıvı metal kırılganlığı, üç faktörle daha da şiddetlenir: bir sıvı metalin varlığı, uygulanan bir yüzey gerilmesi ve duyarlı (genellikle büyük taneli) mikroyapı. Bu kaynaklar için ilk sıvı metal her zaman galvanizli yüzeylerde bulunur.



(a)



(b)

Şekil 1. (a)LME Sıvı Metal Kırılganlığının Mikroskop Altında Görüntüsü. (b) LME Çatlaklarının Sıklıkla Görüldüğü Yerler [2]

İ.Öztürk ve diğerleri (2017) TBF çeliklerinin RSW kaynağı ve sıvı metal çatlaklarının kaynak parametreleri ile kolerasyonunu konu almışlardır. Çalışmalarında farklı kalınlıklarda TRIP1050 çeliği (1mm&1.5mm) tercih edilmiştir. Çalışmalarında 6-10kA akım aralıklarını 1kA arttırarak ve 12-3 cycle kaynak zamanını 8 'er çevrim arttırarak kaynak çiftleri oluşturulmuş, MFDC makine kullanılmış, nugget size'a ve Nugget derinliğine kaynak akımının, kaynak zamanının ve ısı girdisinin «HII» etkileri grafiklendirilmiş, oluşan çatlaklar ve derinliği tespit edilmiş. Bunların parametreler ve HII ile ilgisi olup olmadığı yorumlanmıştır. Çatlak derinliği ile ısı girdisinin kolerasyonuna bakılmıştır. Isı girdisi artışı ile çatlak derinliğinin arttığı tespit edilmiştir. Kaynak çiftlerine çekme testi yapılmış, hata modları belirlenmiş en yüksek çekme makaslama ve tokluk değerlerine sahip bağlantı parametreleri belirlenmiştir. En iyi parametrede toplamda 149 mikron derinliğinde çatlak tespit edilmiştir. Kaynak zamanı veya akım arttıkça çatlak derinliği ~200 mikron'a kadar ulaşmıştır.

Choi vd. TRIP 1180'in elektrot kuvveti ile LME çatlak uzunluğu arasındaki ilişkiyi incelemiştir. Sonlu elemanlar yöntemi, daha zayıf bir elektrot kuvveti uygulandığında, elektrot ile çelik arasındaki bitişik alanın azaldığını ve soğutma etkisinin azaldığını ortaya koymuştur. Bu nedenle, çelik yüzeyin sıcaklığı daha uzun süre 600 C'nin üzerinde tutulur, bu da Zn metalinin yayılması için yeterlidir. En uzun çatlak uzunluğunun artan kuvvetle azaldığı (111 mikron'dan 149 mikron'a) sonucuna ulaşmışlardır.

Murugan vd. elektrot geometrisinin LME çatlakları üzerindeki etkisini araştırmıştır. Kubbe tipi elektrot çapı 6'dan 8 mm'ye çıktığında çatlak uzunluğu 55'ten 15 m'ye düşmüştür.

Tolf vd., 7.2 mm'lik nugget çaplı bir numune, kubbe tipi elektrot yerine yarıçap tipi elektrot kullanıldığında LME çatlaklarının boyutunda ve sayısında çarpıcı bir azalma olduğunu tespit etmiştir.

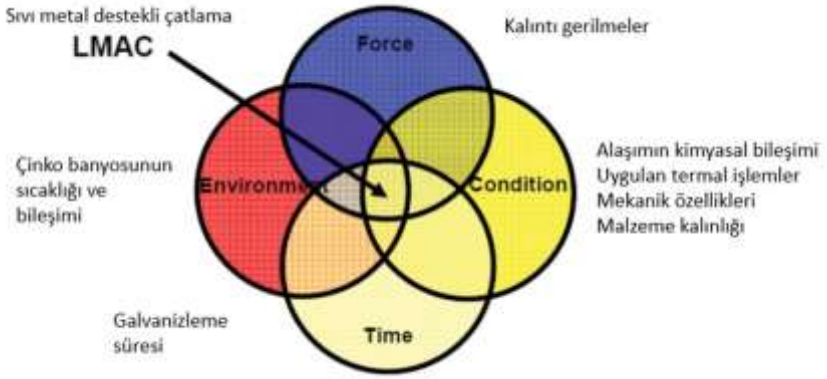
Tolf vd. DP çeliğinin RSW'si sırasında daha düşük bir kaynak akımı (8.0 kA ile 6.5 kA) ve daha uzun bir kaynak süresi (410 ms ile 615 ms) uygulandığında LME çatlaklarının % 50'si azaldığını göstermişlerdir . GI kaplamalı çeliğin yeniden elektro galvanizlenmesinin de önemli ölçüde azalmış çatlak sayısı gösterdiği bulunmuştur. EG kaplamalı çelik sürekli olarak en kısa LME çatlaklarını göstermiştir. Bu sonuçlar, GI'nin LME duyarlılığının EG'den daha yüksek olduğunu göstermektedir ve bu önceki çalışmaların sonuçlarıyla tutarlıdır.

2. SMK (SIVI METAL KIRILGANLIĞI HASSASİYETİ)

3.nesil çeliklerde yüksek dayanım ve yüzeyindeki kaplama nedeniyle kaynak sırasında problemler yaşanmaktadır. Kaynak sırasında yaşanan bu problem sıvı metal kırılganlığı olarak tanımlanır. Yüksek dayanımlı çelik alaşımları, Zn, Hg, Sn, Pb ve Al gibi sıvı metallerle temas ettiğinde kırılganlık oluşur. Galvaniz kaplamaya sahip 3. Nesil alaşımda kaynak sırasında ergiyen Zn atomları (kaplamada bulunan) çelikteki tane sınırlarına nufüs etmesi ile yüzeyde kırılmalar meydana gelmektedir.

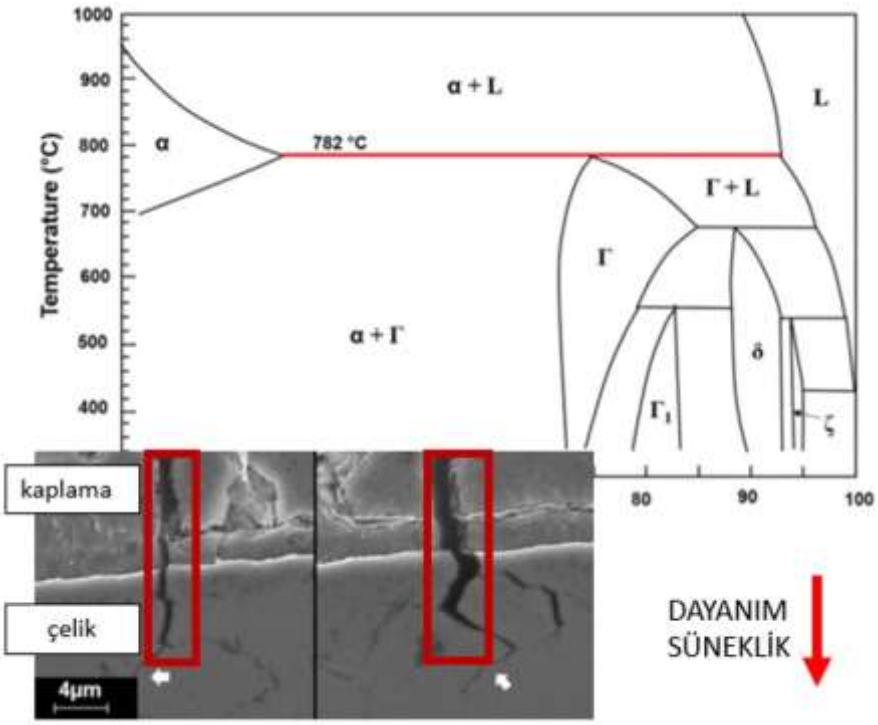
SMK hassasiyetini oluşturan nedenler aşağıda belirtilmiş olup Şekil 2'de gösterilmiştir [2].

1- **Kuvvetler:** Kaynak sırasında oluşan kalıntı gerilmeler ve termal gradyan yoğunlaşması oluşmaktadır.
2- **Malzeme özellikleri:** Malzemenin kimyasal bileşimi, ısıl işlem geçmişi, mekanik özellikleri önemlidir. 3. Nesil çeliklerin mikroyapısında yer alan kalıntı östenitin SMK hassasiyetini arttırdığı raporlanmıştır [1-3]. Malzemenin kalınlığı SMK hassasiyetini etkilemektedir.
3- **Kaplama:** Galvanizleme süresi SMK hassasiyetinde önemlidir. Bununla birlikte malzemeye yapılan galvaniz kaplama cinsine bağlı olarak SMK hassasiyeti artmaktadır.
4- **Çevresel faktörler:** Çinko banyosunun bileşimi ve sıcaklığı SMK hassasiyetini etkilemektedir.



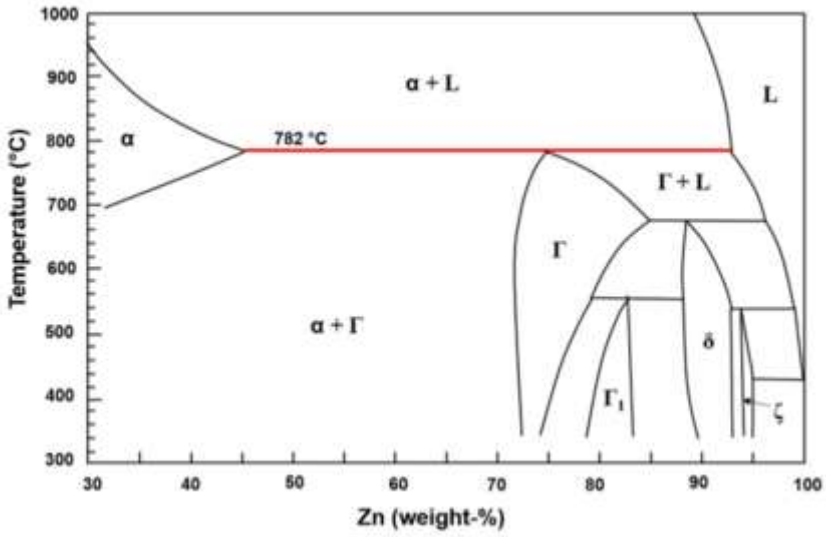
Şekil 2. SMK hassasiyetini oluşturan nedenler [1]

Galvaniz kaplamada yer alan Zn elementinin ergime sıcaklığı 420 °C'dir (Şekil 3). Zn 782 °C'de tamamen sıvı faza geçmektedir. Nokta kaynak sırasında 782 °C'de sıvı Zn (Şekil 4), çelik malzemeye nüfuz etmektedir. Bu durum nokta kaynak sırasında yüzeyde çatlaklara neden olmaktadır. Çeliğin dayanımında ve sünekliğinde ciddi oranda düşüş meydana gelmektedir [1].



Şekil 3. SMK hassasiyetini oluşturan nedenler [1]

Kaynak sırasında oluşan SMK hassasiyeti kaynağı yapılan malzeme özelliklerine ve galvaniz kaplama türüne bağlı olduğu raporlanmaktadır. 2. ve 3. Nesil çeliklerde SMK hassasiyeti 1. Nesil çeliklere göre daha fazladır. Yüksek Si ilavesi SMK oluşumun arttırmaktadır. Ancak literatürde yüksek Si ilavesi olumsuz raporlanmasına rağmen tam net bir kanıt/açıklama bulunmamaktadır.



Şekil 4. Zn ergime sıcaklığını gösteren faz diyagramı

Mikroyapı SMK hassasiyetinde önemlidir. Östenit fazın ferrit faza göre SMK hassasiyeti daha fazladır. SMK hassasiyetinin galvaniz kaplama çeşidine bağlı olduğu raporlanmıştır. Sıcak daldırma galvaniz kaplamada hassasiyet artmaktadır (Tablo 1). Kaplamasız çelikler galvaniz kaplı bir malzeme ile kaynak edildiğinde yüzeyde SMK oluşumu gözlenebilmektedir.

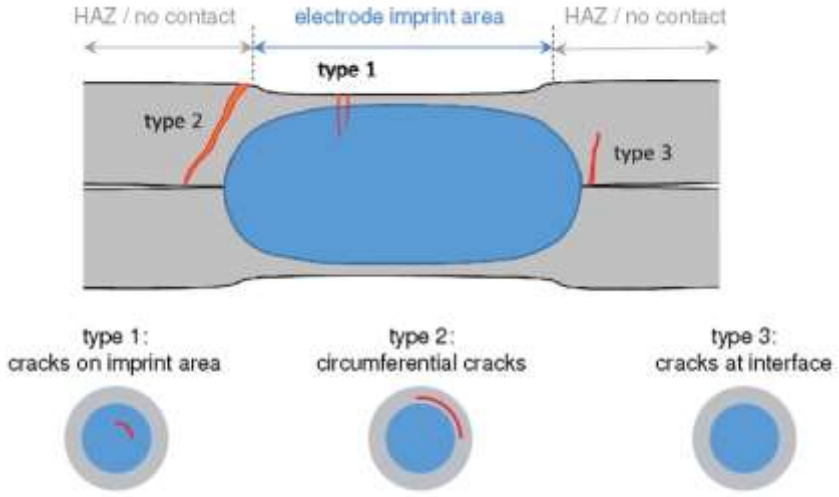
Tablo 1. Literatürde SMK Hassasiyeti ile ilgili gözlemler [1]

HDGI: Hot Dipped Galvanized, HDGA: hot-dipped gal- vanneal, EG: Electrogalvanized
HDGI: Sıcak Daldırma Galvanizli, HDGA: Sıcak Daldırma Galvanizli, EG: Elektrogalvanizli

Çelik kalitesi	Kaplama çeşidi /Kompozisyonu	SMK Hassasiyeti ile ilgili gözlemler
TWIP	HDGI (Zn); HDGA (Fe-Zn); EG (Zn-Ni)	EG < HDGA < HDGI
DP1000	HDGI (Zn); HDGA (Fe-Zn)	HDGA <HDGI
TRIP1180	HDGI (Zn); HDGI (Zn-Mg)	HDGI (Zinc)<HDGI (Zn-Mg)

ÇELİK TİPİ	KAPLAMA	KAYNAK PARAMETRELERİ	SONUÇ
TRIP 590	HDGA	8mm dome/flat type Cu-Cr elektrod 4-6 kN force, 10.5-12.0 kA	Yüzey çatlağı, kuvvet ve tutma zamanın artışı ile azalmış. Flat elektrod, dome elektrod'a göre çatlakları çok az azaltmış.
TRIP 700/800 (Al-Si)	HDGI/ EG	CU-Cr-Zr elektrod	Her iki kaplamada da LME çatlağı gözlenmiş. Isı girdisi artışı ile çatlak oluşumu azalmış.
TRIP 800 (0.2c-1.7 Mn-1.66Si, 0.43Al)	HDGI	5.5 mm küresel Cu-Cr-Zr elektrod, 6kN, 6-9 kA	Geniş ITAB gözlenmiş, kaplamanın yüksek ısı transferi özelliği sebebi ile. Çekme değeri kaynak akımının ve süresinin artması ile iyileşmiş.
TRIP 1180 (0.2C-2.6Mn-1.5Si)	HDGI	5.5 mm dome tipi Cr-Zr elektrod, 3-5 kN, 6-7.5 kA	LME çatlak boyutu elektrot kuvvetinin artması ile arttı. Daha uzun hold time çatlakların çoğalmasına neden oldu.

SMK nedeniyle oluşan çatlakların genellikle oluştuğu bölgeler Şekil 5'de gösterilmiştir [4]



Şekil 5. SMK nedeniyle oluşan çatlakların genellikle oluştuğu bölgelerin şematik gösterimi [4]

Type 1 olarak gösterilen bölge kaynak sırasında baskı uygulanan bölgedir. Baskı alanında oluşan çatlaklar gösterilmektedir. Type 2 bölgesinde çevresel kırılmalar oluşmaktadır. Type 3 de ise çatlaklar malzemenin ara yüzeyinde oluşmaktadır.

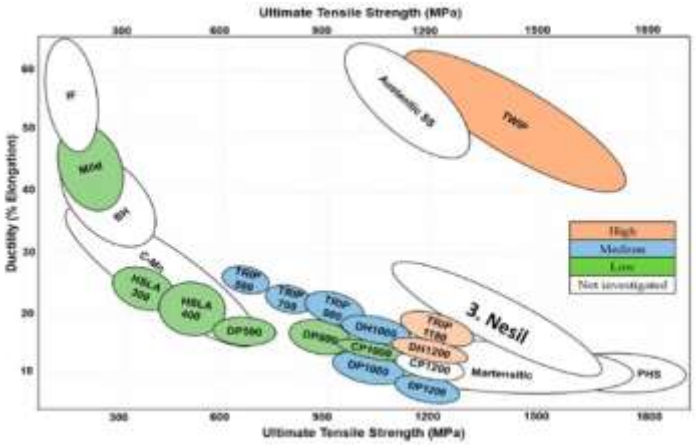
SMK oluşumu çeliğin kimyasal bileşimine, çeliğin mikroyapısına, çeliğin kaplamasına ve nokta kaynağı durumuna (örn. elektrot tipi, kaynak akımı, toplam ısı girdisi vb.) bağlıdır [5].

AHSS/UHSS çelikler %4-5 oranında Mn ve Si içermektedir. Bu çeliklerin içerdiği Mn, Si ve Al gibi elementler dayanıma büyük ölçüde katkı sağladıkları gibi aynı zamanda çeliğin elektrik iletkenliği özelliğini de arttırmaktadır. Bu durum yüksek ısı üretimine neden olduğu için punta kaynağı sırasında daha yüksek gerilmeler ile birlikte düşük alaşınlı çeliklere göre SMK hassasiyeti artmaktadır [5].

2.1. SMK Hassasiyeti Etkileyen Faktörler

2.1.1. Yüksek Dayanımlı Çelik Türü

Çelik alaşımları LME duyarlılığına göre düşük, orta ve yüksek çelikler olmak üzere sınıflandırılmaktadır. Şekil 6'ya göre çeliklerin dayanımı 1000 MPa'ı aştığında SMK hassasiyeti artmaktadır [1].



Şekil 6. Zn kaplı çeliklerin Düşük-Orta-Yüksek SMK hassasiyetine göre sınıflandırılması [1]

2.1.2. Zn Kaplama Çeşidi

Literatürde sıcak daldırma galvaniz (GI) kaplamanın galvaniz-tavlı (GA) ve elektro galvaniz (EG) kaplamaya göre SMK hassasiyetini artırdığı rapor edilmektedir. Sıcak daldırma galvaniz kaplamanın (GI-Zn) ergime noktasının sıcak daldırma galvaniz-tavlı kaplama (GA-FeZn) ve elektro galvaniz kaplamaya (GI-Zn-Ni) göre daha düşük olmasından dolayı, kaynak sırasında daha fazla Zn sıvı olarak bulunduğu için kırılganlık artmaktadır. Buna ek olarak kaplama ile ana malzeme arasında oluşan intermetaliklerin, kaplamanın ergime sıcaklığını artırmalarından dolayı, SMK hassasiyetini azalttığı raporlanmaktadır. GA kaplamada, GI kaplamadan farklı olarak 500 °C'de yapılan tavlama işlemi nedeniyle GA kaplama ile ana malzeme arasında oluşan Fe-Zn intermetalik bileşiği SMK hassasiyetini azaltır. GE kaplamada kaplama ile ana malzeme arasında oluşan Zn-Ni intermetaliği de aynı şekilde SMK hassasiyetini azaltmaktadır [6, 7].

2.1.3. Mikroyapının Etkisi

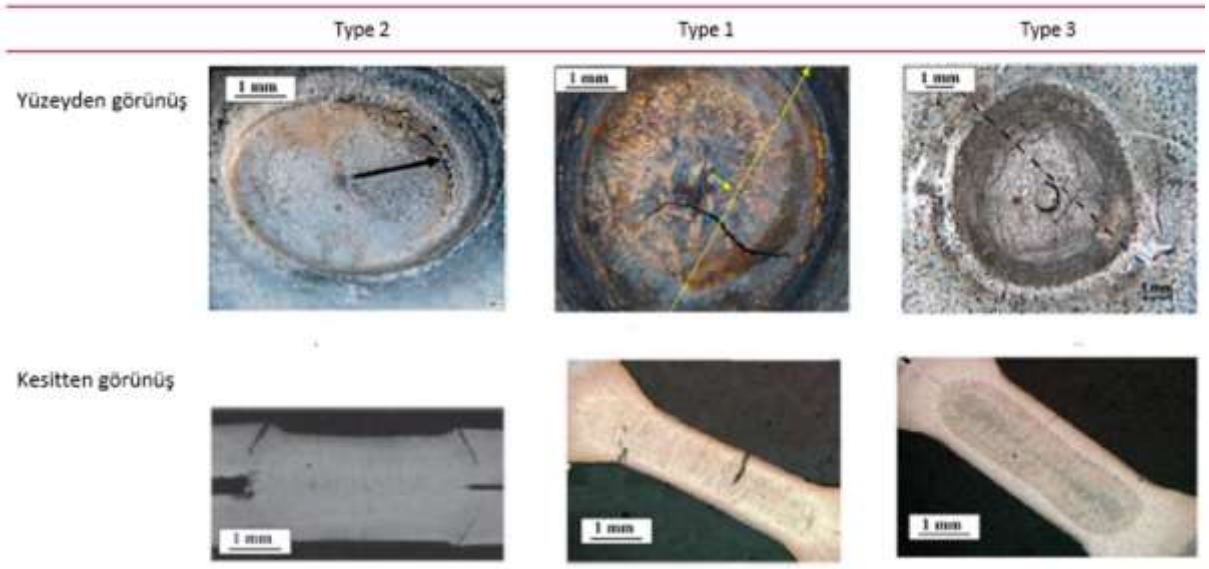
Literatürde TRIP ve TWIP çeliklerindeki SMK hassasiyetinin çok yüksek olduğu rapor edilmiştir. Bununla birlikte dayanımı 1000 MPa'ın üstündeki çeliklerde SMK hassasiyetinin yüksek olduğu belirtilmektedir. Ancak 1000 MPa üstü DP çeliklerindeki hassasiyet TRIP ve TWIP çeliklerinden daha düşük olduğu gözlemlenmiştir. Bunun nedeni TRIP ve TWIP'ın mikroyapısında östenit oranının daha fazla olmasıdır. Mikroyapının SMK hassasiyeti üzerine etkisini anlamak için termo-mekanik çalışmalar yapılmıştır. Yapılan bu çalışmada DP çeliklerinde gevrekleşme östenit oluşum sıcaklığının (A_{c3}) üzerinde gözlemlenmiştir. SMK hassasiyetinin östenit faz oluşumu sonrası ortaya çıktığı raporlanmıştır [3, 8].

2.1.4. Kaynak Parametreleri

Literatürde farklı kaynak koşullarında SMK oluşumu incelenmiştir. Bu incelemelere göre SMK hassasiyeti kaynak akımının artması, uzun kaynak çevirim süresi, küçük elektrot kuvvetleri, tutma süresinin azaltılması, yanlış hizalanmış elektrotlar ve kaynak sırasında ara parçaların birleşimi ile artmaktadır [9, 10].

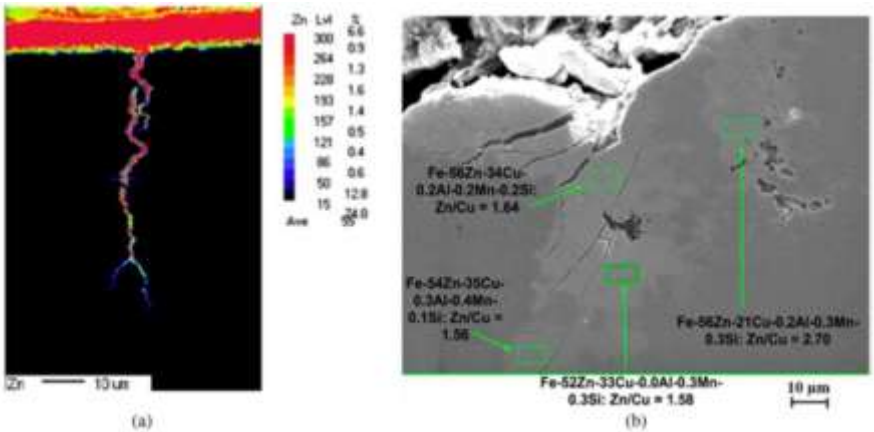
Çelik sac/elektrot girinti bölgesinin kenarları (kaynak omuzları) (Şekil 7) LME kırılganlığına en hassas bölge olarak belirtilmektedir. Tip 2 standart endüstriyel kaynak koşullarında gözlenmektedir. Tip 1 ve 3 uygulanan kaynak koşularında, yüksek ısı ve artan akım ve uzun süreli giriş kaynak çevirimleri ile oluşabilmektedir [11].

LME nedeniyle oluşan çatlaklar genel olarak stereo mikroskopta kolaylıkla görülebilir. Şekil 7'de LME nedeniyle oluşan oluşan çatlakların numune yüzeyi ve kesitinden görüntüleri yer almaktadır. Şekil 7'de belirtilen Type 1, Type 2 ve Type 3 bölgeleri makroskobik olarak gözlemlenmiştir.



Şekil 7. Nokta kaynaklarında LME çatlaklarının makroskopik görünümü ve çatlak yeri ve derecesine göre sınıflandırma [8, 12-14]

Nokta kaynak sırasında oluşan LME çatlaklarının karakteristikleri incelenmiştir [6, 7]. Kırılma yüzeyleri incelendiğinde LME kırılmaların Zn'nin nüfus etmesi nedeniyle taneler arası oluştuğu gözlemlenmiştir. Galvaniz kaplamalı TWIP alaşımı üzerinde electron probu mikro analizi (EPMA) ile elde edilen görüntüler Type 2 LME kırılmaları olarak belirlenmiş olup Şekil 8a'da gösterilmektedir. Literatürdeki araştırmalardan bazıları Zn'nin Type 2'deki gibi yüzeyde LME hassasiyeti oluşturarak çatlaklar oluştuğunu raporlarken [6,7], diğer araştırmalar da LME çatlağının oluştuğu bölgede Zn ile birlikte yüksek oranda Cu (ağırlıkça yaklaşık % 15-20) tespit ettiği Şekil 8b'de gösterilmektedir. [3, 11].



Şekil 8. Nokta kaynakta LME çatlak karakterizasyonu; EPMA characterisation of LME cracks in spot welds: (a) LME çatlak oluşumundaki Zn analizi (b), Zn'nun nüfus ettiği bölgedeki Cu oranı (Zn/Cu konsantrasyonu) [3, 6, 7, 11]

3. SONUÇLAR VE TARTIŞMA

Yapılan araştırmalar çelik türünün, kaplama türünün, mikroyapı etkisinin ve kaynak parametrelerinin sıvı metal kırılganlığı üzerine etkisi olduğunu göstermektedir.

Çeliklerin dayanımı 1000 MPa'ı aştığında SMK hassasiyetinin arttığı gözlenmiştir. Mikroyapının SMK hassasiyetinde önemli olduğu, östenit fazın ferrit faza göre SMK hassasiyetinde daha fazla rol oynadığı görülmüştür. 2. ve 3. Nesil çeliklerde SMK hassasiyetinin 1. Nesil çeliklere göre daha fazla olduğu, yüksek Si ilavesinin SMK oluşumunu arttırdığı gözlenmiştir. Ancak literatürde yüksek Si ilavesi olumsuz raporlanmasına rağmen tam net bir kanıt/açıklama bulunmamaktadır.

Ayrıca SMK hassasiyetinin galvaniz kaplama çeşidine bağlı olduğu da raporlanmıştır. Sıcak daldırma galvaniz kaplamada hassasiyetin artmakta olduğu, kaplamasız çelikler galvaniz kaplı bir malzeme ile kaynak edildiğinde yüzeyde SMK oluşumu gözlenmiştir.

Ayrıca malzemenin kalınlığı, galvanizleme süresi ve çinko banyosunun bileşimi ve sıcaklığı da SMK hassasiyetini etkilemektedir.

Nokta direnç kaynağı uygulanması sonucu görülen sıvı metal kırılganlığı nedeniyle kullanımında kısıtlar olan 3. nesil çeliklerde bu sorunu ortadan kaldırmak mümkün olmasa da azaltmak için çalışmalar yapılmakta olup şu an için bu çeliklerin kullanımını mümkün kılmak için otomobil üreticileri tarafından bir kabul kriteri oluşturulmaya çalışılmaktadır.

ÖZET

Bu çalışmada metal eklemeli imalat yöntemi olan tel ark eklemeli imalat yönteminden bahsedilmiştir. 5cm x100cm boyutlarında bir parçanın tel beslemeli imalat yöntemiyle kaynaklanması durumunda lazer gücü ve lazer hızı parametrelerinin kaynak sonrası oluşan çarpılma değerine ve artık gerilmeye olan etkisi Simufact Welding programında analiz edilerek belirlenmiştir. Simulasyon sonuçları ile elde edilen verilerin artık gerilme ve çarpılma değeri, optimum olan deneyin belirlenebilmesi için Minitab programında Deney Tasarım tablosu oluşturulmuştur. Sonuçlar raporlanmıştır ve elde edilen grafik sonuçları değerlendirilmiştir.

ANALYSIS AND VERIFICATION STUDY WITH WIRE FEED ADDITIVE MANUFACTURING IN THE AUTOMOTIVE INDUSTRY

ABSTRACT

In this study, the wire arc additive manufacturing method, which is a metal additive manufacturing method, is mentioned. The effects of laser power and laser speed parameters on post-welding distortions and effective stress by welding a 5cm x 100cm piece with wire-fed manufacturing method were simulated in Simufact Welding program. A DoE table was created in the Minitab program in order to determine the optimum of the data obtained with the simulation results. The obtained table results were evaluated.

Keywords: Finite Element Analysis, Wire arc additive manufacturing, Additive Manufacturing

1. GİRİŞ

Hızlı prototipleme ve üç boyutlu baskı adlarıyla da bilinen eklemeli imalat, malzemelerin birleştirilerek katmanlar halinde oluşturulup üst üste eklenmesi prensibine dayanan, serbest formlu ve karmaşık geometrili objelerin üretilmesine imkân sağlayan pratik bir imalat metodudur. Günümüzde bu teknolojiler sadece polimerler, seramikler, plastikler vb. gibi hammaddelerin yanında metalleri de bünyesinde barındırmaya başlamıştır. ‘‘Metal eklemeli imalat sistemleri Şekil 1’deki gibi dört ana başlıkta incelenebilir’’.[3]

Şekil 1: Metal katkılı üretimin dört ana yöntemi [1]

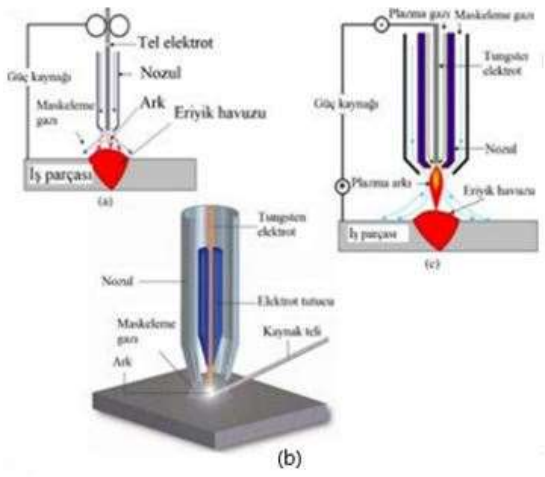
2. TEL ARK EKLEMELİ İMALAT

Tel ark eklemeli imalat ısı kaynağı olarak ark, besleme malzemesi olarak ise tel kullanan bir eklemeli imalat yöntemidir. Bu yöntem çok pasolu kaynak işleminden oluşur.Gaz metal ark kaynağı (MIG-MAG), gaz tungsten ark kaynağı (TIG) ve plazma ark kaynağı kullanılarak Tel ark eklemeli imalatişlemi yapılabilmektedir. [3] Şekil 2'de farklı kaynaklar için şematik görseller verilmiştir.

Tel ark eklemeli imalat yönteminde hammaddeden atık oluşmadan kayıpsız olarak faydalanılabilmesi, büyük boyutlu ve orta seviyedeki karmaşık parçaların sorunsuzca üretilebilmesi ve diğer metal eklemeli imalat yöntemlerine göre ekonomik oluşu bu tekniği talep gören bir üretim yöntemi haline getirmektedir.[4] Ayrıca bu yöntem ''toz yataklı ergitme yönteminde olduğu gibi yorulma ömrünü azaltan yüksek seviyeli gözeneklilik sorunu sergilemez.'' [3]

Toz beslemeli tekniği, oksitlenmeyi ve korozyonu engellemek amacıyla soy gaz ortamına elverişli tezgâhlarda kullanılmaktadır ve çeşitli metal alaşımlarının seçilmesine olanak sağlamaktadır.[5]Büyük metal bileşenlerin tel ark eklemeli imalat'ta olan artık gerilmeleri ve bozulmaları kontrol etmek için proses parametrelerini optimize etmek önemlidir. Ancak verilen büyük metal bileşenler için optimal proses parametrelerini deneysel olarak belirlemek zaman alıcı ve pahalıdır.[6]

Sonlu elemanlar (FE) analizi, gerçek eklemeli üretim süreci için referans sağlamak amacıyla Tel ark eklemeli imalat'taki sıcaklık alanı dağılımını ve deformasyonu tahmin etmek için yaygın olarak kullanılır. Katmanlı imalatta proses ayarları ve termal tepki arasındaki ilişkinin daha iyi anlaşılması, artık stres, deformasyon, mikro yapı ve mekanik özelliklerin yanı sıra proses parametrelerinin optimizasyonunu makul bir şekilde tahmin edebilir. Sayısal simülasyonun hesaplama süresi esas olarak model boyutu, ağ noktalarının sayısı ve kullanılan ısı kaynağı modeli ile ilgilidir. [6]

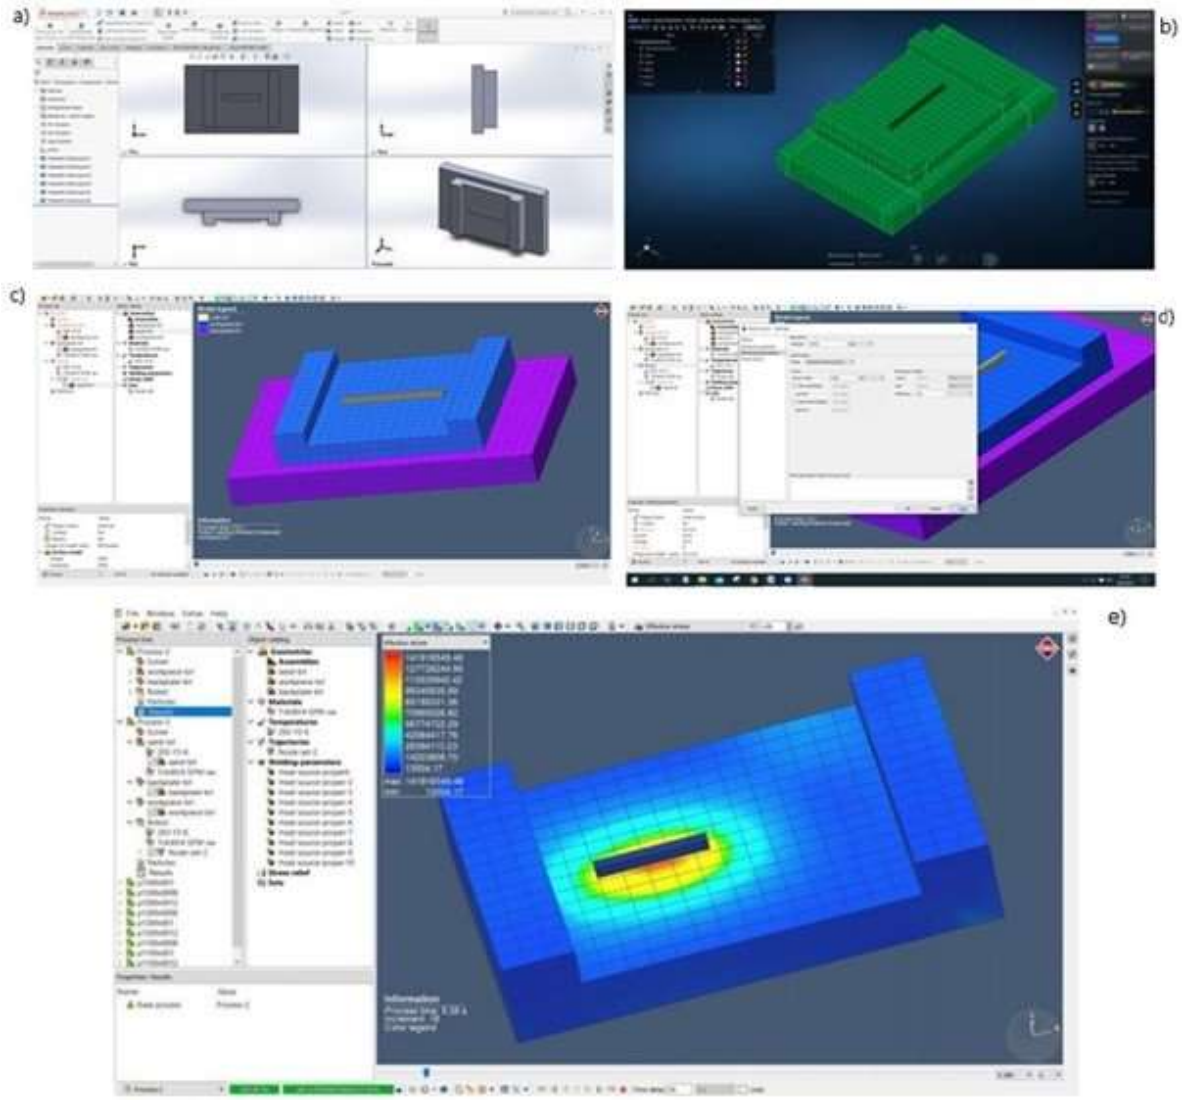


Şekil 2: a) Gaz metal ark kaynağı, b) Plazma kaynağı, c) Gaz tungsten ark kaynağı [2]

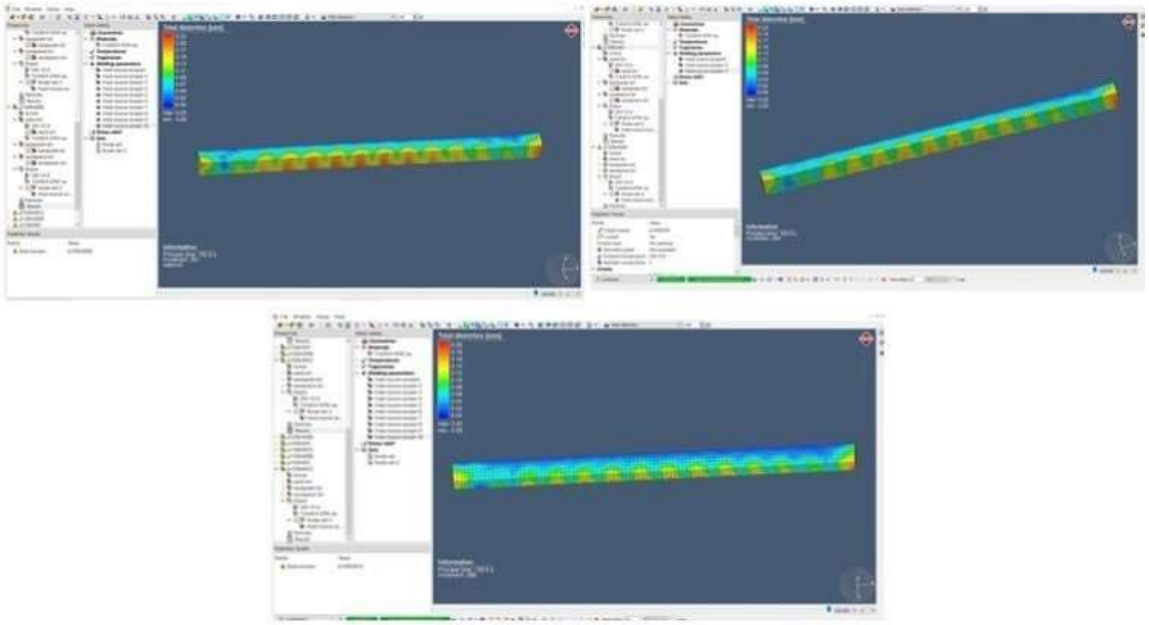
3. MALZEME VE YÖNTEM

Parça tasarımından simülasyon çıktıları elde edilene kadar oluşan süreçteki adımlar Şekil 3'te verilmiştir. Parça Solidworks programında üç boyutlu şekilde modellendikten sonra , MSC Apex programında tasarlanan modele mesh atıldı. Mesh atılan parça Simufact Welding programına aktarılıp, modelin taban kısmı sabitlendi. Malzeme olarak TiAl6V4-SPM seçildi, her kaynak süreci için bitiş süresi 150 saniye olarak belirlendi.

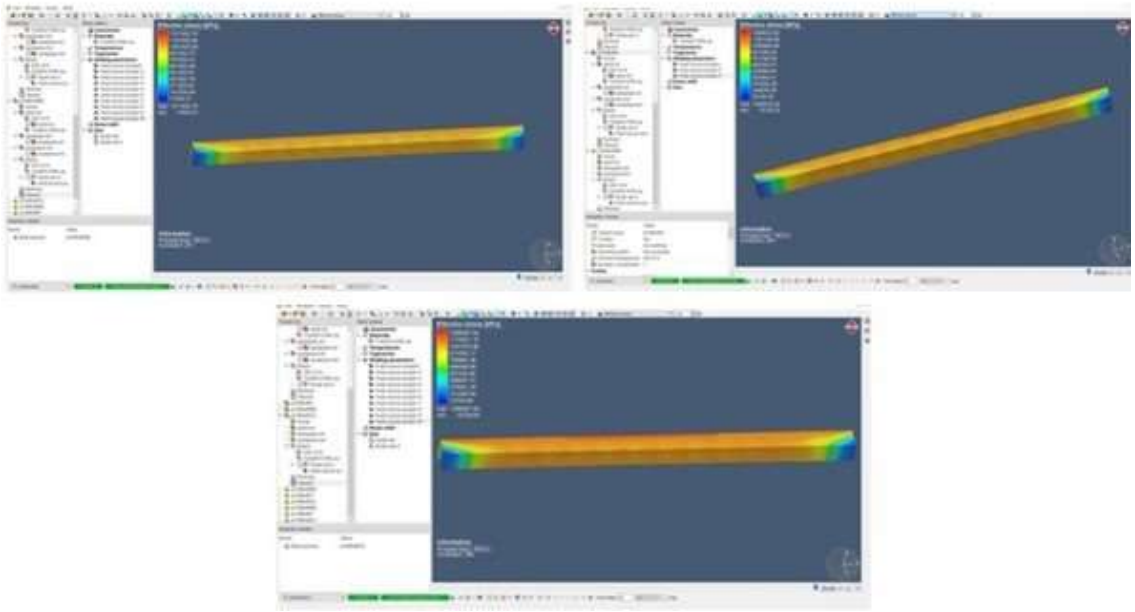
Lazer gücü 1.1 kW, 1.3 kW, 1.5 kW, lazer hızı 0.008 m/s, 0.01 m/s, 0.012 m/s olarak seçildi. Lazer gücü ve lazer hızı parametrelerinin birbiriyle olan tüm kombinasyonları için ısıl girdi parametreleri girildi. Bu parametrelerin kombinasyonu sonucunda elde edilen simülasyonlar Şekil 4'ten itibaren Şekil 9 da dahil olmak üzere aşağıda gösterilmiştir. Deney tablosu oluşturulması için toplamda 9 adet simülasyon elde edilmiştir.



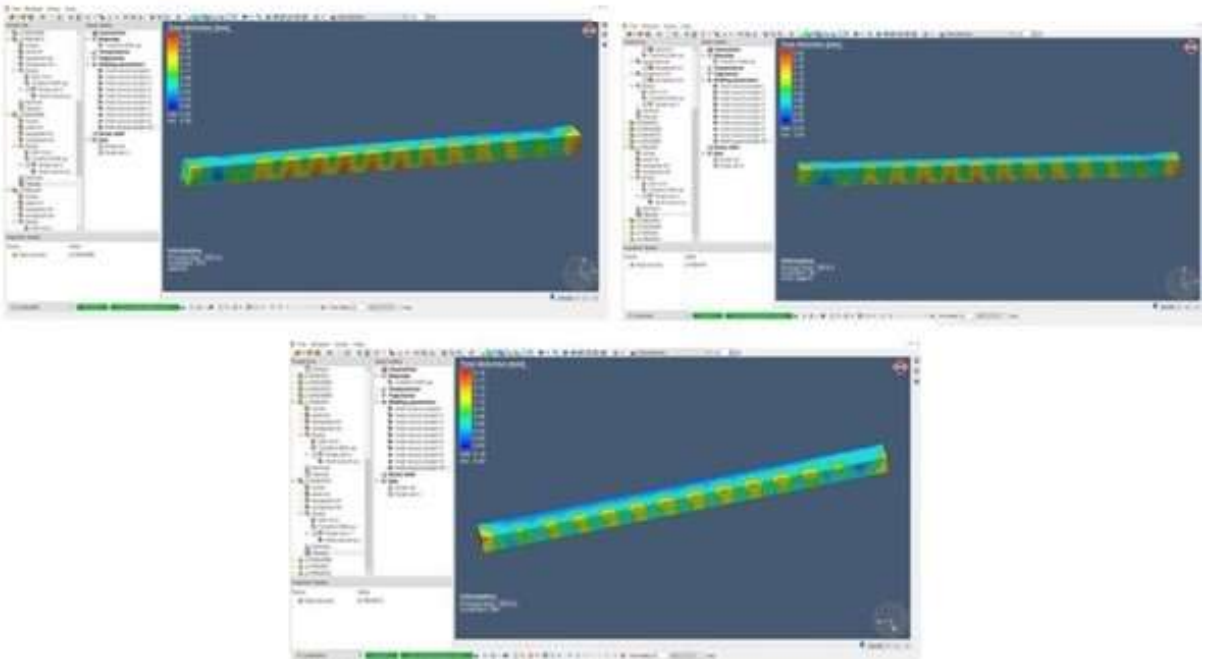
Şekil 3: a) Solidworks programında parçanın üç boyutlu olarak modellenmesi, b) MSC Apex programında mesh oluşturulma işlemi, c) Modelin Simufact Welding programına aktarılması, d) Isıl girdi parametrelerinin girilmesi, e)Tüm durumlar için ısıl girdi girilmesi



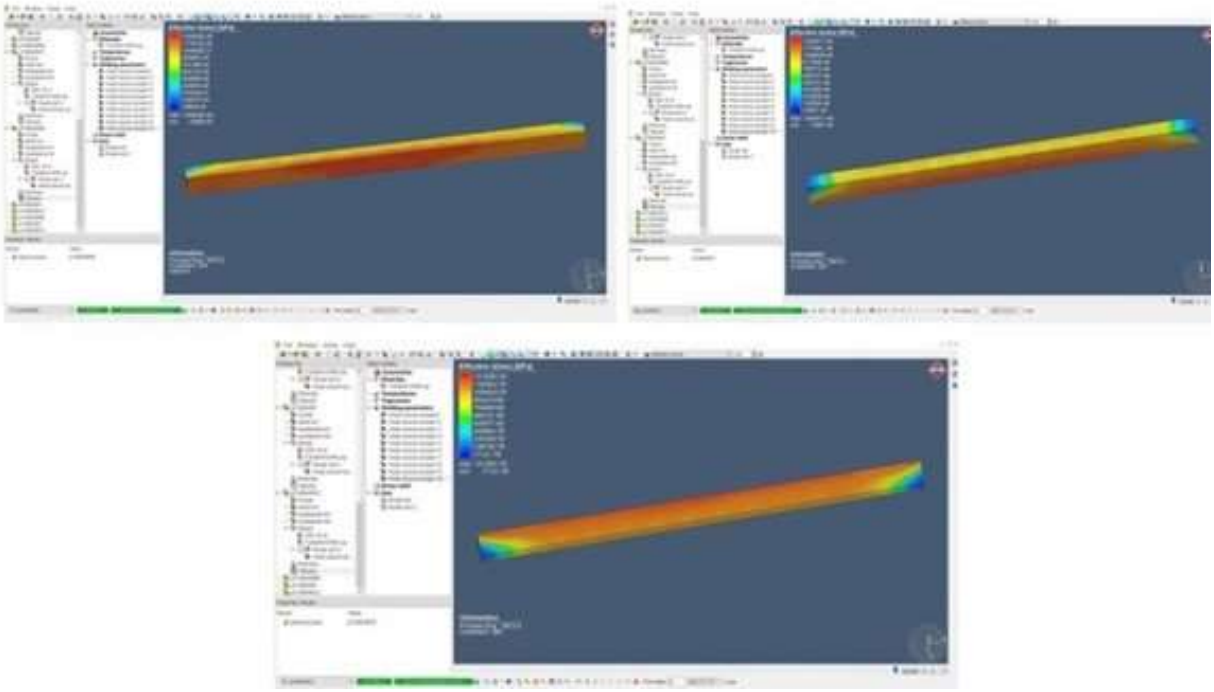
Şekil 4: Lazer gücü 1.5kW iken hızların sırasıyla 0.008 m/s, 0.01 m/s 0.012 m/s olduğu çarpılma simülasyon sonuçları.



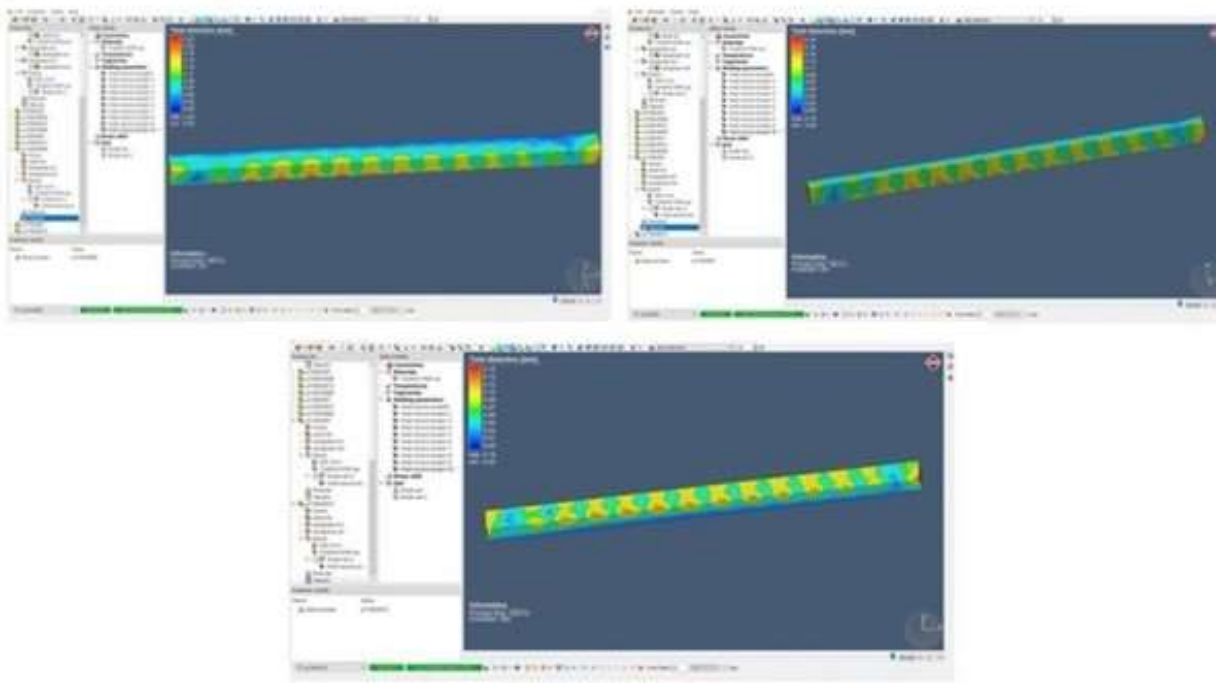
Şekil 5: Lazer gücü 1.5kW iken hızların sırasıyla 0.008 m/s, 0.01 m/s 0.012 m/s olduğu artık gerilme simülasyon sonuçları



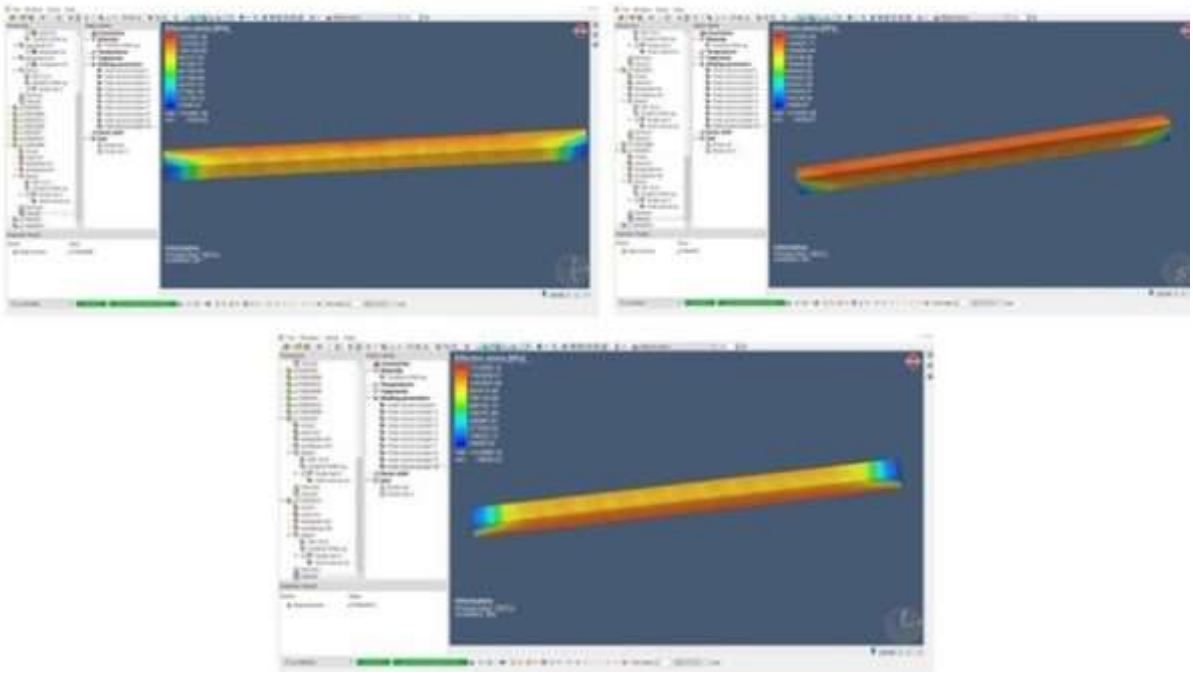
Şekil 6: Lazer gücü 1.3kW iken hızların sırasıyla 0.008 m/s, 0.01 m/s 0.012 m/s olduğu çarpılma simülasyon sonuçları



Şekil 7: Lazer gücü 1.3kW iken hızların sırasıyla 0.008 m/s, 0.01 m/s 0.012 m/s olduğu artık gerilme simülasyon sonuçları



Şekil 8: Lazer gücü 1.1kW iken hızların sırasıyla 0.008 m/s, 0.01 m/s 0.012 m/s olduğu çarpılma simülasyon sonuçları



Şekil 9: Lazer gücü 1.1kW iken hızların sırasıyla 0.008 m/s, 0.01 m/s 0.012 m/s olduğu artık gerilme simülasyon sonuçları

Minitab uygulamasına girilen simülasyon sonucu değerlerinin deney tasarım tablosuna aktarılmış hali Şekil 10'da verilmiştir.

4. DEĞERLENDİRME VE SONUÇ

Metal eklemeli imalat işlemlerinden biri olan tel ark yönteminin tanıtıldığı ve Simufact Welding programında farklı lazer hız ve güçlerinde simülasyon sonuçları elde edilen bu çalışmada;

- Lazer gücünün artması artık gerilmeyi azaltmıştır.
- Lazer hızının artmasını artık gerilmeyiazaltmıştır.
- Lazer gücünün artması çarpılmayı arttırmıştır.
- Lazer hızının artması çarpılmayı azalmıştır.
- Yapılan deney sayısının belirtilen üretim süreci için daha fazla olması gerekliliği, hata oranının artışına sebep olmuştur. Bu yüzden deney sayısı arttırılmalıdır.

TEŞEKKÜR

Akademik Proje Danışmanım Prof.Dr. Ferruh ÖZTÜRK e, bana bu projede çalışma fırsatı veren COŞKUNÖZ HOLDİNG A.Ş ye, projeye yön verdikleri ve bilgilerini paylaştıkları için Firma Proje Danışmanlarım Metin ÇALLI ve Şuayip Muaz GÜÇ e en içten dileklerimle teşekkür ederim.

ABSTRACT

The suspension systems are designed to improve ride comfort and handling behaviour of the vehicle. The current developments in electrification have increased the interest in active suspension systems. In this study, a mathematical model of the quarter car with an active suspension system is developed in MATLAB & Simulink environment. Before developing the full-state feedback control logics; Luenberger observer and Kalman filter are designed and integrated into the system to predict the unmeasured states. LQR and LQG control methods are applied to the developed active suspension model and the system behaviour is simulated to demonstrate the advantages of the methods. The selection process of the LQR and LQG control weighting parameters will be investigated in a further stage of the research.

Keywords: Active suspension systems, observer design, Luenberger observer, Kalman filter, Linear Quadratic Regulator (LQR), Linear Quadratic Gaussian (LQG) control.

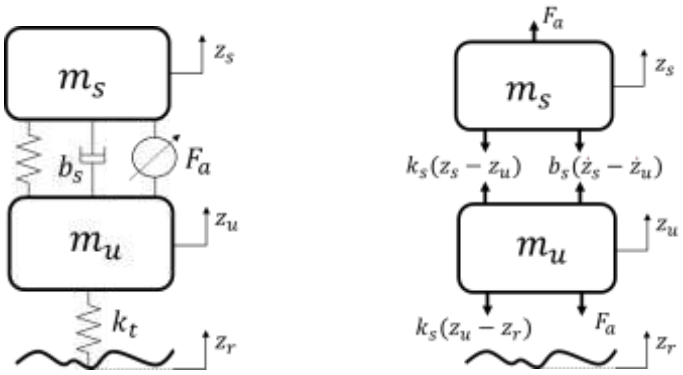
1. INTRODUCTION

The suspension systems are aimed at and designed to improve ride comfort and handling behaviour of the vehicle. Starting from the 1950s researchers worked on active vehicle suspension system design for many years. Especially, high attention on the research in the mid-1980s (Hrovat, 1990 and 1997) and (Handbook, 1996). An extended literature survey on active suspension systems can be found in (Tseng and Hrovat, 2015). Nowadays, automotive technologies are more focused on Autonomous Drive (AD) and Advanced Driver Assistant Systems (ADAS). Autonomous drive functions combined with active suspension systems have tremendous benefits such as; improve safety and reduce the crash impact by adjusting the ground level of the vehicle side crash zone (URL1). Tran et al (2021) showed the benefits of integrating the active suspension system to cruise control of autonomous vehicles. The current developments in electrification and with the help of advance applied optimal control methods and observer techniques have caused the increased attention of researchers to develop active vehicle suspension systems.

In this study, first, a mathematical model of the quarter car with an active suspension system is developed. Additionally, the Luenberger observer and Kalman filter are designed and integrated into the system to predict the unmeasured states. Then, LQR and LQG control methods are applied to the developed active suspension model and the system behaviour is simulated and controller performance evaluated in MATLAB & Simulink environment. The selection process of the LQR and LQG control weighting parameters will be investigated in a further stage of the research.

2. MODELING OF ACTIVE SUSPENSION SYSTEM

In this section; the equation of motion of quarter car model is derived and modelled in Matlab & Simulink environment. The model has advantages based on its simplicity and ability to evaluate performance. The active suspension system of the quarter car model is shown in Figure 1. The sprung mass is denoted by m_s and unsprung mass is by m_u. The control force actuator (F_a) is used in the active suspension system. The tire damping coefficient is so small compared to suspension dampers (b_s) that it can be neglected and is assumed to have only the spring feature (k_t) and is in contact with the road. The spring constant, k_s, represents the elasticity of the suspension.



(a) (b)

Figure 1. (a) Active suspension system configuration (b) free body diagram of Active suspension system

The equations of motion should be derived to perform a numerical simulation of the vertical movement of the vehicle suspension system. The equations of motion of the two-degrees-of-freedom quarter-car model with active suspension system are represented by equations as follows (Rajamani, 2011):

$$\ddot{z}_s = \frac{1}{m_s}\left(F_a - k_s(z_s - z_u) - b_s(\dot{z}_s - \dot{z}_u)\right)$$

$$\ddot{z}_u = \frac{1}{m_u}\left(k_s(z_s - z_u) + b_s(\dot{z}_s - \dot{z}_u) - k_t(z_u - z_r) - F_a\right)$$

The state vector is defined as follows when representing the dynamics of the quarter car model in state space:

$$\dot{x} = Ax + Bu$$
$$y = Cx + Du$$

With the notation $(x_1 ; x_2 ; x_3 ; x_4) = (z_s ; \dot{z}_s ; z_u ; \dot{z}_u)$
Where is the sprung mass $m_s = m_1$; unsprung mass $m_u = m_2$; suspension damper coefficient $b_s = b_1$; spring constant, $k_s = k_1$; tire spring constant $k_u = k_2$; control force $F_a = f$; road disturbance $z_r = w$
Equations (1) and (2) re-written into a vector-matrix form:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -k_1/m_1 & -b_1/m_1 & k_1/m_1 & b_1/m_1 \\ 0 & 0 & 0 & 1 \\ k_1/m_2 & b_1/m_2 & -(k_2 + k_1)/m_2 & -b_1/m_2 \end{bmatrix} \cdot \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 1/m_1 & 0 \\ 0 & 0 \\ -1/m_1 & k_2/m_2 \end{bmatrix} \cdot \begin{bmatrix} f \\ w \end{bmatrix}$$

$$y = \dot{x}_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \cdot \begin{bmatrix} f \\ w \end{bmatrix}$$

Based on the Equations above the quarter car model was developed and simulated in MATLAB & Simulink environment to investigate the effects of different control strategies which will be explained in the next sections in detail.
The selected quarter car active suspension system model parameters can be seen in Table 1.

Table 1. Parameters of the vehicle suspension system for a quarter-car model

Parameters	Symbols	Quantities
Sprung mass	m_s	290 [kg]
Unsprung mass	m_u	59 [kg]
Suspension stiffness	k_s	16182 [N/m]
Suspension damping coefficient	b_s	750 [Ns/m]
Tire Stiffness	k_t	190000 [N/m]
Tire damping coefficient	b_t	-

2. OBSERVER DESIGN

In most real systems, all the state variables are not available through measurements because of costs, technical impossibilities, high power consumption and not robust enough (due to high noise), etc. Estimation of unmeasured state variables is commonly referred to as observation. The algorithm that estimates the state variables is called a state estimator or observer. A state observer is a system that provides an estimate of the states of a given real system based on the measurements of the output and control variables (Akbari et al. 2012). Full state feedback control with observer diagram can be seen in Figure 2.

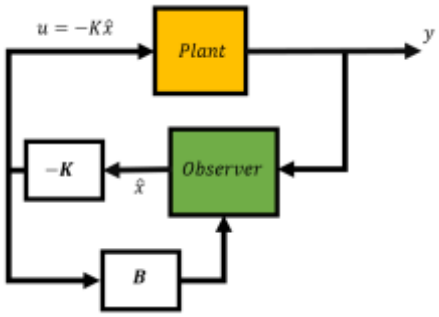


Figure 2. Full state feedback control with observer diagram

In this study, the motivation behind the observer design is the implementation of full state feedback control laws that need estimated state variables. So, before designing the full state feedback control, all state variables need to be available.

2.1 Luenberger Observer

The observer with feedback (without noise) called Luenberger observer. Luenberger was the first who suggested the state observer for estimating the unknown states of deterministic linear systems. Luenberger observer is correcting the estimation states with feedback from the estimation error $e = y(t) - \hat{y}(t)$ (Hernandez et al. 2019). A Block diagram of a system with Luenberger observer can be seen in Figure 3.

Linear system observer equation is given by

$$\dot{\hat{x}} = A\hat{x} + Bu + L(y - \hat{y})$$
$$\hat{y} = C\hat{x}$$
$$\dot{\hat{x}} = A\hat{x} + Bu + L(y - C\hat{x}) = (A - LC)\hat{x} + Bu + Ly$$

L is the observer gain matrix to be determined.

State estimation error dynamics:

$$\varepsilon = x - \hat{x}$$
$$\dot{\varepsilon} = \dot{x} - \dot{\hat{x}} = (Ax + Bu) - \left(A\hat{x} + Bu + L(y - C\hat{x})\right) = (A - LC)\varepsilon$$

The stability of the error dynamics depends on the eigenvalues of $(A - LC)$

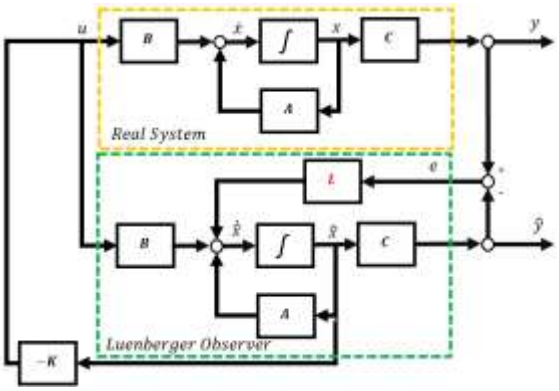

Figure 3. Block diagram of a system with Luenberger observer

Simulated performance results of the designed Luenberger observer in this study will be given next sections.

2.2 Kalman Filter

Optimal estimation algorithm (with noise) called Kalman filter. Kalman filter is one of the good observers against a wide range of disturbances (process and sensor noise). The process noise and the measurement noise, both are considered to be Gaussian. The filter is named after Rudolf E. Kalman, one of the primary developers of its theory (Sharma et al 1994). A Block diagram of a system with Kalman Filter can be seen in Figure 4.

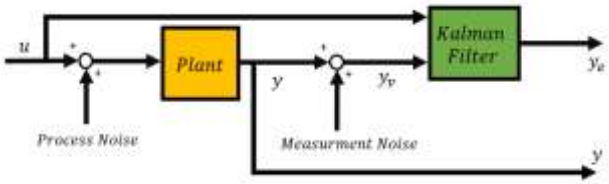

Figure 4. Block diagram of a system with Kalman Filter

The continuous-time system dynamics and measurement equations are given as

$$\dot{x} = Ax + Bu + w$$
$$y = Cx + v$$
$$w \sim (0, Q_c)$$
$$v \sim (0, R_c)$$

Note that $v(t)$ and $w(t)$ are continuous-time white noise processes.

The continuous-time Kalman filter equations are given as

$$\hat{x}(0) = E[x(0)]$$
$$P(0) = E[x(0) - \hat{x}(0))(x(0) - \hat{x}(0))^T]$$
$$K = PC^T R_c^{-1}$$

$$\hat{x} = A\hat{x} + Bu + K(y - \hat{y})$$
$$\hat{y} = C\hat{x}$$
$$\hat{x} = A\hat{x} + Bu + K(y - C\hat{x})$$

K is the Kalman gain minimizes the derivative of the estimation covariance. Simulation results of the designed Kalman filter will be given next sections.

3. OPTIMAL CONTROLLER DESIGN

3.1 LQR controller

Linear quadratic regulator (LQR) is an optimal controller that provides full state feedback. The main advantage of LQR method is that in using it the factor of performance index could be weighted according to the designer's preferences or other constraints (Soliman 2011) and (Sam et al 2000). The optimal LQR controller block diagram can be seen in Figure 5.

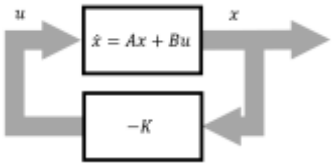

Figure 5. Optimal LQR controller diagram

The main concern of optimal control theory is operating a dynamic system at minimum cost. The plant could be written in state-space form for the derivation of the linear quadratic regulator

$$\dot{x} = Ax + Bu$$

and that all of the n states are available for the controller with a cost function defined as

$$J = \int_0^\infty (x^T Q x + u^T R u)\, dt$$

The feedback control law that minimising the cost is

$$u = -R^{-1} B^T P x$$

where P is found by solving the Riccati equation.

$$A^T P + PA - PBR^{-1} B^T P + Q = 0$$

$$K = R^{-1} B^T P$$

The state variable feedback regulator can be written as follows:

$$u = -Kx$$

where the feedback gain is a matrix K. K and P could be computed using Matlab "lqr" command. The matrices Q and R are the design tuning parameters which are weighting the penalty for the states and control effort. These two matrices are tuned iteratively. The simulated performance of the designed LQR controller in this study will be given next sections.

3.2 LQG controller

Linear Quadratic Gaussian (LQG) or called linear–quadratic state estimator (LQE) combines an LQR control law and a stationary Kalman filter. The LQG controller determines an output feedback law that is optimal in the sense of minimizing the quadratic cost function. LQG optimal state-feedback controller is dynamic and relies on noisy output measurements to generate the control commands. Process and output measurements are assumed to be corrupted by white Gaussian noise (URL2). The Block diagram of LQG control can be seen in Figure 6.

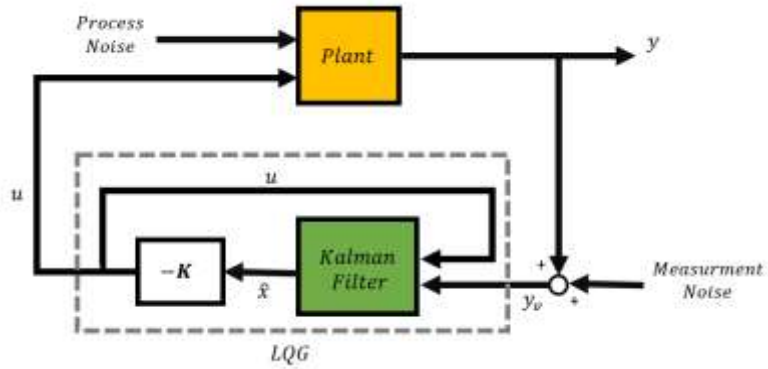

Figure 6. Block diagram of LQG control

The simulated performance of the designed LQG controller in this study will be given next sections.

4. SIMULATION RESULTS

In this section simulated results of designed observer and LQR/LQG controllers are given. Suspended mass displacement $(x_1 = z_s)$ used state for performance analysis of observers and controllers. All figures below show the behaviour of the suspended mass displacement behaviour in Matlab & Simulink environment.

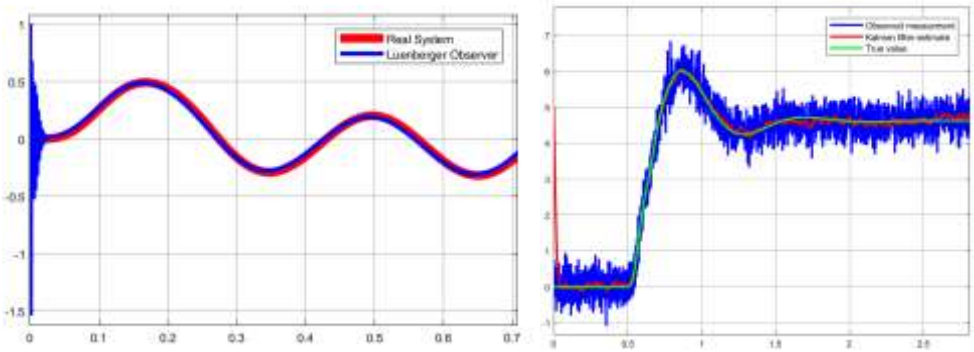

Figure 7. Estimate state with Luenberger observer and Kalman filter

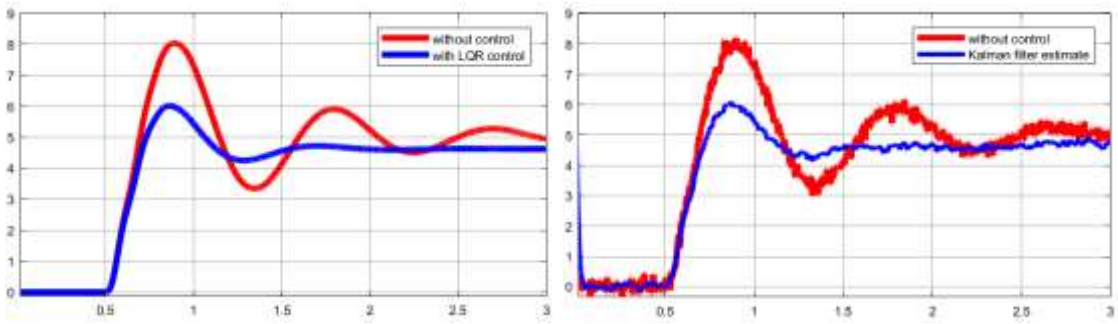

Figure 8. Comparison of passive and LQR and LQG controlled systems

5. CONCLUSION

This paper is about the part of ongoing research on active suspension system development which aims to optimize vehicle ride comfort and handling characteristics. Only the observer design and controller design parts are given with simulation results in this paper. The next step will be the investigation of choosing weighting gains to improve the system performance.

ABSTRACT

One of the uses of hydrogen, known as a clean and renewable energy source, is fuel cells. Although there are areas open to development, fuel cells are promising for vehicles and transportation. One of the important issues in fuel cells is water management and discharge of excess water. This study proposes a second intermediate outlet on the flow channel to discharge excess water and presents the use of the Volume of Fluid method to simulate water movement. Multiphase laminar flow in the created model was solved numerically with fluent software. The movement of a water droplet placed in the channel and the effects of different pressures applied to the extra outlet on the droplet movement were investigated.

Keywords: Fuel Cell, Water Management, Water Droplet, VoF Method

1. INTRODUCTION AND MAIN SECTIONS

In the twenty-first century, fossil fuels are still the main source to meet global energy demand. According to International Energy Agency's share of 2018 energy supply tables, only fifteen percent of the energy demand is met by renewable energy sources [1]. There are several downsides of nonrenewable energy sources, which are mainly fossil fuels. First, carbon emission from fossil fuels is a serious threat to earth. The problem of air pollution and global warming has been recognized after the industry revolution in the 1960s. Then, some limitations on carbon emission are implemented by international agreements. The most recent one is the Paris Agreement, which was adopted by 196 parties in 2015 [2]. However, continuously growing global economy, carbon emission is still increasing according to IEA 2018 data [3]. The second downside of fossil fuels is that they are in control of some specific countries, so other countries lack them. Moreover, fossil fuels are claimed to be consumed away with time advancing [4].

Hydrogen is promising as a clean and renewable energy source. Proton Exchange Membrane Fuel Cell (PEMFC) is one of the types of fuel cells that use hydrogen as fuel. PEMFC stacks are compact and clean, they start up quickly, and they work at low temperatures -around 80 °C. While these features make them a great source for energy need in transportation, the low operating temperature make water management harder, especially for this type of fuel cells. The excessive liquid water may block membrane electrode assembly pores, catalyst areas, or the membrane. This blockage inhibits the proton transfer or reaction and causes dramatic losses of efficiency. On the other hand, if the membrane dries out, its proton conductivity decreases. Therefore, discharge of excessive water should be managed steadily and in control.
Improving the channel design of PEMFC to enhance water management is a current topic in research and development. The Volume of fluid (VOF) method is generally preferred, since CFD studies on water management should cover a two-phase solution. Quan et al. simulated a bubble movement in U shaped channels in ANSYS Fluent. They analyzed the effect of bending area on bubble movement. They claimed that while the bending portion has a critical effect on water transfer, shear stresses, wall adhesion and surface tensions also affect the water transfer [5]. Liu et al., tried to enhance water evacuation by altering the geometry of bending portion of U-shape PEMFC channel also in Fluent. They analyzed separated cases that have different cross-sectional areas on bending portion and different angles of alignment of the exterior wall on bending portion of a PEMFC flow channels. They conclude that altering the cross-sectional area may result in unwanted pressure drops, but providing a slight slope on the exterior wall of the bending portion has positive effect on water evacuation [6]. Bao and Gan analyzed the effect of the roughness and the hydrophobia of channel walls, and they claimed both properties support the water discharge [7].

More research work about water management in PEMFC channels needs to be done. In this work, enhancing water transfer by adding an extra outlet to PEMFC channels is discussed. A water bubble is placed in an air flow in a U form flow channel with two outlets in ANSYS Fluent. Then, movement of the bubble is investigated under different operating conditions.

2. MATERIALS AND METHODS

The structure and working principle of a PEM fuel cell, which is predicted to be one of the favorite power sources for automotive and other sectors demanding portable energy due to its characteristics, can be seen in Fig.1.

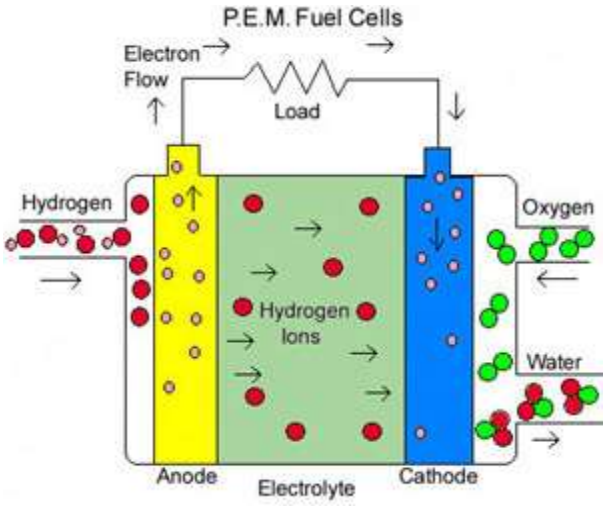

Figure 1. Main components and working principles of a PEM fuel cell

The part that appears as the electrolyte between the anode and the cathode in Fig.1 is called the Membrane Electrode Assembly (MEA). The membrane is a semipermeable (selective) membrane, allowing only positively charged protons to pass through. It has a special structure that does not pass electrons and heavy gases. The hydrogen atoms coming from the anode to this special membrane structure are separated into their protons and electrons here. Protons pass through the MEA and combine with oxygen at the cathode to form water. Electrons also pass to the cathode with an external circuit and chemical equilibrium is achieved. This electron flow creates an electric charge in the circuit. The reactions that take place are as follows:

Anode side : $H_2 \longrightarrow 2H^+ + 2e^-$
Cathode side : $\frac{1}{2} O_2 + 2H^+ + 2e^- \longrightarrow H_2O$
Total : $H_2 + \frac{1}{2} O_2 \longrightarrow H_2O$

While oxygen, hydrogen and cathode form water by chemical reaction, it also provides electrical power from the external circuit.

In order to examine the movement of water formed together with the reactants, the conservation equations of the multiphase flow in the fuel cell channels should be solved. In this work, Volume of fluid (VOF) method is used to model water bubble movement in a PEMFC channel using ANSYS Fluent. In the Volume of Fluid method, multiple non-mixing fluids are solved using one set of momentum equations. For every mesh cell, the amount of a fluid is related to a ratio "α", or volume fraction. If a mesh cell is full of a fluid, then its volume fraction is set to one for that cell. Else, if that cell does not contain the fluid, its volume fraction is set to zero. If the cell contains multiple fluids, then, there is a fluid interface in that cell. For every cell, the sum of volume fractions is equal to one.

$$\sum_{q=1}^{n} \alpha_q = 1 \qquad (1)$$

For each fluid, the product of its physical properties and volume fraction is summed to get the property of that cell.

For example, suppose a cell contains two fluids, a gas, and a liquid.

For a cell containing liquid and a gas:

$$\alpha_g + \alpha_l = 1 \tag{2}$$

Then, each physical property can be calculated by sum of products.

$$\rho = \rho_l \alpha_l - \rho_g (1 - \alpha_l) \tag{3}$$

$$\mu = \mu_l \alpha_l + \mu_g (1 - \alpha_l) \tag{4}$$

Where α_g is volume fraction of gas, α_l is volume fraction of liquid. ρ is density and μ is dynamic viscosity. Continuity equation and momentum equations are calculated by using such those volume average properties.

Continuity equation can be written as

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \vec{v}) = 0 \tag{5}$$

which is implied in Volume of Fluid method as

$$\frac{\partial \alpha_q}{\partial t} + \vec{v} \cdot \nabla \alpha_q = \frac{S_{\alpha_q}}{\rho_q} \tag{6}$$

where t is time, v ⃗ is velocity, S is source term (which is zero by default) and ρ is density.
Momentum equation is,

$$\frac{\partial}{\partial t}(\rho \vec{v}) + \nabla \cdot (\rho \vec{v}\vec{v}) = -\nabla p + \nabla \cdot \left[\mu \left(\nabla \vec{v} + \nabla \overrightarrow{v^T}\right)\right] + \rho \vec{g} + \vec{F} \tag{7}$$

where p is pressure and F ⃗ is the force generated from the shear tension. And finally, the energy equation is to be solved.

$$\frac{\partial}{\partial t}(\rho E) + \nabla \cdot \left(\vec{v}(\rho E + p)\right) = \nabla \cdot (k_{\text{eff}} \nabla T) + S_h \tag{8}$$

where E is energy, k_{eff} is effective thermal conductivity, S_h is the source term.

$$E = \frac{\sum_{q=1}^{n} \alpha_q \rho_q E_q}{\sum_{q=1}^{n} \alpha_q \rho_q} \tag{9}$$

Then for each fluid, energy can be calculated by using Equation 9.
Surface tension of a non-mixing fluid is its tendency to keep its surface area at minimum and it can be calculated using surface tension equation,

$$p_2 - p_1 = \sigma \left(\frac{1}{R_1} + \frac{1}{R_2}\right) \tag{10}$$

where F_{vol} is volumetric force, κ_i is curvature term, σ_{ij} is surface tension for each side.

Surface tension and wall adhesion are crucial factors in multiphase micro flows.

Adhesion force can be resolved as,

$$\hat{n} = \widehat{n_w} \cos\theta_w + \widehat{t_w} \sin\theta_w \quad (11)$$

$\widehat{n_w}$ Wall normal unit force vector, $\widehat{t_w}$ wall tangent unit vector, θ_w Contact angle.

If the contact angle is smaller than the right angle (90°) surface is hydrophilic, else surface is considered hydrophobic (Fig.2).

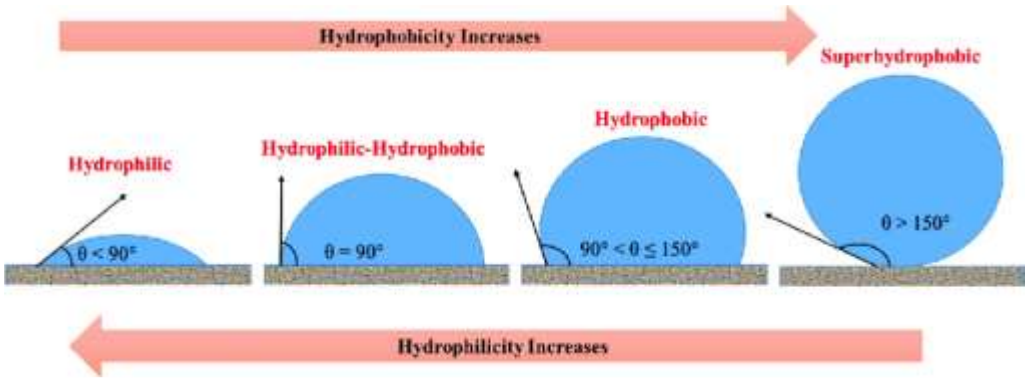

Figure 2. Relation between the hydrophoby and the contact angle

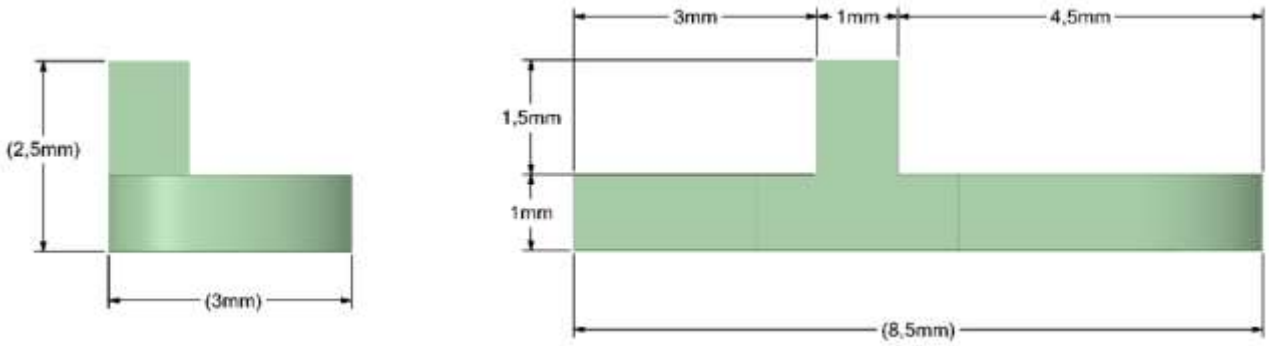
3. NUMERICAL MODEL AND BOUNDARY CONDITIONS

A part of a fuel cell flow channels is considered in this study to simulate the motion of liquid formed in the cell. The part under consideration is a U-shaped channel with 1x1 mm^2 cross section. As a new design, an extra outlet (outlet-1) that can be used to drain excess water is placed on the channel as can be seen in Fig.3. Model is meshed using ANSYS Meshing.



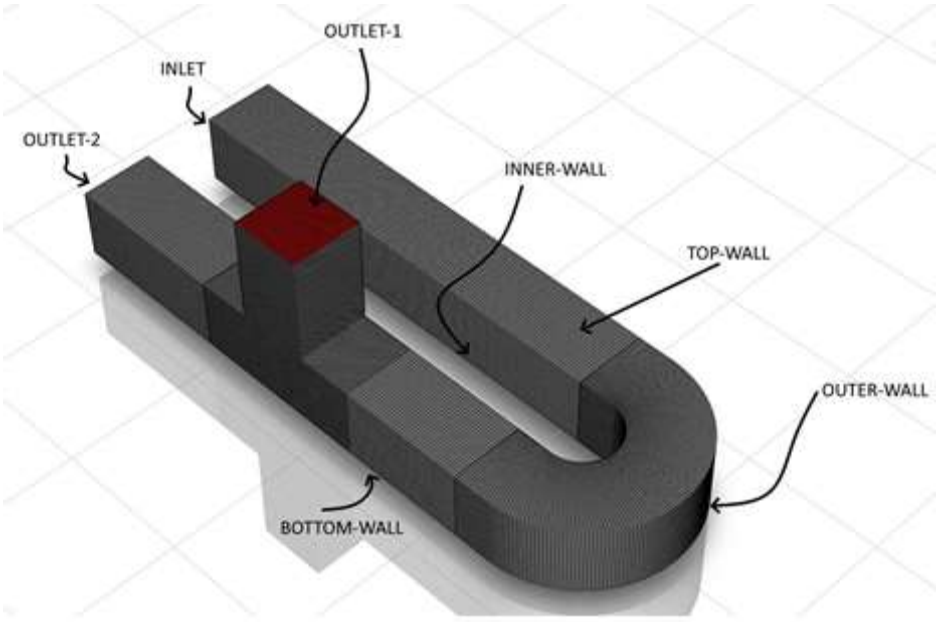


Figure 3. *The geometry and the meshing of U-form channel model with an extra outlet*

A 4 m/s air flow enters from the inlet, while Outlet-2 opens to an atmospheric pressure. A 0.6 mm diameter spherical water bubble is placed near to the inlet. The bubble has the same velocity with water at time zero. Gravitational acceleration is 9.81 m/s on minus y direction. The surface tension is taken constant at 0.073 N/m.

The airflow is defined as laminar flow. Contact angles between all walls and water is set to 140°. Seven cases with different outlet-1 pressures are compared. All settings are given in Table 1.
The methods used in the analyses are as follows. Multiphase: Volume of Fluid Method. PISO for Pressure – Velocity Coupling, Least Squares Cell Based Spatial Discretization, PRESTO! for pressure, Second Order Upwind for Momentum Equation, Geo-Reconstruct for Volume Fraction, and First Order Implicit for Transient Formulation.

Table 1.2 *Boundary Conditions for all cases*

Work / Case		Outlet-1 Pressure (pa)	Bubble Size (Diameter ,mm)	Other Settings	
1	p0	0	0,6		**Contact Angle:** 140°
2	p20	-20	0,6	**Inlet:** 4m/s	**Surface Tension:** 0.073 N/m
3	p30	-30	0,6	**Outlet-2:** 0Pa	**Model Volume:**18,6mm^2
4	p50	-50	0,6	**Bubble Size:** 0.6	**Number of Elements:** 470 426
5	p**	-2/5* Outlet-2	0,6	**Gravity:** -9.81m/s^2	**Pressure URF:** 0.3
6	p2000	-2000	0,6	**Gradient:** Least Square Node Based	**Density URF:** 1
7	p5000	-5000	0,6	**Pressure:** PRESTO!	**Body Forces URF:** 0.8
				Momentum: Second Order Upwind	**Momentum URF:** 0.7
				Volume Fraction: Compressive	**Courant Number:** 0.5
					Bubble Start Velocity: 4m/s

2.1. Mesh Independency Study

Hexa mesh structures were created with 4 different element numbers by changing the maximum mesh element size. The mesh numbers and mesh qualities of these meshes are summarized in Table 2. CFD analyzes with the same initial condition and time step, convergence criteria were performed with these meshes and the results were compared.

Table 2. Mesh characteristics

Node number	Element number	Average Element Quality	Average Skewness	Average Orthogonal Quality	Average Aspect Ratio
467190	435232	0,964	3,10E-03	0,99999	1,204
352107	325832	0,966	3,47E-03	0,99999	1,1813
250796	231250	0,952	2,70E-03	0,99999	1,3066
164268	151250	0,775	4,13E-03	0,99995	1,8102

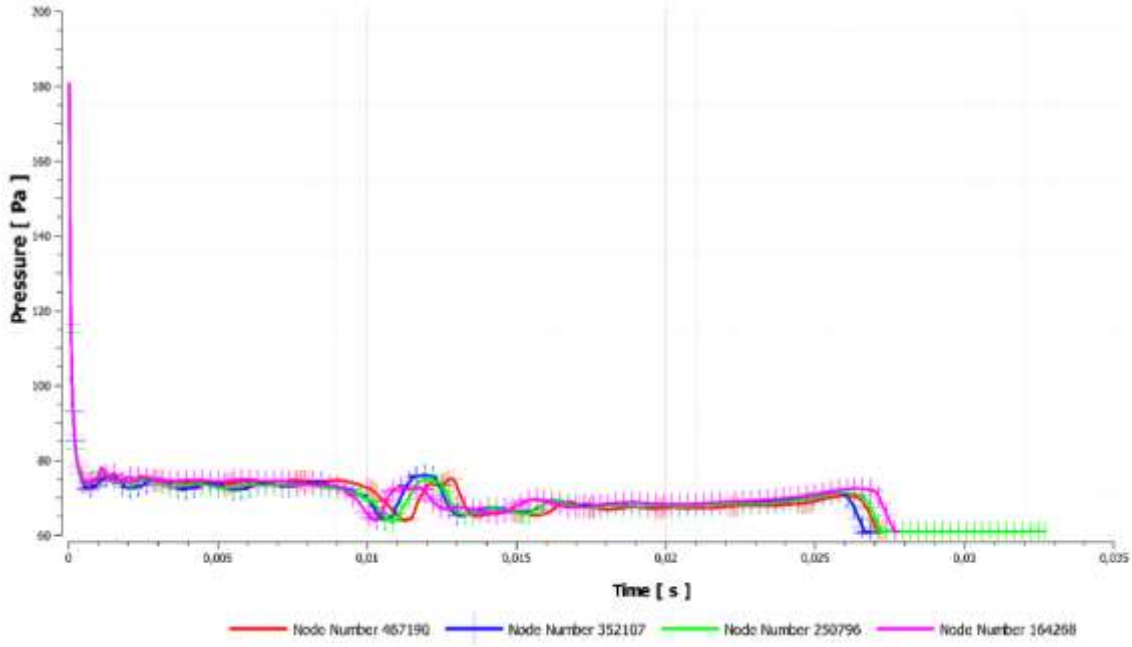

Figure 4. Variation of inlet pressure for different meshes

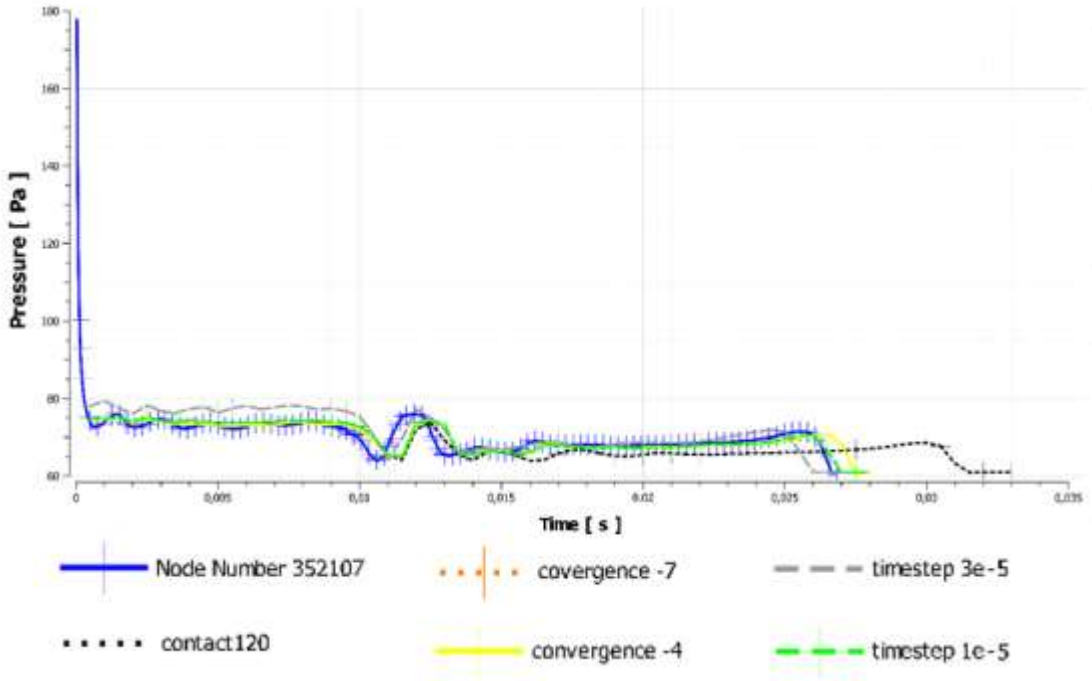

Figure 5. The effect of different solvent settings on the results with the same number of elements

As a result of the solution, the pressure change in the inlet is given in Fig.4 depending on time. The results show a deviation of less than 5% in terms of the pressure value. However, the deviation is greater in terms of time.

Other factors that may affect the results were also wanted to be examined, and for this purpose, some studies were carried out with different solvent settings such as time step, contact angle, convergence criteria with 350 thousand elements. The results were compared in Fig.5. As expected, the convergence criterion did not affect the solution, as both converged. The change of the time step caused changes in the graphs, but the effect on the pressure was limited. In the case of a 120° contact angle, it has clear effects on both the pressure and the changeover times.

Depending on the behavior of the droplet, the duration of the analysis may be less than 6 hours for low element number, light convergence conditions, and long time steps in a personal computer with an 8-core processor, while it can be up to 1 week for denser mesh and heavy convergence conditions and short time steps.

2.2. Validation

Since there was no experimental results, validation was done with a one-dimensional analytical solution.

To confirm numerical solution, an analytical solution is carried out. Since there is a branching in the air flow, the system is a parallel system. Air flow velocity is known at inlet, but inlet pressure and outlet flows are unknown.
For a laminar flow, friction factor which is used in head loss calculation is only function of Reynolds number. Therefore, three unknowns can be calculated from three equation.
The extended Bernouilli equation between two points is,

$$\frac{p_2}{\rho g} + \frac{V_2^2}{2g} + z_2 = \frac{p_1}{\rho g} + \frac{V_1^2}{2g} + z_1 - h_{f1-2} \tag{13}$$

where P is pressure, V is flow velocity, z is the elevation from reference, ρ is density, g is gravitational acceleration, h_{f1-2} is head loss between point 1 and 2.
Reynolds number can be calculated from Equation 14.

$$Re = \frac{\rho VD}{\mu} \tag{14}$$

where D is effective diameter, μ is dynamic viscosity.
For laminar flow in square cross-sectional channel, friction factor can be calculated as

$$f = 56{,}92/Re \tag{15}$$

Finally, from conservation of mass third equation is obtained and added to two extended Bernouilli Equation.

$$V_{inlet} = V_{outlet-1} + V_{outlet-2} \tag{22}$$

In the analytical solution made according to the estimated local loss coefficients and laminar flow assumption, the pressure loss was calculated as approximately 61 Pa, the average velocities were calculated as 0.66 m/s at the outlet-1 and 3.34 m/s at the Outlet -2. In numerical solution, these values were obtained as 59 Pa, 0.7 m/s and 3.3 m/s, respectively, which are quite acceptable.

3. RESULTS AND DISCUSSION

The motion of liquid phase in the air flow was solved by using the VOF method. It was assumed that a spherical water droplet with a diameter of 6 mm was placed initially at the beginning of the U-form channel with an extra outlet. 4 m/s constant air flow is supplied the channel from the inlet. Outlet-2 is opening to 0 gage pressure. The gage pressure of Outlet-2 is set to different pressures as given in Table 1.

Inlet pressures for different cases are given in Fig.6. Inlet pressure changes with time depending on the droplet motion. When the bubble crashes to the bending wall at 2 ms, the minimum inlet pressure is observed. Then, the pressure is increased until the bubble reaches to Outlet-1 portion. After that, the pressure decreased dramatically with open path from Inlet to Outlet-1.

Volume average of velocity of water content is given in Fig. 7. It is observed that bubble velocity is continuously decreases until the evacuation.

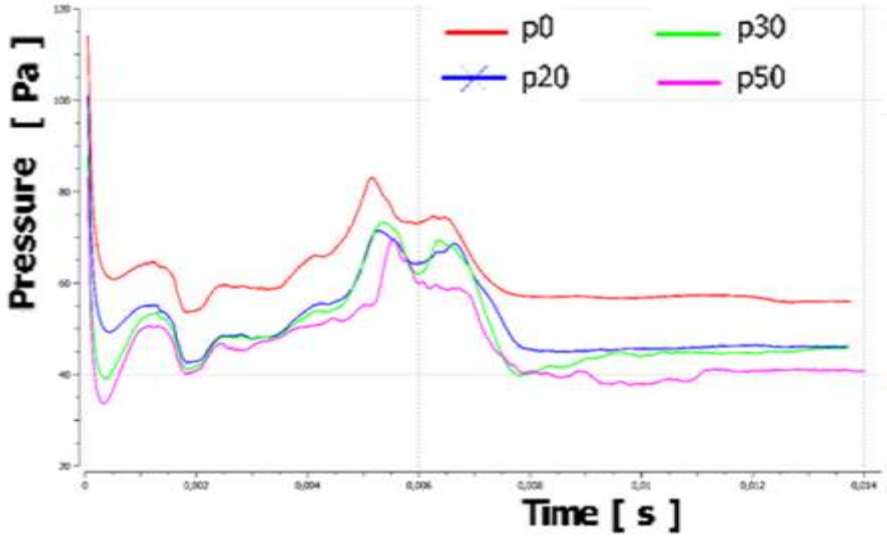

Figure 6. Inlet pressure for different Outlet-1 gage pressures.

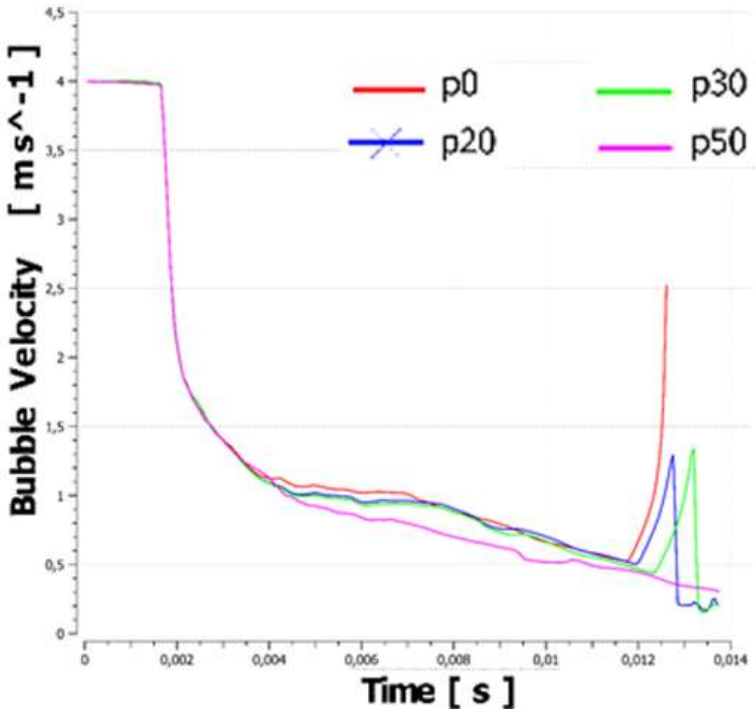

Figure 7. Water Average Velocity for different cases.

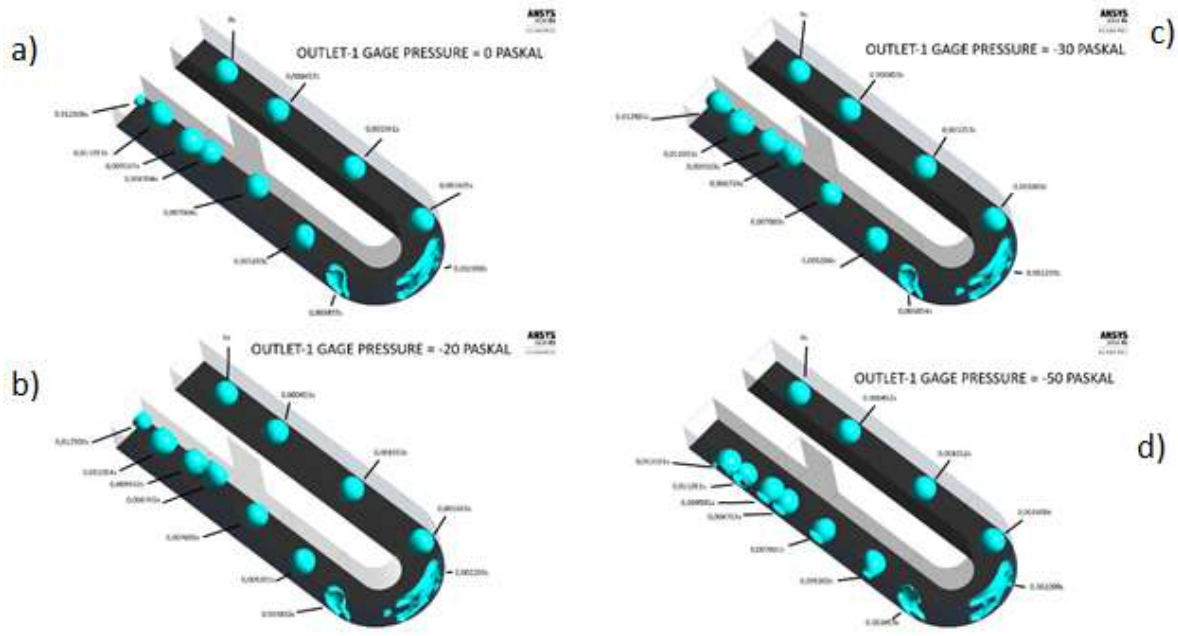

Figure 8. Water droplet positions at different times for different exit pressures at Outlet-2. P2 Pressures: a) 0 Pa b) -20 Pa c) -30 Pa d) -50 Pa

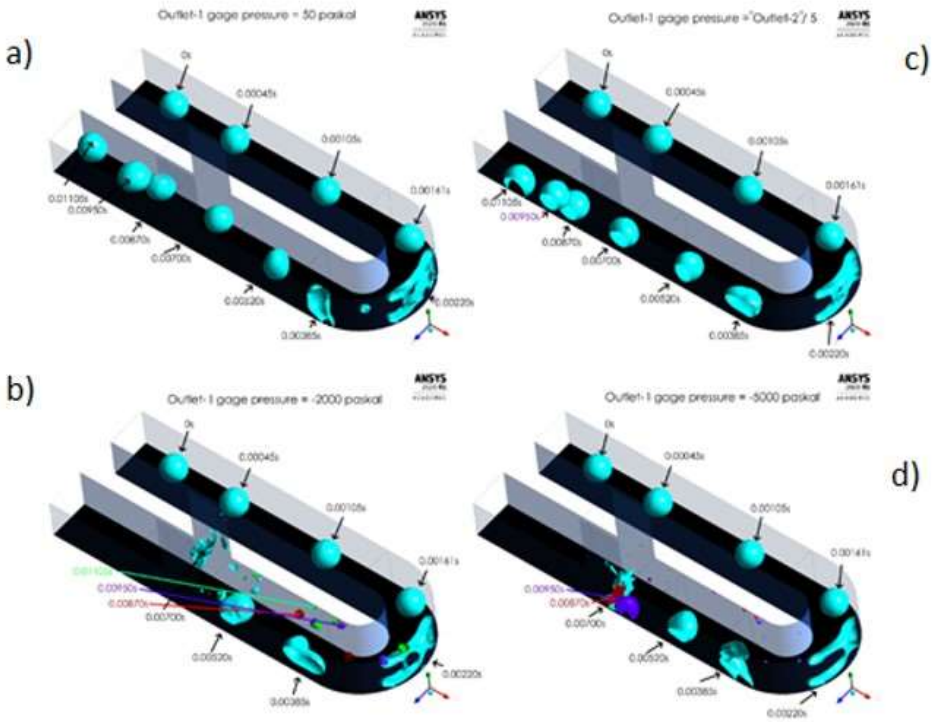

Figure 9. Water droplet positions at different times for different exit pressures at Outlet-2. P2 Pressures:

a) 50 Pa b) "Total Pressure of Outlet-2"/5 c) -2000 Pa d) -5000 Pa

Shape and positions of the water droplet at different times for different exit pressures at Outlet-2 were given in Fig.8., it is observed that changing outlet-2 pressure has no effect in upstream flow of the bending portion. For all cases, water droplet is reached to bending without a deformation at 1,6 ms. The bubble hits the outer bending wall at 0,22 ms and losses its velocity in that direction. Therefore, it is surface area is expanded to balance its inner pressure.
The droplet is stayed in contact with outer bending wall until it exits from bending portion at 3,85 ms. At 5,2 ms the droplet is separated from the outer wall except for the -50 Pa case. For -50 Pa case, this results in high friction forces that causes the bubble to leave the channel much later.
After 7 ms, the effect of different outlet-2 pressures is noticeable. Bubble exits the channel first in 0 Pa case, then respectively in -20 Pa, -30 Pa and -50 Pa cases. A sharp direction change in bubble movement is not observed.

In the second part of first series of analysis, Outlet-1 gage pressure is given 50 Pa, -2000 Pa and,
-5000 Pa and -1/5 of Outlet-2s total pressure. From Figure 9, it is seen that, for -2000 Pa and -5000 Pa cases, bubble is evacuated from outlet-1. For other cases, it is evacuated from outlet-2. When the pressure is set to -5000 Pa and -2000 Pa, some water particles jumped back to inlet direction. While earlier evacuation start is managed for those cases, earlier full water evacuation is not achieved.

4. CONCLUSIONS

Hydrogen is a strong tool for clean renewable energy. Fuel cells use hydrogen as energy carrier and induce zero emission since there is no combustion reaction. PEMFC is one of them. Some advantages of PEMFC are they work at low temperatures, they are compact, and they have fast start-up. Some researches are conducted to optimize PEMFC designs. Water management is one of the concerns. Providing a steady water evacuation to PEMFC is a critical subject. Excessive water can block reaction areas in membrane and lower the cell's efficiency.

In this work, an extra intermediate outlet is added to a U-form flow channel model and a water bubble movement is analyzed in ANSYS Fluent.
Results can be listed as follows:

- For velocity inlet and pressure outlets, an extra intermediate outlet has no effect on upstream flow.
- An extra outlet with lower pressure causes pressure drop in the inlet.
- To discharge the bubble from the intermediate outlet,the bubble should lose almost all of its velocity in the main outlet direction, and it should gain velocity towards the intermediate outlet. Therefore, discharging from intermediate outlet requires strong flow towards intermediate outlet.
- The intermediate outlet may yield breakup and distribution of the bubble, which restrains the channel blockage.

Using the facts that reservoir outlet discharges the water close to it, and dispose water in smaller portions, different designs can be developed.

ÖZET

Motor kabinindeki iç akıştan kaynaklanan sürüklenme, araç toplam sürüklenmesinin yaklaşık %10'unu oluşturmaktadır. Günümüzde bazı araçlarda, sürüklenme katsayısının düşürülmesi ve diğer taraftan motor soğutma performansının etkinliğinin sağlanması amaçlanarak aktif ön ızgara sistemleri tasarlanmaktadır. Bu çalışmada; ön ızgaranın, radyatörün, motorun ve şanzımanın basitleştirilmiş şekilde yer aldığı jenerik bir araç modeli üzerinde aerodinamik incelemeler yapılarak, sürüklenme katsayındaki değişim nümerik olarak değerlendirilmiştir. Değişken olarak, ön ızgara kanatçık açısı alınmıştır. Nümerik analizler sonucunda, kanatçık açısının artmasıyla (kanatçıkların açılması) sürüklenme katsayısının arttığı gözlenmiştir. Artış doğrusal olmamış, ilk artış daha yüksek oranda gerçekleşmiştir. Kanatçıklar açıkken, motor kabini içerisinde basınç değerlerinin arttığı gözlenmiştir. Ancak, ön kısımdaki basınç düşüşü ve dolayısıyla radyatörün arka kısımlarındaki basınç artışı, yüksek düzeylerde olmamıştır. Türbülans kaynaklı kinetik enerji kayıpları, kanatçıkların açılmasıyla radyatörün ön kısmında ve araç altında artmıştır. Yüksek sürüklenme katsayılarına işaret eden toplam basınç = 0 bölgelerinin, özellikle tam açık durumda, motor kabini içerisinde de oluştuğu gözlenmiştir.

Anahtar kelimeler: aktif ön ızgara, aerodinamik, sürüklenme katsayısı, hesaplamalı akışkanlar dinamiği (HAD)

ABSTRACT

The drag due to internal flow in the engine compartment accounts for approximately 10% of the total vehicle drag. Today, active front grille systems are designed in some vehicles with the aim of reducing the drag coefficient and, on the other hand, ensuring the efficiency of engine cooling performance. In this study, aerodynamic studies were performed on a generic vehicle model with a simplified front grille, radiator, engine and transmission, and the change in drag coefficient was evaluated numerically. The front grille fin angle is taken as a variable. As a result of numerical analyses, it was observed that drag coefficient increased with increasing fin angle (i.e., opening the fins). The increase was not linear, the initial increase occurred at a higher rate. It was observed that the pressure values increased in the engine compartment when the fins were open. However, the pressure drop at the front and hence the pressure increase at the rear of the radiator was not high. In the front side of the radiator and under the vehicle, the kinetic energy losses due to turbulence increased with the opening of the fins. It has been observed that the total pressure = 0 regions, which indicate high drag coefficients, also occur in the engine compartment, especially in the fully open condition.

Keywords: active grill, aerodynamics, drag coefficient, computational fluid dynamics (CFD)

1. GİRİŞ

Fosil yakıtlı taşıtlar, günümüzün hâlâ en yaygın olarak kullanılan ulaşım araçlarıdır. Dünyadaki mevcut fosil yakıtların önümüzdeki birkaç yüzyıl içerisinde tükeneceği ön görülmekte ve ayrıca her geçen gün artan yakıt fiyatları ve sıkılaşan çevresel düzenlemeler, yakıt tüketimini düşürmeye yönelik iyileştirmelerin önemini arttırmaktadır.

Bu kapsamda başvurulabilecek bir iyileştirme yöntemi, motor verimliliğinin arttırılmasını ya da elektrikli araçlar gibi alternatif bir araç tahrik sisteminin geliştirilmesini içerir ki bunların gerçekleştirilmesi ve uygulamaya konulması uzun ve zorlu süreçleri barındırır. Bir diğer iyileştirme yöntemi ise araç aerodinamiğinin incelenmesi ve sürüklenme katsayısının düşürülmesini sağlamaktır ki bu yöntem daha hızlı çözümler sunar. Araç aerodinamiğinin geliştirilmesi, yakıt tüketimini düşürmede alternatif bir yöntem olmaktan ziyade, her araç tasarımında gündemde olması gereken bir konu başlığıdır [1].

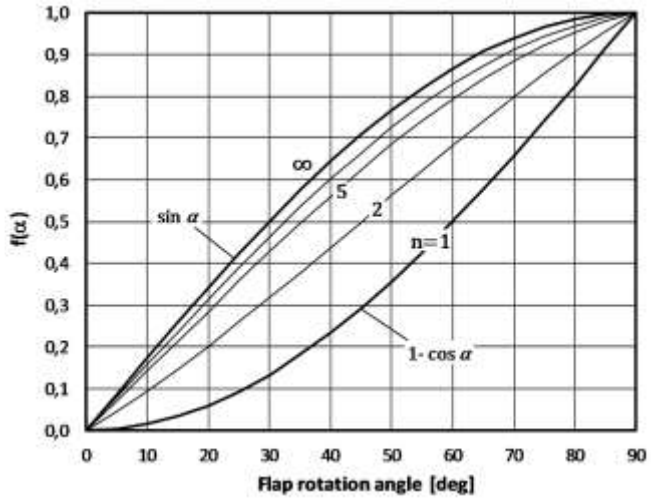
Sürüklenme katsayısının düşürülmesi ve diğer taraftan motor soğutma performansının etkinliğinin sağlanması amaçlanarak aktif ön ızgara sistemleri tasarlanmaktadır. Aktif ön ızgara sistemlerinin sağladığı faydaların başında, sürüş halinde araçların ön kısmında oluşan pozitif basınç bölgesini iyileştirerek sürüklenme direncini düşürmeleri gelir.
Diğer yandan, soğutma modülü bölgesinde fark basınçlar artabilmektedir. Bu durum, fanların daha erken devreye girmesine ve gerekli soğutma debisini sağlayabilmek için daha fazla devrede kalmasına neden olacaktır. Böylece, ızgara kapatıcının iyi tasarlanmış bir kontrol algoritması ile sürülmesi, en fazla faydayı sağlayacak ve ortaya faydalı bir ürün çıkacaktır [2]. Motor kabinindeki iç akıştan kaynaklanan sürüklenme, araç toplam sürüklenmesinin yaklaşık %10'unu oluşturmaktadır [3].

Erdoğan [2], çalışmasında M2 sınıfındaki bir aracın aktif ön ızgara sistemi ile motor bölgesi soğutma performansını ve bu sistemin, aracın sürüklenme katsayısına etkisini nümerik olarak incelemiştir. Analiz geometrisine; aracın dış geometrisini, motor bileşenlerini ve soğutma sistemini dahil etmiştir. Analizler 25 m/s hızda ızgaranın açık ve kapalı olma durumuna göre yapılmıştır. Analiz hacmi 15.000 x 30.000 x 9.375 mm^3 olarak tasarlamıştır. Türbülans modeli olarak realizable k-ε, sınır tabaka davranışı için standart duvar fonksiyonu kullanmıştır. Analiz şartları olarak, giriş kısmı hız ve çıkış kısmı atmosferik basınç, yan duvarlar simetrik ve zemin ise hareketli duvar alınmıştır. Aracın soğutma modülünde bulunan ısı değiştiriciler ve fanlar haricinde diğer tüm yüzeyler duvar olarak tanımlanmıştır. Analizlerde; basınç, hız, enerji ve momentum değişkenlerinin çözümü birinci dereceden ve ikinci dereceden olmak üzere 5.000 iterasyon sonucundaki değerler üzerinden değerlendirilmiştir.

Sonuç olarak [2]; sürüklenme katsayısı değerlerinde %7,58'lik iyileşme olduğu ve bu değerin teorik olarak %2,5'lik yakıt tasarrufu sağlayacağı, aktif ön ızgara sisteminin sağlayacağı sürüklenme katsayısı avantajının, yüksek hız koşullarında gerçekleştiği, soğuk iklim şartlarında motorun daha erken ısınmasını sağladığı, bu tip bir sistemin motor gürültüsünün azaltılması bakımından da avantajlı olduğu tespit edilmiştir.

Wolf [4] çalışmasında, aktif ön ızgaradaki kanatçık sayısına (n) ve açısına (α) bağlı olarak, aracın soğutma havası kütlesel debisinin ($\dot{m}$) ve sürüklenme katsayısının (C_D) elde edildiği bir teori oluşturmuştur. Teori için; sürekli-sıkıştırılamaz akış ve sıfır ızgara kalınlığı kabulleri yapılmıştır. Normalize formdaki Denklem 1'in sağ tarafı, havanın geçtiği alandaki değişimi vermektedir. Soğutma havasının kütlesel debisindeki ve soğutma kaynaklı sürüklenmedeki değişimin, havanın içinden geçtiği alanla orantılı olduğuna dair kabulü esas alınca, elde edilen denklem, kütlesel debideki ve sürüklenmedeki değişimi ifade etmede de kullanılmıştır. En büyük değişim, α=90° (%100 açıklık) hali ile α=0° (%0 açıklık) arasında gerçekleşmektedir. Şekil 1, α ve n'ye göre gerçekleşen değişimi vermektedir. Elde ettikleri teori, rüzgâr tüneli testleriyle uyumluluk göstermiştir. Modelden elde edilen sonuçlar, hem Porsche Cayenne SUV 2014 modelle (önden motorlu, orta kısımda aktif ön ızgara sistemli) hem de 911 Carrera MY 2016 spor modelle (yan kısımda aktif ön ızgara sistemli) yapılan rüzgâr tüneli testlerinden elde edilen sonuçlarla karşılaştırılmıştır.

$$\frac{\Delta c_D(\alpha)}{\Delta c_{D,max}} = \frac{\dot{m}(\alpha)}{\dot{m}_{max}} = \left(1-\frac{1}{n}\right)\sin\alpha + \frac{1-\cos\alpha}{n} \qquad (1)$$



Şekil 1. Kanatçık sayısına (n) ve açısına (α) göre f (α) fonksiyonu [4]

Li ve ark. [5] çalışmalarında, motor kabini sıcaklığı ve sürüklenme katsayısının aktif ön ızgara sistemine bağlı olarak nasıl bir değişim gösterdiğini nümerik olarak incelemişlerdir. Sedan bir model araç için farklı ağ yapısı yoğunluğunda

iki hesaplama alanı oluşturulmuştur. İlkinin ölçüleri 5,5 x 2,4 x 1,7 m^3; ikinci hesaplama alanı ölçüleri ise 11 x 6 x 3 m^3 olarak alınmış ve toplamda 11,6 milyon ağ eleman sayısında hesaplamalar yapılmıştır. Analizlerde 1 km/sa (araç rölanti hızı), 30 km/sa, 60 km/sa, 90 km/sa ve 120 km/sa olmak üzere 5 farklı hız ve 0°, 18°, 36°, 54°, 72° ve 90° olmak üzere 6 farklı ızgara açıklığı kullanılarak radyatöre giren hava debisi ve radyatör ortalama giriş ve çıkış sıcaklıklarına bakılmıştır. Ayrıca 120 km/sa hız için tüm ızgara açıklıklarında araç sürüklenme katsayısı grafiği oluşturulmuştur.
Elde edilen analiz sonuçları [5], aktif ön ızgara açıklığının azalmasıyla araç sürüklenme katsayısının düşeceğini ve bu nedenle de araç yakıt tüketiminin belirli bir dereceye kadar azaltılabileceğini ortaya koymuştur. Radyatörün hava debisi, giriş ve çıkışındaki hava sıcaklığından elde edilen veriler ve sürüklenme katsayısı dikkate alınarak aktif ön ızgara sistemi için optimum açılma kontrol eğrisi elde edilmiştir.

Kim ve ark. [6] çalışmalarında, parametrik çalışma kullanarak küçük yolcu araçları için ızgara açıklığını nümerik olarak incelemişlerdir. Çalışmalarında ızgara açıklığı model tasarımı için temel geometrik parametreler; dikey yükseklik, yatay genişlik, boyut, doğrusal deformasyon, konum ve blokaj olmuştur. Nümerik çalışmada, aerodinamik performans ve araç aktarma organlarının soğutulması için önemli olan aerodinamik sürüklenme ve ızgara giriş akış hızı üzerinde bu parametrelerin etkileri araştırılmıştır.

Akış simülasyonlarında; 110 km/sa akış hızını giriş akışı için, atmosferik basıncı ise çıkış akışı için sınır şartı olarak almışlardır. Zeminde 110 km/sa hareketli duvar sınır şartı kullanılmıştır. Hesaplama hacmi; modelin 6 katı uzunluk, 5,7 katı genişlik ve 3,3 katı yükseklik alınarak oluşturulmuştur. Yüzey ve hacim ağ eleman sayıları yaklaşık olarak, sırasıyla, 1.000.000 ve 15.500.000'dir. Türbülans modeli olarak realizable k-ε modeli kullanılmıştır.

Buna göre; ızgara açıklığı alanında genişlemeye sebep olduğu için, dikey yükseklik arttıkça ızgara ve radyatör kütlesel debisi artmıştır. Toplam sürüklenme katsayısı da artan kütlesel debi nedeniyle yükselmiştir. Yatay genişlik parametresi için de aynı durum geçerlidir. Öte yandan, radyatör kütlesel debisinin artışı, sadece ızgara açıklığının boyutlarına değil; aynı zamanda ızgara açıklığının ve radyatörün ön alanının hangi hizada olduğuna bağlı olarak değişmiştir. Toplam sürüklenme katsayısının değişimi, radyatör kütlesel debisindekine benzer olmuştur; çünkü toplam sürüklenme katsayısı büyük ölçüde ızgara girişine ve radyatör boyunca olan kütlesel debiye bağlıdır. Ayrıca, ızgara ve radyatör kütlesel debisi, ızgara açıklığı girişinin konumuna göre değişmiştir. Konum yükseldikçe bu debi azalmıştır. Çünkü akış hızının normal bileşeni (ızgara girişine doğru olan bileşen) azalmıştır. Bununla birlikte, ızgara açıklığı girişinin konumu fazla düştüğünde de debi azalmıştır. Blokaj (ön ızgaranın bir kısmının perdelenmesi) parametresi, radyatör kütlesel debisini, akışı CRFM'ye (Condenser, Radiator, and Fan Module) denk getirdiği ölçüde artırmıştır. Ön panel ve darbe kirişinin arka tarafındaki basınçları azalttığından, blokaj simetrisi bozuldukça toplam sürüklenme katsayısı artmıştır.

Sawaguchi ve Takakura [3] çalışmalarını, 1/5 ölçekli araç modeli ile hareketli zeminli rüzgâr tünelinde gerçekleştirmişlerdir. Motor soğutma akışı ile ilgili olarak hava akış sistemi; radyatörlü ve radyatörsüz, FF (önden motorlu, önden çekişli) ve FR (önden motorlu, arkadan çekişli) tahrik tipleri, farklı ızgara yükseklikleri ve konumları için farklı tasarımlar kullanılarak incelenmiştir. Hava giriş açıklığının genişliği 180 mm olarak, yüksekliği ise 0-20-40-60-80-100 mm olmak üzere 6 farklı değerde ele alınmıştır. Deneyler 48 farklı kombinasyonda ve 20 m/s hız için yapılmıştır.

Genel sonuçlar, açılış alanının genişletilmesiyle sürüklenmenin ve ön kaldırmanın arttığı ve arka kaldırmanın azaldığını göstermiştir. Burada, soğutma hava akışına bağlı olarak aerodinamik özelliklerde meydana gelen değişikliğin nedeninin, motor süpürme akışı ile zemin altı akışının birleşmesinden kaynaklanan zemin altındaki düzensizlik (disturbance) olduğu açıklığa kavuşturulmuştur. Olguların korelasyonunda, hava giriş yüksekliğinin genişlemesi (ve dolayısıyla soğutma akış hızının artması) motor bölmesi içinde basınç artışına neden olur ve ayrıca aracın ön ucundakine ve penceresindekine uyum sağlar, ancak basınç düşüşüne neden olur. Radyatörün etkisi, sürüklenme ve kaldırmadaki değişiklik aralığını azaltmak olmuştur.

Sawaguchi ve Takakura [3], motor soğutma akışının aerodinamik etkilerini aşağıdaki gibi özetlemiştir:

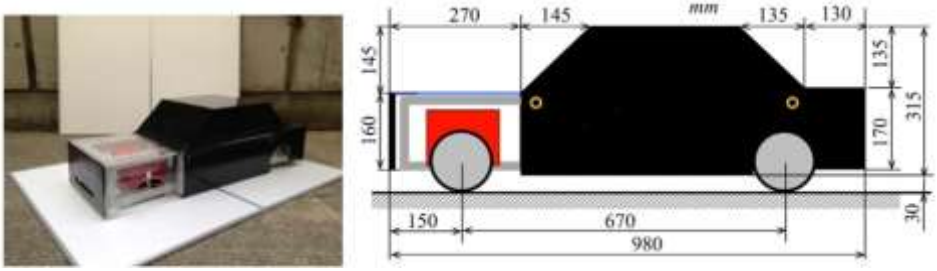
- Sürüklenme, motor bölmesi içindeki basınca, araç gövdesinin ön ucuna ve ön penceresine bağlıdır.
- Ön kaldırma, motor ünitesinin altındaki basınca, ön cama ve tavanın ön kısmına bağlıdır. Aynı zamanda, motor bölmesinden zemine doğru süpüren akışın momentumuna da bağlıdır.
- Arka kaldırma, motor bölmesinin arkasındaki zemin altı basıncına bağlıdır.
- Radyatörün montajı, aerodinamik karakteristiklerde gerçekleşen değişikliklerin aralığını düşürür. Bu farklılık, esas olarak, giriş alanının etkisinin azalması ile oluşur.

Bu çalışmada, taşıtlardaki aktif ön ızgara sistemi, aerodinamik açıdan nümerik olarak incelenmiştir. Geometrik model, literatürdeki bir deneysel çalışmadan alınmıştır. Akış denklemlerine ait nümerik modelin sağlama işlemi, yine aynı

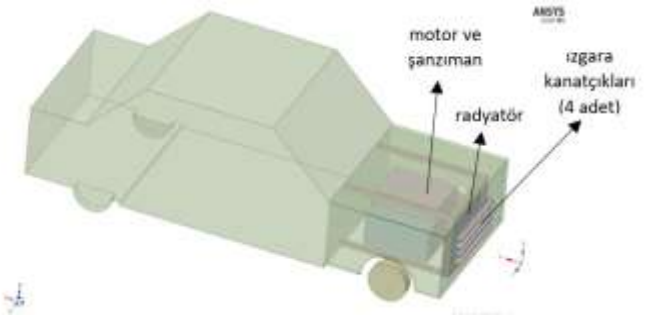
deneysel çalışmanın sonuçları kullanılarak gerçekleştirilmiştir. Farklı kanatçık açıları denenerek, kanatçık açısına bağlı olarak sürüklenme katsayısındaki değişim, aerodinamik açıdan gerçekleşen değişimler yardımıyla açıklanmaya çalışılmıştır.

2. MATERYAL ve YÖNTEM

Sawaguchi ve Takakura'nın deneysel çalışmalarında [3] kullandığı model (Şekil 2) kullanılarak analize ait geometrik model (Şekil 3) oluşturulmuştur. Söz konusu model 1/5 ölçeklidir. Nümerik analizler, aynı çalışmada kullanılmış olan 20 m/s hızda gerçekleştirilmiştir.

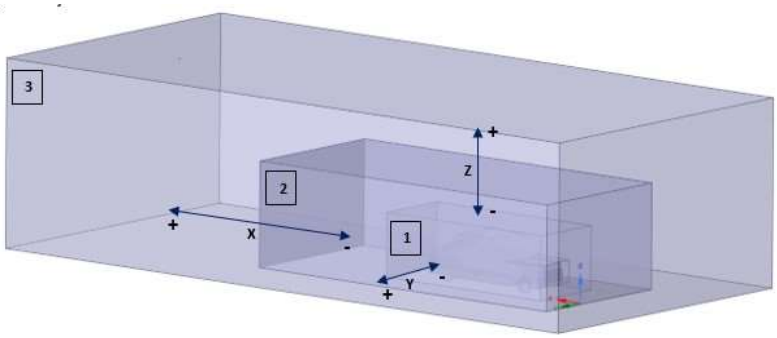


Şekil 2. Literatürden referans alınan geometri [3]



Şekil 3. Analizlerde kullanılan araç geometrik modeli

Analiz hacmi belirlenirken araç ard bölgesinde oluşan girdaplı yapıların yakalanabilmesi için ard bölge ön kısma göre uzun tutulmuştur. Ayrıca, analiz hacmi 3 alt hacimde ele alınmıştır. Böylece, araca daha yakın hacimlerde daha ince ağ yapısı kullanmak amaçlanmıştır. Kullanılan analiz hacmi Şekil 4'te görüldüğü gibidir. Ölçülerin artı (+) ve eksi (-) yönleri Şekil 4'te, bir önceki hacimden itibaren eklenen değerler ise Tablo 1'de sunulmuştur. Örneğin, iç hacimde, araçtan itibaren artı X-yönünde (aracın arkasına) 300 mm, eksi X-yönünde ise (aracın önüne) 100 mm verilerek alt hacim oluşturulmuştur.

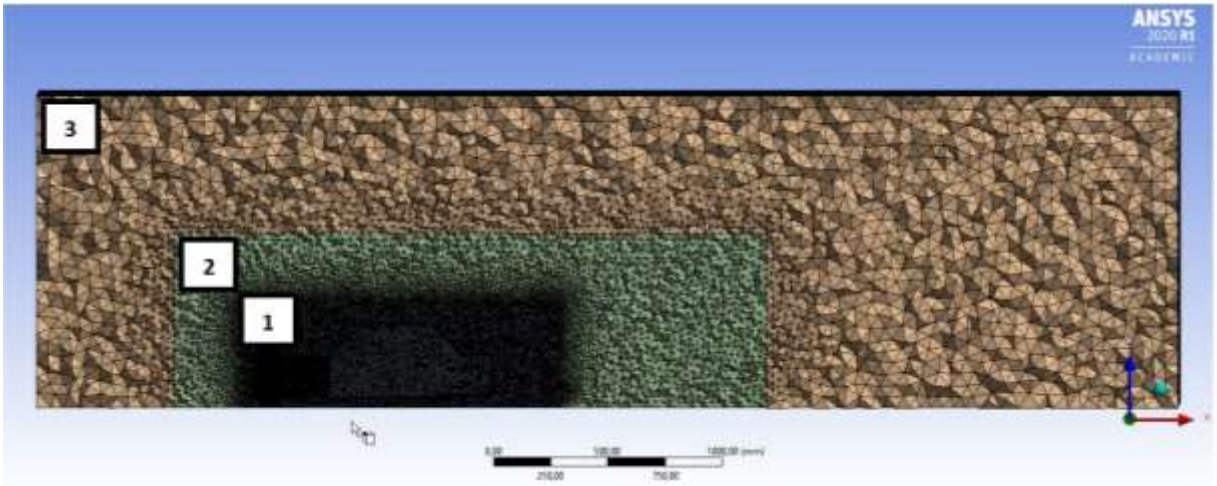


Şekil 4. Analiz hacmi

Tablo 1. Analiz hacmi ölçüleri

Alt hacim no	Alt hacim adı	Ölçüler (mm)		
		X	Y	Z
1	İç	-100 +300	-100 +100	-13 +100
2	Orta	-300 +900	-300 +300	0 +300
3	Dış	-600 +1.800	-600 +600	0 +600

Alt hacimlerin her birine hacim boyutlandırma (body sizing); araç iç ve dış yüzeylerine, radyatör, motor ve şanzıman yüzeylerine, kanatçık yüzeylerine yüzey boyutlandırma (face sizing), daha detaylı ve doğru verileri yakalamak için tüm yüzeylere prizmatik katman (inflation layer) ağ atılmıştır. Radyatör, akışkan yapıda bir gözenekli bölge (porous zone) olarak tanımlanmıştır. Gözenekli bölge parametreleri, otomobil radyatörünün nümerik olarak modellendiği, literatürdeki bir çalışmadan [7] alınmıştır. Analiz hacminde oluşan ağ yapısı Şekil 5'te görülmektedir.



Şekil 5. Nümerik analizlerde kullanılan, alt hacimler (1, 2, 3) içeren ağ yapısı

Nümerik çözümler, basınç esaslı ve sürekli rejimde gerçekleştirilmiştir. Araç aerodinamiği; akış ayrılmaları, vorteks ve bölgesel geçişli akışlar gibi karmaşık akış durumlarını içerir. Bu karışık akış durumu ve bu konudaki bilimsel araştırmalar değerlendirildiğinde, analizlerde, bu tip akışların çözümü için uygun olan realizable k-ε türbülans modeli ölçeklenebilir (scalable) duvar fonksiyonu ile beraber kullanılmıştır. Nümerik çözümde kullanılan parametreler Tablo 2'de verilmiştir.

Tablo 2. Nümerik çözüm parametreleri

Akışkan	Hava
Akışkan hızı (m/s)	20
Çıkış basıncı (kPa)	0
Akış rejimi	Sürekli
Çözüm modeli	Basınç esaslı
Türbülans modeli	Realizable k-ε
Duvar fonksiyonu	Ölçeklenebilir (Scalable)
Çözüm algoritması	SIMPLEC
Yakınsama kriterleri (Süreklilik, hızlar, k, ε)	10^{-3}

Çalışmada 3 adet kanatçık açısı değeri (Tablo 3) nümerik olarak test edilmiştir. Kanatçık açısındaki (α) değişimin sürüklenme katsayısına (C_D) etkisi değerlendirilmiştir. Sonuçlar; statik basınç, türbülans kinetik enerjisi gibi aerodinamik karakteristiklerde yaşanan değişimlerden faydalanarak yorumlanmaya çalışılmıştır.

Tablo 3. Test edilen kanatçık oryantasyonları

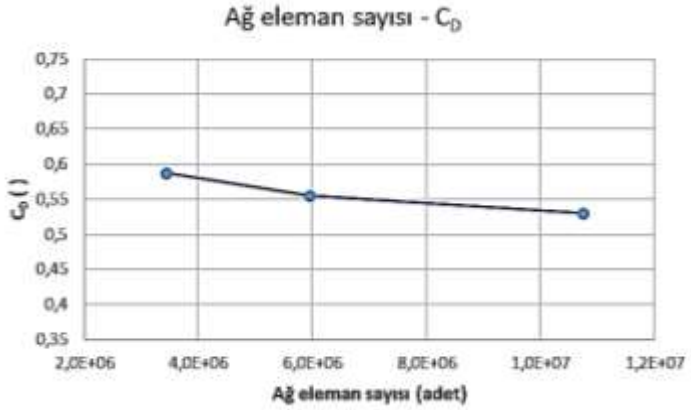
Kanatçık oryantasyonu	Kanatçık açısı (°)
Kapalı	0
Yarı-kapalı	45
Açık	90

Doğrulama (verification) çalışması kanatçıkların kapalı olduğu durumda (α=0º) gerçekleştirilmiştir. Bu amaçla, yaklaşık 1,8 ağ sıklaştırma oranı kullanılarak 3 ayrı sıklıkta ağ yapısı kullanılmış ve çıktı parametresi olarak C_D esas alınarak

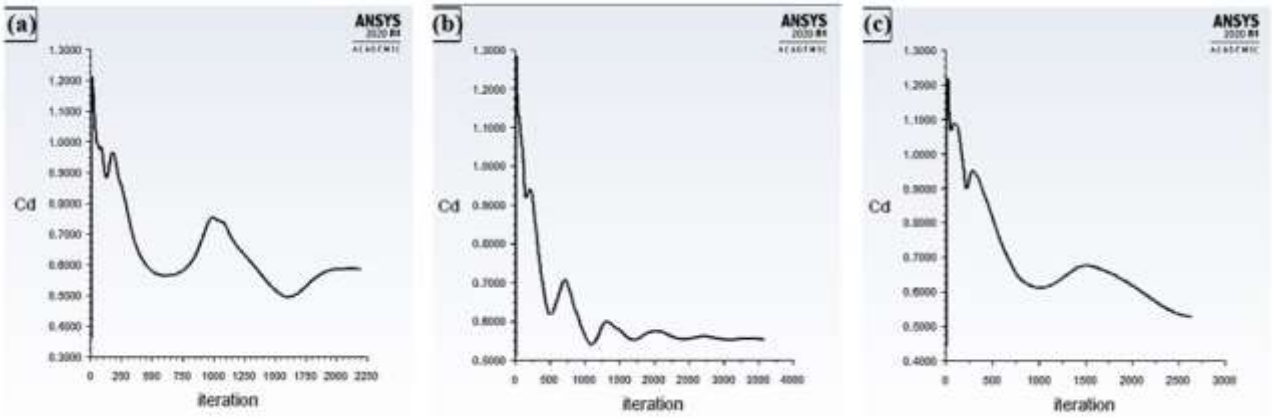
ağdan bağımsızlık yakalanmaya çalışılmıştır. Doğrulama çalışmasına ait veriler Tablo 4'te ve Şekil 6'da, yakınsama grafikleri ise Şekil 7'de görüldüğü gibidir. Çalışmadaki nümerik analizlerde ince ağ yapısı tercih edilmiştir.

Tablo 4. C_D esas alınarak yapılan ağdan bağımsızlık (doğrulama) çalışmasına ait veri tablosu

Ağ kalitesi	Ağ sıklaştırma oranı	Ağ eleman sayısı	C_D
Kaba	-	3.442.286	0,587
Orta	1,73	5.948.446	0,555
İnce	1,81	10.754.739	0,530



Şekil 6. C_D esas alınarak yapılan ağdan bağımsızlık çalışmasına ait grafik



Şekil 7. C_D esas alınarak yapılan ağdan bağımsızlık çalışmasına ait yakınsama grafikleri:
(a) Kaba ağ, **(a)** Orta ağ, **(a)** İnce ağ

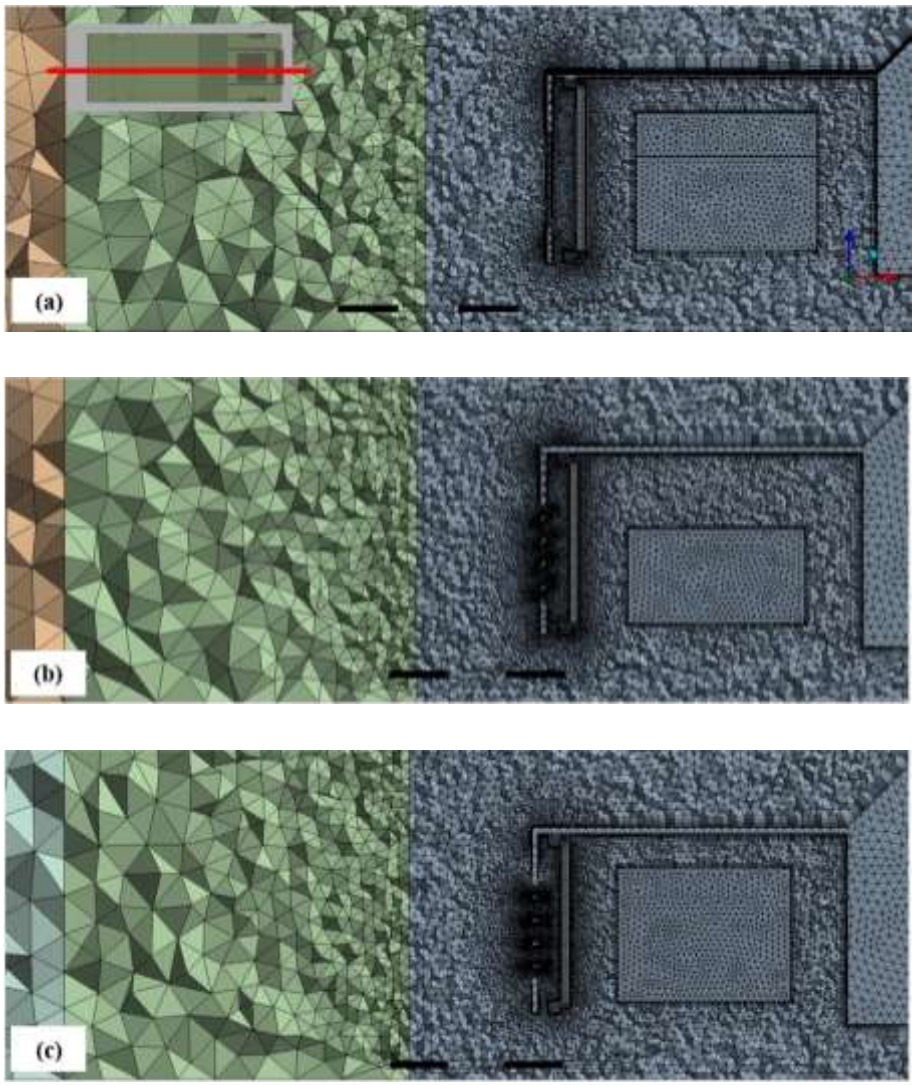
4. BULGULAR ve TARTIŞMA

Deneysel verilerin alındığı referans çalışmada kanatçıkların kapalı olduğu durum kullanılarak tek değerli bir sağlama (validation) işlemi yapılmıştır. Buna göre, referans çalışmada kanatçıkların kapalı olduğu deneysel veri C_D=0,69 iken, nümerik analizde aynı durum için C_D=0,53 değeri elde edilmiştir. Buna göre, %77'lik bir sağlama ölçütü yakalanmıştır. Deneysel çalışmada aracın hareketli bir bant üzerinde hareket etmesi, tekerleklerinin hareketli olması, rüzgar türbininin geometrisinin nümerik çalışmadakine göre bazı farklılıklar içermesi, analiz parametrelerindeki hata payı, gibi faktörlerde iyileştirmeye gidilmesiyle sağlama ölçütünde artış elde edilebilir.

Sağlama işleminin ardından diğer kanatçık açıları için de analizler koşturulmuştur. Her 3 durum için motor kabini civarındaki ağ yapısı Şekil 8'de görülmektedir. Kanatçıkların kapalı olmadığı durumlarda, kanatçıkların dar kesitindeki (dar kesitteki boyut = 2 mm) ağ yapısına adapte olabilmek için ağ yapısının sıklaştığı görülmüştür. Elde edilen C_D değerleri, y^+ değerleri, kullanılan ağ eleman sayıları, ağ kaliteleri ("minimum ortogonal kalite") Tablo 5'te sunulmuştur. C_D değerinin kanatçık açısıyla (α) değişimine ait grafik Şekil 9'da verilmiştir.

Kanatçık açısının artmasıyla (kanatçıkların açılması) C_D'nin arttığı görülmüştür. Artışın doğrusal olmadığı, ilk artışın daha yüksek olduğu gözlenmiştir. Çözümlerde y^+ değerleri ortalama yaklaşık 11 olmuştur. Bu, ilk tabakadaki çözüm

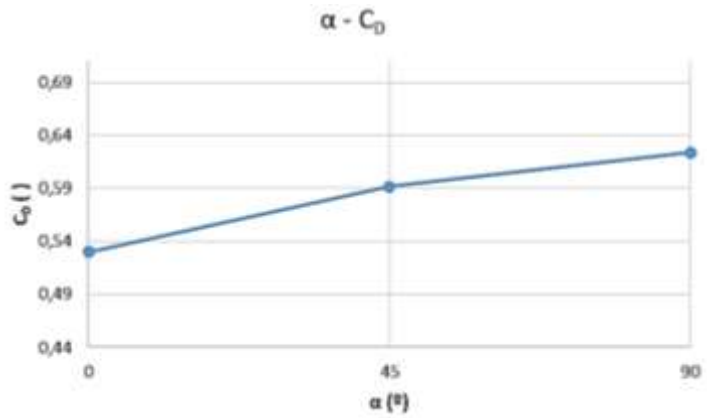
noktalarının ara tabakada ($5 < y^+ < 30$) kaldığına işaret etmektedir. Ara tabaka, logaritmik duvar yasasının geçerli olduğu logaritmik tabakanın ($y^+ > 30$) altındadır. Ancak, y^+ değerleri, iki duvar yasasının (doğrusal ve logaritmik) çakıştığı noktanın (y^+=11,126) üzerindedir. Ayrıca, çözümde, ölçeklenebilir duvar fonksiyonu kullanılmıştır. Bu fonksiyon her halükarda $y^+ \geq 11,126$ olacak şekilde düzenleme yapmaktadır.



Şekil 8. Farklı kanatçık oryantasyonları için motor kabini civarında ağ yapısı:
(a) Kapalı (0º), **(b)** Yarı-kapalı (45º), **(c)** Açık (90º)

Tablo 5. Nümerik analiz karakteristikleri ve sonuçlar

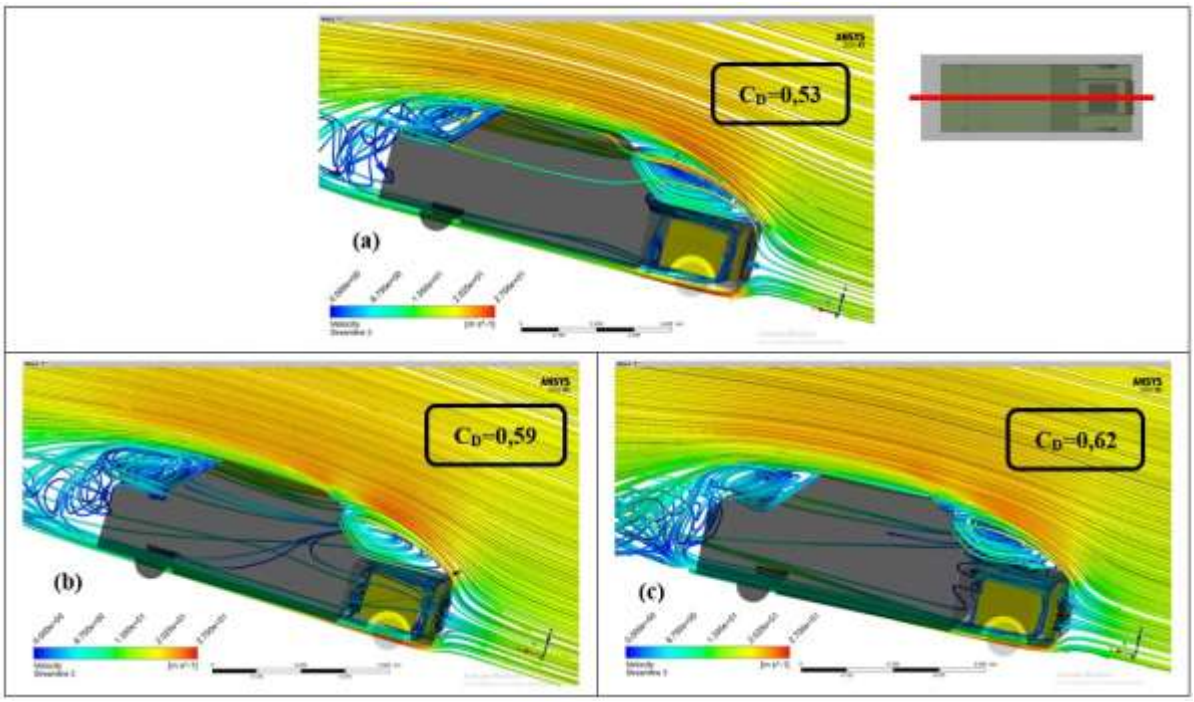
Kanatçık oryantasyonu	α (°)	C_D ( )	y+ ( )	Ağ eleman sayısı (adet)	Ağ kalitesi ("Minimum ortogonal kalite")	İterasyon sayısı (adet)
Kapalı	0	0,530	11,249	10.754.739	$1,51*10^{-2}$	2.632
Yarı-kapalı	45	0,592	11,227	13.217.257	$1,04*10^{-2}$	2.930
Açık	90	0,624	11,309	11.023.269	$1,29*10^{-2}$	2.108



Şekil 9. C_D değerinin kanatçık açısıyla (α) değişimi

Nümerik analizler ile elde edilen sonuçlar; statik basınç, türbülans kinetik enerjisi gibi aerodinamik karakteristiklerde yaşanan değişimlerle yorumlanabilir. Bu değişimler, Şekil 10-13'te 3 durum için karşılaştırmalı olarak ele alınmıştır. İncelenen her bir karakteristik her 3 durum için aynı skalada renklendirilerek (örneğin, hız skalası her defasında 0-27 m/s aralığında olacak şekilde) görsel karşılaştırmanın doğru yapılabilmesi sağlanmıştır. İncelemelerin yapıldığı kesit düzlemin nerede oluşturulduğu, aracın üstten görünüşü üzerinde kırmızı çizgi ile gösterilmiştir. Oluşturulan kesit düzlem, aracın tam ortasından geçmektedir.

Aracın orta düzleminden alınan kesit etrafında oluşan 3-boyutlu akım çizgileri Şekil 10'da verilmiştir. Kanatçıklar açıldığında, radyatörün ön kısmında orta hızda ve türbülanslı bir akımın gerçekleştiği tespit edilmiştir. Ayrıca, aracın üst ön ve üst arka kısımlarında oluşan girdaplardaki hız değerlerinde ve girdap boyutlarında artış olduğu görülmektedir. Kanatçıkların kapalı olduğu durumda, ön ızgaradan motor kabinine giremeyen hava akımı, motor ve şanzımanın arka kısmından motor kabinine doğru girmiştir. Ancak, bu akış düşük hızlarda gerçekleştiği için önemli bir enerji kaybına sebep olacak nitelikte değildir. Kanatçıklar kapalı olduğunda, aracın üst ve alt kısımlarında hızların daha yüksek olduğu gözlenmiştir.

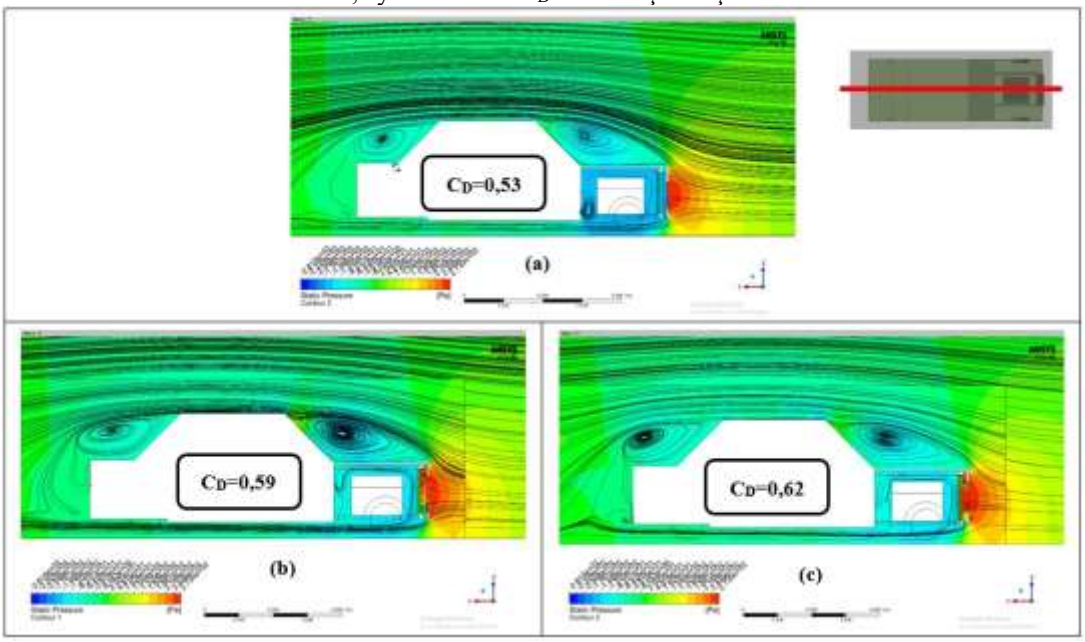


Şekil 10. Farklı kanatçık oryantasyonları için 3-boyutlu akım çizgileri:
(a) Kapalı (0º), **(b)** Yarı-kapalı (45º), **(c)** Açık (90º)

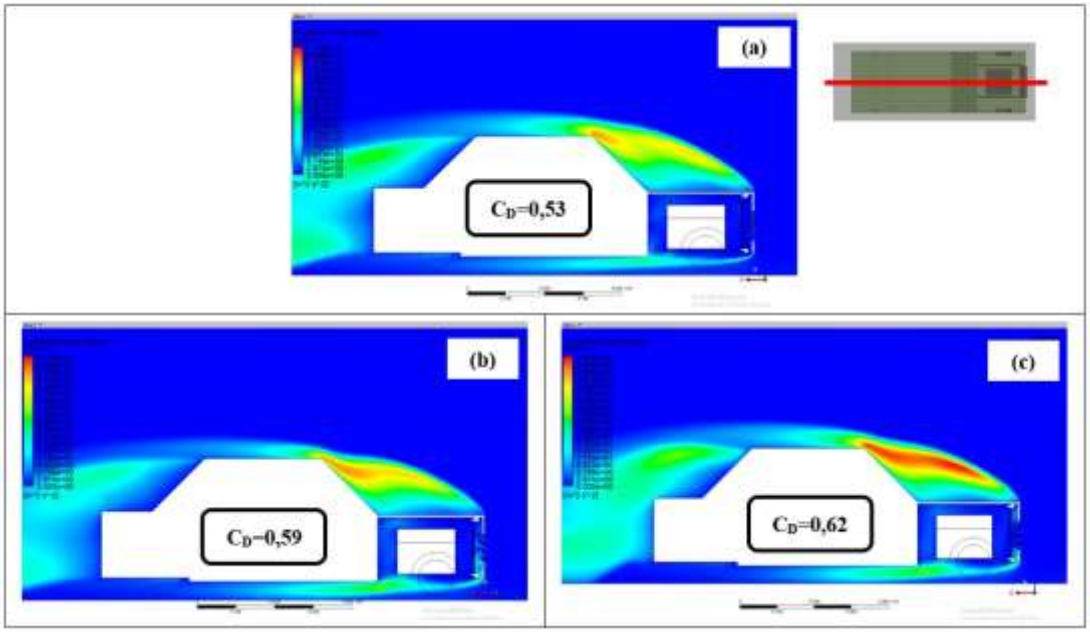
Aracın orta düzleminden alınan kesitte oluşan statik basınç konturları Şekil 11'de verilmiştir. Kanatçıklar açıldığında, motor kabini içerisinde (akışkan girişine bağlı olarak kütlesel debinin artmasıyla) basınç değerlerinin arttığı görülmektedir. Beklendiği gibi, en yüksek basınç değerleri (akışın engellenmesi ve hızın sıfıra yaklaşması dolayısıyla) aracın ön kısmında ön yüzeyde oluşmuştur. Kanatçıkların açılmasıyla ön kısımdaki basınç radyatöre doğru dağılsa da ön kısımdaki basınç düşüşü ve dolayısıyla radyatörün arka kısımlarındaki basınç artışı yüksek seviyelerde olmamıştır.

Yarı-kapalı durumda, radyatörün üst ön kısımlarında basınç artışı yaşanırken, hava akımının daha az gerçekleştiği alt kısımlarda basınç artışı daha düşük kalmıştır. Ayrıca, aracın üst ön ve üst arka kısımlarında oluşan girdapların hız değeri ve girdap boyutu olarak artış göstermiş olması (Şekil 10), düşük basınç bölgelerinde büyümeye (Şekil 11) sebep olmuştur.

Aracın orta düzleminden alınan kesitte oluşan türbülans kinetik enerjisi konturları Şekil 12'de verilmiştir. Türbülanstan kaynaklanan kinetik enerji kayıpları, kanatçıkların açılmasıyla radyatörün ön kısmında ve araç altında artış göstermiştir. Ayrıca, kanatçıkların açıldığı durumlarda aracın üst ön ve üst arka kısımlarındaki türbülans kinetik enerjisinin daha büyük alanlarda ve daha yüksek değerlerde oluştuğu gözlenmiştir. Bu kinetik enerji kayıplarının telafi edilmesi için araç enerji sarf etmek durumunda olacaktır. Bu, aynı zamanda C_D'deki artışa da işaret etmektedir.



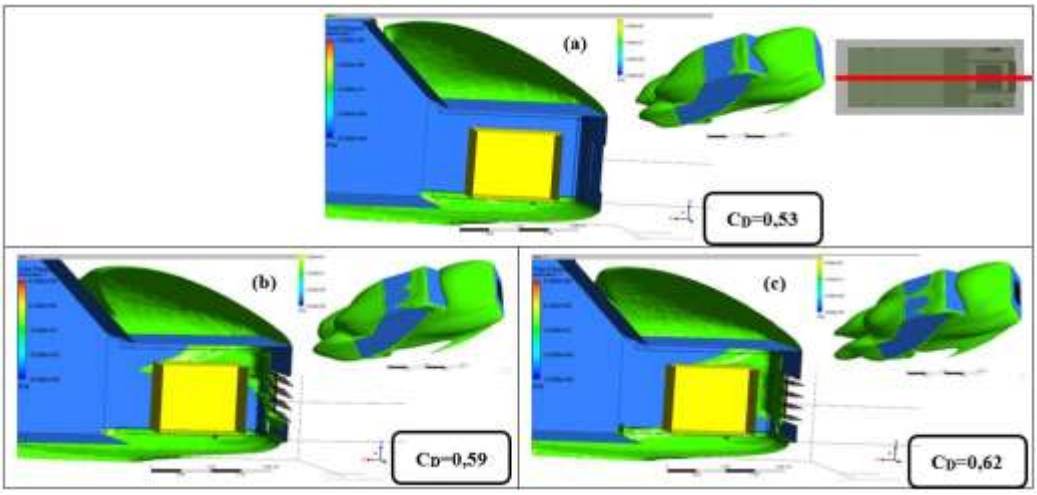
Şekil 11. Statik basınç konturları: **(a)** Kapalı (0º), **(b)** Yarı-kapalı (45º), **(c)** Açık (90º)



Şekil 12. Türbülans kinetik enerjisi konturları: **(a)** Kapalı (0º), **(b)** Yarı-kapalı (45º), **(c)** Açık (90º)

Aracın orta düzleminden alınan kesitten itibaren oluşan ve aracın tüm çevresi etrafında oluşan toplam basınç = 0 bölgeleri (yeşil bölgeler) Şekil 13'te verilmiştir. Sürüklenme kuvveti için oluşturulan analitik denklemlerde toplam basınç kayıpları ile ilgili bir terim de yer almaktadır. Bu anlamda, toplam basıncın sıfır olduğu bölgeler, yüksek sürüklenme katsayılarına işaret etmektedir. Kanatçıklar açıldığında, motor kabini içerisinde de toplam basınç = 0 bölgelerinin oluştuğu ve açı arttıkça bu bölgelerin büyüdüğü görülmüştür. Ayrıca, aracın tüm çevresi incelendiğinde,

toplam basınç = 0 bölgelerinin; alt kısımda kalınlaştığı, araç arkasında ise uzadığı tespit edilmiştir. Bu değişimler, C_D'deki değişimlerle paralellik göstermektedir.



Şekil 13. Toplam basınç = 0 bölgeleri: **(a)** Kapalı (0º), **(b)** Yarı-kapalı (45º), **(c)** Açık (90º)

5. SONUÇ

Ön ızgaranın, radyatörün, motorun ve şanzımanın basitleştirilmiş şekilde yer aldığı jenerik bir araç modeli üzerinde aerodinamik incelemeler yapılarak, sürüklenme katsayındaki değişim nümerik olarak değerlendirilmiştir. Değişken olarak, ön ızgara kanatçık açısı alınmıştır. Elde edilen sürüklenme katsayısı değerleri ile referans alınmış olan literatürdeki [3] deneysel değerler karşılaştırıldığında %77'lik bir sağlama ölçütü elde edilmiştir.

Nümerik analizler sonucunda, kanatçık açısının artmasıyla (kanatçıkların açılması) C_D'nin arttığı gözlenmiştir. Artış doğrusal olmamış, ilk artış daha yüksek oranda gerçekleşmiştir.

Kanatçıkların açık olduğu durumda, radyatörün ön kısmında orta hızda ve türbülanslı bir akım gerçekleştiği görülmüştür. Ayrıca, aracın üst ön ve üst arka kısımlarında oluşan girdaplardaki hız değerlerinde ve girdap boyutlarında artış olmuştur.

Yine kanatçıklar açıkken, motor kabini içerisinde basınç değerlerinin arttığı gözlenmiştir. Kanatçıkların açılmasıyla ön kısımdaki basınç radyatöre doğru dağılmıştır. Ancak, ön kısımdaki basınç düşüşü ve dolayısıyla radyatörün arka kısımlarındaki basınç artışı, yüksek düzeylerde olmamıştır.

Türbülans kaynaklı kinetik enerji kayıpları, kanatçıkların açılmasıyla radyatörün ön kısmında ve araç altında artmıştır. Yüksek sürüklenme katsayılarına işaret eden toplam basınç = 0 bölgelerinin, özellikle tam açık durumda, motor kabini içerisinde de oluştuğu gözlenmiştir.

Radyatörün arka kısmındaki akım çizgileri ve basınç konturları değerlendirildiğinde, radyatör modelinin iyileştirilmesi gerektiği düşünülmüştür. Sağlama ölçütünün daha fazla veri kullanılarak (kanatçıksız durumu ilave ederek) hesaplandığı ve modeldeki iyileştirmelerle daha yüksek sağlama düzeyinin yakalandığı, motor kabini içerisindeki sürüklenme katsayısı değişiminin ayrı ele alındığı, daha fazla kanatçık açısının test edildiği, araç hızının değişken olarak katıldığı, motor ve radyatör sıcaklıklarının ve enerji denkleminin de dahil edildiği çalışmalar planlanmış ve devam etmektedir.

ABSTRACT

This paper presents a global skyhook and groundhook control strategy for reducing vertical motions of the body and increasing the comfort with a semi-active suspension system, considering the real life applications. A continuous skyhook control was synthesized to reject the disturbances of the sprung mass motions by input decoupling transformation. Externally, groundhook control was utilized to damp the unsprung mass motions. Different scenarios were tested for the comparison between passive dampers, skyhook and skyhook-groundhook control. A global control of the sprung and unsprung masses motions were achieved, simultaneously. The control logic which was built in MATLAB®-Simulink® environment, co-simulated with IPG-Carmaker®'s high fidelity vehicle model for a realistic assessment of the system performance. Simulation results indicated that the semi-active dampers with global skyhook and groundhook control improved the vehicle dynamics behaviour in terms of handling and comfort.

Keywords: Semi-Active Damper, Skyhook Control, Groundhook Control

1.INTRODUCTION

Suspension systems play a key role in vehicle design in terms of vehicle comfort and safety. The main roles of the suspension systems are to isolate vehicle body from the road inputs, provide a continuous tyre road contact and improve handling. Controlled suspensions have been important tools to satisfy the inherently conflicted comfort and handling criteria for over four decades in vehicle applications of semi active and active suspension. Lower energy consumption and cost are major advantages of the semi-active suspension systems when compared to a fully active suspension system. Therefore, it engages the interest of the researchers and engineers in the control field.

An important milestone for control of a semi-active damper, especially the idea of using semi-active dampers as force generators, was development of the Skyhook(SH) control (Karnopp continued, 1973), having relatively simple feedback control logic with some unique advantages for noise attenuation, especially resonant frequency of the vehicle body (Emura continued, 1994). After the first conceptual idea, various methods of SH Control were developed to solve different problems such as balancing the trade-off between sprung and unsprung mass, increasing the road holding oriented-ground hook and gain adaptive SH to reach the optimal comfort bound (Besinger continued, 1995; Valášek continued, 1997; Hong, continued, 2002; Savaresi, Spelta, 2007).

Because of the flexibility and simplicity well known quarter car model is preferred to develop a control logic, in general. The model, in its simplest form, can also be used for the more complex analyses. For instance, Ahmadian studied "four quarter car" model to extend the quarter car experiences of hybrid control over a full vehicle model to damp the bounce, roll and pitch motions (Ahmadian, Blanchard, 2008). In the model, four virtual dampers at each corner of the body and four virtual dampers for each wheel motions were proposed. Unlike Ahmadian's study, Campos calculated bounce, pitch and roll motions using a single linear and two angular virtual dampers at the center of gravity (CoG). He also calculated the virtual restoring forces and moments at the CoG, then, these forces and moments were distributed as actuators' forces, by the input decoupling transformation (IDT)(J. Campos continued, 1999). Ikenega used IDT, which can be described as right inverse of the input mapping, to control the combined vertical motions as a result of bounce, roll and pitch for active suspension case. The body and wheels were controlled by inner and outer

loops (Ikenaga continued, 2000). Afterwards, the same technic was used for a semi-active control strategy, but the study was limited with on-off SH control(Yao continued, 2014). Binder used optimal control allocation for coordinated suspension control considering dissipative constraint of semi active damper as a part of optimization (Binder, Khajepour, 2014).

In this study, as a contribution to the literature, Ikenega's IDT approach was combined with Ahmadian's skyhook-groundhook control approach with the aim of a centralized control. Continuous SH control was also used as a high-level controller to calculate the restoring force and moments at the CoG rather than on-off SH control. Then, the restoring force and moments were transformed into actuator force requests with IDT. Actuator force requests were evaluated inside the low-level controller as in real life applications. The sprung mass motions were attenuated by centralized SH control in the framework of the IDT, and the unsprung masses were attenuated, externally by groundhook (GH) control. The control logic which was built in MATLAB®-Simulink® environment co-simulated with IPG-Carmaker®'s high fidelity vehicle model for a realistic assessment of the system performance.

2.SKYHOOK CONTROL

SH control is a model free control approach to design a controller. Therefore, IPG-Carmaker vehicle model was utilised for realistic assessment of the control logic. Some of the features such as position of virtual SH, GH dampers, and position of accelerometers, are shown with a representative model in Figure 1.

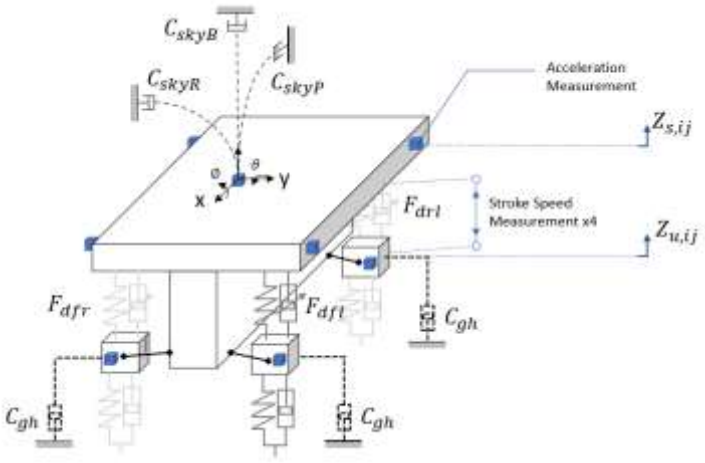

Figure 1. Virtual skyhook, groundhook dampers positions and sensor positions.

In the well known SH control approach, a fictious damper is mounted between sprung mass and virtual reference plane in the sky. The semi-active damper, which is mounted parallel to the spring, act as the fictious damper (later referred as SH damper in this paper). In fully active systems the force supply is continuous, however, semi-active systems can only dissipate the force (called passivity constraint). Due to the passivity constraint SH approach requires vertical speed measurements of the sprung and unsprung masses for a control action. Therefore, SH control for semi-active systems is rule based (equation 1). The product of sprung mass speed and stroke speed satisfies the first part of the rule, which is greater than or equal to zero. This means that the directions of semi-active damper force and SH damper are the same. Then, the SH control releases the control force depending on skyhook damping request, 'C_{sky}', otherwise, semi-active damper force is adjusted to the minimum damping, '$C_{\min}$'. Semi-active dampers used in the past could provide limited number of damping levels as maximum and minimum (also called on-off). Current semi-active damper technology, on the other hand, can provides us infinite number of damping coefficients to provide the accurate forces (Savaresi continued, 2010).

$$C_{s,ij} = \begin{cases} C_{sky*} \ , \ \dot{Z}_{s,ij}\left(\dot{Z}_{s,ij} - \dot{Z}_{u,ij}\right) \geq 0 \\ C_{min} \ , \ \dot{Z}_{s,ij}\left(\dot{Z}_{s,ij} - \dot{Z}_{u,ij}\right) < 0 \end{cases} \quad \text{(eq.1)}$$

Because the SH control was simply introduced on a quarter car model, the global force distribution was not considered. However, in this study, each individual actuator was responsible to release the control force and moments of globally distributed SH dampers. For simplicity, 'C_{sky}' was replaced with the 'C_{sky*}' which is the equivalent damping coefficient of the damping force '$Fd_{,ij}$'in the equation 1, by taking into account the global force distribution.

In addition to the vertical SH damper, angular dampers about the lateral and longitudinal axes were introduced to the sprung mass. The full vehicle model in this study has four control inputs as Fd_{fl}, Fd_{fr}, Fd_{rl}, Fd_{rr}. Considering the control of four unsprung masses in addition to the body motions -point out an under-actuation problem due to the numbers of actuator and control variable. That problem was tackled by controlling the sprung masses externally with GH control. Hence, a four-input three-output control problem was obtained. The three measured outputs of the vehicle were velocity of the bounce, $\dot{Z}_s$, pitch, $\dot{\theta}$ and roll, $\dot{\emptyset}$, and they were multiplied by SH damping coefficients in equations 2, 3, and 4.

$$F_z = C_{sky-bounce}\,\dot{Z}_s \quad \text{(eq.2)}$$

$$M_\theta = C_{sky-pitch}\,\dot{\theta} \quad \text{(eq.3)}$$

$$M_\emptyset = C_{sky-roll}\,\dot{\emptyset} \quad \text{(eq.4)}$$

The equivalent forces and moments for bounce, pitch and roll motions were defined in equations 5, 6, and 7. The Equations were also written in matrix form in equation 8. L_f, L_r and t_f are the distance of the front and rear axles to the CoG and the axle width (front and rear were assumed equal), respectively.

$$F_z = -Fd_{fl} - Fd_{fr} - Fd_{rl} - Fd_{rr} \quad \text{(eq.5)}$$

$$M_\theta = L_f.Fd_{fl} + L_f.Fd_{fr} - L_r.Fd_{rl} - L_r.Fd_{rr} \quad \text{(eq.6)}$$

$$M_\emptyset = 0.5\,t_f\,(-Fd_{fl} + Fd_{fr} - Fd_{rl} + Fd_{rr}) \quad \text{(eq.7)}$$

$$\begin{bmatrix} F_z \\ M_\theta \\ M_\emptyset \end{bmatrix} = \begin{bmatrix} -1 & -1 & -1 & -1 \\ L_f & L_f & -L_r & -L_r \\ -0.5\,t_f & 0.5\,t_f & -0.5\,t_f & 0.5\,t_f \end{bmatrix} \begin{bmatrix} Fd_{fl} \\ Fd_{fr} \\ Fd_{rl} \\ Fd_{rr} \end{bmatrix} \quad \text{(eq.8)}$$

The linear equations $\boldsymbol{y = Wx}$ and $\boldsymbol{W} \in \mathrm{R}^{mxn}$ have full row rank, the right inverse (pseudo-inverse) can be calculated as $\boldsymbol{W^{\dagger} = W^T(WW^T)^{-1}}$. Thus, the equation 8 could be transformed to equation 9.

$$\begin{bmatrix} Fd_{fl} \\ Fd_{fr} \\ Fd_{rl} \\ Fd_{rr} \end{bmatrix} = \begin{bmatrix} \frac{-L_r}{2(L_f+L_r)} & \frac{1}{2(L_f+L_r)} & -\frac{1}{2t_f} \\ \frac{-L_r}{2(L_f+L_r)} & \frac{1}{2(L_f+L_r)} & \frac{1}{2t_f} \\ \frac{-L_f}{2(L_f+L_r)} & -\frac{1}{2(L_f+L_r)} & -\frac{1}{2t_f} \\ \frac{-L_r}{2(L_f+L_r)} & -\frac{1}{2(L_f+L_r)} & \frac{1}{2t_f} \end{bmatrix} \begin{bmatrix} F_z \\ M_\theta \\ M_\emptyset \end{bmatrix} \quad \text{(eq.9)}$$

GH control is a variant of the SH and was developed for the purpose of road holding improvement. A fictious damper (later referred as groundhook damper in this paper) is mounted between each wheel and the road surface. GH damper, unlike the SH, applies continuously variable damping depending on the vertical movement of the wheel, which is relative to the reference plane. GH control rule is given in equation 10.

$$C_{s,ij} = \begin{cases} C_{gh} \;, & -\dot{Z}_{u,ij}\left(\dot{Z}_{s,ij} - \dot{Z}_{u,ij}\right) \le 0 \\ C_{min} \;, & \dot{Z}_{s,ij}\left(\dot{Z}_{s,ij} - \dot{Z}_{u,ij}\right) > 0 \end{cases} \quad \text{(eq.10)}$$

Although SH control can improve the comfort of the vehicle, it worsens road holding due to the sudden force changes together with the control effort to reduce only the body movement. On the other hand, the suspension is responsible to keep the wheel on the variety of the road surface. The conflict between the comfort and road holding should be

formulated in some way to ensure a minimum but safe level of road holding in comfort mode. The driving mode and the movement of the wheel in the z-axis are good indicators for keeping the wheel in contact with the road. While the driving mode determines the ratio between comfort and road holding, the vertical movement of the wheel is proportionally damped by the GH control.

Both SH and GH control generate discontinuous force. However, their targets are conflicted. As a result of this conflict, one (SH or GH) needs the maximum control force while other needs the minimum control effort. This conflict also helps to reduce discontinuities in some cases, as seen in Figure 2, especially for the consecutive control commands which reduces the difference between the maximum and minimum force requests. However, it should be noted that a semi-active damper's minimum damping coefficient always greater than zero and that would also be helpful to reduce the force variation of SH, providing a better road holding.

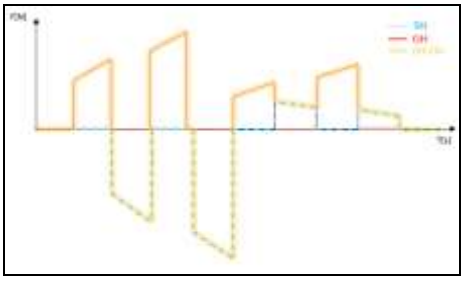

Figure 2. *Skyhook Ground Hook control*

2.1. Data Acquisition

A semi-active damper can generate the force depending on the direction of motion. Therefore, stroke speed, sprung and unsprung mass velocity should be measured. For this purpose, accelerometers are widely used in the research studies (Carratù continued, 2017; Thenozhi continued, 2012). On the other hand, a stroke sensor is also used to measure the relative speed between the sprung and unsprung mass motions (Kojima continued, 1991). These two alternative measurement methods are available within the context of virtual sensors on IPG® Carmaker® and its user-accessible quantities (UAQ). Even though, the virtual velocity sensor is available in UAQs, considering the real-life applications, acceleration sensor was preferred instead the velocity.

Therefore, two accelerometers were needed to place on sprung and unsprung masses (as shown in Figure 1). The acceleration needs to be converted into velocity using integration as it cannot be measured directly. However, due to the integration, the velocity includes some offset and sometimes data is drifted. To remove the drift and offset over the acceleration, a high pass filter can be used. Then, a low pass filter can be used instead of an integration, by selecting a proper cut-off frequency. A low pass filter act as an integrator above the cut-off frequency, however, the lower frequencies are more attenuated. As a result, to remove only the bias over the signal, high pass filter frequency, f_{hpf}, is selected in the range of 0.1-3Hz. The phase lead, which is the result of high pass filtering, can be removed by selecting the low pass filter frequency, f_{lpf}, between 0.1 and 0.007Hz (van Casteren continued, 2013; Xubin Song, 1999). The global parameters such as roll rate, $\dot{\emptyset}$, and pitch rate, $\dot{\theta}$, were measured from virtual sensors, however, the bounce speed, $\dot{Z}_s$, was measured from the accelerometer located at the CoG.

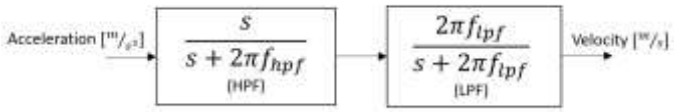

Figure 3. Transformation of the acceleration into the velocity

A stroke sensor was used as a reference to calibrate the filters in order to have reliable stroke speed measurements from the accelerometers. It should be noted that the virtual sensors used in this study do not contain noise. As shown in Figure 4, the difference between the two accelerometers that were attached to the FL wheel and the body provided the similar results with the stroke sensor.

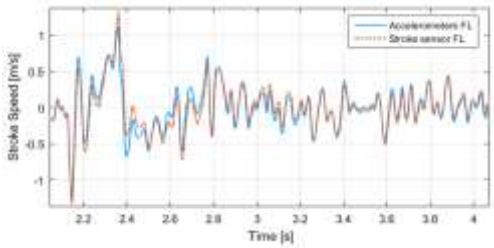

Figure 4. Comparison stroke speed sensor and accelerometers attached body and wheel.

The block diagram is represented in Figure 5. In accordance with the diagram, the bounce speed $\dot{Z}_s$, roll rate $\dot{\emptyset}$ and pitch rate, $\dot{\theta}$ were fed back into the SH. Then, global restoring force and moments were calculated using the equations 2, 3, 4 and the resultant forces were decoupled and transferred to the SH rule block, which applies the SH rule, using the equation 1, for each actuator and calculated the desired forces, $Fd_{s,ij}$. Similarly, GH control block applies the GH rules and calculates the desired forces $Fd_{g,ij}$, using the equation 10, for each of the actuators. The desired forces were collected into summing junctions before transmitting them to the low-level controllers. The low-level controllers calculated the equivalent electric current of desired forces, which would be explained in the low level controller section.

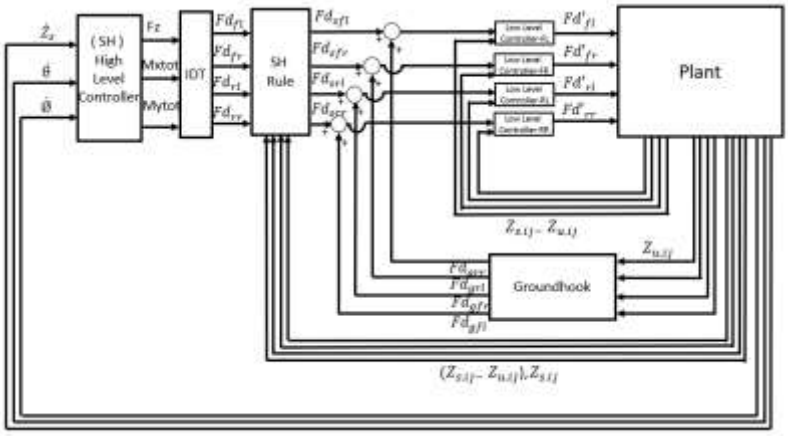

Figure 5. Full vehicle skyhook-groundhook control block diagram. IDT(Input Decoupling Transformation)

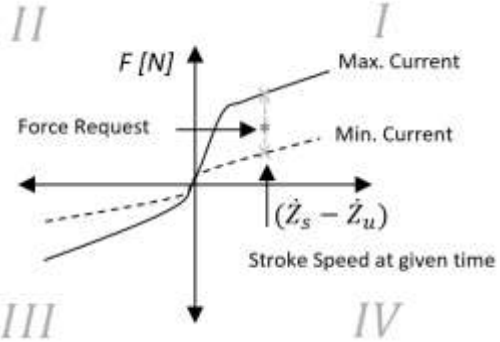
2.2. Low Level Controllers

The semi-active dampers can generate force when the dampers under the excitation. This means that the force depends on the magnitude of stroke speed when it is either in extension or compression. The semi-active damper used in this study was controlled by electric current. An equivalent electric current was calculated by interpolation between the maximum(F_{max}) and minimum force (F_{min}), based on the force-stroke speed map as in Figure 6, using the expression given 11 and 12.



$$i = f^{-1}(F_d, \dot{Z}_s - \dot{Z}_u) \quad \text{(eq.11)}$$

$$I_{control} = \frac{F_{request} - F_{min}}{F_{max} - F_{min}}(I_{max} - I_{min}) + I_{min} \quad \text{(eq.12)}$$

$$1.6A \geq I_{control} \geq 0.32A$$

Figure 6. Semi-active damper stroke speed and force curve

3.SIMULATIONS

The vertical vehicle dynamics control system was developed in Simulink® and co-simulations were performed in Simulink-IPG Carmaker® interface. The simulated vehicle was a D segment SUV, and the vehicle parameters are given in table 1. In the first scenario, the vehicle was driven at varying speeds that was controlled by IPG-Carmaker®'s driver model featuring the digitalized Renault® test track (during 40s and 630m). In that scenario, road profile was symmetrical on the horizontal axis. Thus, the vehicle was mostly exposed to the inputs causing the bounce and pitch motions; therefore, the tuning was done specifically to reduce these motions. In order to make a comparison with passive dampers, the semi-active damper control current was set to constant values for comfort and sport characteristics. The groundhook control gain GH2 was two times of the GH. In the second scenario, vehicle was moved straight for 100m, then, made cornering with a curve radius of 100m for 90deg, with varying speeds which was controlled by IPG-Carmaker® driver model. SH CskyR2 gain was five times of the CskyR1, and SH CskyR3 gain was fifty times of CskyR1.

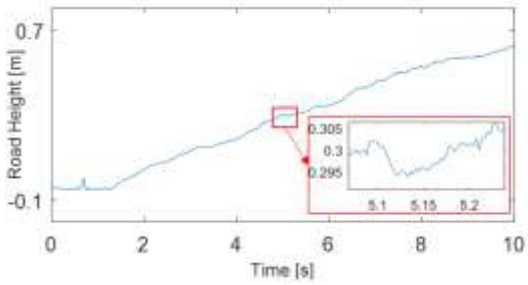


Figure 7. CRG road profile section corresponding to 10s.

Table 1. Vehicle Parameters

Sprung mass	$M_s = 1500\text{kg}$
Unsprung mass	M_{uf}=55kg, M_{ur} =45kg
Spring constant	$k_{sf} = 29kN/m$, $k_{sr} = 32kN/m$
Front, rear min., max. damping force at extension-compression	$F_{df} = [-550N, -750N; 650N, 2500N]$, $F_{dr} = [-1000N, -1500N; 1500N, 5000N]$
Tire spring constant, damping coefficient	$k_{tf,r}$ =350 kN/m , $C_{tf,r}$ = 1000Ns/m.
Distance between axles-CoG, and Axle width	$L_f = 1.1m$ $L_r = 1.8m$ t_f =1.6m

The restoring force and moments at the CoG can be seen in Figure 8. They were decoupled into the force requests of each actuator, in Figure 8. Then, SH rule was applied on the force requests and each of them were summed with GH forces requests before sending to the low-level controller.

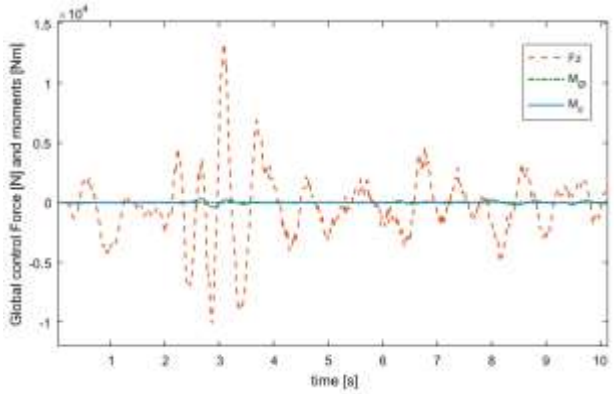

Figure 8. Restoring force and moments at the COG

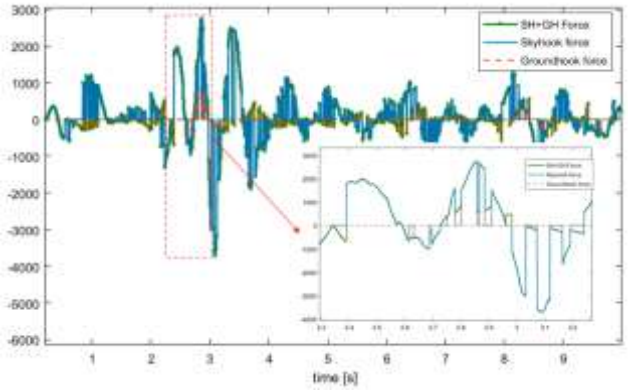

Figure 9. SH and GH, and SH-GH force requests for [FL] actuator

4.RESULTS

4.1.First Scenario

The body acceleration's power spectral density (PSD) is shown in Figure 10. The figures were sampled with 1kHz and filtered with moving average filter, 'window size=15Hz', to improve the readability. It is clearly seen in the graph that active control of the semi-active dampers performed well in all frequency regions when compared to the passive dampers. SH control method provided the best performance in all regions. SH-GH control method showed the second-best performance after SH control in terms of comfort. SH-GH2, on the other hand, showed the third best performance in terms of vibration transmissibility. The results seen in the PSD chart matches the rout mean square (RMS) values presented in the table 2. According to the results shown in the table, the best results in terms of body acceleration can be seen as SH-, SH-GH, SH-GH2 respectively. In terms of road holding, dampers configured as passive sport, SH-GH2, SH-GH, SH, Passive comfort, respectively showed the best performance. Vertical load variation shows similar results as the rms of the wheel deflection speed.

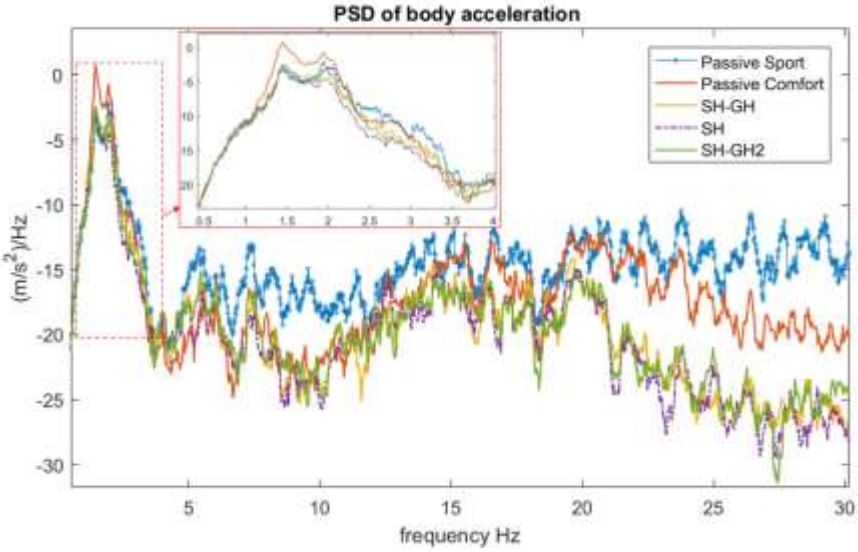

Figure 10. PSD body acceleration

As the road is symmetrical on the horizontal axis, there was no roll moment occurred due to the road surface irregularities. According to rms values of the pitch acceleration in table 2, SH, SH-GH, SH-GH2, Passive Comfort, Passive sport, respectively showed best performance. It can be seen that rms of body acceleration is inversely proportional to the rms wheel deflection speed and tire vertical load.

***Table* 2.** *Rms values of the simulations*

Controller Type	Rms Body Acc. [m/s^2]	Rms [FL] Wheel Deflection [m/s]	Rms [FL] Tire Vertical Load [N]	Rms pitch Acc. [rad/s^2]
SH	1.1083	0.2360	5385.8	0.9899
Passive Comfort	1.5249	0.2536	5407.3	1.1080
Passive Sport	1.6917	0.2161	5357.8	1.3593
SH-GH	1.1618	0.2343	5386.2	1.0446
SH-GH2	1.2497	0.2276	53829	1.1200

4.2.Second Scenario

For the second scenario, passive and SH logics were compared. Three SH control logics with different tuning parameters for roll motion control showed better performances for the body and pitch accelerations. On the other hand, according to table 3, the same logic showed poor performance for the roll acceleration and velocity, while gains were particularly tuned the roll-oriented for SH- CksyR1, SH- CksyR2, and SH- CksyR3. During the cornering, the roll angle, force request and delivered force can be in figure 11. It can be seen that the actuator's response is not sufficient for the force request. Figure 12 shows the stroke speed of the dampers during the cornering.

Table 3. Cornering Test (Flat Surface)

Controller Type	Rms Body Acc. [m/s^2]	Roll Acc. [rad/s^2]	Roll Vel. [rad/s]	Pitch Acc. [rad/s^2]	Rms pitch Vel. [rad/s]	Rms Body lateral acc. [m/s^2]
Passive Comfort	0.1553	0.0714	0.0057	0.2001	0.0189	2.3053
Passive Sport	0.1508	0.0721	0.0056	0.2080	0.0154	2.3044
SH CskyR1	0.1230	0.0735	0.0057	0.1856	0.0176	2.3055
SH CskyR2	0.1237	0.0735	0.0057	0.1868	0.0176	2.3054
SH CskyR3	0.1227	0.0788	0.0058	0.1854	0.0175	2.3054

5.DISCUSSION

In this study, the SH control approach was applied to the full vehicle model. The virtual restoring forces and moments resulting from the SH approach at the center of gravity of the vehicle were calculated using the input decoupling transformation method. The SH controller was used to control the sprung mass, while the GH method was used to control the unsprung mass of the vehicle. GH method controlled each of the tire, independently. The force-request was distributed to each actuator from the global SH and GH controllers, continuously. However, the GH and SH rules were applied to the force request, separately, depending on the body speed and stroke speeds of the actuators, meaning the force requests were discontinuous. The force requests were collected into the summing junctions, then, passed into the low-level controllers those calculated the necessary electric current depending on the force request and stroke speed.

In the first scenario, the proposed road profile had a wide frequency spectrum (up to 150Hz). According to the results in table 2, SH control could provide the minimum vibration transmissibility. When the GH was integrated into the SH to balance the conflict between comfort and road holding, it reduced the rms of wheel deflection speed, but it also reduced the ride performance with respect to pure SH, as expected. According to rms body acceleration, SH control provided about 27% and 34% improvements in terms of vibration transmissibility when compared to the passive suspension's comfort and sport characteristics, respectively. As expected, the centralized SH control had superior vibration attenuation performance, when the GH control improved the road holding.

In the second scenario, due to the low excitation of the dampers, expected forces could not be generated to reduce the roll motion. However, as the semi-active damper does not have continuous force supply and control strategy causes sudden force-change, thus relatively low-reduction of roll motions. The lower roll prevention performance in the second scenario of this study, can also be supported by Ahmadian (Ahmadian, Simon, 2004) and Binder's studies (Binder,

Khajepour, 2014). Reductions provided in the sudden force changes can be a solution to improve roll motion behaviour. However, sudden force changes can further be improved in a future study, by the modification of the high-level control strategy to increase the minimum level of the damping while vehicle is cornering, and/or applying additional low pass filters to reduce the damping force variation.

Abstract

In this study, iron oxide pieces were taken as samples from rolling plant of 6 different domestic companies which placed in iron and steel manufactring industry in Turkey. By examining the crystal structures of the raw samples, the closest primary iron oxide sample that could reach the targeted hematite (Fe_2O_3) ratio was determined. In addition to the study, the crystal structures of the treated iron oxide samples were examined by applying grinding for 15 seconds each of these iron oxide samples and 800 °C heat treatment processes, and the closest secondary iron oxide sample that could reach the targeted hematite ratio was determined. The mechanical synthesis process was realized via high energy wet milling process. The stoichiometric ratio ($SrCO_3/Fe_2O_3$) was changed from 1:5 to 1:6 and the influence of stoichiometric ratio was investigated with regards to magnetic properties. Different strontium hexaferrite ($SrFe_{12}O_{19}$) powder output was produced by mechanically synthesised primary and secondary optimum iron oxide samples with strontium carbonate raw material in different variations according to stoichiometric ratios by performing crystal structure and magnetic analysis of the obtained powder outputs, the magnetic performance of commercially produced magnets was partially achieved. The maximum magnetic properties were obtained with 1:5.0 $SrCO_3/Fe_2O_3$ stoichiometric ratio. The coercivity (Hc) value for 1:5.0 stoichiometric ratio were obtained as 1041.184 Oe.

Keywords: Strontium hexaferrite; Heat treatment; Mechanochemical synthesis

Code availability: Not applicable

1. Introduction

Ferrites with hexagonal structures, called hexaferrites. They are used as permanent magnets, magnetic recording media, data storage devices, microwave components, high frequency circuits and operating devices. Since the last lan60 years enormous progress in fundamental, theoretical and experimental laboratory studies of different properties of hexaferrites, their synthesis, and engineering of a wide range of microwave and mm-wave coatings and devices on their basis, has been achieved. In the last decades there has been great interest in the hexaferrites because of their room temperature ferromagnetic and insulating properties. On account of their superior chemical stability, mechanical hardness, excellent corrosion and wear resistance, low level of media noise and high Curie temperature, they are suitable for rigid disk media [1-2]. Hexagonal ferrites are divided into six different types: M, W, Y, X, U and Z. A ferrite having high value of coercivity (Hc) is known as a hard ferrite; while having low value of Hc is known as a soft ferrite. Magnetic properties of hexaferrites are linked to their crystal structures.

The aim of this study is to produce strontium ferrite magnet by using strontium carbonate that can be obtained from iron oxide and celestine which are national raw material and to investigate the parameters (calcination temperature, and duration, impurities etc.) that affect final material of synthesis process also to make the process more cost efficient and decrease dependence on overseas regarding production of magnets. Mixing ratio of compositions and reaction times determined as parameters in experiment conditions. Moreover, experiments carried out with high purity strontium carbonate and hematite to comparison Compositions calcined with different times. The composition of materials measured phases' semi-quantitative analysis characterized by XRD.

2. Experimental

In this study, It was taken below materials from China;

S1 : Strontium carbonate ($SrCO_3$) powder: 98% purity
S2 : Strontium carbonate ($SrCO_3$) powder: 99% purity
R1 : Red iron powder: 99% purity
XK1 : Pre-sintered prepared magnetic powder of Y30 ferritic magnet grade ($SrFe_{12}O_{19}$)

XK1 sample was taken from China as ready sample in order to check and compare experiment results of this article. Any production process or treatment were not performed to XK1, just measured magnetic performance and was drawn hysteresis loop of XK1 by vibrating-sample magnetometer (VSM) withing working conditionals of 0.0693 gr, 75 Hz frequency and room temperature. Furthermore, semi-quantitative analyses of XK1, S1 and S2 were carried out and the crystalline phases were identified by XRD measurements using a Panalytical Empyrean model X-ray diffractometer device with CuKα radiation at room temperature. The patterns were collected in the range of $10 \leq 2\theta \leq 110°$ intervals with a step size of 0.01313° and time per step of 15.300 (s).

Iron oxide samples were taken as samples from rolling plant of 6 different companies which placed in iron and steel manufactring industry in Turkey. Iron oxide pieces were crushed through vibratory disc mill within 15 seconds for every each sample for preparing convenient particle size to sample holder of XRD. All of pieces were performed cyrstal structure analysis by XRD which was used above same analysis conditionals as XK1, in order to determine hematite and other phase ingredients. According to results of elemental analysis and crystal structure of iron oxide samples, T11 sample additionally was determined and called as T1 max. value when it was compared Fe_2O_3 values of all samples. So, we had T11, T14, T15, T16, T18, T19, T1max. (has highest Fe_2O_3 value) samples.

Before the calcination stage, it is necessary to keep the iron oxide powder in the sintering kiln furnace at a high temperature in order to ensure the stoichiometric ratio with the strontium carbonate powder. Thus, it is ensured that the whole structure is transformed into Fe_2O_3 structure [8]. After determine sample numbers, it was performed heat treatment process to T11, T14, T15, T16, T18, T19 samples which placed different alumina crucibles separately within heat specifications of 800 °C, 12 hours, 8 °C/min. and made cool inside furnace from 800 °C until 400 °C and outside from 400 °C to room temperature by sintering kiln furnace. Besides, it was performed heat treatment process to T1 max. sample within heat specifications of 800 °C, 6 hours, 5 rpm by rotary kiln furnace. Application purpose of study both sintering kiln furnace and rotary kiln furnace to compare hematite amounts. End of rotary kiln process, T1max. sample was called as T2 max.
In following heat treatment processes, all output samples were crushed coarsely through mortar which had ceramic structure and then crushed through vibratory disc mill within 15 seconds for each sample as fine particle size in order to prepare samples to sample holder of XRD. Semi-quantitative analyzes of all samples were carried out by XRD which

was used above same analysis conditionals as XK1. Whole crushing and heat treatment processes were shown in Table 5 in order to make understandable sample names and values.

Common method used for the production of hexagonal ferrites is the traditional ceramic method. In the traditional ceramic method, iron oxide (Fe_2O_3) is mixed with strontium carbonate ($SrCO_3$) or strontium oxide (SrO) as the starting material. The stoichiometric ratio ($SrCO_3/Fe_2O_3$) was changed from 1:5.5 to 1:6.6 by 0.1 increments, and the influence of stoichiometric ratio was investigated with regards to phase structure and magnetic properties. [31]

K5 : S1/5R1 (used sintering kiln furnace)
K6 : S1/6R1
K8 : S2/6R1
K14 : S1/6T2 max.
K21 : S1/5T28

K5 Sample Process: S1/5R1 (used sintering kiln furnace)

480g K5 powder was used totally and put 20g S1 + 100g R1 materials inside 1 stainless steel jar which placed on dry ball mill machine in order to milling as dry during 30 minutes within 200 rpm and 15 pieces of 10 mm steel balls. There were 4 stainless steel jars such (4 jar x 120g = 480g). Also, milling process was performed 350 rpm and 5 minutes in same machine as addition process. Then, milled powder was put in alumina crucible for heat treatment which was performed by sintering kiln furnace within 1150 °C, 12 hours and 8 °C/min. specifications. After heat treatment, amount of powder was measured as 20g. High energy wet ball machine was used for milling process. 20g powder, 4.8 mm steel ball with 150g, 20 mL isopropyl were put inside hard steel jar and wet milled. After wet milling process, slurry (milled powder) was cleaned with isopropyl on 2 mm sieve. Clean slurry was dried in fume cupboard with 80 °C heat table during 6 hours. End of all process, Semi-quantitative analysis of K5 powder were performed by XRD.

K6 Sample Process: S1/6R1

28g K6 powder was used totally and put 4g S1 + 24g R1 materials inside 1 stainless steel jar which placed on high energy wet ball machine in order to milling as dry during 12 minutes within 10 mm steel balls. Then, milled powder was put in alumina crucible for heat treatment which was performed by sintering kiln furnace within 1150 °C, 12 hours and 8 °C/min. specifications. After heat treatment, amount of powder was measured as 20g. High energy wet ball machine was used for milling process. 20g powder, 4.8 mm steel ball with 150g, 20 mL isopropyl were put inside hard steel jar and wet milled. After wet milling process, slurry (milled powder) was cleaned with isopropyl on 2 mm sieve. Clean slurry was dried in fume cupboard with 80 °C heat table during 6 hours. End of all process, Semi-quantitative analysis of K6 powder were performed by XRD.

K8 Sample Process: S2/6R1

28g K8 powder was used totally and put 4g S2 + 24g R1 materials inside 1 stainless steel jar which placed on high energy wet ball machine in order to milling as dry during 12 minutes within 10 mm steel balls. Then, milled powder was put in alumina crucible for heat treatment which was performed by sintering kiln furnace within 1150 °C, 12 hours and 8 °C/min. specifications. After heat treatment, amount of powder was measured as 20.92g. High energy wet ball machine was used for milling process. 20.92g powder, 4.8 mm steel ball with 150g, 20 mL isopropyl were put inside hard steel jar and wet milled. After wet milling process, slurry (milled powder) was cleaned with isopropyl on 2 mm sieve. Clean slurry was dried in fume cupboard with 80 °C heat table during 6 hours. End of all process, Semi-quantitative analysis of K6 powder were performed by XRD.

K14 Sample Process: S1/6T2 max.

28g K14 powder was used totally and put 4g S1 + 24g T2 max. materials inside 1 stainless steel jar which placed on high energy wet ball machine in order to milling as dry during 12 minutes within 10 mm steel balls. Then, milled powder was put in alumina crucible for heat treatment which was performed by sintering kiln furnace within 1150 °C, 12 hours and 8 °C/min. specifications. After heat treatment, amount of powder was measured as 20.10g. High energy wet ball machine was used for milling process. 20.10g powder, 4.8 mm steel ball with 150g, 20 mL isopropyl were put inside hard steel jar and wet milled. After wet milling process, slurry (milled powder) was cleaned with isopropyl on 2 mm sieve. Clean slurry was dried in fume cupboard with 80 °C heat table during 6 hours. End of all process, Semi-quantitative analysis of K6 powder were performed by XRD.

K21 Sample Process: S1/5T28

24.17g K21 powder was used totally and put 4g S1 + 20.17g T28 materials inside 1 stainless steel jar which placed on high energy wet ball machine in order to milling as dry during 12 minutes within 10 mm steel balls. Then, milled powder was put in alumina crucible for heat treatment which was performed by sintering kiln furnace within 1250 °C, 6 hours and 8 °C/min. specifications. After heat treatment, amount of powder was measured as 18.8g. High energy wet ball machine was used for milling process. 18.8g powder, 4.8 mm steel ball with 150g, 20 mL isopropyl were put inside hard steel jar and wet milled. After wet milling process, slurry (milled powder) was cleaned with isopropyl on 2 mm sieve. Clean slurry was dried in fume cupboard with 80 °C heat table during 6 hours. End of all process, Semi-quantitative analysis of K6 powder were performed by XRD.

It was performed semi-quantitative analyzes to 5 different compositions of ferritic powders by XRD. After determined K21 final magnetic powder, magnetic specifications of K21 were measured and drawn hysteresis loop through by vibrating-sample magnetometer (VSM) and compared it with magnetic performance of XK1.

3. Results and Discussion

Magnetic parameters of XK1 were shown in Table 1.

Table 1. Magnetic parameters of XK1

Measurement Spec.	Upward Part	Downward Part	Average	Parameter 'definition'
Hysteresis Loop				Hysteresis Parameters
Hc (Oe)	11.234	-19.318	15.276	Coercive Field: Field at which M/H change sign
Ms (emu)	5.875E+0	-5.828E+0	5.851E+0	Saturation Magnetization: maximum M measured
Hc offset (Oe)	11.23	-19.32	-4.04	(Hc upward curve + Hc Downward curve)/2
Mr (emu)	-73.913E-3	127.524E-3	100.719E-3	Remanent Magnetization: m at H=0
S	0.01	0.02	0.02	Squareness: Mr/Ms
Area (Oe*emu)	842.909E+0	-	-	Area enclosed by the hysteresis loop
Slope at Hc (emu/Oe)	0.007	0.007	0.007	Sloop at Hc

It was observed and checked through XRD analysis that pre-sintered prepared magnetic powder of Y30 ferritic magnet grade ($SrFe_{12}O_{19}$) had 98% purity as description of raw material supplier.

Ingredients of S1 and S2 was determined by XRD in order to check impurity which is shown in Table 2.

Table 2. Chemical composition results of S1 and S2 (%)

Element	S1	S2
Strontianite	100	100

It was taken results of elemental analysis of iron oxides which were taken from 6 different companies and performed by X-ray fluorescence (XRF) of factories which gave samples. Quantitative results of elemental analyzes were given in Table 4. Elemental analysis conditionals were not known due to carried out before by own laboratories of factories. It was seen that elemental ingredients of iron oxides samples include different elements in alloy.

Table 4. Elemental analysis results (%)

Element	T11	T14	T15	T16	T18
Fe_2O_3	95.08	72.56	72.86	69,75	71.83
SiO_2	1.01	-	0.69	3.481	0.55
Cr_2O_3	0.67	-	-	-	-
MnO	0.89	-	0.66	-	0.441
MgO	0.20	-	0.36	0.286	-
CaO	0.66	-	0.13	3.513	0.33
Al_2O_3	0.40	-	0.03	0.905	0.14
NiO	0.11	-	-	-	-
Ni	-	-	0.033	-	-
Na_2O	0.00	-	0.035	0.484	-
CuO	0.58	-	-	-	0.1442
Cu		-	0.057	0.044	-
Cl	0.10	-	-	-	-
C	0.06	-	0.049	-	-
S	0.04	-	0.018	-	0.079
P	-	-	0.015	-	-
Zn	-	-	0.008	0.005	0.0071

As	-	-	0.004	-	0.0065
Humidity	1.08	3.94	-	-	-
Oil	-	0.04	0.03	-	1.14

It was observed that chemical compositions rates of iron oxide samples had different from each other because of alloy varieties and oil amounts of companies through XRF anaylsis chemical compositions of iron oxide samples which was shown in Table 4 . The chemical composition results of iron oxide samples were given in Table 3.

Table 3. Chemical composition results of iron oxide samples (%)

	T11	T14	T15	T16	T18	T19
Wuestite	68,8	22,2	73,2	34,0	63	71,4
Magnetite	19,6	26,0	19,6	44,8	27,2	24,2
Iron	3,3	41,7	3,4	3,0	3,7	2,8
Hematite	8,3	10,1	3,8	9,5	6,0	1,6
Akermanite	-	-	-	8,7	-	-

After heat treatment of iron oxide samples which performed through sintering and rotary kiln furnaces, it was observed that treated samples were agglomerated as coarse particle. Therefore, it needed to crush through mortar and disc mill machine. Semi-quantitative analyzes results of heat treatment iron oxide samples were shown in Table 6.

Table 6. Results of semi-quantitative analyzes (%)

	T21	**T24**	**T25**	**T26**	**T28**	**T29**	**T2 max.**
Wuestite	-	-	-	-	-	-	14.4
Magnetite	17.5	17.5	6.9	11.2	-	6.7	65.4
Iron	1.7	1.8	1.7	1.5	1.6	2.0	1.8
Hematite	80.9	80.7	91.4	78.2	98.4	91.3	18.3
Akermanite	-	-	-	9.2	-	-	-

According to results of Table 5 and Table 6, it was chosen T1 max., T2 max, and T28 which had highest hematite amount as 98.4% among all samples. Although T1 max. and T2 max did not have high hematite, we chose these samples in order to determine effect of rotary kiln furnace which is known that rotary kiln process increase magnetic performance of magnetic powder as literature sources. Furthermore, it was observed that wuestite phases of iron oxide samples transform to magnetite phase within effect of heat treatment process.

After heat treatment processes of final magnetic powders (K5, ……, K21), it was observed that treated powder was agglomerated as coarse particle. Therefore, wet milling processes were performed to powders in order to decrease micron sizes as well drying in fume cupboard in following step for drying and preparing samples to XRD analysis. Results of semi-quantitative analyzes of the final powders was show in Table 7.

Table 7. Results of semi-quantitative analyzes of the final powders (%)

	K5	**K6**	**K8**	**K14**	**K21**
Strontium Dodecairon (III) Oxide	97.4	97.8	98.0	-	98.0
Strontium Dodecaferrate (III)	-	-	-	75.7	-
Strontium Iron Oxide (1/1/2,79)	-	-	-	-	-
Iron	2.6	2.2	2.0	2.4	2.0
Hematite	-	-	-	21.9	-

T1 max. was chosen due to had highest hematite value without heat treatment for strontium hexaferrite synthesis. T2 max. was chosen in order to observe effect of heat treatment in strontium hexaferrite synthesis. T28 was chosen as highest hematite value among all processed samples for strontium hexaferrite synthesis. S1and S2 were chosen in order to observe effect of purity in strontium hexaferrite synthesis. R1 was also chosen for strontium hexaferrite synthesis. After determined above samples as most optimum and convenient synthesis ingredients, all of them were synthesised with each other at certain values which refer K5, K6, K8, K14, K21.

4. Conclusions

In this study, it was studied to produce strontium hexaferrite magnetic powder within iron oxide synthesis which was taken from domestic factories. Based on the test results and crystal structure analyses the following conclusions were derived:

According to results of all synthesis experiments (was given in Table 7), it was observed that K21 synthesis had highest strontium hexaferrite value which was chosen as the final magnetic powder within 98%.

Magnetic performance comparison of K21 and XK1 was shown in Table 9.

Table 9. Magnetic Performance Comparison of K21 and XK1

Average Values	K21	XK1	Parameter 'definition'
Hysteresis Loop			Hysteresis Parameters
Hc (Oe)	1041.184	15.276	Coercive Field: Field at which M/H change sign
Ms (emu)	3.646E+0	5.851E+0	Saturation Magnetization: maximum M measured
Hc offset (Oe)	-2.57	-4.04	(Hc upward curve + Hc Downward curve)/2
Mr (emu)	1.841E+0	100.719E-3	Remanent Magnetization: m at H=0
S	0.50	0.02	Squareness: Mr/Ms
Area (Oe*emu)		-	Area enclosed by the hysteresis loop
Slope at Hc (emu/Oe)	0.002	0.007	Sloop at Hc

- Synthesises of red iron (R1) within different purities of strontium carbonate (S1 and S2) did not reach to aimed strontium hexaferrite value which indicate K5, K6, K8.
- 3 different samples of domestic iron oxide as optimum and most convenient sample were chosen which refer T1 max., T2 max. and T28. It was observed that synthesises of T1 max. and T2 max. with strontium carbonate did not reach to aimed strontium hexaferrite value which indicate K14, K21 as much as much as T28 which indicate K21 and 98% strontium hexaferrite value. In briefly, raw phase of iron oxide of T1 max. and heat treatment phase of rotary kiln process of T2 max. did not affect to reach to aimed strontium hexaferrite value. Therefore, T28 sample was most convenient iron oxide sample for synthesis.
- K21 sample reached to highest strontium hexaferrite value. Magnetic performance of K21 was compared with XK1, was observed that K21 reached to coercivity value of XK1 within 15-fold lower which was shown in Table 9.

ABSTRACT

This paper describes the random-mechanical test of an electric vehicle battery on an electrodynamic Shaker system in order to investigate the performance and life-cycle of the battery. Instrumented accelerometers, pressure transducers and thermocouples give the simultaneous behavior of the system under the given conditions.

Inner temperature and the pressure variations give the test signoff criteria suitability of the system.

Keywords: Electric Battery Test, Shaker, Durability Test.

1. INTRODUCTION

Electric batteries are the increasing demand of the green-technology markets for future vehicle systems. As being the most expensive and one of the most critical vehicle component, design and validation of battery systems require though testing [1]. Goal of these tests are not only to ensure durability of battery system, but also to ensure its safety under various abuse conditions.

Today's fast paced market, drives companies to accelerate battery design and validation testing using both analytical and rig resting, rather than on vehicle testing. Several methods are used for these performance tests: actuating the system with the vehicle position, on a Shaker system is the most preferred method for durability and mechanical abuse testing of the system. Vibration durability tests play an important role in the selection of components [2]. In particular, the relative exposure of the EV to different road surfaces and how such measurements were sequenced to form a representative vehicle life from which an accelerated life durability assessment of the design could be made [2].

This paper describes the random-mechanical test of an electric vehicle battery on an electrodynamic Shaker system in order to investigate the performance and life-cycle of the battery. There are many methods for vibrational tests of EV batteries [3-4]. Instrumented accelerometers, pressure transducers and thermocouples give the simultaneous behavior of the system under the given conditions.

2. TEST SYSTEM

The electric battery system is tested with the Shaker system in Durability Test Cell at Ford OTOSAN Gölcük Plant. Before the vibrational tests in order to reduce and eliminate fatigue modes NF (Natural Frequency) test and simulations completed. The convenience between test and simulations examined. Fixture modal analysis is correlated with test data and the battery tests started.

Electro dynamic shaker is a commercial test system that can collect acceleration data and calculate displacements on given Force levels. It is a durability based test system, that shakes the part under the road conditions.

Three movement directions can be tested on separate tests and the data is reported. Geometric dimensions of the system is given in the figure below. Mass and acceleration level of the requested test must be considered under this geometric limit and "F=ma" formula.

Vibration is applied on two modules: 1. Slip Table and 2. Head Expander. As given in the figure detailly, slip table tests the x and y direction and head expander run at z-direction tests.

For each test a specialized fixture must be designed and produced for putting the test part on the Slip table or head expander of the system.

Electro-dynamic shaker system tests the parts in a frequency range of 5-2500 Hz. The geometric dimensions of the system is given in the figure below. Shaker system has two main tables for three different testing directions(x-y-z). First one is the slip table and the x-y tests are run on this part. For z testing, head expender is mounted on the shaker for oscillating the system.

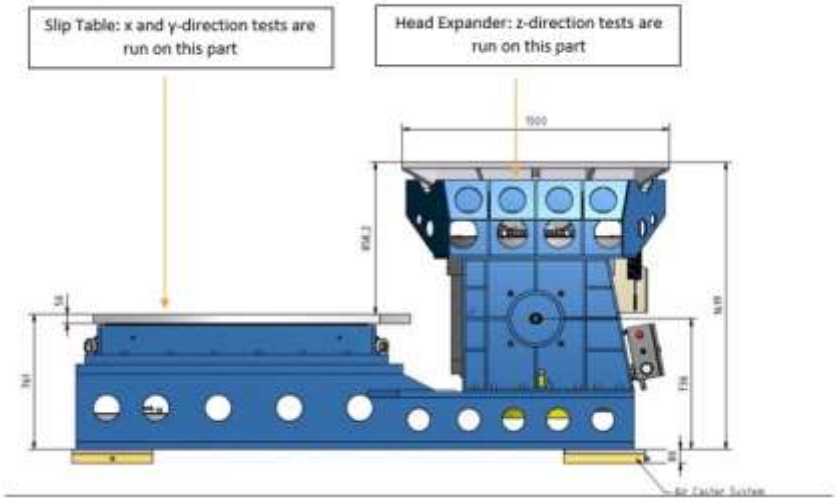

Figure 1. Durability Test Cell Shaker System

The vibration movement is generated by the interaction of electric current passing through the plunger coil and a magnetic field.

The force used to accelerate the moving element comprised of a ribbed body and the wrapped plunger coil is proportional to the coil current, the magnetic flux density, and the length of conductor in the magnetic field.

The vibration level of shaker can therefore be controlled by electric current intensity.

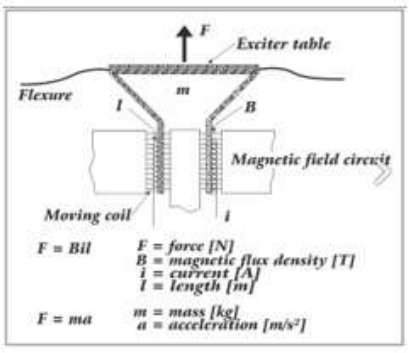

Figure 2. Shaker Vibration Body Diagram

Figure 2 shows the sectional view of a shaker. The magnetic field is generated by means of permanent magnets and, in case of larger, base-mounted ones, by means of electromagnets.

The maximum achievable acceleration is dependent on current intensity and total effective mass to be moved. At low frequencies, however, the limits of vibration velocity and displacement (travel) are reached earlier than those of acceleration.

Durability tests of battery components on shaker system can be organized by sine or random profiles. Tests are defined by a frequency or frequency range in Hz and acceleration. The acceleration is defined with respect to the gravitational constant g (9.81ms-2). With sinusoidal tests, both the frequency and acceleration can vary with time. A common sine vibration test is to sweep from a low to a high frequency with fixed or varying acceleration.

3. NFT Test

First step of durability testing is the Natural Frequency (NF) analysis of the system empirically. NF of the fixture and the battery must be measured and the system must be excited under the NF limits.

In order to investigate the NFs accelerometers are instrumented on the fixture walls as seen in the figures below:

Figure 3. NF Test Accelerometer Instrumentation

NF test profile is a sine (sinus profile) vibration test between 7-200 Hz. Acceleration data is collected for each instrumented accelerometer location.

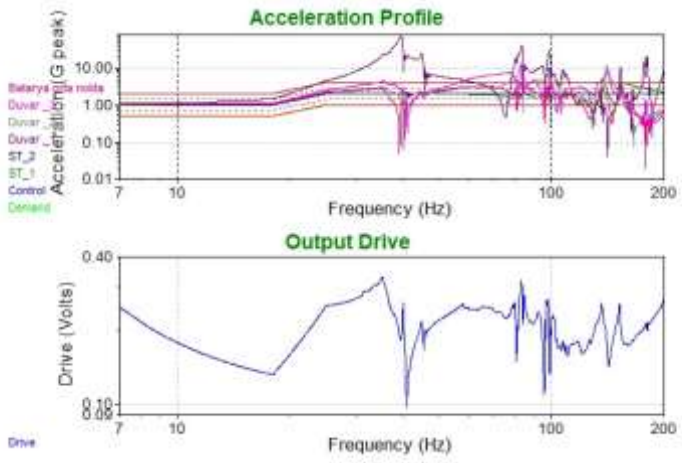

Figure 4. NF Test Result-x

Natural frequency peaks are at 40 Hz, 80 Hz and 185 Hz for x-direction.

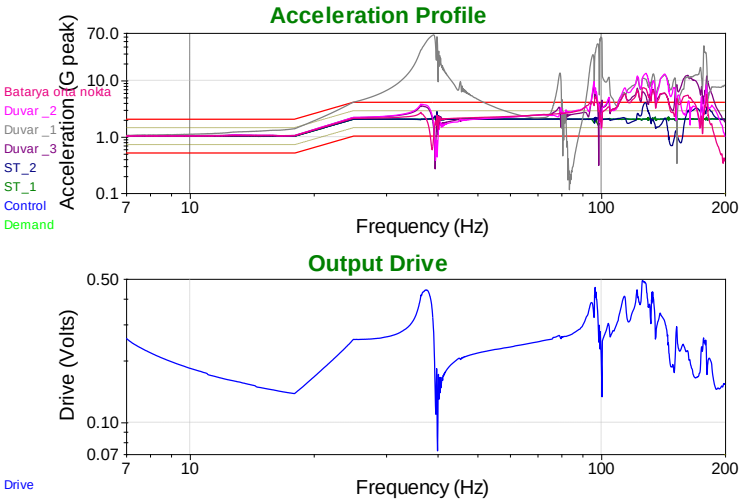

Figure 5. NF Test Result-y

The natural frequency peak points are similar with x-direction at y-direction. There are 3 critical points.

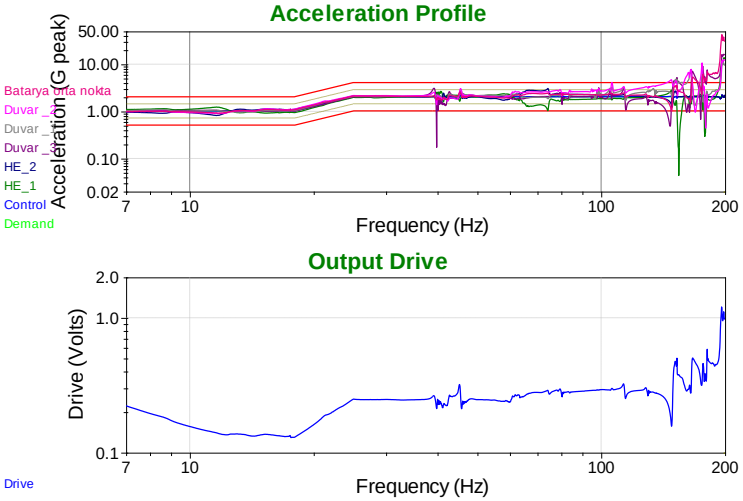

Figure 6. NF Test Results-z

There is no sudden peak on the Acceleration-Frequency graph, so that vibrational mode is not related with z-direction. X and y-directions have significantly greater fatigue damage potential and greater shock loading when compared to vibration profiles at z-direction.

4. Vibration Tests

Vibration test profile is sine sweep under requested conditions below.

	Test Procedure	*Cycles*	12	
No	Step	Step Description	Duration (min)	
1	Sinusoidal Wave with a Logaritmic Sweep	from 7 Hz to 200 Hz and 7 Hz	15	
		1 Cycle	15	min
		Total Cycle	180	min

Figure 7. Testing Specs

Sweep starts for 7 Hz and ends for 200 Hz than return to 7 Hz again in 15 minutes as 1 cycle. 12 total cycle is run. Total test time is 180 minutes for each direction.

Test sinus profile acceleration data is changed by frequency limits. Between 7-18 Hz the acceleration is 10 G, 18-25 Hz gradually increase from 10 G to 20 G, then for 25-200 Hz acceleration is 20 G.

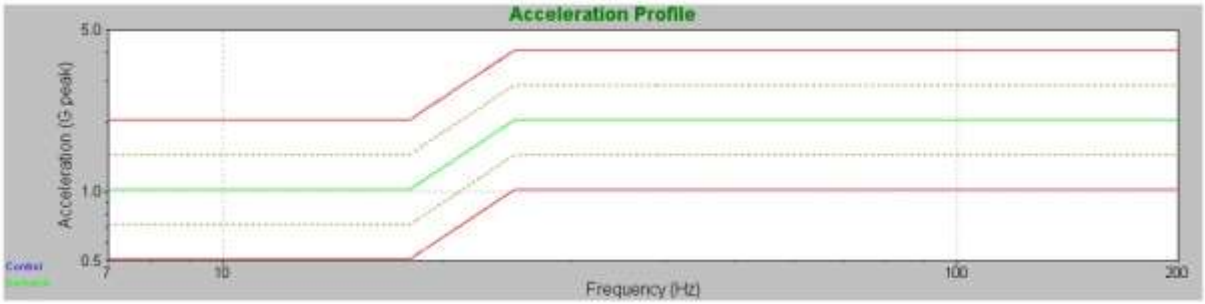

Figure 8. Test Vibration Profile

Total peak to peak velocity for the sine test is 0.22 m/s for each direction and the total displacement of the fixture is 10.33 mm for peak to peak.

Vibrational test are run on electro dynamic shaker system separately for each directions (x-y-z). The test requests are acceleration, temperature and pressure over the test time on requested instrumentation points.

First of all acceleration will be collected on accelerometers over the test time with shaker data acquisition box.

Three dimensional accelerometers are used for the tests and instrumentation points are as below:

Point-1: battery inner side

Point-2: battery upper-box

Point-3: battery wall

Point-1 is preferred in order to understand the inner movement of the battery through the test time.

Point-2 is mounted for understanding the vibration of upper-box and Point-3 is for investigating the wall excitations.

The instrumentation of Points are given on Figure.

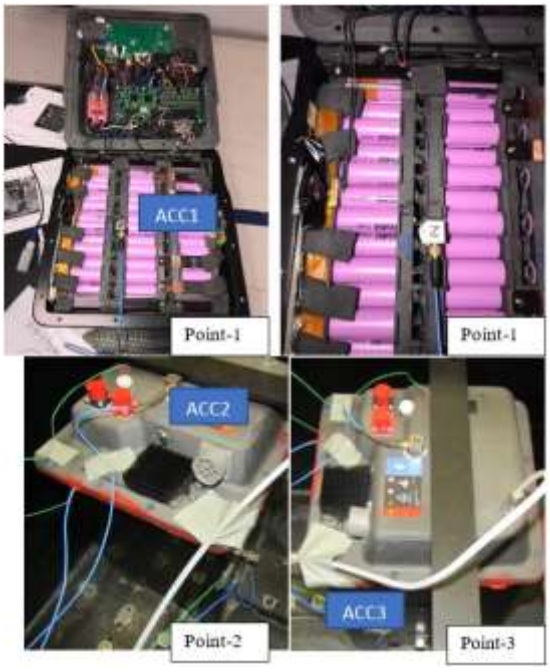

Figure 9. Accelerometer Instrumentation

After accelerometer instrumentation leakage control is completed and there is no leak on the battery instrumentation points.

Also, wall temperature of the battery is critical for Safety issues, so that the wall temperature is controlled on 3 different locations on the battery as given in the figure below. Thermocouple-1 and 2 are on the horizontal walls of the battery and Thermocouple-3 is on the upper box.

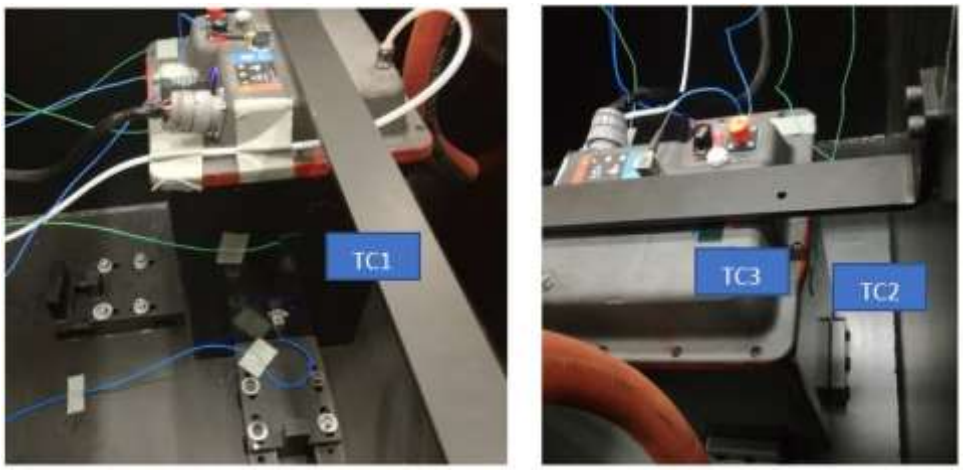

Figure 10. Thermocouple Instrumentation Points for Thermal Control

Figure 11. Test Part on Shaker for x, y and z-direction tests

Test fixture with the battery (total test part) is mounted on shaker system as given above. As explained in previous chapter, slip table is used for x-y directions tests and head expander is for z-direction.

The vibration of the slip table and head-expander must be under control through the test time so, two more accelerometers are instrumented on the table as given in the below in each test location (x-y-z). ACC3 and ACC4 is collecting the independent vibration data of the slip table under test conditions.

Figure 12. Slip Table and Head Expander Accelerometer Locations

Inner Pressure is also controlled over the test time for explosion risks. Inner pressure is collected on the pressure-meter for the upper box instrumentation location. Pressure sensor is named as PS as seen in the Figure below.

Figure 13. Pressure Sensor Location

Pressure data is processed by LMS Data Acquisition unit and also monitored the simultaneous data on screen visually over the test time for reducing the safety risks and leakage.

5. RESULTS

Vibration tests are completed for 3 different direcitons (x-y-z). The collected data over the test time are:

1. Vibration data for battery for 3 different instrumentation points
2. Inner pressure data for 1 inst. point
3. Surface temperature data for 3 instrumentation points

All data is examined under the test conditions and all the data is OK after the tests. No leakage, No non-excited accelerometer, No damaged thermocouple exist after the tests.

Vibration test is completed for 3 hours for each direction as requested. Demand and the tested acceleration values are adaptable with each other.

There is no deformation on the battery system after durability tests.

There is no deformation on the fixture after durability tests.

Natural frequencies of the vibration tests are convenient with computational durability analysis.

There is no sudden inner pressure rise through the test time that shows the system leakage, so there is no leak over the test time.

Surface temperatures are convenient with the electric-temperature screen values. No sudden temperature rise existed.

ÖZET

Plastik ürünler, artık hayatımızın birçok alanında sağladığı avantajlar bakımından yaygın bir şekilde tercih edilmektedir. Fakat plastik parçaların üretiminde boyutsal kararlılık, estetik ve kalite yönlerinden kararlı bir üretim her zaman çok kolay olmayabilir. Kalıp ve makinedeki aşınma, parça geometrisindeki hatalar, ölçme cihazlarındaki hassasiyet ve kalibrasyon yetersizliği, hava şartları, hammaddedeki farklılıklar ve makine elektrik hattındaki dalgalanmalar vb. durumlar parça kalitesi üzerinde etkilidir. Bu gibi durumların iyileştirilmesi tamamen kontrol altına alınarak mümkün olabilir. Bu çalışmada, plastik bir parçanın üretim sahasında ilk üretim denemelerinde parça üzerinde yaşanan birleşim izi probleminin çözümüne yönelik olarak çalışmalar yapılmıştır. Bunun için ürün tasarımında ve üretim prosesinde yapılan değişikliklerin parçanın üretimi üzerindeki etkisi incelenmiştir. İyileştirme sürecinde parçanın görsel kaynaklı bu problemin iyileşim sürecini takip etmek için Autodesk Moldflow Insight yazılımından faydalanılmıştır. Her bir enjeksiyon parametresi faktörü tek tek değiştirilerek analizler tekrar gözlemlenmiştir. Elde edilen sonuçlar değerlendirilerek optimum enjeksiyon parametrelerine ulaşılmıştır. Son aşamada elde edilen optimum güncel moldflow parametreleri ile üretim denemeleri tekrarlanmış ve bu denemelerde malzemenin akış durumuna göre birleşim izi kontrol altına alınarak, parametre kontrolü sağlanmış ve en uygun durum optimize edilmiştir.

Anahtar Kelimeler: Plastik Enjeksiyon, Moldflow, Kalıp, Sıcaklık, Basınç, Enjeksiyon Zamanı, Birleşim Çizgisi

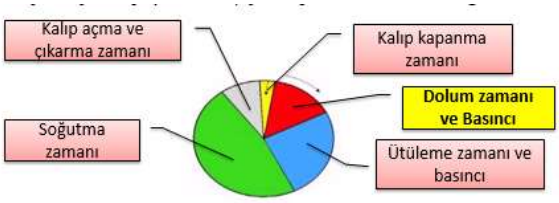
1. GİRİŞ

Dünyada sınırlı olan malzeme kullanımı, bilim ve teknolojideki yeni gelişmeler sonucunda çeşit ve kalite yönünden büyük gelişmeler göstermiştir. Bu malzemelerden biri ve belki de en önemlisi plastiklerdir. Plastiklerin son 20 yılda önemi giderek artmakta ve daha yaygın bir kullanım alanı bulmaktadır(Bknz. Şekil 1).

Şekil 1. Plastiğin kullanıldığı bazı alanlar

2. ÇALIŞMANIN KONUSU

Her sektörde olduğu gibi plastik sektöründe de hedef, düşük maliyetle üretim ile kalite seviyesi en üst düzeyde üretim yapmaktır. Buna bağlı olarak plastik proses sürecinde ürünlerin plastifikasyon oluşumu esnasında kalıp gözündeki iç basınç ve sıcaklık parametreleri de parça kalitesi açısından çok önemlidir. Bu parametreler hedeflenen değerde olmalıdır. Aksi taktirde hedefin dışında olması demek bazı enjeksiyon problemlerine (Birleşim izi, Eksik enjeksiyon, çapak, vb.) yol açması anlamına gelir.



Şekil 2. Bu proses parametreleri kalıp gözünün tam bir şekilde dolmasında önemli bir yer teşkil etmektedir.

3. DENEYSEL ÇALIŞMANIN YAPISI

Yapılacak olan deney çalışmasın da enjeksiyon kalıbında kullanılan güncel yolluk sistemleri ve makine parametrelerinin kontrolü ile birlikte, ürün tasarımında yapılacak değişikliğin basılan parçadaki birleşim çizgisi görünürlük durumuna etkisi hem simülasyon ortamında, hem de makine başında incelenmiştir.

Deneysel çalışmanın işlem basamaklarında aşağıdaki destek ekipmanlarından faydalanıldı. Bunlar;

A. 350 tonluk plastik enjeksiyon makinası
B. Geri sis lens kalıbı
C. Moldflow simülasyon yazılımı
D. Deney çalışmasında PMMA hammaddesi
E. MiniTab R14 deney tasarımı programı

3.1. Parça Geometrisi ve Termoplastik Malzemenin Özellikleri

Parça geometrisi x ve y eksenlerinde sırası ile 55mm x 190mm olup, prizmatik et kalınlığı 2,8 ile 2.2 mm aralığında değişmektedir. Şekil 3'de parça geometrisinin görseli verilmiştir.

Şekil 3. Lens 3D Cad data görseli

4. PROBLEM TANIMI

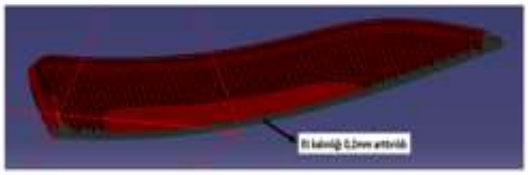
İlk üretim denemelerinde parçaların görsel kontrolleri sağlanarak lens parçası üzerinde, son dolum noktalarında birleşim izine rastlandı (Bknz. Şekil 4).

Şekil 4. Yaşanan birleşim izi problemi

Bu çalışmada amaç, parçanın plastik enjeksiyonda basılması sürecinde oluşan probleme etki eden faktörlerin hem sanal hem de gerçekteki durumun karşılaştırılması olduğu için çözüme yönelik metodların belirlenmesi yönünde çalışmalar yürütüldü.

5. İYİLEŞTİRME ADIMLARI

- İlk etapta ürün tasarımı yeniden gözden geçirilerek daha tasarım sürecinde yapılaması gereken adımlar belirlenmiştir. Sis bölgesinin et kalınlığında 0.2mm'lik et kalınlığı arttırımı yapılmıştır (Bknz. Şekil 5).



Şekil 5. Orijinal ürün tasarımında yapılan değişiklik

- Simülasyon çalışmaları başlangıcında önce süreci etkileyen girdi parametrelerinin minimum ve maksimum aralıkları belirlendi(Bknz. Tablo 1).
- Devamında Mini tab R14 programı kullanılarak deneysel tasarıma göre planlanmış 27 adet parametre belirlendi.
- Daha sonra belirtilen miktar da Moldflow plastik akış analizi yapıldı.
- Elde edilen sonuçlar incelenerek en iyi kalitede sonucu sağlayan en uygun enjeksiyon işleme parametrelerinin aralıkları saptandı.
- Son aşamada da taguchi yönteminin güvenirliliğini ve efektifliğini kontrol etmek için hem Moldflow programında hem de üretim sahasında son bir doğrulama testi yapılmıştır.

		SEVİYE NO:

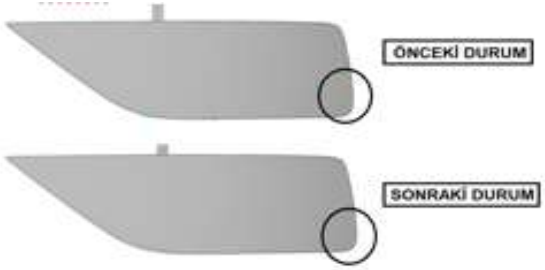
Tablo 2. Taguchi tasarımı girdi tablosu

- Bahsedildiği gibi ardından bu parametrelere göre belirtilen miktarda Moldflow plastik akış analizi yapıldı.

- Son olarak her analiz sonucu detaylı olarak incelendi ve görsel olarak birleşim izinin en iyi olduğu durumu elde etme için parametreler optimize edildi(Bknz. Şekil 6).



Şekil 6. Moldflow'da optimize edilen birleşim izi görüntüleri

- Performans karakteristiği olarak enjeksiyon sonrasında plastik üründe oluşan birleşim izi durumu kabul edilmiştir.
- Birleşim izi enjeksiyon probleminin yok olması, plastik ürün kalitesinin daha iyi olmasını sağlayacağından kalite karakteristiği olarak '**daha küçük daha kaliteli**' olması seçilmiştir.
- Sonuç olarak parametrelerin lens için yaklaşık en iyi parametre ayarları aşağıdaki tablo 3'de verilen şekilde olacağı hesaplanmıştır(Sanal ortama göre).

No.	FAKTÖRLER	Parametreler
1	Malzeme Sıcaklığı (°C)	235
2	Kalıp Sıcaklığı (°C)	60
3	Enjeksiyon Zamanı (sn)	3
4	Ütüleme basıncı(%P)	60
5	Ütüleme Zamanı (sn)	3

Tablo 3. Moldflow'da optimize edilen en iyi parametre durumunun yaklaşık kombinasyonu

- Üretim sahasında ilgili çalışmada elde edilen optimum güncel moldflow parametreleri baz alınarak üretim tekrarlanmış ve herhangi görsel bir problem görülmemiştir(Bknz. Şekil 7).

Şekil 7. Optimize edilen parametreler neticesinde kalıplanan parça görüntüleri

7. SONUÇ

- Uygulanan metotlar sonucunda, parçanın üretim sürecinde hedeflenen birleşim izi çizgisinin en iyi olduğu durumun enjeksiyon işleme parametreleri Taguchi yöntemiyle belirlendi ve sayısal olarak en iyi seviyeye ulaşıldı.
- Bu çalışmalarda parametre faktörlerinin yanı sıra geometride yapılan değişikliğin basılan parça üzerinde karşılaşılan birleşim izi durumuna etkisi hem sanal ortamda, hem de laboratuar ortamında incelendi. Deneysel ve sayısal sonuçların uyumluluğu oldukça yakın olduğu görülmüştür.
- Elde edilen en iyi parametre durumunun yaklaşık kombinasyonu neticesinde yapılan enjeksiyon denemeleri ile birleşim izi problemine yönelik en uygun enjeksiyon işleme parametresi aralıklarının aşağıdaki tablo 4'de belirtildiği şekilde olduğu görülmüştür.

PARAMETRELER	DEĞERLER
Kalıp Sıcaklığı	(80-60)°C
Erivik Sıcaklığı	(235-255)°C
Enjeksiyon Basıncı	(85-90)Mpa
Enjeksiyon Süresi	(1-3)sn
Ütüleme Basıncı	(50-55)Mpa
Ütüleme Süresi	(3-5)sn
Soğutma Süresi	(15-20)sn

ROTİLLİ KOL PARÇASINA ETKİYEN KUVVETLERİN TESPİTİNDE SANAL STRAIN GAUGE UYGULAMASI VE STRAIN GAUGE KONUMLARININ DOĞRULANMASI

Fatih Selman EREN, Ercan OLCAY

[1,2] Teknorot Otomotiv A.Ş., Ar-Ge Merkezi, Düzce, Türkiye
[3] Sorumlu Yazar: Fatih Selman EREN, fatihselman.eren@teknorot.com

ÖZET

Rotilli kollar araç süspansiyon sisteminin bir parçası olup ana karakteristiği şokları absorbe etmek, yoldan gelen titreşimleri sönümlemek ve daha konforlu bir sürüş sağlamak olan önemli parçalardan biridir. Araçlarda emniyet parçası olarak görev yapan bu parçaların mukavemetli olması ve aynı zamanda hafif olması istenmektedir. Bu sebeple rotilli kollar hayati önem taşımaktadır. Bu çalışma ağırlık azaltma ve parça mukavemetini artırmaya yönelik projenin bir parçasıdır. Bu çalışmanın amacı rotilli kol parçasına etkiyen kuvvetlerin tespiti için strain gauge uygulanması ve belirlenen konumların test ortamında kalibrasyonudur. Rotilli kol parçasına birim analiz uygulanarak nCode programında sanal strain gaugelerin lokasyonları belirlenmiştir. Strain gaugelerin parça üzerine enstrümantsyonu yapılarak test ortamında strain gauge konumlarının doğrulaması yapılmıştır. Çalışma sonucunda doğru konumları belirlenen strain gaugelerin üzerinde bulunduğu rotilli kol parçası araca monte edilerek veri toplamak üzere yol testi için kullanılmıştır.

Anahtar Kelimeler: Rotilli Kol, Strain Gauge, nCode, Sonlu Elemanlar Analizi

1. GİRİŞ

Rotilli kol parçası, otomobilde ön tekerleklerin şaseye bağlantısını sağlayan elemanlardır. Salıncak kolu şaseye burçlar vasıtasıyla araç sürüş ekseninde dönme serbestliği verilerek monte edilmektedir. Tekerlek tarafından yapıya araç sürüş ekseninde ve aracın yanal yönünde kuvvet girişi olmaktadır [1].

Sonu elemanlar analizi (FEA) yöntemi günümüzde mühendislik problemlerinin çözümünde en çok kullanılan numerik yöntemdir. Bu yöntem çok yönlü olup birçok çeşitlilikte mühendislik problemlerinin çözümünde kullanılabilir [2].

Farklı yol koşullarında salıncak koluna gelen yüklerin elde edilmesi amacıyla salıncak kolunun belirli bölgelerine strain gauge tanımlanarak servis koşullarında parçadan birim uzamalar toplanmıştır. Strain gaugeler yardımıyla kol üzerine gelen verilerden özel mühendislik yöntemleri kullanılarak kuvvet datası çıkarılmış ve sonlu elemanlar analizleri için kullanılmıştır. Salıncak koluna monte edilen strain gaugelerin konumları birim analiz yöntemi kullanılarak, parça üzerine etkiyen yüke oranla birbirinden lineer bağımsız noktalar belirlenerek doğrulanmıştır. Noktaların belirlenme çalışmalarında ayrıca nCode Glyphworks programı kullanılarak sanal ortamda belirlenen noktalara sanal strain gaugeler bağlanmış, kalibrasyon testleri ile çalışmalar doğrulanmıştır.

2. AMAÇ

Bu çalışmada rotilli kol parçasına etkiyen kuvvetlerin belirlenmesi için tasarım üzerinde Ansys Workbench ve nCode programları yardımıyla sanal strain gauge uygulanması ve elde edilen strain gauge konumlarının parça üzerine enstrümantasyonu yapılarak test makinesinde strain gauge konumlarının doğrulanması amaçlanmaktadır.

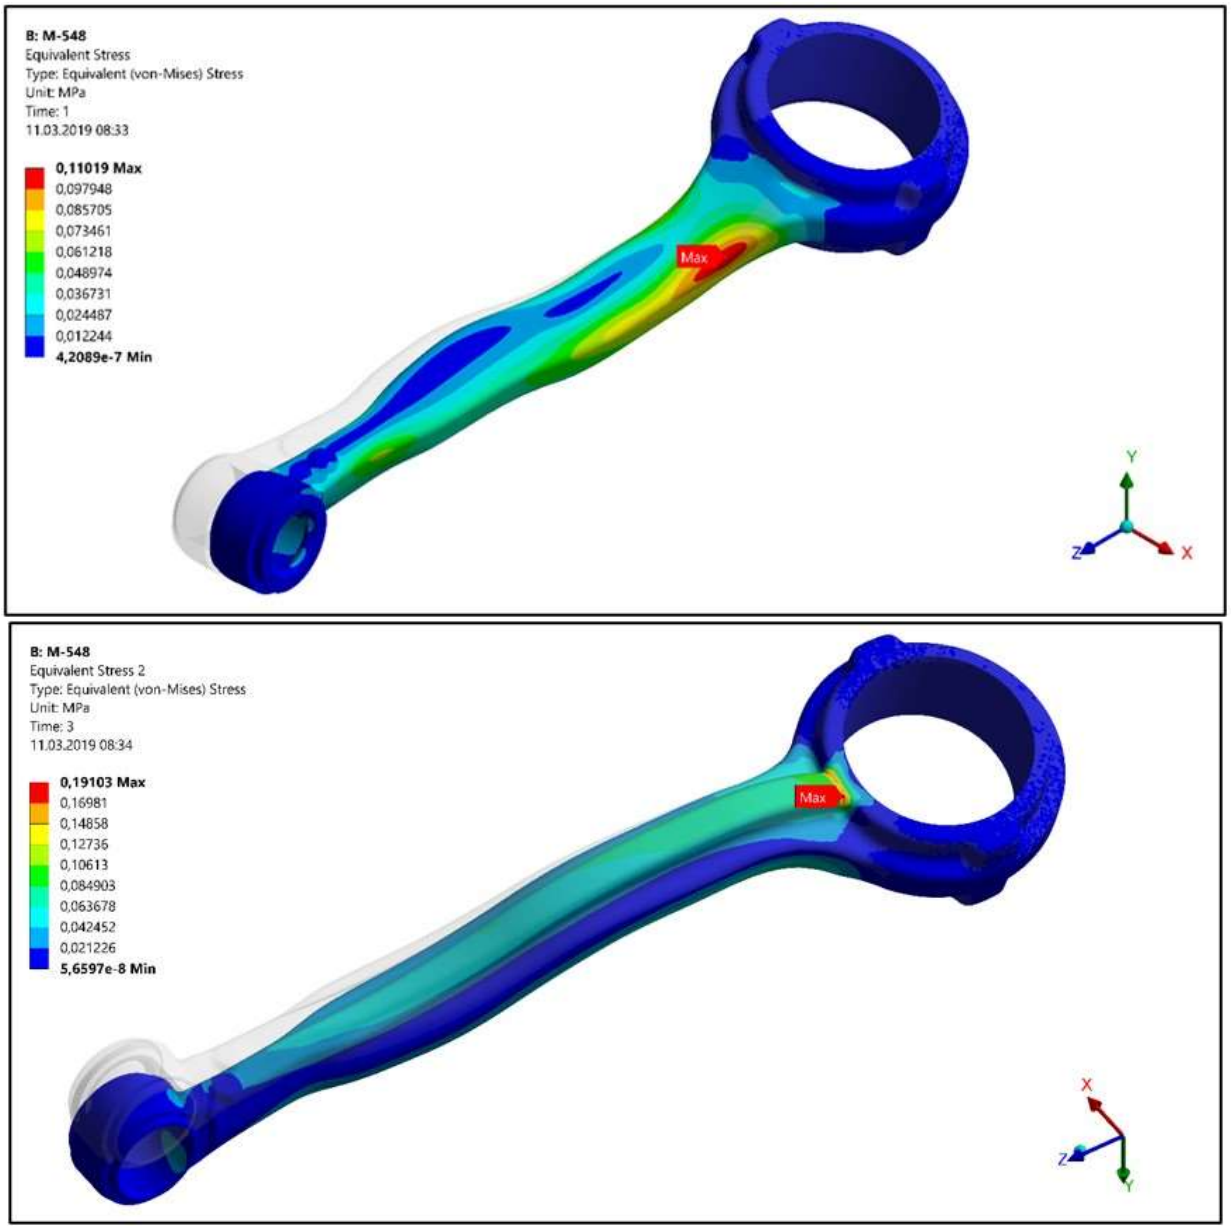
3. METOT

Parça üzerinden ölçümlerin alınacağı noktaların belirlenmesi adına strain gauge lokasyonlarının tespiti için parçaya aşağıda görüldüğü üzere ANSYS Workbench programında X, Y, Z yönlerinde birim yükler uygulanarak birbirinden lineer bağımsız bölgeler tespit edilmiştir.

Şekil 1; Parça Geometrisinin ANSYS Ortamında Gösterilmesi

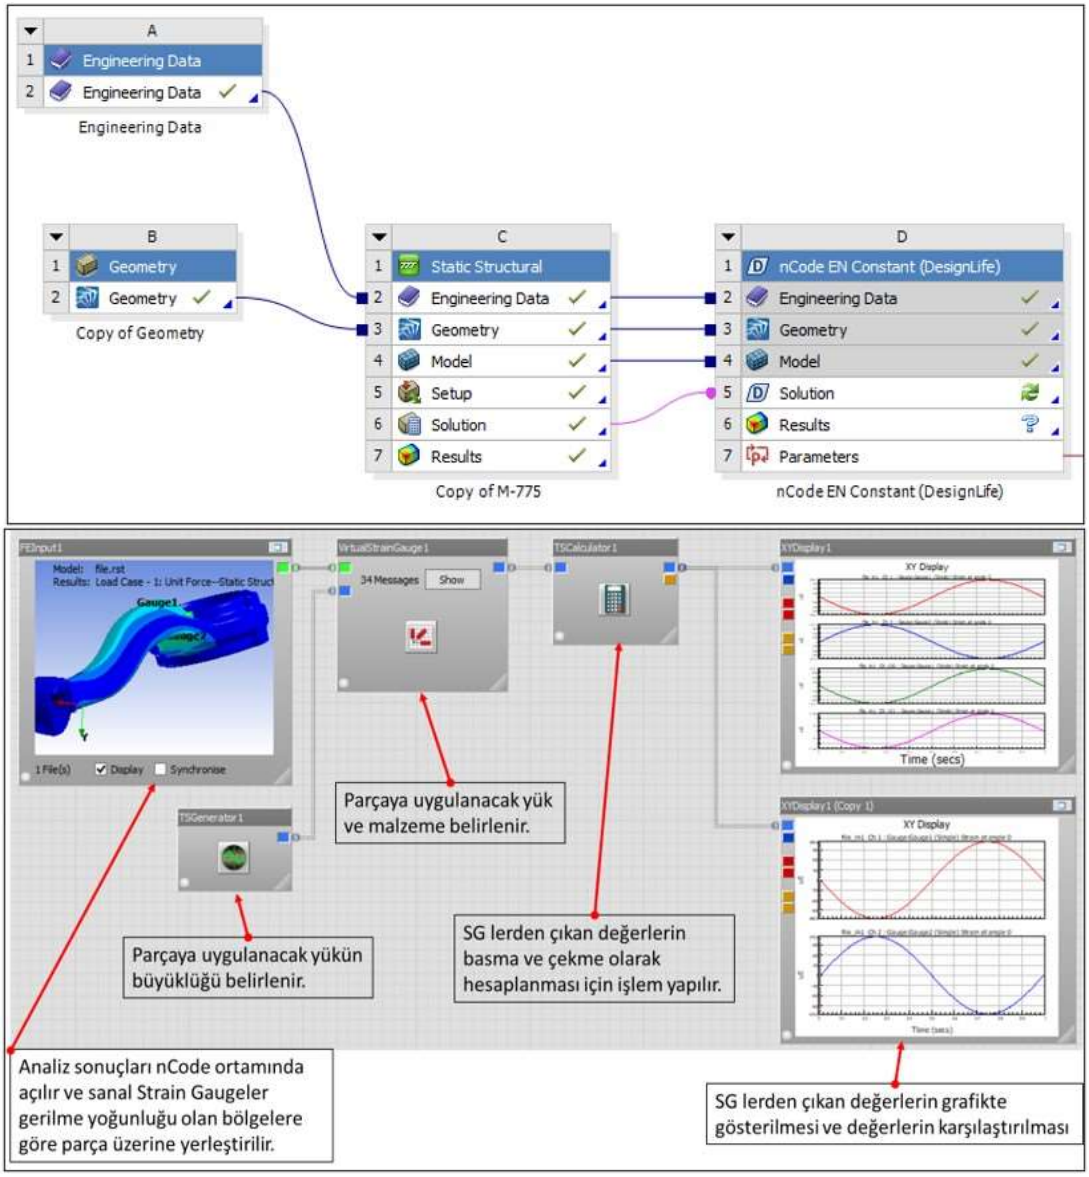
Şekil 2; Rotilli Kol Parçasının Birim Analiz için Sınır Koşulları

Şekil 1'de görülen parça geometrisinde gerçek araçtaki montaj konumu göz önüne alınarak Şekil 2 deki gibi parça burç kısmından sabitlenmiş, rotil kısmından ise birim analiz uygulanarak sonuçlar alınmıştır.



Şekil 3; X,Y Yönündeki Eşdeğer Gerilme Değerleri

Parçaya Z yönünde uygulanan birim kuvvet X ve Y yönünde uygulanan kuvvetlere kıyasla daha düşük gerilmelere sebep olduğu için ihmal edilmiştir.



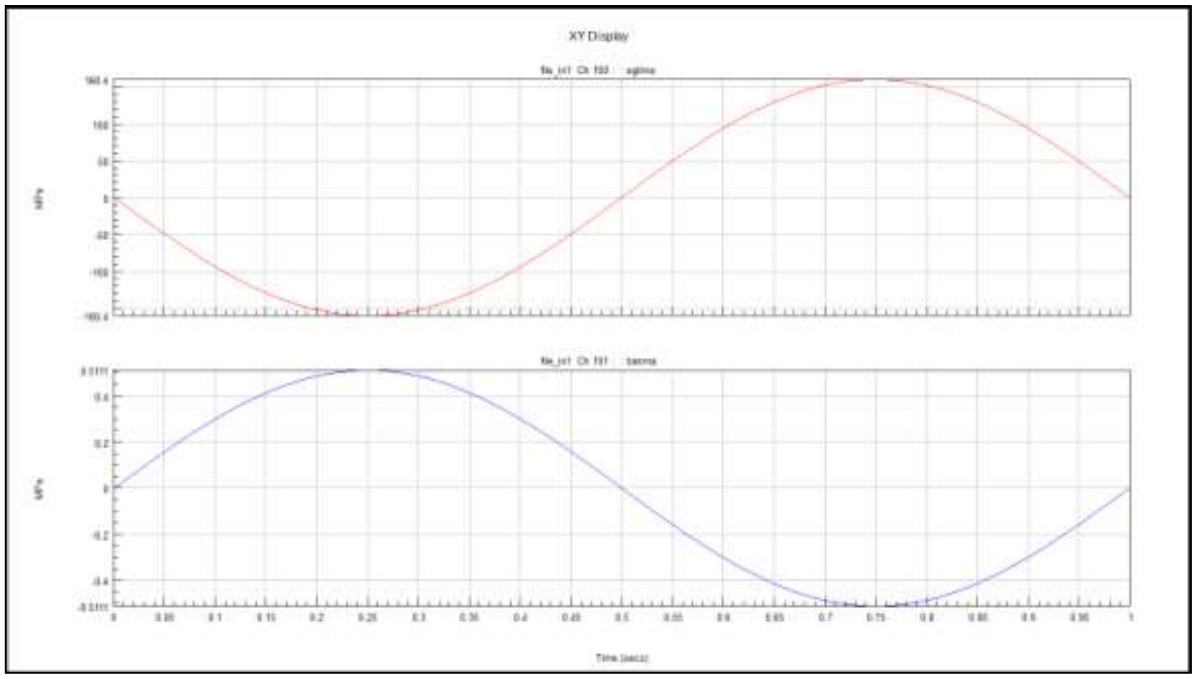
Şekil 4; Proses Akışının nCode Üzerinde Gösterilmesi

Parça geometrisine X, Y, Z yönlerinde birim analizler yapıldıktan sonra nCode sekmesine geçilmiştir [3]. nCode programında sanal strain gauge uygulaması yapılarak gaugelerden okunan kuvvet çıktıları grafik olarak elde edilmiştir.

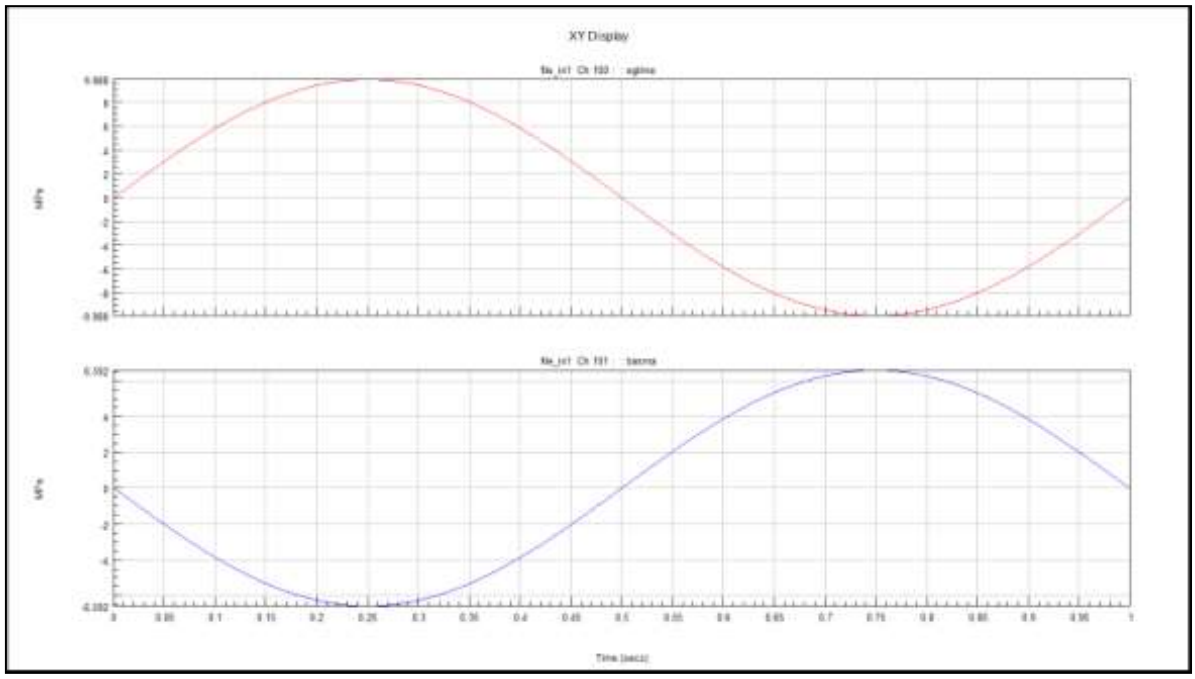
Ölçülen birim şekil değiştirmeler ile uygulanan kuvvet arasında lineer ilişki, kalibrasyon katsayıları vasıtasıyla kurulmuştur. Bu doğrultuda yapılan hesap Eğilme Kuvveti=0.0004333($SG1 - 1.05967 * \mathrm{SG2}$) [k$N$] ve
Basma Kuvveti= 0.0326624($SG1 + 1.05967 * \mathrm{SG2}$) [k$N$]
Şeklindedir. Formülde yer alan SG1 ve SG2 birim şekil değiştirme değerleri $\mu\epsilon$ cinsindendir. Sonuç ise kN biriminde çıkmaktadır.

4. ÇIKTILAR

Yapı üzerine 4 adet lineer strain gauge, 2 tanesi parçaya gelen basma kuvvetini ölçmek için, iki tanesi de eğilme kuvvetini ölçmek için kullanılmıştır

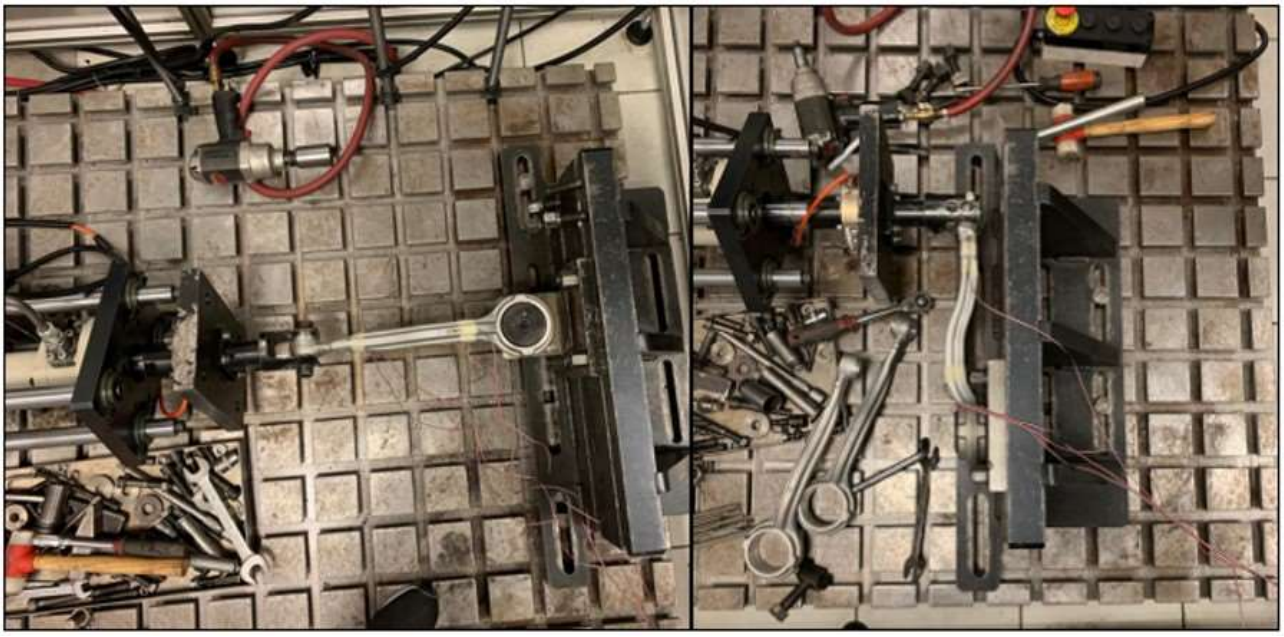


Şekil 5; Tamamen Eğilme Yönündeki Çıkışlar



Şekil 6; Tamamen Basma Yönünde Çıkışlar

Analiz sonucunda basma yönünde parça eğilme davranışı sergilemekte ve kuvvet çıktıları görece düşük çıkmaktadır.

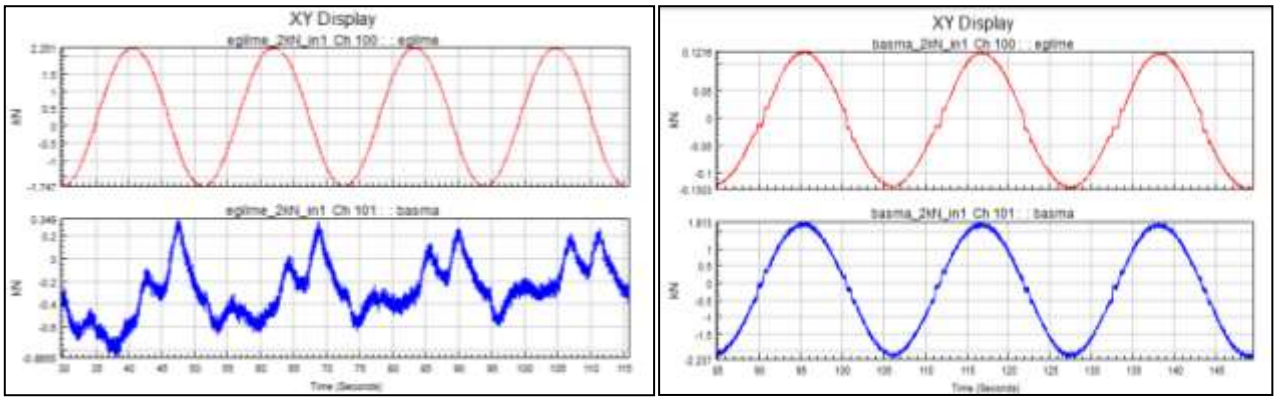


Şekil 5; Strain Gauge Enstrümantasyonu ve Rotilli Kol Parçasına Test Ortamında Birim Yük Uygulanması

SG kalibrasyonu için daha önce sanal ortamda belirlenen SG lokasyonlarının parça üzerine enstrümantasyonu yapılmıştır. Parçaya 4 adet SG bağlanmıştır ve eğme ve basma yönlerinde birim yükler parçaya uygulanarak cevaplar incelenmiştir. Analiz sonucunda basma yönünde parça eğilmeye meyletmekte ve gerilmeler az çıkmaktaydı. Aynı şekilde, kalibrasyon testinde de basma yönünde okunan cevaplar eğilmeye nispeten düşük çıkmıştır. Bu sebeple sadece eğilme yönünde cevap verecek 2 adet SG ile ölçüm yapılmasına karar verilmiştir.

5. SONUÇ

İki farklı yüklemede elde edilen kuvvet sonuçları aşağıda gösterilmektedir.



Şekil 6; Farklı Yükleme Koşullarındaki Kuvvet Sonuçları

Şekil 6'da 1 kN eğilme yüklemesi için hesaplanan değerleri ve 1 kN basma yüklemesi için hesaplanan değerleri gösterilmektedir. Salt basma yüklemesi altında eğilme kuvveti 0.1 kN mertebesinde hesaplanmıştır. Eğilme yönündeki kuvvet hesabında %6 - %7 mertebesinde bir hata söz konusudur. Salt eğilme yüklemesi altında hesaplanan basma kuvveti ise 0.5 kN civarındadır. Bu durum yüklemenin sadece eğilme yönünde gelmesi durumunda, basma kuvvetinde hesaplanan hatayı göstermektedir.

6. TEŞEKKÜR

Bu çalışma Teknorot Otomotiv A.Ş Ar-Ge Merkezi tarafından desteklenmiştir. Bu makalenin hazırlanmasında emeği geçen Teknorot Ar-Ge Merkezi ve BİAS Mühendislik çalışanlarına teşekkür ederiz. Ayrıca Ar-Ge Direktörü Sayın Murat ARSLANOĞLU'na ve Ar-Ge Proje Müdürü Sayın Fatih ÇAĞIRANKAYA'ya destekleri için teşekkür ederiz.

ÖZET

Otomobil ve hafif ticari araç satın alan kişilerin, İnternet'te Google arama motorunu kullanarak yaptıkları araştırmalar ile aldıkları araç markası arasındaki ilişkiyi araştırdık. Beklentimiz Google aramalarındaki artışın, satış rakamlarını da artırması ve bu etkinin geriye dönük üç aya kadar sürebildiğiydi. Otomobil Distribütörleri Derneği'ne göre 2019'da en çok satılan 5 marka (Ford, Renault, Volkswagen, Fiat, Toyota) için 2015 – 2019 arasında yapılan aramaları inceledik. Regresyon analizi ve yapay sinir ağları kullanarak yaptığımız analizlerde, beklentilerimize uygun olarak arama verileri ile satış rakamları arasında güçlü ilişkiler bulduk.

Anahtar sözcükler: regresyon, yapay sinir ağı, Google, otomobil, hafif ticari araç

1. GİRİŞ

Google 2016 yılında yayınladığı raporunda (URL5) araba alan insanların arabalarını almadan önce Google'da o araba markası ve modeli hakkında araştırma yaptıklarını anlatmaktadır. ABD'de Google tarafından 3165 tüketici üzerinde gerçekleştirilen bu araştırmaya göre, araba satın alanların %95'i dijitali bir bilgi kaynağı olarak kullanmaktadır.

Think with Google'da yayınlanan bir makaleye göre bir müşteri araba alım sürecinde 3 ayda 900'den fazla dijital etkileşim sonunda karar vermektedir. Dijital etkileşimlerin %71'i mobil cihazlardan gerçekleşmektedir. (URL4). Bu etkileşimler Google'da yapılan aramalar, Youtube videolarını izlemek ve otomobil satıcısının veya üreticisinin web sitesini ziyaret etmeyi kapsamaktadır.

Çeşitli pazar araştırmalarının sonuçlarına göre araba satın alma süreci 3 aydan kısa sürmektedir (URL1). Bu süre ABD'liler için 3 ayı bulurken, Kanadalılar için 62 günden bahsedilmektedir (URL3). Cox Automotive tarafından yapılan bir başka araştırmaya göreyse, araba alış süresi 108 güne kadar çıkabilmektedir (URL2). Arama erilerini modele katarken, kaç ay öncesine kadar yapılan aramaların satış rakamları üzerinde etkisi olabileceğini, bu çalışmalara dayanarak öngördük.

2. VERİ ÖNİŞLEME

Bu araştırma için Otomobil Distribütörleri Derneği'nin yayınladığı aylık araba ve hafif ticari araç satış rakamlarını kullandık (URL7). Bu rakamlar birinci el araç satışlarını göstermektedir.

Veri önişlemede öncelikle veri birleştirme yaptık. Excel tablosu şeklinde sunulan markalara göre aylık toplam otomobil ve hafif ticari araç satış rakamlarını veri tabanına aktardık. ODD'nin açıkladığı satış rakamlarına göre 2019 yılında Türkiye'de en çok satılan 5 marka ile kendimizi sınırladık: Ford, Renault, Tofaş, Volkswagen ve Toyota.

Google Trends'ten indirdiğimiz son 5 yılın (1 Ocak 2015 - 31 Aralık 2019) arama sayılarını kullandık. Aramaları Türkiye'den yapılan Google Web aramalarıyla sınırladık. Google Trends verileri en yüksek değer 100 puan olacak şekilde yapılan aramaların karşılaştırılabileceği normalize edilmiş değerlerden oluşuyor (URL6). 100 değeri, terimin en yüksek popülerliğe sahip olmasıdır. 50 değeri, terimin bunun yarısı kadar popüler olduğu anlamına gelir. 0 değeri ise bu terim için yeterince veri olmadığı anlamına gelir. Bu rakamlar arama terimlerine zaman içinde gösterilen ilgiyi göstermektedir. Google Trends'ten hepsi otomobil markası olarak sınıflandırılmış Ford, Renault, Tofaş, Volkswagen ve Toyota sözcükleri için yapılan aramaları sorguladık. Önceki 3 ayda yapılan aramaların da satış rakamını etkileyebileceğini düşündüğümüzden, arama verilerini geriye doğru üç ay genişlettik (1 Ekim 2014 – 31 Aralık 2019). Bu aralıkta Google Trends verileri aylık olarak geldi. Verilerin tarih biçimini elle düzeltip kullandık.

Tüm verileri daha kolay işlemek için MySQL veri tabanına aktardık. Orada PHP ve SQL kullanarak istediğimiz gibi süzdük, birleştirdik, grupladık ve her marka için ayrı tablolar oluşturduk. Sonra da bu tabloları CSV dosyaları olarak kaydedip SPSS ile veya doğrudan R ile veri tabanına bağlanarak kullandık.

3. REGRESYON ANALİZİ

Her bir marka için ayrı ayrı regresyon analizi yaptık. Google'da bir araba markasının aratılmasıyla, o dönemdeki araba satış rakamları arasındaki ilişkiyi araştırdık. Model kurmak için yaptığımız denemelerde, en başarılı regresyon modellerini kesme terimi olmadan kurabildiğimizi gördük.

$$\widehat{Satis} = \hat{\beta}_1 Arama \tag{1}$$

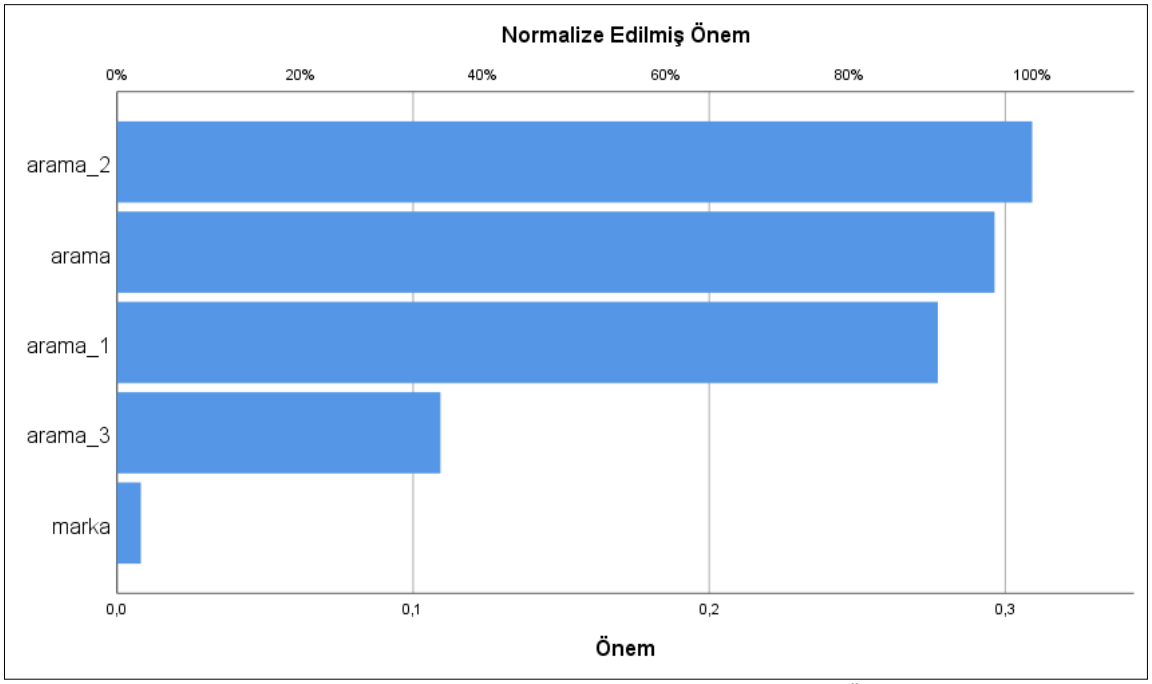
1 nolu denklem şeklinde regresyon analizi yapıldığında düzeltilmiş R^2 değerlerinin oldukça yüksek olduğu görüldü. Önsel beklentimiz bir ay içinde bir otomobil markası Türkiye'den Google'da ne kadar çok aratılmışsa, o ay o markanın Türkiye satış rakamlarının da o kadar artmasıydı. Analiz sonuçları bu beklentimizi doğruladı.

Tablo 1. Markalara Göre Regresyon Analizi Sonuçları

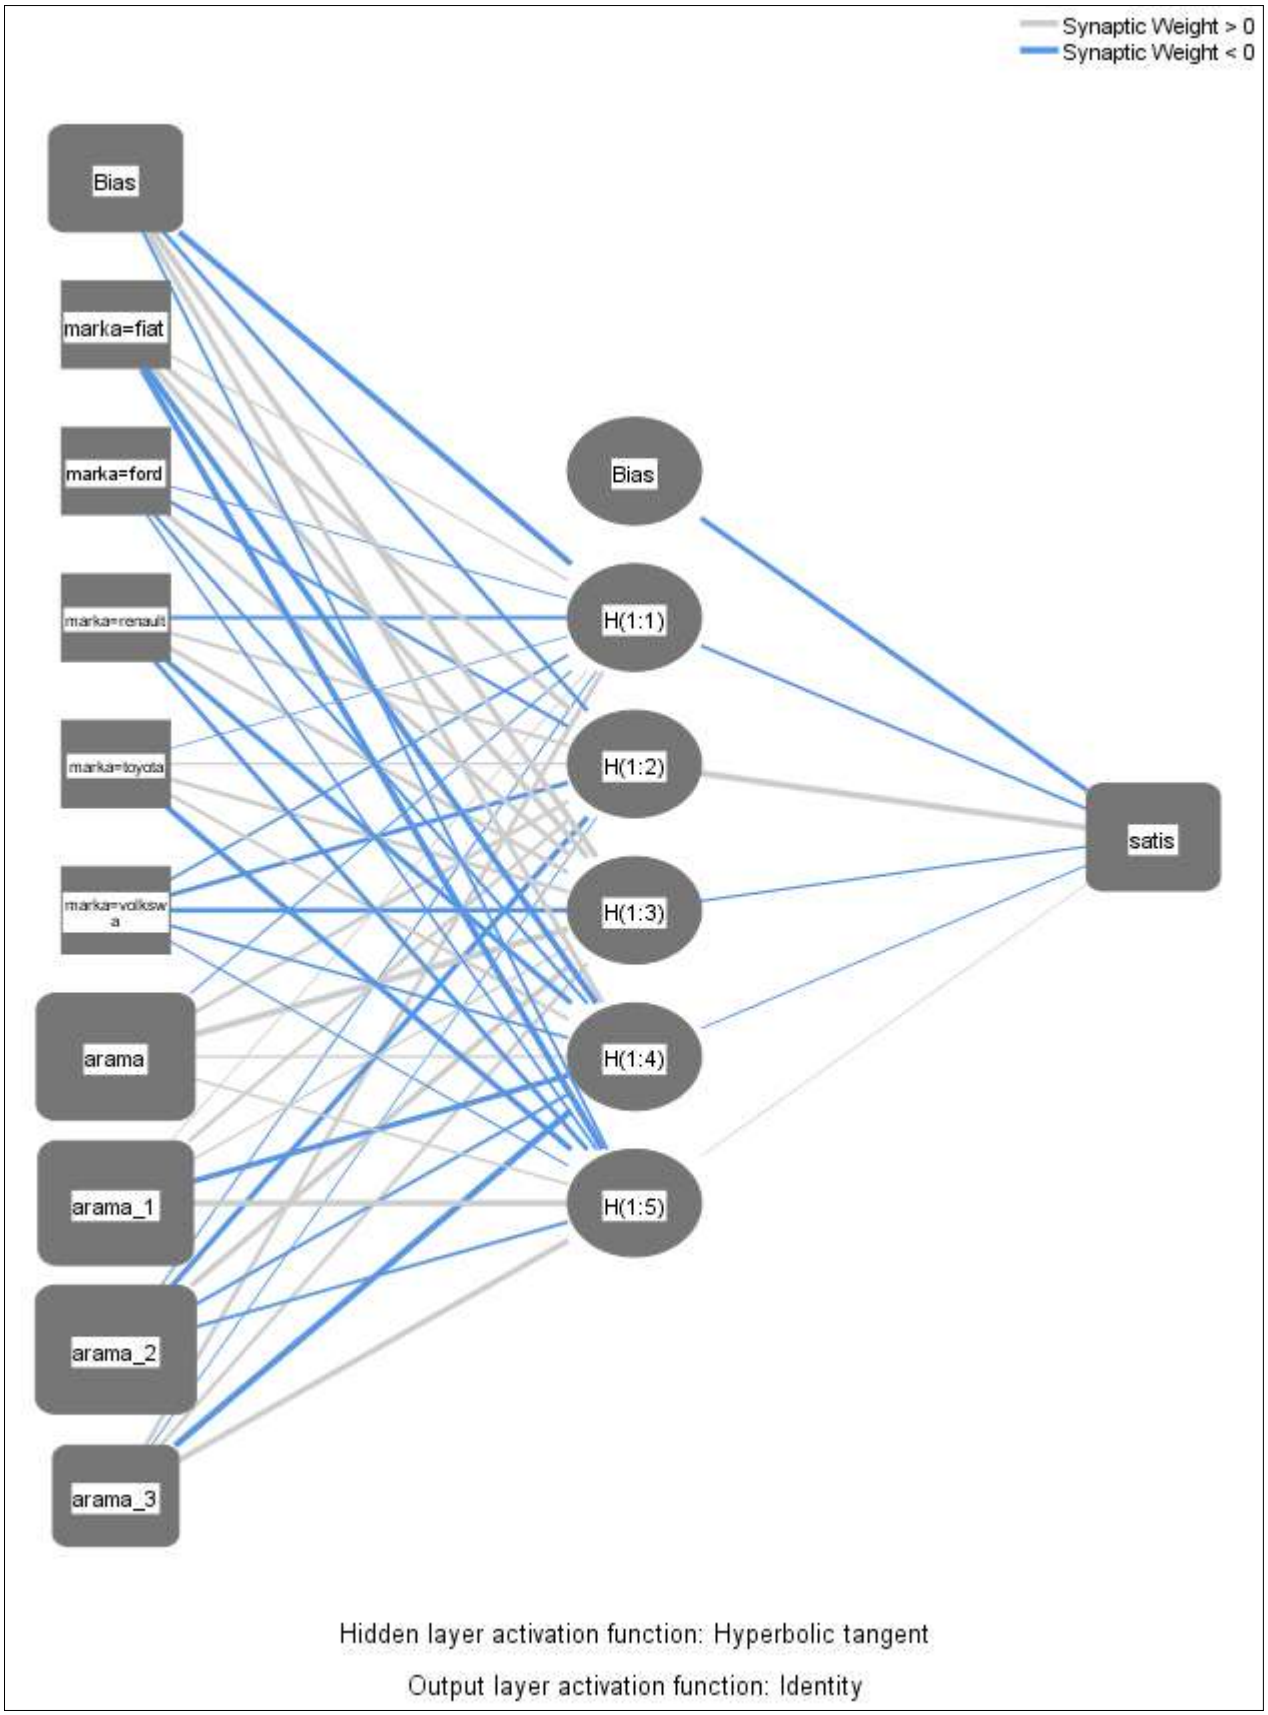
	β_1	std. hata	t	p	R^2	Düz. R^2	F-stat
Fiat	253,190	14,510	17,45	0,000	0,840	0,837	304,4
Toyota	63,402	3,777	16,78	0,000	0,829	0,826	281,7
VW	223,240	12,360	18,06	0,000	0,849	0,846	326,2
Renault	120,680	7,145	16,89	0,000	0,831	0,828	285,3
Ford	90,538	5,775	15,68	0,000	0,809	0,806	245,8

4. YAPAY SİNİR AĞLARI

İkinci yöntem olarak yapay sinir ağlarını kullandık. Yapay sinir ağlarını kullanma nedenimiz satış analizlerinde yaygın olarak kullanılmasıydı (Thiesing ve Vornberger 1997) (Yücesan 2018).



Şekil 1. Yapay Sinir Ağı Sonuçları, Verilerin Normalize Edilmiş Önemleri



Şekil 2. Yapay Sinir Ağı

Yapay sinir ağları analizini yaparken, markayı da kategorik veri olarak modele dahil ettik ve verileri birleştirdik. Arama yapılan ayın (arama) yanısıra bir önceki (arama_1), iki önceki (arama_2) ve üç önceki (arama_3) aylarda yapılan aramaları da modelde kullandık. Üç ay geriye gitme nedenimiz, ABD ve Kanada'da yapılan araştırmalara göre araba alım karar sürecinin üç buçuk aya kadar (108 gün) uzayabilmesiydi (URL2). Biz bunu Türkiye verileriyle inceledik.

SPSS ile yapılan analizde, yapay sinir ağında çok katmanlı algılayıcılar (multilayer perceptron) tercih edilmiştir. 2015 - 2018 arasındaki veriler eğitim, 2019 verileri de modeli denemek için kullanılmıştır.

Yapay sinir ağı sonuçlarına baktığımızda, iki ay önceden yapılan aramaların en önemli etken olduğunu, arabanın satın alındığı ay yapılan aramaların ise ikinci sırada geldiğiydi. Marka is en az önemli değişkendir. Yani otomobil markasından bağımız olarak, yapılan arama sayıları satış rakamları üzerinde etkilidir diyebiliriz. Aslında bu sonuç regresyon analizi sonuçlarıyla da benzeşmektedir. Regresyon analizinde de tüm markalar için arama sayıları satış rakamlarını %80'in üzerinde açıklamaktaydı (düzeltilmiş R^2).

5. SONUÇ

Bu çalışmaya başlarken ABD ve Kanada'da yapılan, araba satın alanların karar verirken İnternet'te yaptıkları sorgulamaları inceleyen araştırmalardan [Aussant 2019] ilham almıştık. O çalışmalar araba satın alanların %95'inin İnternet'te araştırma yaptığını söylüyordu. Biz de Google aramaları ve satış rakamları arasındaki ilişkiyi Türkiye için araştırdık. Türkiye'de yapılan markalara göre otomobil ve hafif ticari araç satış rakamlarıyla, Türkiye'den yapılan o otomobil markalarının Google'da aratılma verilerini karşılaştırdık. 2019 yılında Türkiye'de en çok satılan 5 marka için, son 5 yılın aylık verileri incelendiğinde, önsel beklentilerimize uygun olarak, regresyon analizi aramalar ile satış rakamları arasında doğrusal ilişki olduğunu gösterdi. Düzeltilmiş R^2 değerleri tüm markalar için %80'in üzerinde çıktı.

Bu analizi biraz daha ileriye götürerek, yapay sinir ağları ile tekrarladık. Yapay sinir ağında çok katmanlı algılayıcılar (multilayer perceptron) kullanılmış ve eğitilmiştir. 2015 -2018 arasındaki veriler eğitim, 2019 verileri de modeli denemek için kullanılmıştır.

Yapay sinir ağları analizi sonunda en önemli değişkenin satın almanın iki ay öncesindeki aramalar, ikinci sırada ise arabanın alındığı ay yapılan aramalar olduğunu gördük. Markanın en az önemli değişken olması ayrıca dikkat çekiciydi ve bu regresyon analizindeki bulgularımızla da örtüşüyordu. Tüm markalar için Google'da yapılan aramalar arttıkça, aratılan markanın satış rakamları da artmaktadır.

ABSTRACT

In recent years, technological advances have been affected by vehicles and have been harmoniously adapted. Many designs have been made considering the comfort and ease of use of the driver and passengers. This, in turn, necessitates an increase in the number of control buttons in the vehicle, leading to increased distraction and increased risk of accidents in the driver. Various work has been done to prevent these problems and to provide more comfortable and safe driving.

This study was conducted with the objective of performing an application of the technology that recognizes hand movements on vehicles using comparative examination of hand movement recognition technologies and using the changes in electric field lines. Controlling interior equipment in vehicles reduces the safety of driving and increases the risk of accidents. The result of this study is the prototype produced to reduce these risks and increase driving safety.

Key words: Hand Gesture Control, Human-Car Interaction, Electric Field Sensing

1. INTRODUCTION

This study is designed to compare the hand motion recognition technologies and to implement an application of the technology that recognizes hand movements by using the changes in electric field lines in vehicle vehicles. Checking interior equipment in vehicles is a factor that reduces driving safety and increases the risk of accidents. The prototype to be obtained as a result of this study is aimed to reduce these risks and increase driving safety.

With the development of technology, human life becomes easier. Technology is now used in almost every field. Vehicle technology is just one of them. Combining technology and imagination is a continuous improvement for drivers and users to travel more comfortably and safely. Nowadays, vehicles are gradually increasing and they can be shaped according to the wishes of the users. With the development of in-car technology, driving of cars becomes more enjoyable and user control becomes easier. However, with the increase of these features, distraction occurs in the user. Examples of these features include interior lighting in the vehicle, glass, fan, outer lighting, multimedia etc. During the control of the processes, the driving safety is compromised and the risk of accidents increases. Therefore, many studies have been done on in-vehicle controls and the methods of these studies have been different. For example; Touch, sound and gesture controls are provided. The desired recycling could not be obtained in voice control. Touch control is currently actively used, but still poses a threat to driving safety. Gesture control is safer and more comfortable than other methods if it is designed perfectly. As technology related to motion-based control systems progresses, more features can be added to the car.

In this study, for controlling the interior lighting, glass, etc. in the vehicle, the original design and implementation of the control system with both touch and gesture functions will be done. The driver will be able to perform these functions comfortably by means of specified hand gestures and touch. In this way, the risk of accidents and distractions are reduced

Hand gesture recognition system design technologies can be gathered under 5 main headings below:

Intrusive, Non-Intrusive , Device-Based, Vision-Based, Sensor-Based.

In intrusive systems, the user must wear gloves or a device to perform that task in order to recognize motion. A light input device has been described using only a bending sensor on the index finger, an acceleration sensor in hand and a micro switch for activation. User tests show that various test subjects complain about the necessary cables and other physical properties of the input device. Various attempts have been made to reduce the physical constraints imposed by the cables. The wireless finger tracker is also available, an ultrasonic transmitter is attached to the index

finger and mounted on a head-mounted device (HMD), which can track the position of the transmitter in 3D. To prevent sensors from being placed on the hands and fingers, the "Motion Bell" uses capacitive sensors on a wristband to determine the configuration of the fingers, but this has only been used to distinguish between the two movements (punch and dot). Active infrared imaging can be used to facilitate the task of separating hands and palm objects from the background and is therefore used in several wearable gesture interface systems. It is a gesture interface designed for automation and as an aid for disabled, elderly people. Suspended motion recognition is performed by Secret Markov Models (HMM). It is not preferred because drivers wear gloves or body suits during in-car use, making it difficult to facilitate secondary controls inside the vehicle and are not practical. Therefore, the preferred technology should be Non-Intrusive. Non-Intrusive (uninterrupted) systems are preferred by vehicle manufacturers.

On Device-Based systems, it uses a glove, pen, or other location tracker whose movements send signals that the system uses to describe its motion. The glove is equipped with a variety of sensors to give information about hand positions, orientation and flexibility of the fingers. In our application, any device or glove etc. This system is not preferred because it cannot be used.

In Vision Based systems, there are two approaches to vision based motion recognition; They are model-based techniques that try to create a three-dimensional model in the hands of users and use it for recognition. It is also known as image-based techniques that calculate recognition characteristics directly from the hand image. Image based methods often break apart hand shades from background images to find hands, and then try to extract features such as fingertips, hand edges, or gross hand geometry to use in hand sign recognition. It realizes the recognition process by using the definition of Hidden Markov Model (HMM). Some technical difficulties may arise in systems based on vision, such as dynamic backgrounds, variable lighting conditions and response times. Also, it is not preferred in the automotive industry because it requires cameras etc. devices.

Sensor Based systems have been implemented using a sensor-based approach to find a solution that overcomes some limitations of Vision-based systems. Lasers were used for motion music applications, but automotive use of lasers for hand movements was not observed. Capacitive and infrared techniques have been cited in some literature, but no evidence or publications of working hand gesture systems have been identified. Electric Field Detection (EFS) was initially initiated by the Massachusetts Institute of Technology (MIT) and can detect the presence of a human hand on or near a conductive object. EFS is not affected by dynamic backgrounds or variable lighting conditions and has very fast response times. Also camera, device, etc. It can be designed independently of the devices. Electrodes that will create an electric field are mounted under the plastic, allowing design without damaging the surface and creating visual pollution. Therefore, these systems are preferred in the automotive field in recent years.

1.1. Electric Near Area (e-field) Detection

This device is a 3D sensor technology which utilizes an electric field (E-field) for advanced proximity sensing. It allows realization of new user interface applications by detection, tracking and classification of a user's hand gestures in free space. E-fields are generated by electrical charges and propagate three-dimensionally around the surface, carrying the electrical charge. Applying direct voltages (DC) to an electrode results in a constant electric field. Applying alternating voltages (AC) makes the charges vary over time and thus, the field. When the charge varies sinusoidal with frequency f, the resulting electromagnetic wave is characterized by wavelength

$$\{\lambda\} = \{c\} / \{f\} \quad (1)$$

where c is the wave propagation velocity — in vacuum, the speed of light. In cases where the wavelength is much larger than the electrode geometry, the magnetic component is practically zero and no wave propagation takes place. The result is quasi-static electrical near field that can be used for sensing conductive objects such as the human body. This technology uses transmit (Tx) frequencies in the range of 100 kHz which reflects a wavelength of about three kilometers. With electrode geometries of typically less than fourteen by fourteen centimeters, this wavelength is much larger in comparison. This systems work w/o wave propagation. In case a person's hand or finger intrudes the electrical field, the field becomes distorted. The field lines are drawn to the hand due to the conductivity of the human body itself and shunted to ground. The three dimensional electric field decreases locally. This technology uses a minimum number of four receiver (Rx) electrodes to detect the E-field variations at different positions to measure the origin of the electric field distortion from the varying signals received. The information is used to calculate the position, track movements and to classify movement patterns Figure 1 and Figure 2 show the influence of an earth-grounded body to the electric field. The proximity of the body causes a compression of the equipotential lines and shifts the Rx electrode signal levels to a lower potential which is measured.

Interior lighting in the vehicle, glass, fan, light, multimedia etc. During the control of the processes, the driving safety is compromised and the risk of accidents increases. Therefore, many studies have been done on in-vehicle controls and the methods of these studies have been different. For example; Touch, sound and gesture controls are provided. The desired recycling could not be obtained in voice control. Touch control is currently actively used, but still poses a threat to driving safety. Gesture control is safer and more comfortable than other methods if it is designed perfectly. As technology related to motion-based control systems progresses, more features can be added to the car.

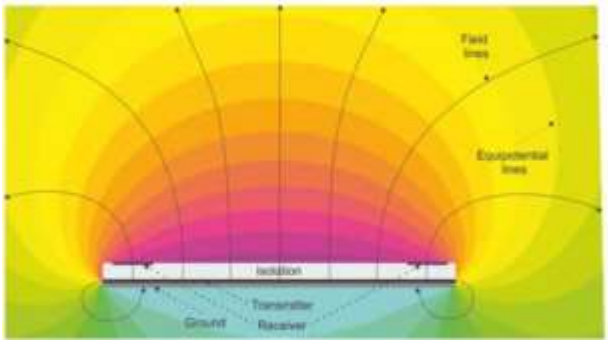

Figure 1. Equipotential Lines of an Undistorted e-field

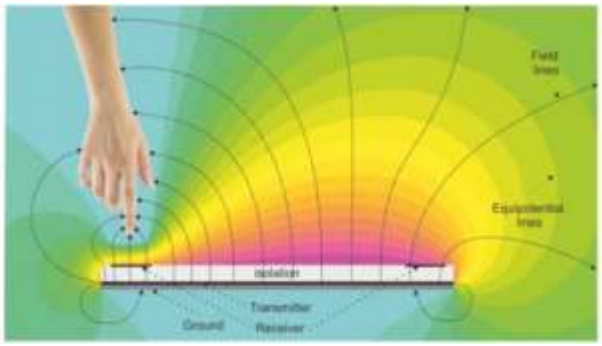

Figure 2. Equipotential Lines of a Distorted e-field

1.2. Hidden Markov Model (HMM)

Markov analysis is a powerful prediction technique used in an uncertain environment to predict future behavior of cases. The uncertainty of a system results from the inability of the said system to be fully controlled. The term Markov Analysis refers to a technique used to predict future behavior, taking into account the current behavior of the system. Having the Markov feature means that when the current situation is given, future situations depend on past situations. In other words, the description of the current situation covers all the information that may affect the future state of the process. The Hidden Markov Models are a series of statistical models used to characterize the statistical properties of a signal. An HMM is used to identify a movement in the recognition system. It provides modeling of Markov chains in their unobservable situations. The Hidden Markov Model is used in signal processing as a classifier, recognizing fluent examples such as voice, handwriting, body motion recognition, music notation monitoring, partial load discharge, bioinformatics (biological information), gene prediction and crypto analysis. In the normal Markov Model, states are visible to the observer, so the only parameter is state transition probabilities. In the Hidden Markov Model, the situation is not directly visible, but the state-related outputs are visible.

The probability parameters of the Hidden Markov Model, shown in the figure below, are as follows:

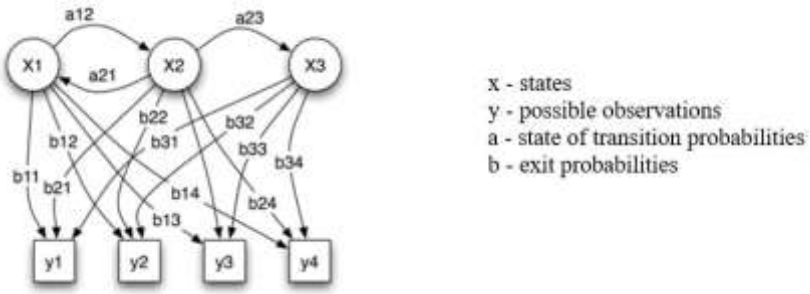

Figure 3. Markov Model Probability Parameters

According to the diagram below, the conditional probability distribution of the hidden variable x (t) at time t, the value of x (t-1) depends only on the variable x (t-1). t-2 and previous moments have no effect. This is called the Markov Feature. Similarly, the observed y (t) state depends only on the value of the hidden variable x (t).

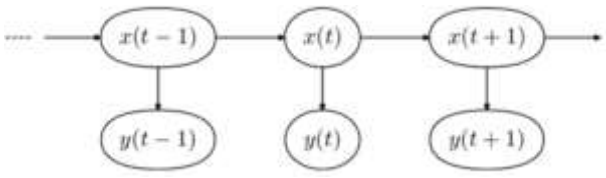

Figure 4. Hidden Markov Model Architecture

Hidden Markov Model Algorithms:

Three important algorithms are used to find the state sequence in the Hidden Markov Model.

- Advanced Algorithm: It is used to find the order of the states in the model. The possibilities of all the sequences that may arise are summed up. Recognition Problem_ Advanced Direction Algorithm.

- Viterbi Algorithm: Instead of collecting all the possibilities like in the Advanced Algorithm, in the Viterbi algorithm, each situation is chosen to best match the sound vectors. Thus, a healthier result is obtained. Status Sequence Problem Viterbi Algorithm

- Baum-Welch Algorithm: Calculates the observation possibilities by going from start to finish and back to end. So he finds more precise results. Learning Model Parameters _ Baum Welch Algorithm

In this study, human vehicle interaction will be ensured by using electric field sensing technology from the technologies mentioned. In the first stage, ventilation fan, windows, interior lamps etc. Functions such as will be checked. In the next stage, the multimedia unit of the vehicle will be checked. After the signals from the electrodes are received with the I2C communication protocol, they will be processed in the ADC unit of the microprocessor. The signals processed in the microprocessor the desired application can be made according to the situation. For example; Operations such as motor driving, control of the multimedia unit via can bus, opening and closing of the vehicle sun visor can be performed.

1.3. Literature Review

The first research on Gesture control technology was carried out by MIT in the early 1980s. The first step was taken using sound and gloves to interact with objects on a large screen (Bolt R.A. (1980)). Gesture control technology has been used since the 1990s to make life easier for people with disabilities. These include applications such as camera based web interface and controlling white goods with a necklace. Visual Touchpad in 2004; It was first introduced as a low cost vision based input device that interacts with desktop computers, laptops, public kiosks or large wall screens with two hands (Malik S., Laszlo J. (2004)). In 2006, the Gesture visualization method began testing the application of the accelerometer data and the animation of the hand movement during gesture control. Accelerometer based motion control is considered as a complementary or alternative interaction model. Movement commands that can be freely trained by the user can be used to control external devices with the movable wireless sensor unit (Sanna K. JK, Jani M. and Johan M. (2006)). In 2007, a prototype of the smart wheelchair control system was introduced to the market, where users can control the wheelchair using head movements combined with laptop and webcam (Jia P., Hu H., Lu T., Yuan K. (2007)).

1. Martin Zobl (2003). They think that the integration of more functionality in vehicles by increasing human interface increases the complexity of using the device. Therefore, the optimal use of different human sense channels is an approach that simplifies the interaction with in-vehicle devices. In this way, it will increase ease of use and reduce distraction. They use video-based real-time hand gesture recognition system for in-car use. He worked with widely available movements. With the optimized movement and dynamic hand movements combined with a human machine interface, they have enabled various in-car multimedia and infotainment devices to work intuitively and effectively.

In this study, motion recognition feature is provided by using Hidden Markov Model (HMM) technique. The basis of the system we will develop is based on HMM. In the system we will develop, this model and the embedded system will be combined and a more flexible and more stable work will be provided. Since the Electrodes can be designed flexibly in our system, it will take up little space and will be low cost.

2. Carl A. Pickering et al. (2007) This article describes the primary and secondary driving task, along with Human Machine Interface (HMI) trends and topics that drive car user interface designers to see manual motion recognition as a realistic alternative for user controls. A range of hand motion recognition technologies and Human Tools Interaction (HVI) applications are discussed, including a summary of current automotive hand motion recognition research.

In this study, we describe the researches on motion detection system design technologies, applications and interface techniques that we use in our study. According to the study; The gesture recognition application to be used in the car should support a non-device-based approach and a non-worn or non-intrusive approach, as the automotive environment is safety-critical, spatially limited and has practical user restrictions. In addition, dynamic and non-contact techniques are mostly used as hand movement techniques.

3. Hao-Chan Ting, et al. (2012). In this article, an automotive infotainment system equipped with smart applications is presented. The proposed system combines interactive motion control to control in-car applications that can improve safety and driving performance while also improving the level of comfort in modern vehicles.

In this study, motion recognition is done with RGB camera. Our system will not be connected to the camera and can be installed in the area we want in the vehicle. Only one transmitter electrode will be used for the e-field. Thanks to this feature, it will provide low power consumption. Also, since it will operate at low frequencies, it will not be affected by interference and interference.

4. Parada-Loira F. Vd. (2014). They think that controlling more than one device while driving causes the driver to be distracted. Therefore, they have worked on interfaces that provide human-machine communication. The system works with a visible infrared camera mounted on the roof of the vehicle. The scanning area points around the gearshift rod. These three modules work in parallel to analyze the field of activity and divide the hand if a hand is found:

    - Edge-based Foreground-Background Model (EBM)
    - Mixture of Gaussians background Model (BG_MoG)
    - Maximally Stable Extremal Regions segmenter (MSER)

These three modules feed on the current frame (grayscale or color) and combine their output to give a more obscure answer.

In this study, motion is detected with the camera. In the system, the camera is exposed and has a certain scanning area. Also, when you want to achieve this control in a different place, another camera will be required and it will increase the image pollution. Since the electrodes will be completely under the product in the system we will develop, they can be used as much as desired. It will work centrally over the entire detection area. Thus, it will provide full surface coverage without any blind spots in any sensing. Also, E-field detection sensors are not affected by environmental influences such as light or sound.

5. Pablo Sauras-Perez et al. (2014). In this article, he analyzes the variability of non-contact movements to control secondary functions in the car. A Wizard of Oz has been created in a driving simulator where participants perform the action they think they will use to control the functions of the music player. According to the results of the experiment, it is observed that there is a high level of variability in movements when the same function is performed by different drivers. He states that this variability may cause distraction.

In this study, experiments were carried out using RGB Camera. As a result of the study, it was observed that the same movements were variable by different people. Since our system is independent of the camera and our design is flexible in terms of hardware and software, the same motion will be promoted in an optimum manner with software and hardware filtering operations in motion definition. It will be able to provide a highly flexible user interface technology for all types of electronic devices, as it will basically process the raw electrode signals and convert them into pre-processed movements and x, y, z position information in real time.

6. Rahman ASMM et al. (2011). The aim of this study is to create a simple and intuitive interaction plan for in-car multimedia devices. Motion recognition is done using the camera on the game consoles. While the camera follows the hands of the users, it generates a series of movement points in the body connections and syntactically analyzes this movement to recognize hand movements later. This gesture is also used to interact with in-car multimedia devices to access various entertainment services.

In this study, motion recognition is done with the camera on the game consoles. As in other studies, the camera causes image pollution and restriction. Since our system is based on electric field sensing, it does not allow any restrictions or image pollution. There will be no blind spot since the sensing will take place centrally. With the benefit of being outside the regulated radio frequency range, a carrier frequency in the range of 44-115 kHz is used. Likewise, it is not affected by radio interference, effects such as light and sound.

7. Jia PaHHH et al. (2007). In this study, it is aimed to control the disabled vehicles with the head movements of the disabled people. When the device is placed in front of the wheelchair, it detects head movements with the help of a camera and controls the movement of the wheelchair due to the head turning left and right.

In this study, motion was detected with the camera. Therefore, image pollution occurs. Also, the camera is more likely to be affected by environmental conditions. Since the electrodes will be placed under the surface of the body in our system, they will not create image pollution and they will not be affected by environmental conditions since they will work at low frequency.

1.4. Original Value

With the developing technology, many studies are carried out on in-car controls. However, these studies cannot provide full optimization. In addition, since the field surveys are carried out with the camera in general and gloves, devices, etc. are used. As auxiliary elements are used, it causes image pollution, restriction and usability. Unlike the generally preferred optical systems in the system we will develop, motion control will be provided with the help of electric field lines. With the electric field detection technology, this confusion will disappear. Control movements will be determined and recorded during the design. It can also be controlled by touch. The system expresses its originality that the motion detection process is much more efficient than the systems designed so far and that a design can be made so that it is not affected by noise and environmental factors thanks to the filter. In addition, our system will be flexible both hardware and software.

Benefits of Electric Field Sensing Technology:

- E-field sensors are not affected by ambient effects such as light, sound, and radio frequency interference that negatively affect most other 3D technologies.
- E-field technology enables motion / position tracking
- E-field technology has a high immunity to noise, provides high update rates and resolution, low latency and is not affected by complex signals by clothing, surface texture or reflection.
- It provides low cost due to the use of thin electrodes.
- More use of existing capacitive sensor structures such as the ITO (Indium tin oxide) coating of the touch panel saves cost and simplifies the integration of the technology.
- Since the electrodes are placed under the surface of the body or integrated into the ITO structure of a touch panel, it does not create visual pollution.
- E-field works centrally over the entire detection area. Thus, it provides full surface coverage without any blind spots in any sensing.
- Only one transmitter electrode is used for the e-field. Thanks to this feature, it provides low power consumption.
- Since the e-field basically processes the raw electrode signals and converts them to pre-processed movements and x, y, z position information in real time, it can provide a highly flexible user interface technology for any electronic device.

2. MAIN BODY

The electric field will be created by designing the electrodes that will detect hand movements. After the received data is processed properly, it will be communicated by communicating over the I2C communication protocol. The desired controls can be provided according to the transmitted data.

Methods to be used in the project:

2.1. Creating an Electric Field

Five electrode designs will be made to create an electric field. It will have interfaces for five receiving electrodes and a single transmitter. The receive and transmit electrodes will be made of any conductive material such as copper or indium tin oxide (ITO). The insulation between the electrodes can be any non-conductive material, including glass or plastic. A non-conductive coating will be made on the electrode. The delivery electrode will be placed under the array of receiving electrodes.

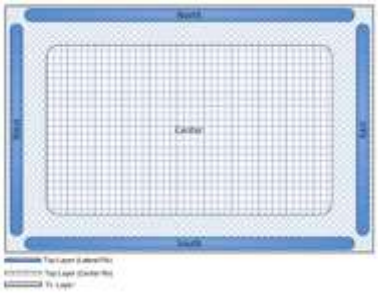

Figure 5. Frame Shape Electrode

Figure 6. PCB Electrode

The electrode system is typically a double layer design with a Tx transmit electrode at the bottom layer to shield against device ground and thus, ensure high receive sensitivity. Up to five comparably smaller Rx electrodes are placed above the Tx layer providing the spatial resolution of the this system. Tx and Rx are separated by a thin isolating layer. The Rx electrodes are typically arranged in a frame configuration as shown in Figure 5. The frame defines the inside sensing area with maximum dimensions of 14x14 centimeters. An optional fifth electrode in the center of the frame may be used to improve the distance measurement and add simple touch functionality. The electrodes' shapes can be designed solid or structured. In addition to the distance and the material between the Rx and Tx electrodes, the shape structure density also controls the capacitance CRxTx and thus, the sensitivity of the system.

2.2. Hardware Design

The lines of the area that the user's hand enters in the detection area flows from the user's body to the ground, resulting in distortion in the area. The effect reduces the electrode signal levels near the hand to lower than the level detected by a set of sensors. As the hand moves, different parts of the knee receive movement and potential changes are detected. The sensed signals are filtered and the reading is done with an analog digital converter. Signals from the converter are processed and sent to the output. The signals received from the output units are communicated over the I2C protocol.

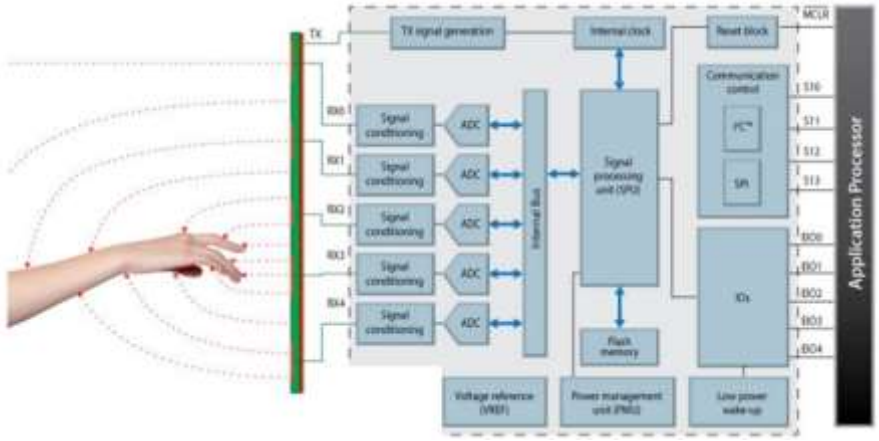

Figure 7. Sample Block Diagram

2.3. Software Design

After the data received from the electric field sensor is made meaningful, it can be communicated with a motherboard and the desired operation can be performed.

I2C Communication Protocol:

Outputs can be controlled with the desired algorithm according to the sensor data coming through the I2C protocol. I2C (Inter-Integrated Circuit) is an example of synchronous communication from serial communication types. For communication, two lines, SDA and SCL, are needed outside the ground line. Due to the large number of lines, it is not preferred for long-distance communications. It is generally used in short distance and where low data transfer rate is sufficient. The I2C communication has a master device controlling the communication. There should be one master in each communication. In order to ensure communication, at least one slave device must be connected to the communication line. The master device decides which of the multiple slave devices connected to the data stream. Thus, communication is made with more than one device without any change in the number of lines.

Master and slave devices do not need to be connected to the same supply line. But the ground lines must be the same for communication. In addition, there are two communication lines for data transfer: SDA (Serial Data Line) and SCL (Serial Clock). SDA from these lines is the line where data transfer between devices is provided. This would be bidirectional data transfer on the line. The synchronization of the data transferred to the line is carried out by the SCL line. The SCL line contains the clock signal produced by the master device. Communication on the SDA line is organized according to this signal.

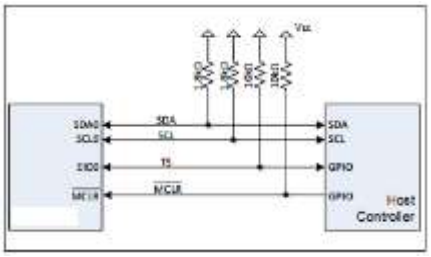

Figure 8. Sample I2C Communication Connection

Motion Definition:

The motion algorithms of the inputs and outputs to be controlled will be introduced and a database will be created. 8 types of motion can be introduced basically: proximity detection, position tracking, touch, rotary, right, left, up and down.

3. CONCLUSIONS AND RECOMMENDATIONS

With the completion of our project, according to the literature review in the automotive field, it is a project that has been carried out abroad but has not been done domestically. This system will enable drivers to be more careful and reduce the risk of accidents. Our project will provide low power consumption and will not be affected by environmental and electrical noise by designing according to EMC rules. In our system, it is aimed to integrate digital electronic and electric field sensing technology, and provide an open and flexible control and touch control.

With the completion of our project, according to the literature review in the automotive field, it is a project that has been carried out abroad but has not been done domestically. This system will enable drivers to be more careful and reduce the risk of accidents. Our project will provide low power consumption and will not be affected by environmental and electrical noise by designing according to EMC rules. In our system, it is aimed to integrate digital electronic and electric field sensing technology, and provide an open and flexible control and touch control.

As a result, with the developing technology, many studies are carried out on in-car controls. However, these studies cannot provide full optimization. In addition, since the field surveys are carried out with the camera in general and gloves, devices, etc. are used. As auxiliary elements are used, it causes image pollution, restriction and usability. Unlike the generally preferred optical systems in the developed system, motion control is provided with the help of electric field lines. With the electric field sensing technology, this confusion will disappear. Control movements are determined and recorded during the design. It can also be controlled on the touch. The fact that the system is much more efficient than the systems designed so far and the motion detection process and the processing of movements, and the ability to make a design that will not be affected by noise and environmental factors thanks to the analog and digital filter. In addition, our system is flexible both hardware and software. As a prototype, the glove box on the dashboard is now opened with gesture. The handle on the glove box is removed. Figure 9 and Figure 10 are also shown.
